ABOUT NCUR

The National Conference on Undergraduate Research (NCUR) is dedicated to promoting undergraduate research, scholarship and creative activity in all fields of study by sponsoring an annual conference for students. Unlike meetings of academic professional organizations, this gathering of student scholars welcomes presenters from all institutions of higher learning and from all disciplines. Overall, this conference offers a unique environment for the celebration and promotion of undergraduate student achievement; provides models of exemplary research, scholarship, and creative activity; and offers student career readiness development.

History of NCUR

The idea for a national conference open to all undergraduates was conceived and implemented at the University of North Carolina at Asheville in 1987. The first conference drew more than 400 participants from institutions across the country.

The Council on Undergraduate Research (CUR) and the National Conferences on Undergraduate Research (NCUR) historically existed as two separate organizations, but on October 1, 2010, the two officially joined. To commemorate this occasion, CUR and NCUR held a number of special events, including a reception, congressional briefing, and book release.

Attending a Professional Research Symposium

NCUR is the largest symposium of its kind in the world, bringing together nearly 4,000 undergraduate students each year from all fields and disciplines. The symposium is organized just like a professional meeting of scholarly societies. In this case, the audience is composed of other students, faculty mentors, and administrators. This is your opportunity to share with your peers the expertise you have gained over the course of your research experience. You can also learn what your colleagues have discovered through their projects. This is your chance to see the vast array of research taking place in all fields and disciplines, and meet students from other campuses who are doing similar research. We encourage you to be an active participant in the conference. Use this event as an opportunity to teach and learn. Most NCURs also include a graduate school and/or career fair, providing you with opportunities to meet with recruiters and consider next steps in your education and career path.

NCUR for Faculty and Administrators

NCUR is a great opportunity for students, faculty, and administrators—for students to present their research to peers and faculty from around the world; for faculty to connect with colleagues across disciplines; and for administrators to meet students, faculty, and undergraduate research program directors.

Student presentations are welcome in all fields and disciplines from the creative and performing arts to the biomedical, engineering, and social science fields. NCUR provides a wonderful opportunity for your students to meet peers and faculty working in similar research fields at institutions across the globe, to learn about the conduct of research and scholarship in a wide range of fields, to learn about advanced degree and employment opportunities at the graduate school fair, and to develop presentation skills. All student abstracts and applications are reviewed by faculty members.

NCUR Statement on Diversity and Inclusion

The Council on Undergraduate Research (CUR) is strongly committed to the wide expression of all forms and topics of undergraduate research, by all members of the undergraduate research community, and views with great concern any actions or policies that affect that commitment to inclusivity.

For questions or additional information about NCUR, please email NCUR@CUR.org. For information about upcoming NCUR occurences, please visit CUR.org/NCUR.

Abstract Name: Comparative Analysis of Large Language Models Essay Assessment Outcomes

Essay grading and feedback provision are fundamental components of the educational assessment process. One of the most significant challenges of manual essay assessment is the immense time and effort it demands which often leads to inconsistencies and delays. Moreover, the inherent complexity of language and the subjective nature of some grading criteria continue to pose obstacles to conformity. This research examines the effectiveness of three advanced large language models (LLMs) - Mistral-7B-Instruct, Llama-2-13b, and Llama-2-13b-finetuned - in the automation of essay assessment. The study compares the performance of these models on a dataset of 1,500 argumentative essays from Kaggle based on six essential proficiency criteria including cohesion, syntax, vocabulary, phraseology, grammar, and conventions. It employs four statistical metrics for evaluation: Mean Absolute Error (MAE), Mean Squared Error (MSE), Root Mean Squared Error (RMSE), and Mean Absolute Percentage Error (MAPE). Findings reveal significant variability in model performance across different assessment criteria. Mistral-7B-Instruct consistently outperformed the Llama models across most categories. The Llama-2-13B-finetuned model demonstrated notable improvements over its base model in several criteria which shows the potential of fine-tuning base models for specific tasks like essay assessment. The results' implications are significant for both educational and technological sectors as they can leverage these advancements to enhance the efficiency of large-scale essay evaluations. Future work could focus on expanding the scope of the analysis by fine-tuning a broader range of transformer models to better understand how various architectures influence performance in automated essay assessment.

Abstract Name: State Laws in Reporting of Pregnant and Lactating Parent Cannabis Use

The increased legalization and use of medicinal and recreational cannabis have raised concerns about its impact on pregnant and lactating individuals. Postnatal care providers are pivotal in guiding care during pregnancy and lactation. However, their care is confined by both federal and state law. Discrepancies in cannabis regulation at the State and Federal level can complicate the guidance of postnatal care providers and may affect patient outcomes. This study aims to describe state laws in reporting birth-parent cannabis use during pregnancy and lactation. Categorical and descriptive data were obtained from publicly available state laws on the Internet or personal communication with Child and Protective Services (CPS) and/or Health and Human Services (HHS) representatives from all 50 states of the United States of America. Cannabis is fully legalized in most states (n=23, 46%), with 10 states continuing to have laws making cannabis use illegal. Over half of states (n= 27) have no reporting requirements when cannabis is consumed during pregnancy, and

no states have specific reporting laws during lactation. Most states have a majority Republican party affiliation (n= 22). The percentage of the state's population with Medicaid was equal across states. The median years since the last cannabis legislation was 5 years (Q1: 2, Q3: 7). There were no significant relationships between required reporting and legalization status, political affiliation, percent population with Medicaid, or years since the last legislation. Limitations include inconsistent publicly available information, state reporting policies, and legal terminology and no laws about cannabis use during lactation. The findings from this analysis pave the way for a broader investigation centered on postnatal care provider knowledge, attitudes, and practices when caring for patients using cannabis during lactation. These insights can shape evidence-based policies and practices within postnatal care, aiming to enhance patient care and outcomes.

Abstract Name: The Politicization of Pre-university Education in Egypt

Education has played a pivotal role in preparing the next generations for the job market by providing students with knowledge and skills. Although President Abdel-Fatah Al-Sisi declared in 2019 that the government established a national project to reform the educational system, Egypt ranks 133rd in the quality of education globally in 2022. The thesis examines how the Egyptian educational system operates from Nasser's to El-Sisi's regimes and the reasons for the low quality of education. It combines historical discourse with political analysis about the conditions of education, leading to a massive discussion of the current situation of the educational system. The thesis provides scholars interested in education and politics with a clear vision of education conditions in Egypt to understand why pre-university education in public schools does not improve. The thesis provides a scope of information using primary data, such as an analysis of educational textbooks, focus group, and in-depth interview, as well as secondary data using previous research by different scholars concerning the topic. The primary outcome is that the regime controls the curriculum to maintain discipline in the authoritarian regime by imposing specific agendas for pupils to study. The curriculum does not match students' needs or interests, but they do not have other choices because they cannot afford the fees of private or international schools. Therefore, educational decision-makers need to reform the educational system to give more space for students to foster their individuality.

Abstract Name: Revolutionizing Pharmaceutical Analysis: Amisulpride Quantification via Innovative Paper Analytical Devices

Pioneering a groundbreaking approach to quantify Amisulpride is a critical pursuit in pharmaceutical development given its precise targeting of D2 and D3 dopamine receptors. Harnessing the innovation of custom-designed barrier-type Paper Analytical Devices (PADs), our study achieves a milestone by producing

the first-ever application of PADs for the high-precision analysis of Amisulpride.. In comparison to conventional methods, our approach not only enhances accuracy and precision but also addresses paramount concerns in pharmaceutical development. PADs emerge as a low-cost, flexible, and replicable platform, revolutionizing the landscape of drug analysis. Their adaptability allows for cost-effective techniques in pharmaceutical quality control, laying the foundation for entrepreneurial opportunities in the realm of pharmaceutical research and development. Two distinct spectrophotometric methods, generating a pink chromagen and an orange chromagen, are explored on the PADs. Initial results underscore the unparalleled sensitivity of PADs, particularly evident in the calibration curve for the pink chromagen method. The linear dynamic range of the PAD calibration curve accommodates even lower concentrations of Amisulpride, a critical advantage for pharmaceutical formulations. Significantly, this study demonstrates comparable accuracy and precision between in-solution data and PAD data, reinforcing the reliability of this innovative approach. Beyond the immediate application, our research envisions a radical shift in pharmaceutical analysis. PADs not only offer a low-toxicity alternative but also preclude a new era of entrepreneurship, providing an accessible platform for researchers and developers to contribute to pharmaceutical advancements. This groundbreaking research not only fills a crucial gap in Amisulpride quantification but also positions PADs as a transformative technology for pharmaceutical development. Our work promises to unlock cost-effective, scalable, and innovative methods for drug analysis, fostering a future where entrepreneurial endeavors can thrive in the realm of pharmaceutical research and development

Abstract Name: Disassembly of Cholera Toxin by Protein Disulfide Isomerase

Cholera toxin (CT) is a protein designed to cause life-threatening diarrhea. CT is classified as an AB-type protein toxin which contains multiple subunits. CTA1 is the catalytic subunit which is linked to CTA2 by a single disulfide bridge. CTB is the cell-binding pentamer. When the disulfide bond between CTA1 and CTA2 is cleaved, CTA1 remains associated with CTA2 and CTB. Protein disulfide isomerase (PDI) will recognize CTA1 and bind to it, causing PDI to unfold and expand its size. This results in CTA1 detaching from the CT holotoxin, which is required for the activation of cholera. Once CTA1 detaches, it increases cAMP levels in the host cell. The result of this signal leads to the release of chloride ions which causes the body to have diarrhea. The purpose of this project was to determine which domain(s) of PDI is necessary for the disassembly of CT.PDI has four domains and an x linker, organized as abb'xa'. Individual domains of PDI were produced with an epitope tag and purified. To verify the purification, a sample of each protein was used for SDS-PAGE. After verification, ELISA-based disassembly assays were performed to determine which specific domains of PDI disassemble CT. The results suggest that the a domain of PDI can disassemble CT. Experiments using Q3R present evidence that the b' domain is responsible for the regulation of the a domain. The results of this project can be implemented into further studies of therapeutic treatment to cure patients with this disease.

Abstract Name: Motile Tracheal Model for Awake Fiberoptic Intubation Simulator

Severe effects such as brain damage and death can result from inadequate management of difficult airways. Due to difficult airways, anesthesiologists face problems in ventilating the patient with a facemask and/or inducing general anesthesia which is required before surgical interventions. In such cases, awake fiberoptic intubation is considered the golden standard treatment. It is an oxygen delivery where the tracheal tube is placed while the patient is awake and given a numbing agent for the airway to prevent discomfort. One of the main challenges that persist when intubating while the patient is awake is coughing, followed by movement and reflexes within the body. This may cause the anesthesiologist to hit the sides of their windpipe, leading to possible complications for the patient. In cases where this procedure is necessary, it is life-saving, and an anesthesiologist must know how to do it. This project aims to create a device that mimics the upper airway which includes realistic movement of vocal cords to mimic a coughing patient. This will be accomplished using the motors modulated by the Arduino software written in the C++ programming language. The main feature of this solution that separates it from pre-existing devices is its motile function. The vocal cords in this device will move as they do in awake patients. This movement will be tuned in cadence with typical vocal cord movement in patients via a motor modulated by Arduino with C++ programming.The development of this device would not only improve the training of future medical professionals but also the care of patients. With the current training devices, non-moving manikins, it is very difficult to go from inserting a bronchoscope on a still manikin to a person who is moving. This device will practice that missing aspect which is a need for the medical industry.

Abstract Name: Using FIJI and the 3D Slicer image computing platform to measure microglial lipofuscinosis in a mouse model of frontotemporal dementia

Heterozygous loss of function mutations in progranulin (GRN) causes frontotemporal dementia with TDP43 pathology, lipofuscinosis and neuroinflammatory changes. Progranulin homozygous knockout mice recapitulate several neuropathological features of FTD caused by progranulin mutations, including lipofuscinosis and microgliosis. Brightfield microscopy of brain sections immunolabeled with IBA1, a microglial marker, indicates that microgliosis develops at around 6 months of age in this mouse model. We have developed a novel method combining high-resolution confocal microscopy and a Python-based script to segment and characterize microglial morphology that suggest microglial morphological changes in the progranulin knockout mice occur earlier than 6 months. We imaged 25-micron Z-stacks of the stratum radiatum/lacunosum layer of the hippocampus from IBA1-labeled sections of wild-type and progranulin knockout mice at 3-5 months, 5-7 months and 18-22 months of age. We pre-processed the Z-stacks using FIJI and then used 3D Slicer, an open-source 3D image analysis software, to segment and measure the properties of isolated microglia. Using this method we were able to determine that progranulin-deficient microglia adopt

a reactive non-ramified phenotype as early as 3-5 months of age, which progressively gets worse with age. Interestingly, progranulin-deficient microglia adopt a dystrophic, shrunken and more fragmented appearance by 18-22 months of age, suggesting that progranulin deficiency has ramifications for microglial function both early and late in the disease course. We hope this method is useful for multiple models of neuroinflammation.

Abstract Name: Experiential Programs Innovation Central at the University of Maine (EPIC)

Experiential Programs Innovation Central (EPIC) at the University of Maine provides a unique approach to igniting and sustaining the research flame among students. We define research broadly to be inclusive of scholarly and creative activities, and bring the power of interdisciplinary collaboration to the forefront of students' minds. Early College and first-year students from a variety of disciplines participate in a semester-long course to learn what research is and how it is done, including defining a question or formulating a problem, strategizing solutions and communicating findings. In this program, students tour various research centers, spend time in teams working on real-world problems, and are supported beyond the one semester training to continue their research to experience an authentic research process all the way through presenting at an annual symposium. EPIC is also developing additional strategies to support students as they continue their research beyond the semester in applied settings such as fellowships and internships. This presentation will discuss various real-world project examples that bring students together and will highlight how these efforts can be sustained within various institutional models.

Abstract Name: Mechanism of Action of Antifungal Peptoids

Due to the rise of drug resistant strains of fungal pathogens such as Cryptococcus neoformans and Candida albicans, there has been a need to identify new antifungal agents. In comparison to naturally produced antifungal peptides, antifungal peptoids, sequence-specific oligo-N-substituted glycines, mainly differ in structure, which prevents protease recognition giving higher bioavailability. Previous studies have shown that peptoids are effective fungicides. RMG8-8 and RMG9-11, two peptoids recently discovered in the Bicker Lab, have proven to be effective antifungal agents against C. neoformans and C. albicans, respectively. Reported here will be studies to determine the mechanism of action and other vital therapeutic properties of RMG8-8 and RMG9-11 using various biochemical and microbiological assays. Preliminary results of critical micelle concentration, the minimum concentration of a compound needed to form micelles, testing indicate that RMG8-8 as well as RMG9-11 do not exist as micelles at their minimum inhibitory concentrations, but rather function unimolecularly. Using a PAMPA assay, it was found that RMG8-8 is likely unable to penetrate

the blood brain barrier (BBB). However, RMG9-11 demonstrated good permeability, indicating that it may be able to penetrate the BBB to treat dangerous neurological infections of fungi. Through a cytoplasmic membrane depolarization assay of RMG9-11 against C. albicans, it was discovered that the peptoid was able to depolarize the cell membrane in a concentration dependent manner. In future work, assays will be conducted to further understand the mechanism of action of both peptoid compounds to address the rising concern of drug resistant strains of fungal pathogens.

Abstract Name: Integrating Hybrid Neural Networks with Neuroimaging in Identifying Novel Biomarkers for Amyotrophic Lateral Sclerosis (ALS)

Current literature lacks notable diagnostic methods for the detection of sporadic Amyotrophic Lateral Sclerosis (sALS) and, as such, leads to substantial diagnostic delays, which can detrimentally affect an individual due to the absence of timely treatment. While conventional testing may not be effective, in recent years, neural networks have had an increasing impact on the diagnosis of neurodegenerative diseases. In particular, the combination of two or more neural networks, a hybrid neural network (HNN), has shown distinct advantages over just a single neural network in architecture for disease diagnosis, and spiking neural networks (SNNs) and artificial neural networks (ANNs) were shown to have high performance individually. However, an HNN with an SNN and ANN specifically has yet to have significant research for use in the diagnosis of sALS. This study focused on the utilization of ANNs and SNNs to find out how data-image analysis using an HNN, specifically an HRN model, could help with identifying biomarkers of sALS to understand how HNNs could be used in diagnosis methods as a potential alternative in the diagnosis of neurodegenerative disorders. Through a meta-analysis study, it was found that the utilization of an ANN-SNN hybrid in an HNN utilizing hybrid units and MRI imaging focused on the ADNI dataset could provide greater performance than currently used methodologies in analyzing for biomarkers in sALS progression. The identification of additional biomarkers has the potential to expedite the creation of novel therapeutics and shorten the time for diagnosis, providing a stronger foundation for decelerating sALS progression.

Abstract Name: Gateway to Merced: Filipina/x/o American Community

As early as 1908, the city of Merced in California has been known as “Gateway to Yosemite", a term coined as its tourism slogan. The phrase is still prominent on official signage around town. The Gateway to Merced project aims to shift the narrative of Merced’s reputation as being another rest stop or college town to instead acknowledging and celebrating Merced County’s inclusive history of underrepresented communities. This

project is a community collaboration of collected oral histories that uplifts and preserves underrepresented groups. In this research, the focus is on gathering the history and lived experience of the Filipinx American Community in Merced County. The collection is through guided interviews of audio and video recordings. Conducting these guided interviews aims to facilitate open-ended discussion with community members that will be transcribed. These transcriptions will be analyzed to examine the ways of how the community has experienced the complex process of assimilation, challenges faced in navigating cultural identity, and if presence of a university affects intergenerational dynamics. The study offers insights into looking at the diverse experiences and struggles that are faced by the community. With active community participation, the outcomes of this research will promote inclusivity, understanding, and cultural pride. Ultimately, this study's results empower and preserve culturally significant stories in Merced County while contributing to a more positive and comprehensive understanding of the region's history.

Abstract Name: Determining the Impact of Valley Fog on Forest Function in Central Appalachia

When atmospheric water (i.e., fog or low-lying clouds) moves across a forested habitat, it is intercepted by leaf surfaces and condenses serving as a water source to the leaf directly (i.e., foliar water uptake), or to the forest floor. Research has been conducted in several cloud forests on this interaction, where fog supplements tree growth in place of typical water uptake from the roots during times of stress. However, this connection between foliar water uptake and forest function has not been studied in Central Appalachia, despite morning fog being common throughout the growing season. This research will improve our understanding of feedback between microclimate and tree productivity in Central Appalachian forests. The results will also inform modeling efforts aimed at understanding how average changes in climate parameters or extreme events can influence forest productivity. The proposed research is a continuation of activities that began in Robinson Forest in Breathitt County, Kentucky, focusing on the Little Millseat Watershed at different slope positions (i.e., valley, mid-slope, ridge top) and aspects (i.e., north versus south facing). At each position, microclimate stations measured air temperature, relative humidity, leaf wetness, and solar radiation, and trail cameras detected fog visually. Internal sap flow sensors were installed in the canopies of chosen mature trees (i.e., tulip poplar, A. beech). The following questions were investigated: How variable is the duration of valley fog in Central Appalachia? How do diurnal fluctuations of valley fog in Central Appalachian forests affect the water relations and productivity of trees? The expected results include increased tree productivity during foggy periods, and a potential increase in foliar water uptake during precipitation events. This will determine if the chosen trees are dependent on these atmospheric inputs of water to buffer stress caused by high summer temperatures and possible drought.

Abstract Name: Music in our Lives: Understanding its Impact in Everyday Life

This study aims to understand the impact listening to music may have on individuals. Guided through the questions of, what emotional impact does music have on people and does music have positive effects on well-being, this study takes a deeper look at what it means to listen to music. This qualitative study was done through the use of ethnographic observations and interviews. Participants consisted of a convenience sampling of college students and older family adults, to compare any differences in demographics. A set of questions guided interviews, but participants were also encouraged to treat interviews in a casual conversational setting, which allowed them to reflect on perspectives they hadn't given much thought to before. As the study continued iterative steps were taken due to new themes appearing as interviews and observations progressed. Results varied; it was found that for most individuals listening to music does have an overall positive effect on both well-being and people's emotions. However, it was also found that for most participants music has a way of bringing nostalgia to listeners thus leading most individuals to give special meanings to their music, regardless of demographic background.

Abstract Name: An Analysis of Homocysteine and Homocysteic Acid in Bipolar Disorder

Homocysteine (HCY) is involved in methionine metabolism in the body. This chemical is also associated with the progression of neurodegenerative disorders such as bipolar disorder, schizophrenia, and Alzheimer's disease, as reported in several papers. When HCY reaches high concentrations in the body, it is believed to be converted into homocysteic acid (HCA), which contributes to cell neurotoxicity. Following analysis of our cell and media samples using liquid chromatography/mass spec (LC/MS) and high performance liquid chromatography (HPLC) with electrochemical detection (EC), we found abundances of HCY, and nitro-HCY. Other LCMS and HPLC data collected from the rat samples yielded high concentrations of what we believe to be homocysteine sulfinic acid and low concentrations of HCY. The oxidized forms of HCY, nitro-HCY, and homocysteine sulfinic acid have the potential to be either intermediates in the HCY to HCA transformation or simply alternative oxidized forms of HCY. We will continue to investigate the relationship between bipolar disorder and the presence of these compounds.

Abstract Name: Assessing Real-World Medication Adherence in People Living with HIV in the Era of One-Pill Regimens: The Role of Cognition, Self-Report, and Performance-Based Assessments

Medication adherence is critical for health in people living with HIV (PWH). There is an ongoing need to determine the best ways to identify people at risk of adherence problems, as newer one-pill-a-day regimens may involve different cognitive demands than previous complex regimens. This study investigates the relationships among neuropsychological functioning, medication management performance, self-reported adherence, and viral load in people living with HIV. We hypothesize that cognitive impairment will negatively influence medication management and virologic control, and that performance-based adherence measures will better predict virologic control than self-report. Participants were 70 HIV+ adults (ages 30-77, 79% Black) receiving cART (combined retroviral therapy). 67% had undetectable HIV RNA. 87% were prescribed one-pill-a-day regimens. Participants completed neuropsychological assessments, the Medication Management Test-Revised (MMT-R), the AIDS Clinical Trails Group Adherence Questionnaire, and blood sample collection. Pearson correlations examined cognitive domains in relation to MMT-R performance, and cognition, MMT-R, and self-reported adherence in relation to viral load. Most cognitive domains, particularly verbal memory (r=.38, p=.001) and executive function (r=.36, p=.002), were positively associated with MMT-R. Working memory was significantly associated with log viral load (r=-.26, p=.050). One aspect of MMT-R, which involved filling a pillbox (r =-.242, p=.069), showed a trend for being associated with log viral load. Self-reported adherence was not associated with log viral load (r=-.131, p=.335). In sum, multiple cognitive domains were related to better MMT-R performance, but only working memory was associated with viral load. The pillbox domain of the MMT-R showed a trend for being a predictor for real-world virologic control and provided a more objective measure of adherence than self-report. In the era of one-pill-a-day regimens, simple adherence assessments (e.g., filling a pillbox) appear to be more important than assessing other aspects of adherence (e.g., arithmetic) that were more relevant during the era of more complex regimens.

Abstract Name: Potamogeton crispus Interrelationships with Ecosystem Metabolism: An Aquatic Plant Survey of Lake Menomin

Lake Menomin has been experiencing declining water quality due to high levels of nitrogen and phosphorus. In addition to its hyper-eutrophic status, there is also a restricted aquatic species known as Potamogeton

crispus present throughout the water body. This exotic plant is equipped with aggressive traits like early spring emergence, low light tolerance, and high resilience. Coupled with its preference for eutrophic waters, P. crispus can outcompete native aquatic vegetation, forming dense monocultures. We conducted a survey of present macrophytes and ecosystem metabolism across six fishing docks and one open-water site, to determine the frequency of occurrence of P. crispus. Plant biomass, dissolved oxygen, light, temperature, and water quality data were recorded to examine a possible additional effect of the invasive within the altered ecosystem. No correlation was found between P. crispus and gross primary productivity, or native abundance. However, there was a higher abundance of native species than hypothesized, suggesting high native diversity is likely able to compete with invasive species. Our findings indicate a lake-wide macrophyte survey is necessary to fully understand ecosystem composition and metabolism; furthermore, how these processes fluctuate as eutrophic conditions increase.

Abstract Name: Public School Per Pupil Expenditure and Crime Rates

How is educational funding implemented at the local level to affect crime rates in various cities? The school to prison pipeline is prevalent in discussions surrounding crime and incarceration rates in modern day America. Past research has suggested that the level of education an inmate has impacts their likelihood of facing incarceration, as well as recidivism rates, with the higher degree received, the less likely someone is to face additional prison time. Furthermore, the addition of Student Resource Officers into schools in recent years has suggested that a zero tolerance policy in the classroom links to rising crime rates in the area. I aim to address how state educational expenditures in schools can affect crime rates in three cities– Boston Massachusetts, Portland Oregon and El Paso Texas, looking specifically at violent crime and property crime over a 10 year time period. The three selected cities will allow us to examine funding on a broad level to better apply state and local funding to school districts in the future. My research suggests that higher per pupil expenditure in public school districts reduces both violent and property crime rates in the United States at large, which is translated to the above municipal governments and their school districts. I suggest where cities see success based on where funds are allocated, and how improvement can continue to drive down city wide crime rates.

Abstract Name: Sticking to the Plan: An Analysis of Coping Styles and Treatment Perceptions

This project intends to synthesize two research studies to address our research question: How do various coping strategies correlate with behavior, benefit, and burden distinctions in treatment perceptions?Low

adherence to treatment plans is prevalent in caregivers of children with disabilities and people with Type II diabetes (T2D). Just as individuals with T2D are responsible for adherence to their treatment plans, primary caregivers of children with disabilities are also largely responsible for ensuring adherence to their child's treatment plan. Previous studies indicate that coping techniques and treatment perceptions significantly influence treatment adherence in both populations. More specifically, treatment perceptions of one's adherence are important as they provide insight into cognitive aspects of treatment adherence; these can be defined into three distinctions: benefit, burden, and behavior. This project aims to bridge a gap in existing research by comparing how these different dimensions of treatment perceptions relate to various coping mechanisms.Study 1 recruited 300 individuals with T2D and administered the survey virtually. Participants reported their use of various coping strategies, as well as their perceived adherence and attitudes regarding their treatment plan. Study 2, targeting 500 primary caregivers of children with disabilities, will employ similar tools for a comparative analysis.Results from Study 1 reveal that each coping strategy is associated with at least one dimension of treatment perception. Active, professional support, positive growth, and emotional support strategies show positive correlations with benefit and behavior perceptions and negative correlations with burden perceptions; avoidant and self-blame strategies are linked to negative behavior perceptions and positive burden perceptions. Although data collection for Study 2 is ongoing, similar patterns are expected. Ultimately, the synthesis of these studies will provide insights into the relationship between treatment perceptions and coping strategies across varied populations with implications for targeted applications for treatment adherence improvement.

Abstract Name: Menstruation, Products, and Education in Jails

Incarceration leaves individuals with incredibly few rights, however incarcerated individuals should still be entitled to medical needs, no matter their incarceration location or length of sentence. In 2023, there were about 76,000 women incarcerated in jails across the United States (Kajstura & Sawyer, 2023). These women have unique health needs, one of which is menstruation. Individuals who menstruate need to have access to medical supplies to adequately care for themselves, for their both their physical needs and mental health. Since inmates do not have extensive autonomy, advocating for their right to a minimum of health rights is at the upmost important. Lack of access to menstruation products could be considered inhumane treatment of the incarcerated. The goal of this study was to evaluate if Colorado jails provide adequate amounts and 'good quality' menstrual products and if these jails provide education about menstruation and menstruation-related care. There is currently no definition of 'good quality' menstruation products which was another important factor identified within this research. A survey was distributed to 4 different jail sites, and a total of 136 incarcerated women along with another 21 individuals from the general public completed the survey. The survey results found that 57.4% of participants indicated a desire for menstruation related education, 47.8% of participants indicated that they did not have adequate access to menstruation products, and 48.5% of participants indicated that they did not believe the quality of products were satisfactory or of 'good quality'. This research is breaking barriers as prior to this study, there was no published literature regarding menstruation in jails.

Abstract Name: Comparison and Identification of Fungi in Glaciated and Non-glaciated Areas of Ohio

Of the estimated 1.5 to 5.1 million species of eukaryotic organisms on the planet, fungi are the second largest group. Despite this, only a small portion, roughly 100,000, are described and known to science, and many of these are very difficult to identify based on visual assessment alone. Thus, there are many unidentified fungal species that could be beneficial or detrimental to humans and other organisms. Fungi can inhabit and survive in many different environments; for instance, they can be found in both glaciated and non-glaciated ecosystems of the Midwestern US. The objective of this research was to identify and compare fungi species present in Ohio. Two 75-acre properties with similar ecosystems (forest, grasslands, stream, wetland) were selected for comparison; one is in the glaciated part of the state, and one is in the non-glaciated part. Although the ecosystems are similar, differences in soils and tree species exist due to the glacial patterns of the past. Permission to obtain samples was obtained for both properties. A total of 95 samples from the non-glaciated property were photographed in-situ and collected; samples were stored in the freezer pending DNA analysis. A total of 108 samples were obtained from the glaciated property for similar analysis. DNA was extracted from each sample, amplified through PCR, and analyzed for species identification through the International Barcode of Life (IBOL) database. Surprisingly, more than 90% of species identified existed in both glaciated and non-glaciated soil, and all major North American taxa of fungi were found in these samples. Additional work from this study will include an educational field guide for each of these two properties (both are educational sites used by both students and the public) for use in the identification of local fungi.

Abstract Name: Analysis of the Portrayal of Science at the Creation Museum (Petersburg, KY).

Anti-science rhetoric is not new and generally comes from a lack of understanding of science and its theories or a desire to promote another way of thinking. To determine the extent of such rhetoric being used at the Creation Museum in Petersburg, KY, a day was spent analyzing each exhibit from start to finish. The museum is the product of a group of “Young Earth Creationists”; this religious philosophy begins with the assumption that the world is 12,000 years old (rather than billions) and that God created the universe, the world, and all life forms in six 24-hour days (rather than evolving over time). As opposed to the glowing views of the showcased creationists, scientists are depicted as anti-God and untrustworthy. Scientific theories (such as evolution) and methods (such as radiometric dating) are dismissed by showing singular examples that do not fit the theories well. For instance, it is stated that death (and therefore the presence of carnivores, omnivores, most fungi, and viruses) did not exist initially and is not part of God’s plan; yet, there is no explanation for their presence today. Visitors with any amount of science background are left with a lot of unanswered questions throughout. Analysis of the creationist and scientific accounts of more than forty hypotheses, theories, and Biblical references are ongoing, with the goal of constructing a comparative educational poster that includes similarities and differences in understanding of creation, evolution, age of the earth, catastrophic events, mutations, death, and other relevant topics.

Abstract Name: “My Country, The Country of Heroes”: Resistance, Resilience, and Music During the Eritrean Struggle for Independence

In 1991, Eritrea was finally recognized as an independent nation after decades of Western colonization, intervention, and a thirty-year long war for independence. Music played an integral part in shaping the revolution. It strengthened Eritrean revolutionaries, fostered a fledgling sense of national identity across the diaspora, and united the fighters across sociolinguistic divides. This paper examines the music of the revolution, with particular emphasis on its lyrical content, instrumentation, and sociopolitical impact. The text presents a sampling of popular songs recorded over the span of the war: “My Country, The Country of Heroes” (1958), “Meley” (1972), and “Yohana” (1991). The methodology for this work draws from musicological analysis, published sources, and an interview conducted with Aron Kibreab, a prominent Eritrean singer who resides in the United States.

Abstract Name: The Art of the Regime Change: Navigating the Product of Cultural Effects of Revolution in Modern-day Mongolia

Mongolia is a present-day nation that was built upon many different regime changes over the past century. Throughout these vast changes in political structure, there has been one unending constant: Mongolian societal and cultural norms. Nation-states are built on traditions and cultural norms that define the societal fabric of a particular nation. Mongolia throughout its recent regime change history has undertaken a socialist and communist socioeconomic political structure for the majority of its post-feudal era. Its adherence to socialist principles was likened to its geopolitical standing as China and Russia were also going through socialist revolutions during this period, but the present-day democratic state of Mongolia is reverting to electing and sustaining support for socialist leaders. The fundamental economic problems that Mongolia has faced in the twenty-first century along with corruption sentences for many founding leaders of democratic Mongolia have played a major role in this shift. However, there are innate cultural practices that draw the communal nature of Mongolian society to socialist tendencies. Culture and political landscape are inextricably connected with the Buddhist Sangha, a major bedrock of the community driving socialist change and revolution. The Buddhist Sangha was later detached from the government due to a move to secularize, but the innate Buddhist ideals have proliferated within the government to create a unique Mongolian political structure. Secularization in this case isn’t a case of removing culture, rather it allows Mongolia to create social change and allows access to freedoms while also holding onto cultural norms that have been established for centuries before. This push for modernization in the past decade has allowed Mongolia to disassociate itself from being answerable to the free market and has allowed it to be first responsible to its people allowing for the most sustainable cultural growth.

Abstract Name: SHIFTING NARRATIVES: EXPLORING GENERATIONAL CHANGES IN GHANAIAN LITERARY DEPICTIONS OF MENTAL ILLNESS

Ghana's storytelling tradition, once rooted in oral literature, has undergone a profound shift. The prominence of print and digital literature in recent years has reshaped the entire landscape (Osa, 1985). This resurgence of literature, particularly in the form of contemporary novels or "storybooks," has made fiction more accessible, particularly to children across the nation (Ghana Book Development Council, 2021). This shift has not been limited merely to the medium of dissemination, but also in its portrayal of health conditions such as mental illnesses. This is pertinent as media, including various literary forms, have played a major role in the perception of the stigma surrounding mental illness in Ghana. Drawing upon the historical context of mental illness portrayals in Ghana, this paper undertakes a comparative analysis of the changing depiction of mental illnesses within the Ghanaian literary scene. By examining the evolution of these portrayals across generations, the paper argues that there has been a discernible generational shift in Ghanaian literary representations of mental illness. This paper uses labeling theory and content analysis to analyze various forms of recorded oral tradition. These analyses will illustrate how these literary forms have presented mental illness and mentally ill people in Ghana, bearing in mind that literature not only entertains but echoes and informs the opinion of society (Dei, 2013). Subsequently, these same measures are also taken into account when analyzing some of the most popular Ghanaian contemporary novels of the past few decades and their portrayal of mental illness. These will be key in determining the presence of a discernible shift within these portrayals. Hopefully, the results from this research will spark some discourse on the lingering effects of stigmatization of mental illness in Ghana, and hopefully steer the government and individuals to enact changes that will move the country forward.

Abstract Name: In vitro evaluation of Platinum-Gold Compounds as potential chemotherapeutics and targeted agents for ovarian cancer and study their interactions with DNA and DNA Quadruplexes.

Cancer chemotherapy is limited by intrinsic and acquired resistance of tumors to treatment, and lack of selectivity that leads to off-site toxicity and serious side effects. Despite multiple advances in cancer targeted therapies, Platinum(II)-based drugs such as FDA-approved cisplatin, carboplatin, and oxaliplatin are widely used as chemotherapeutics. However, these drugs are limited by lack of selectivity and appearance of resistance. Therefore, to improve the pharmacological profile of these drugs, a Platinum IV core based on

carboplatin and linked to a Gold (I) moiety will be biologically evaluated. Pt (IV) compounds can improve stability and bioavailability of platinum drugs due to its octahedral geometry, which allows for the attachment of two extra ligands in the axial position that can then be selectively released after reduction. The solubility, activity, and selectivity of the Pt(IV) compounds may be improved by choosing moieties with well-known anticancer effects and/or targeting vectors, such as Gold (Au) moieties. Therefore, our modified drug Pt (IV) - Au (I) will be evaluated in vitro as a potential chemotherapeutic and targeted agent for ovarian cancer since we hypothesize that the presence of two different biologically active metallodrugs (Pt IV and Au I) on the same molecule may improve the pharmacological profile due to synergistic or cooperative effects and thus warrant further preclinical studies with selected/optimized compounds. To investigate its anticancer properties various biological assays such as the cell-viability, anti-angiogenesis, anti-migratory, and cell-death assay will be performed. G-quadruplex structures have been identified in biologically significant genomic loci, notably in telomeres and thus they play a pivotal role in cancer progression and development, with their drug-induced stabilization emerging as a potential novel anticancer strategy. To assess the stabilization and binding capabilities, in vitro spectroscopic techniques such as the FRET DNA Melting Assay, UV-vis spectroscopy and Circular Dichroism will be performed.

Abstract Name: Predicting Commercial Apps Success Using AI/Machine Learning Techniques

In today’s world, designing successful applications is challenging due to the large variety of existing apps that users can choose from to address all sorts of customer needs. To minimize the shortcomings of these applications, it is important for app designers to know what attributes can help their apps stand out. To do so, we analyzed a dataset from kaggle consisting of 9660 apps from the Google Play Store using IBM Watson, a data-analytics processor, to create multiple machine learning models based on this data. The models used features like category, size, price, and content rating of the apps to predict their ratings after its release, which are used as a measure of success. Various aspects of the models were analyzed such as F1 score, accuracy, precision, and recall. We predicted that the most significant factor is the category, which determined the type and functionality of the app. Our reasoning behind this was “if nobody was interested in a type of app, nobody would download it.” We implemented the Snap Random Forest Classifier and XGBClassifier, which are both supervised learning models, with enhancements such as HPO-1, HPO-2, and FE. The XGBClassifier with all 3 enhancements was the most accurate (69%, 68%, & 67% respectively), while the Snap Random Forest Classifier pipelines were less accurate. The overall accuracy of the experiment was up to 69% correct using the highest performing classifier, and the ROC Curve had a result of 65-100%. Finally, the confusion matrix shows that the model most accurately predicted ratings of 4 and 5. The results demonstrate that the app’s category and content rating had the biggest impact when predicting the rating, similar to our hypothesis. In conclusion, by implementing the XGBClassifier with enhancements, we can effectively predict app success based on app categories and content ratings.

Abstract Name: Investigating the neural circuitry of hyperarousal using a novel mouse model of stress-induced fear sensitization

Pavlovian fear conditioning is the process by which a neutral environment becomes associated with an aversive event, resulting in conditioned fear responses to the previously innocuous stimuli. Dysregulation of this process is believed to contribute to the development of trauma-related disorders, particularly post-traumatic stress disorder (PTSD). Despite extensive pre-clinical investigation in rodent models, current therapeutic strategies for PTSD have limited efficacy. A potential reason is the insufficient understanding of how a single stressful incident can broadly sensitize fear behavior in response to situations unrelated to the original trauma. This phenomenon, termed fear sensitization, may underlie PTSD symptoms of hyperarousal and reactivity in which patients exhibit disproportionate reactions to mild, non-associated threats. The purpose is to develop and characterize a mouse model of fear sensitization that focuses on non-associative fear learning, which does not require the formation or retrieval of an associative fear memory resulting from stress exposure. This will facilitate investigation into the neural consequences of heightened fear sensitivity in specific brain regions, and potential therapeutic interventions for symptoms that may be resistant to Pavlovian frameworks. Our model involves placing mice in various contexts, each distinguished by unique visual and olfactory cues. Additionally, we utilize the mouse's freezing behavior as an index of an enhanced fear response. The mice are divided into two groups: a Stress group, subjected to four footshocks, and a No Stress group, which receives no shocks. Subsequent exposure to a tone, a harmless and novel stimulus, gives rise to an exaggerated fear reaction of the Stress group which is a significant distinction. The immediate early gene, c-Fos, has enabled us to identify brain regions hyperactive during periods of stress and sensitization, like the paraventricular thalamus. Overall, these findings illuminate the neurological basis and circuitry of stress-enhanced fear learning, and insights into the mechanism of PTSD.

Abstract Name: Demonstration of Multimodal Sensing in Characterizing an Exoskeleton Device for Leg Muscle Rehabilitation

Leg muscle rehabilitation is mostly required for elderly patients. At San Jose State University, an automated exoskeleton device was designed for aiding such patients. This study delves into the integration and sophisticated utilization of multiple sensors, including EMG sensors, rotary encoders, inclinometers (accelerometer-like sensors), and pressure sensors. Electromyography (EMG) sensors are pivotal in detecting and processing muscle impulses, enabling precise control of the exoskeleton's movements. The MyoWare EMG sensors employed were calibrated to allow for automatic filtration of the baseline muscle activity to capture a range of 0 to 450mV. Moreover, optimizing the placement of these sensors at varying lateral distances has enhanced signal strength and reliability, essential for accurate muscle activity detection. For this purpose, multiple pairs of EMG sensors with variable separation were mounted on the leg and optimum position and separation was determined. Additionally, the introduction of a WitMotion WT901C inclinometer provided critical insights into limb orientation and movement dynamics. This sensor was used to further characterize the orientation and movement of the knee brace. Signswise Optical 360-step rotary encoders

were calibrated and utilized to offer precise measurements of knee-joint angles and rotational velocities. Results indicate measurements of 18.355 deg/s for extension and 19.321 deg/s for contraction. A software program was developed to utilize a time-interval-tracker for time of operation measurements, with a reported average time varying from 1.773-1.578 seconds as pressure increases from 30-60 psi. The addition of pressure sensors allows for the assessment of interaction forces between the patient and the device, crucial for tailored adjustments and comfort during rehabilitation exercises. Such feedback minimizes the risk of injury during rehabilitation exercises. The current presentation will include the details on the leg muscle exoskeleton device along with the performance of each sensor mounted on it for its characterization.

Abstract Name: Testing for Genetic Associations with Sex in the Sunflower Sea Star

The sunflower sea star (Pycnopodia helianthoides) is a keystone species along the West Coast of North America that contributes towards the health of marine ecosystems. Sea star wasting of the spongy limb tissues of the species has been prevalent, leading to a rapid decline in population density and reproduction. Current literature regarding sex-specific single-nucleotide polymorphisms (SNPs) in the species is lacking, but genetic associations with sex have been documented in other echinoderms. Determining genetic associations with sex could provide insight into potential relationships between genes, sex, and differential vulnerability to disease due to sex. Using whole genome sequencing (WGS) of 19 female and 16 male Pycnopodia samples, we tested for genetic associations with sex. Results of this study may provide insight on sex ratios of the sunflower sea star in the wild and exploring whether sex ratios changed after mass mortality due to wasting and other stressors. This could aid in captive breeding and conservation efforts of the critically endangered species.

Abstract Name: DNA transfer via blood with varying substrates, pressures, and times

There is a pressing need for research that enables forensic scientists to better understand what facilitates DNA transfer because of the concern of false convictions due to indirect transfer. In this study, the effects of pressure, duration of contact, and substrate were examined to see how they influenced the amount of DNA transferred. Others have investigated these variables, but this study utilized new variations that more closely resembled crime scenes, including heavier pressures and a semi-porous substrate. Blood was transferred from glass to another substrate using a varying pressure and a varying time. The samples were dried completely, and DNA was extracted using forensic-grade DNA extraction kits. Of the three factors investigated, the

substrate variable was the only one that demonstrated significant differences between the substrates in the amount of DNA recovered; semi-porous magazine returned quantitations of DNA larger than the evaluated porous substrate cotton. As a result, the ink was evaluated to determine whether that background was artificially inflating the data through interference. Ethanol was added to magazine pieces to recover only the ink portion of the substrate. When quantitated, the samples indicated DNA concentrations even though no DNA extraction had been conducted. The results from this study indicate that the recovery of DNA from surfaces with ink needs to to account for background information, which is often difficult with the heterogeneity of ink used on a page. Namely, if forensic scientists cannot obtain an accurate DNA quantitation, the sample could be overdiluted which could cause further issues in the DNA workflow such as allelic dropout. Therefore, there is a significant need for further research into inks and the effect on DNA quantitation using spectrophotometry techniques.

Abstract Name: Understanding the relationship between pollen to ovule ratios and pollination methods in Justicia (Acanthaceae)

Justicia (Acanthaceae) are flowering plants with diverse floral morphology that vary across species with various corolla colors and corolla tubes ranging from short and wide to long and narrow. The flowers have two anthers and usually two thecae in each anther, but are often displaced along the filament, different sizes, and may have hooks or other extensions of the filament. Flower morphology and pollinator groups have co-evolved, and flower morphology in the genus is correlated to pollinator group to ensure reproductive success. This diversity of floral morphology and pollinators makes Justicia a useful study system for the evolution of reproductive biology. We studied the relationship between pollen to ovule ratios and pollination methods across seven Justicia species to test why different species may produce varying quantities of pollen and have heteromorphic anthers. We counted total pollen grains in each anther sac and number of ovules to consider the ratio of pollen to ovules as the reproductive potential of the flower. We found that pollen to ovule ratios in these species ranged from 203:4 to 21670:4. Justicia betonica, a bee-pollinated, obligate outcrosser, has a pollen to ovule ratio higher than hummingbird-pollinated, facultative outcrossers, J. californica, J. candicans, and hummingbird-pollinated J. sonorae. Both bee and hummingbird-pollinated species have higher pollen to ovule ratios than lepidopteran-pollinated J. petiolaris, J. lythroides, and J. longii. The differences in pollen to ovule ratios between species pollinated by different animal groups suggests there may be differences in pollination efficiency in the pollinator groups. Some species exhibited large variability in pollen production between inner and outer thecae, while others had very little. Our study will aid in understanding potential relationships between pollen production and animal pollination methods.

Abstract Name: When Two Worlds Col-Light: Chemical Confirmation of Bioluminescence in Antarctic Krill

Deep sea species are the most common organisms to exhibit bioluminescence in the marine ecosystem. However, not all bioluminescent species reside solely in the deep sea as organisms like Euphausia superba (Antarctic Krill) appear to exhibit bioluminescence as opposed to their Pacific Krill counterparts. It is not confirmed if these krill are in fact, bioluminescent. Typically, histological techniques are employed to identify the presence of bioluminescent cells in various locations within this species. However, chemical reactions are also used to confirm this bioluminescence by determining the presence of luciferin (substrate) and luciferase (enzyme) within the tissue, both of which are necessary to produce light, and reacting the tissue samples with adenosine triphosphate to confirm visual light production. The confirmation of this bioluminescence in the form of a flash of light during the reaction suggests that the organ is, in fact, intrinsically bioluminescent and the organ does contain the photophores required for exhibiting this phenomenon. The chemical techniques used will assert that the mechanisms used for light production are functioning properly within the organism. Not much is known about bioluminescence within marine organisms and to be able to shed light on this species may help to bring more awareness to the global efforts to take care of our oceans in order to save these rarities.

Abstract Name: Exploring the Stereospecificity of the Bromination of Substituted beta-Methylstyrene Derivatives

Reaction stereospecificity is incredibly important in fields such as medicinal and synthetic chemistry. Normally, bromination reactions are stereospecific, but with trans-beta-methylstyrene, a mixture of stereoisomers forms. By varying the R-groups on the reactant, a different reaction outcome may occur which can restore diastereoselectivity as we believe that the electronic nature of the substituents can influence the selectivity in a predictable way. By attaching these different R-groups with various electronic natures and positions (ortho vs. meta. vs. para) we predict that we can improve selectivity in these brominations. Using Suzuki coupling to generate the o-nitro-substituted-trans-beta-methylstyrene, a bromination with this reactant who has a strongly electron withdrawing group (o-nitro) is expected to result in a completely selective reaction for the product, anti-dibromide as compared to the minor product syn-dibromide.

Abstract Name: Trends in Anatoxin-a and Microcystin Concentrations in Two Eutrophic Lakes: The Role of Habitat and Season

Cyanobacterial Harmful Algal Blooms (cHABS) are an overabundance of cyanobacteria and are most prevalent in waterbodies that have high levels of nutrient pollution and biological productivity which are referred to as eutrophic. Anatoxin and microcystin are two types of toxins produced by cyanobacteria (cyanotoxins) that have been found in waterbodies globally and pose serious challenges to human and ecological health, while predicting their presence spatially and temporally remains a difficulty. This project explored anatoxin and microcystin levels in the water column near the benthic zone at the bottom of the lake (near-bottom) and in the pelagic zone near the surface (near-surface). Differential habitat preference for the water column (pelagic) or lake-bottom substrate (benthic) and differential toxin production by various cyanobacterial taxa suggest that toxin levels will differ across lake depths. We sampled near-surface and near-bottom lake depths in June and July for eight locations across two eutrophic lakes in west-central Wisconsin. Total biomass and cyanobacterial biomass were quantified with fluorometric analysis of the photopigments chlorophyll-a and phycocyanin from water samples. Anatoxin and microcystin concentrations were determined using ELISA immunoassays. We observed a seasonal increase in near-surface biomass during June and July which correlated with an increase in microcystin and phycocyanin levels that were significantly greater in near-surface samples than near-bottom samples according to independent t-tests (p<0.05). Although we did not identify significant relationships between anatoxin levels and season, sampling depth, or microcystin levels, elevated anatoxin detections at near-surface depth are suggestive of anatoxin production by pelagic cyanobacteria near the surface of these lakes. While toxin levels were typically higher at near-surface depth where a surface cHAB bloom was observed, relationships between toxin levels across the seasons and at different waterbody depths need to be further elucidated.

Abstract Name: Modeling COVID-19: Pandemic and Endemic Analysis with Mitigation

The Coronavirus Disease of 2019 is a disease caused by the SARS-CoV2 virus [2]. During 2020, the disease spread to many countries in the world and led to a worldwide pandemic. The SIR epidemic model [1], which is a simple nonlinear differential equation model, has been used to analyze quantitatively the spread and control of different infectious diseases and predict their future outcomes. In this project, we considered an SIR model for COVID 19 implementing a mitigation factor which covers the effect of vaccination and public health measures. In the first part of the project, we considered a closed system and derived explicit solutions to the model variables using the Lambert W function and derived a formula that determines the maximum infected populations over the course of the pandemic. We analyzed and validated our solutions using Python and matplotlib and recent COVID-19 data from Shelby and Davidson counties in Tennessee. In the second part of the project, we conducted endemic analysis of COVID-19 by including new arrivals and reinfection factor into the SIR system. We derived the endemic equilibrium point providing the long-term solutions of S, I, and R, and a formula to compute the reduction in population occurred through the course of COVID-19.

Abstract Name: Magnetic Innovations: Redesigning a Magnetometer Circuit Board

In collaboration with Fermilab for the renowned Muon G-2 experiment, this research at North Central College involved the design and development of a magnetometer circuit board for the G-2 experiment. The project, guided by professor Dr. Paul Bloom, who works closely with Fermi lab, aimed to overcome the limitations of the existing circuit board, which was restricted by proprietary software and vendor dependence, and plagued with design issues like inadequate strain relief on input and output connectors, and ultimately contribute to the data collection for the g-2 experiment as it is a critical instrument for the experiment.Addressing these limitations, the project shifted to open-source software, broadening manufacturing options and augmenting board functionality. The redesigned board features a sophisticated 3-axis Hall sensor system. Each channel, with a dedicated constant current source for the Hall sensor, ensures refined signal conditioning before digitization. This enhancement not only overcomes the original design's shortcomings but also extends its applicational reach.Key challenges in this redesign included interpreting intricate circuit diagrams, mastering layout software, analyzing data files, and refining soldering techniques. These barriers were essential in the development and iterative testing of the prototype, ensuring its efficacy and reliability.The implications of this redesign are vast. The circuit board's versatility allows for its application in significant particle physics experiments, akin to "Muon g-2," and in advanced optical instruments like MOKE Microscopes.In conclusion, this research underscores the necessity and impact of redesigning the magnetometer circuit board. It not only enhances its functionality and availability but also demonstrates the substantial contributions of undergraduate research in evolving experimental physics tools, particularly in settings with limited resources. thereby contributing to the scientific community.

Abstract Name: Contribution of Infection with Cytomegalovirus (CMV) to the Production of Alzheimer’s Disease-associated Beta Amyloid in Rat Neurons

Neurological disorders like Alzheimer's disease are a pressing global health concern. We are investigating the intricate relationship between cytomegalovirus (CMV) infection in neurons and production of pathological markers of Alzheimer’s disease, particularly how CMV influences the production of beta-amyloid, a hallmark feature of Alzheimer's disease. In this context, our central hypothesis posits that primary neurons exposed to CMV exhibit an elevated rate of beta-amyloid production, unraveling a potential link between viral infections and Alzheimer's pathology. Simultaneously, we assess how CMV infection may lead to increased production of beta-amyloid using western blotting, enzyme-linked immunosorbant assays (ELISAs), and immunocytochemical analysis of B35 cells infected with mouse CMV (MCMV). Concurrently, we are exploring the regulatory role of cholesterol in Alzheimer's disease using pharmacological tools (statins) to

decrease cholesterol production with and without MCMV infection. Our preliminary data indicates that MCMV infection decreases the levels of amyloid precursor protein concomitant with an increase in the production of the 1-42 beta-amyloid fragment by western blotting and ELISAs, respectively. This multifaceted approach, spanning diverse experimental techniques and temporal dimensions, enables a comprehensive understanding of the interplay between CMV, beta-amyloid production, and the preventive potential of statins in Alzheimer's disease. In future experimentation, we plan to confirm the results obtained using B35 cells in primary cultures of rat cortical neurons. The study shed light on the specific effects of cholesterol and statins on cultural rat neurons, providing a solid foundation for developing interventions that can potentially mitigate or prevent the progression of Alzheimer's disease.

Abstract Name: The Effect of Anxiety on the Brain

Anxiety disorders are mental illnesses that cause feelings of fear and worry. The criteria for an anxiety diagnosis, according to DSM-5 criteria, is excessive worrying lasting for a period of at least 6 months, along with experiencing associated symptoms like fatigue and brain fog. Almost a third of U.S adults experience an anxiety disorder at some point in their lives. It, like many other mental conditions, have physical effects on the mind such as weakened connections between parts of the brain and altered neurocircuitry. Microglia are immune cells in the brain that are essential to investigate because of the role they play in anxiety. Multiple studies conducted on rats and mice have found that these cells are activated when anxious behaviors such as obsessive grooming behaviors, hair pulling, and elevated heart rates are displayed. Optogenetics is a groundbreaking tool that has been used in many studies researching anxiety. It utilizes light to control the activity of neurons, as well as microglia. Through a literature overview, I provide an analysis of the current research on findings of optogenetics investigations into how anxiety disorders and microglia impact the structure of neurocircuitry in the brain. Investigations into the neurocircuitry of the hippocampus, lateral septum, and amygdala are vital to understanding how anxiety works in the brain. These specific regions contain cells that have been found to be activated during anxiety and as a result, these parts of the brain are directly involved in anxiety. During chronic anxiety, certain parts of the brain can undergo physical changes in addition to altered functions.

Abstract Name: Bridging Financial Gaps: Enhancing Expat Workers’ Financial Inclusion in the United Arab Emirates

This research aimed to uncover the challenges expat workers face in accessing financial services and evaluated potential Fintech (Financial Technology) solutions to these challenges. Many Low-wage workers in the United Arab Emirates (UAE) do not have access to traditional bank accounts due to the minimum income threshold, resulting in lower financial accessibility. As such, completing international remittance are logistically challenging and often come with higher costs, which is a significant issue for low-wage workers. This research utilized semi-structured individual interviews with expat workers, bankers, fintech experts, and entrepreneurs as the main data collection tools. It also used secondary research to understand the UAE's financial inclusion policies. The study aimed to identify the barriers to financial accessibility and utilization of financial services. The investigation revealed key issues such as a lack of financial literacy, stringent regulations, and limited banking options tailored to expats' needs, all hindering their full financial participation in the UAE economy. This study's findings highlight the critical need for innovative, inclusive financial frameworks tailored to the diverse expat workforce in the UAE. It underscores the urgency of integrating advanced technological tools and policy reforms to ensure comprehensive financial participation and security for expats. The research reveals the complex interplay of factors contributing to financial exclusion in the UAE. The findings suggest that addressing these challenges is essential for enhancing the expat community's welfare and ensuring the UAE's socio-economic stability. This research paves the way for policy reforms and the introduction of tailored financial products and educational programs to bridge the existing financial gaps. By cultivating a more inclusive financial environment, this study promotes sustainable economic practices, benefiting the expat community, and contributing globally by setting a precedence for expat-centric financial inclusion strategies.

Abstract Name: Recurrent ethanol treatment does not produce a cumulative effect on plasma leptin levels in rats

Background: Hypoleptinemia is a potent orexigenic signal. Chronic ethanol (EtOH) consumption is associated with weight gain in humans, and acute ethanol treatment leads to reductions in leptin concentrations in both fasted humans and rats. The objective of this study was to determine whether short-term recurrent ethanol treatment has a cumulative effect on plasma leptin levels in rats, and whether treatment in the fed or fasted state influences the leptin lowering effect of EtOH. Methods: Two separate groups of male Sprague Dawley rats were exposed to either oral or intravenous (IV) treatment with EtOH (2g/kg via oral gavage or 0.067 g/kg/min IV for 30 min; n=7/group) on three consecutive days. Each rat served as its own control and received saline treatment either 7 d prior to or 7 d following exposure to EtOH. The oral group was fasted 12-14 h (overnight) prior to treatment, while the IV group was not fasted. Plasma leptin and EtOH levels were measured each day at baseline and 3 h following EtOH treatment. Data are expressed as mean + SEM. A two-way repeated measures ANOVA was used to test for differences in plasma leptin and EtOH levels due to treatment (saline vs. EtOH) or day (cumulative effect of treatment).Conclusion: Although we were able to replicate previous work indicating reduced leptin levels following acute EtOH treatment in fasted rats, our results do not support a cumulative leptin-lowering effect of recurrent EtOH treatment. Furthermore, IV EtOH treatment in the fed state did not have any impact on leptin levels. This suggests that the leptin-lowering effects of EtOH may either require the fasted state or may require ingestion and exposure of the GI system to EtOH.

Abstract Name: A Study of the Antimicrobial Properties of Black Cumin (Nigella Sativa) and its Associated Bacteria

The emergence of multi-drug resistant bacteria has led to a shortage of effective antibiotics and a potential public health crisis worldwide. Black cumin (Sativa nigella) is an annual flowering herb that has been used medicinally in many cultures and contains the active antimicrobial ingredient Thymoquinone. We investigated the presence of antibiotic producing bacteria associated with Black cumin plants and examined their antimicrobial activity. We hypothesized that the bacteria associated with the rhizosphere (soil attached to roots) of these plants had antimicrobial activity against safe ESKAPE relatives. Bacteria were extracted by mixing different parts of the plants (roots, leaves and roots plus soil) with 1X PBS buffer and vigorous shaking for 10 minutes. Aliquots of each extraction were serially diluted and plated on different growth media including ½ strength Tryptic Soy Agar, Starch-M agar, and Potato Dextrose Agar. After 24-48 hours of incubation, bacterial colonies were counted and analyzed for physical morphology distinctiveness. A set of distinctive isolates were tested for antimicrobial activity against safe relatives of ESKAPE pathogens. Antibiotic production was detected by the appearance of clear inhibition zones around microbial isolates when grown on plates containing ESKAPE relatives. The phyllosphere and roots had the largest microbial burden. A total of 33 antibiotic-producing isolates with activity against the following ESKAPE relatives were found; S. epidermidis, B. subtilis, E. coli, A. bayli. 56.6% of these isolates were associated with the rhizosphere of the plant. Eight antibiotic producers were selected for detailed characterization. 16S rRNA identification analyses, these isolates belong to the following genera: Entrobacter, Psudemonus, Stenotrophmans, and Exigroubacterium. Future studies will focus on genome sequence analyses to identify the antimicrobials produced by these bacteria and examine the genes and proteins involved in their biosynthesis.

Abstract Name: Enhancing Continuous User Authentication

As the world increasingly relies on the internet for exchanging and storing sensitive data, the demand for a highly secure system becomes paramount. Traditional authentication methods, like PINs and passwords, are insufficient due to susceptibility to breaches and difficult usability. In response, there's a rising interest in biometrics, specifically in touch dynamics, as a means of continuous user authentication, especially for mobile and computer devices. This approach is interesting because it encapsulates both user-friendliness while also ensuring strong security. It actively monitors various aspects of how the user interacts with the device, such as their typing patterns, swiping gestures, or touch pressure. By analyzing this diverse range of actions, the system builds a fairly accurate profile of the user’s unique patterns. For example, when a person swipes around their phone, the system considers multiple factors like touch coordinates, duration of the

swipes, and touch pressures. By evaluating these broad user's behaviour, the system is able to create an authentic profile. The system then uses this profile to verify the user's identity over time. Essentially, this system does not rely on one source of data for verification but rather stores a wide spectrum of features and uses those behaviours to make the authentication process efficient.

Abstract Name: Evaluating the Efficacy of Vacancy Taxation: Evidence from Washington D.C. Using Synthetic Difference-in-Differences

Vacancy taxation is increasingly viewed by policymakers as a potential solution to the challenges of affordable housing scarcity and urban revitalization. Despite this growing interest, there remains a significant gap in the empirical research evaluating the policy's effectiveness. This paper leverages a major reform of a vacant property tax in Washington, D.C. as a natural experiment to explore its impact on vacancies, home prices, and rents. Using a synthetic difference-in-differences design, I find that the policy led to a substantial decline in vacancies and concurrently increased the number of occupancies. However, I also find mixed evidence that suggests the policy increased home prices and rents.

Abstract Name: Dictator or Savior: Indiana Governor Oliver P. Morton

Oliver P. Morton served as the Indiana Governor from 1861-1867. During his tenure, he guided Indian through the American Civil War. To some, he was known as the "soldiers' friend" due to his constant support of service members and routinely visiting them while stationed in camps in Indiana and Kentucky. To others, he was known as a "state dictator." This research project argues that Morton did everything in his power to help the Union and President Abraham Lincoln during the war, including abusing his political power against rival Indiana Democrats. He worked with General Ambrose Burnside to keep Democrat state legislators of out the statehouse and arrest anyone who publicly spoke out against the war. There have been several historians who have examined Indiana's political history and Oliver Morton's wartime actions and legacies, including James Fuller and William Foulke. These historians, however, overlooked the collaborative relationship between Morton and Lincoln from 1860-1865. To address this gap in scholarship, I analyzed both Lincoln and Morton's collections of private correspondence including countless letters between the two leaders. I also examined executive actions, proclamations, newsletters, and additional letters from politicians and Hoosiers throughout the state. This research illustrates that Morton developed positive relationships with fellow Union Party state legislatures to secure support for the Union. As his tenure progressed, he increasingly abused his political power against his opposition, all in the name of supporting the Union and President Lincoln. After 150 years, we can see that Morton's actions could be justified to save the Union.

Today, when we hear politicians breaking rules and threatening political opponents, we should ask questions. Why are the politicians willing to take these actions and what are the costs? How should we respond when politicians go too far and threaten the very foundations of the Union?

Abstract Name: The role of neurotrophic factors in the ability of exercise to facilitate extinction of methamphetamine conditioned place preference and attenuation of drug-primed reinstatement

About 12.3 million Americans have reported using methamphetamine (METH) at one point in their lives. METH is a highly addictive psychostimulant that can negatively impact an individual's brain structure and function. Lowered dopamine (DA) levels, particularly in the striatum, have been recorded in those who suffer from METH addiction, as well as in rodent METH addiction models. These long-lasting effects on the brain can provoke behavioral changes such as reduced memory function, impaired decision making and executive functions, ultimately driving patients to struggle with addiction recovery and treatments. It is reported that 61% of METH users relapse within the first year of seeking treatments. Conditioned place preference (CPP) is a paradigm used to simulate addiction and recovery patterns in rats. Rats are given the option to choose between two different chambers; one chamber is paired with METH administration while the other is paired with saline administration. Over time, rats develop a preference for the METH paired chamber. Using this technique, we can study the cues and stress triggers that cause drug seeking behaviors leading to relapse. After voluntarily exercising, rats no longer show a preference for the METH chamber, indicating decreased motivational power of the drug paired cues. Although exercise has shown to reduce the rats' preference for the METH chamber, there have been no studies to date that examine the mechanisms underlying the change in behavior. Using a brain staining technique, immunohistochemistry, we investigated the role that neurotrophic factors such as brain-derived neurotrophic factor (BDNF) play in the relationship between exercise and METH-cue memory. These results may suggest exercise as a valid non-pharmacological treatment for patients recovering from a METH addiction, reducing the drug crisis.

Abstract Name: The Frontier Nursing Service: Community Based Care for Modern Healthcare

At a time when rural areas lacked access to healthcare, the Frontier Nursing Service (FNS), founded in 1925 by Mary Breckinridge, aimed to provide healthcare and medical services in the Appalachian region of

Eastern Kentucky. Breckinridge brought trained midwives into the state and nurses rode horseback to provide care for mothers and children in remote areas that lacked roads, indoor plumbing, and basic services. The Dorothy Annabelle Caldwell Frontier Nursing scrapbook, 1930s, at the University of Kentucky Libraries Special Collections Research Center, will be used to explore the community-based care of the Frontier Nursing Service and why such methods were successful during the Great Depression. Dorothy Caldwell, the author of the scrapbook, was a courier for the service, and her photos capture everyday life of those in Eastern Kentucky who were served by the FNS. In an area that is known for not trusting outsiders, the caregivers from the service successfully integrated themselves into Appalachian communities and earned the trust of the people they served. Included in the scrapbook are photos of nurses providing care to those in the community, children playing, and daily Appalachian life. Research methods will utilize this scrapbook and additional accounts of other FNS nurses and couriers, FNS literature, and quantitative data surrounding healthcare at the time to gain insight as to how the service impacted healthcare in Eastern Kentucky. Quantitative data will include historical and modern statistics from Eastern Kentucky to delve into the impact FNS had on the region. This data will play a key role in shaping solutions for current healthcare gaps in Eastern Kentucky.

Abstract Name: Chemoselective Acylation of the Least Nucleophilic Spot on Complex Molecules

To achieve more effective and greener syntheses, new and selective synthetic methods are needed. For instance, reliable chemoselective acylation at the least nucleophilic site of a complex molecule would streamline synthesis by removing the need for protecting group strategies. 1,8-diazabicyclo(5.4.0)undec-7-ene, or DBU, has been shown to be an effective catalyst for chemoselective acylation; however, reversible acylations end up yielding thermodynamic products that typically reflect acylation of the most nucleophilic available site.In this project, we sought to develop a general chemoselective acylation of indoles, even in the presence of alcohols. Previous research has shown that indole acylation is reversible and that DBU catalyzes acyl transfer to afford esters. Two potential solutions to overcome this limitation were studied: altering the organocatalyst and acyl electrophile such that indole acylation is irreversible, or using an in-situ protecting group strategy that did not add additional synthetic steps.In the first study, different nitrogen-containing organocatalysts were tested twice: once for favorable acylation at a weak nucleophilic site and once for unfavorable acylation at a strong nucleophilic site. Once catalyst candidates that only performed acylation at weak nucleophilic sites were identified, reaction conditions were varied and the acyl donor was structurally modified for more favorable acyl donation in attempt to increase the acylation rate. We also tested the ability of 1-trimethylsilylimidazole to selectively inhibit acyl migration without the need for separate protection and deprotection steps.Catalyst and electrophile screening, NMR analysis of dynamic acyl transfers, and an optimized protocol for chemoselective indole acylations in the presence of much more nucleophilic groups such as alcohols will be discussed.

Abstract Name: Analysis of Cell Functions on Tantalum Coated Polycaprolactone Samples

Polycaprolactone (PCL) has become a promising bioresorbable biomaterials for biomedical implants. However, the poor visibility under angiogram or x-ray images limits its potential use in endovascular devices such as coronary stents and flow diverters for aneurysm treatment. Our research explores the possible use of Tantalum powder as a thin coating radiopaque material on PCL samples to develop PCL-based bioresorbable flow diverters for treating brain aneurysms. This poster presents the effect of Tantalum coatings on the viability and cell functions of human umbilical vein endothelial cells (HUVEC) on PCL samples. Medical grade PCL samples of 10 mm by 10 mm by 1 mm were designed and 3D printed. Tantalum coating paste with four different concentrations was made by pouring finely grained Tantalum powder into the PCL-acetone solution and mixing them using a sonicator. PCL samples were coated with Tantalum paste using a paintbrush and dried. The X-ray visibility of the Tantalum coating was tested using a hand-held X-ray machine, and pick intensities of each sample were recorded using ImageJ software. The coated samples were sterilized under UV lights for cell culture. HUVECs were cultured on the Tantalum-coated PCL squares for 36 hours and stained the cells with fluorescent markers after cell fixing. The images of stained cells were taken under a fluorescent microscope with appropriate filters and analyzed using ImageJ software. Cell viability, proliferation, and adhesions were quantified and compared among the samples with concentrations of Tantalum coatings. The results show that the higher the concentration of the Tantalum, the better the X-ray visibility. However, the cell performance were not impacted up to a certain concentration of the Tantalum. The overall results showed great promise for the potential use of Tantalum as a radiopaque coating materials for the endovascular biomedical device.

Abstract Name: Investigating Endoreduplication in Plants

In contrast, plants employ endoreduplication widely across a variety of organs where it is hypothesized to be advantageous for intercellular transport and increased metabolic activity, though this work is confined to a limited number of taxa. In this study, we attempt to broaden our understanding of the phylogenetic distribution of endoreduplication in plants by improving methods for its detection. We planted over 20 different species for this project in the greenhouse, collected samples from different locations of each plant, extracted and stained the nuclear DNA from each sample, and analyzed it under a flow cytometer to assess the presence, absence, and extent of endoreduplication. We found variation in endoreduplication across species and tissue types, however the amount of samples we found it in were limited. This work will increase our knowledge of plant physiology and open up future research into organogenesis.

Abstract Name: Qualitative and Quantitative Analyses of a Life Course Framework to Prevent Victimization Recurrence Among Traumatized Homeless Women

The present study has undertaken an examination of the effects of services rendered by a transitional shelter that accommodates individuals of both genders. Specifically, the study aimed to ascertain whether these services have yielded discernible improvements in the circumstances of homeless women. Additionally, the study sought to determine whether certain subgroups of homeless women derive greater benefits from the services provided in comparison to others. The study employed a life-course theory to elucidate whether homeless women who have received assistance from the shelter have acquired the skills to effectively navigate and cope with adverse life circumstances, thereby mitigating the risk of experiencing further victimization. Both qualitative and quantitative analyses were used in a mixed-methods approach. The data has been drawn from three in-depth interviews and from secondary data obtained from Ozanam Manor. The data collected by Ozanam Manor has been analyzed within the study, encompassing past and present-day data provided by the survey participants. The study applied a qualitative approach that employed a naturalistic perspective to examine the experiences of homeless women within their own living environments. The primary objective was to gain insight into the adverse life events recounted by participants subjected to victimization.

Abstract Name: Neurodevelopmental Vulnerability to Gestational Ozone Exposure

About 99% of the global population resides in areas with substandard air quality according to the World Health Organization. Ozone is a reactive air pollutant that forms radicals and other reactive oxygen species that can induce cellular damage. Ozone adversely affects neonatal and maternal outcomes including fetal birth weight and risk of pre-eclampsia with air pollution increasing the risk for behavioral and cognitive outcomes, such as autism and attention deficit/hyperactivity disorders. Yet, little is known about ozone's

impact on fetal neurodevelopment.To investigate effects on fetal brains, pregnant Sprague-Dawley rats were exposed to 0.3 ppm of ozone via whole-body inhalation at either gestational day (GD) 10 or GD20 while controls received filtered air only. Brains were collected at term (GD21). GD10 is shortly after placentation with neuronal migration and circuit initiation ensuing. GD20 exposure allowed subtraction of acute-phase effects. Discovery neuroproteomics was performed as an unbiased view into cellular processes altered by ozone. Significant responses were interrogated through enrichment, network, and predictive effects analyses. Subsequent molecular assays targeted markers of altered protein processes with antibodies.Key impacts indicated with GD10 ozone were increased apoptosis (z-score = 2.541, p = 0.0018) and decreased neuritogenesis (z-score = -2.494, p-value = 0.00128), both essential in neurodevelopment. In follow-up, antibodies were used to target selected markers of these processes, including cytochrome C and caspase 3 to confirm apoptosis dynamics among different cell types and Git1 and Mapt (axons), Map2 (dendrites), and Snap25 (synaptic impacts) to assess altered neuritogenesis and circuit formation.In conclusion, ozone exposure early in fetal neurodevelopment appears to decrease neurite formation and increase cell death, impacting critical periods of circuit development that can contribute to childhood behavioral and cognitive outcomes. Ongoing studies will affirm these findings and assess altered synaptic balance.

Abstract Name: Quantum emitters in hexagonal boron nitride for quantum information processing applications

Defects in hexagonal boron nitride (hBN) have attracted wide interest as quantum sensors and single photon sources. Due to its ultra-wide bandgap, hBN has been found to host a variety of optically active point defects. We focus on the negatively charged boron vacancy (VB-) within hBN as it has been shown to be an especially sensitive quantum sensor. Although these defects provide promising results for quantum sensing, current non-deterministic fabrication methods preclude their use in large structured arrays or photonic devices. Ultrafast laser fabrication has been demonstrated to deterministically create single defects with high spatial precision and yield within the solid state. Here, we present confocal fluorescence spectroscopy and optically detected magnetic resonance (ODMR) of VB- ensembles in helium ion-irradiated hBN as well as spectroscopy of laser written arrays of VB- in multilayer hBN. We detect broadband emission between 700nm and 1000nm, indicating the presence of the VB- defect. Measured ODMR contrast of these defects reaches a maximum contrast of 13.4% at an optimized microwave power of 22dBm. These results are comparable and, in some cases, exceed the ODMR values observed by other researchers. These results will help further optimize the deterministic fabrication of VB- defects with desired properties for applications in future quantum sensing technologies.

Abstract Name: De Novo Mutation Discovery in Mouse Models and Human Patient Samples of Non-Hodgkin's Lymphoma

Cancer is a disease driven by genomic anomalies; however, discovering genetic aberrations in cancer from sequencing data remains a challenge because of the high degree of divergence from reference genomes. This study investigated how the RNA-Seq programs klue and kallisto can be used to extract cancer-unique sequences of non-Hodgkin's lymphoma in the EμSRα-tTA/TetO-MYC mouse tumor model and a human patient with B-cell follicular lymphoma from the Texas Cancer Research Biobank. The goal was to perform de novo discovery of mutations present in cancer samples from sequencing data. We used klue and kallisto to identify sequences that were present in sequencing data from tumor tissue but were not present in normal control tissue or in the reference genome. The tumor-unique sequences were then analyzed using BLAST. Additionally, using BLAT, we could identify whether the mutations in protein-coding genes were synonymous or nonsynonymous. In many of the cancer-unique sequences extracted, an amino acid change was observed. We discovered thousands of cancer-unique sequences. In one case in the human patient sample, we discovered a nonsynonymous oncogene, SPI1. The sequencing reads showed both the "normal variant" as well as the mutated SPI1:H268P; suggesting a heterozygous mutation. Using this procedure, we developed an approach to extract sequences from sequencing data that are unique to non-Hodgkin's lymphoma cancer tissue in mice and humans. However, we were only able to characterize point mutations because they were the most abundant and easiest to validate using BLAST and BLAT. Work in characterizing other mutation types in the cancer-unique sequences is ongoing.

Abstract Name: Justice Denied: The Supreme Court's Role in the American Empire's subjugation of Puerto Rico

This paper deals with the role that the Supreme Court has played in allowing an American empire to rule over the territory of Puerto Rico. The United States has expanded into territory that was native to foreign populations from its conception, but with the expansion of overseas territories, the United States government had to come face to face with the consequences of its empire. However, instead of punishing the government or restricting it from being able to wield imperial power, the United States Supreme Court allowed and sustained a renegade Congress. The consequences of the Court's decisions in the insular cases, especially Downes V Bidwell, echo throughout the 20th century into today, creating two classes of Americans, those fully protected by the constitution, and those who are not. This division was recently reaffirmed in the 2022 case United States vs. Vaello Madero.

Abstract Name: The Effect of COVID-19 on the Experience Levels of Registered Nurses on Veterans Affairs Inpatient Units.

Importance: Registered Nurses (RNs) compose more than 30% of hospital workforce and the Veterans Health Administration (VHA) is the largest employer of nurses in the US. While RNs were strongly affected by the COVID-19 pandemic, little is know about how it impacted inpatient RN experience levels, which is known to influence patient outcomes.Objective: Determine how COVID-19 affected the experience levels of RNs in the VHA.Design: Panel study using 351 acute care units from 108 VHA medical centers and CDC data from January 2018 to December 2021 on RN turnover, depature, and experience / tenure.Exposure: Differential pandemic exposure across VHA.Outcomes: Monthly average unit tenure in days taken and monthly unique RN unit departures.Results: The panel included 351 acute care units (mean RN count 28.5 [SD 11.1]). Units were divided into 5 types with Critical Care having the highest average unit tenure / experience level (5.9 [2.5] years vs. 4.7 [2.2] for the whole sample) and percent of RN departures that left the VA (43.4 [45.8] percent vs full sample 38.4 [44.8]). Critical Care had the highest experience level lost (323.7 [126.8] days, p < 0.05 vs. full sample 66.2 [43.7]) when COVID-19 severity was high. This experience loss seemed related to Critical Care's increased incidence rates of regular (4.536 [2.343] IRR, p < 0.01 vs full sample 1.624 [0.433], p < 0.1) and experienced departures (3.868 [1.714] IRR, p < 0.01 vs full sample 1.723 [0.832]) when COVID-19 severity was high.Conclusion: The strongest relationships between COVID-19 exposure levels and RN unit experience level & depatures existed among units worse affected by the pandemic: Critical Care units. The VHA should investigate how these losses affected patient outcomes and ways to retain RNs.

Abstract Name: The Association of GDF15 and Treatment-Induced Nausea in Women with Breast Cancer

Background: GDF15 gene, a growth-differentiation factor with stress-related metabolic signatures, is associated with the GFRAL receptor localized in the brainstem to feed behaviors related to nausea. Recent work has shown a strong association with variants of the GDF15 gene and pregnancy-induced nausea. The purpose of this study was to determine the association of GDF15 and nausea experienced by women with breast cancer during treatment. Methodology: This study utilized a cross-sectional design, measuring nausea experienced three months following surgery–when adjuvant therapy usually begins. All data were collected as part of a larger, longitudinal study designed to precisely phenotype symptoms experienced by women with breast cancer for one full year. Informed consent was obtained at the time of surgery. Nausea was measured with the Patient-Reported Outcomes Measurement Information System Gastrointestinal Scale (PROMIS®GI). Data collection occurred by telephone or by email, with study participants completing the PROMIS®GI online. DNA was collected using the DNA Genotek® saliva kits. Genotyping was conducted

with Illumina Infinium Global Diversity Array. Results: The sample included 284 women with an average age of 60 years (range 26-88). The sample was 88% white yet represented diverse backgrounds for rural/urban and neighborhood deprivation status. Single-factor variance analysis (ANOVA) was conducted over calibrated nausea (T-scores) versus three variants: rs8101804, rs1059369, and rs1227731. The variant rs1059369 was significantly (F=2.996, p<0.05) associated with nausea occurring three months after surgery–when adjuvant therapy usually begins. Conclusions: Personalized health care is our goal, as we work to determine potential predictors for those women who continue to experience nausea during treatment. The metabolic signature of GDF15 may present a potential genetic marker for identifying trends in nausea to determine earlier interventions.

Abstract Name: U.S. Army's Reaction to the Liberation of Concentration Camps: Attempts to Handle the Crises of Displaced Persons from April to October 1945.

On April 4th, 1945, the United States Army was tasked with something its soldiers never received training for. As the Allies advanced into Nazi-occupied territory, they began uncovering the horrors of the realities of Hitler’s regime. There was no blueprint available for what to do when stumbling across concentration camps. What happened once the soldiers got to the sight of the camps? How do you clean and care for the survivors, and who should be cared for first? After the survivors have received care where are they to go? These are all just the beginning of questions that the United States Army faced as they came across the first subcamp, Ohrdruf. Only days later would the Army realize that Ohrdruf was just a glimpse of what was discovered at the main camp, Buchenwald. The typical American soldier’s job now consisted of caring for the victims in ways such as delousing the survivors and providing medical care, food and temporary housing. As the summer of 1945 goes on, another question arises as to what will happen to the displaced persons in the camps. April to October 1945 is a window of time that until recently, has been overlooked in the overall historiography of the Holocaust. This is the key to understanding how the United States handled the displaced persons crises. There are memoirs, diaries, letters and interviews of American generals, G.I.s, medics, etc., at the researcher’s disposal to follow the soldier’s efforts from the start of liberation leading up to the displaced persons crises. Utilizing these accounts helps in the attempt to assess the U.S. Army’s efforts in liberating. The narrative of the Holocaust does not just stop at the end of the Second World War. The consequences of the Nazi regime would haunt the world for decades to follow.

Abstract Name: The Effect of Stress on Pavlovian Conditioning

The purpose of this study is to identify how a single stressful experience affects Pavlovian learning. Prior research demonstrates that a single exposure to stress produces a long-lasting increase in Pavlovian conditioned responding, and this increase involves the midbrain dopamine system. However, the stress-related signals mediating this increase remain unknown. Stress promotes the release of corticotropin-releasing factor (CRF) into the ventral tegmental area (VTA), a key dopamine-producing nucleus in the brain. Dopamine neurons in the ventral tegmental area (VTA) have been shown to mediate reward intake, memory, and learning. Additionally, it is unclear whether sex or the estrous cycle may influence Pavlovian conditioning, as sex- and estrous-differences have been identified in stress responses. I hypothesize that CRF receptors in the VTA are required for stress to enhance conditioned responding. To test this hypothesis, I will inject a CRF receptor antagonist (alpha-helical CRF) or a vehicle control into the VTA prior to stress in male and female rats. I will then determine how these intra-VTA injections prior to stress subsequently affects conditioned responding across Pavlovian training sessions.

Abstract Name: USE OF SYSTEMIC THINKING TO MITIGATE THE RISKS OF EARLY-STAGE ENTREPRENEURS

Despite the growth of corporate sustainability, the business sector continues to have negative impacts on the environment and communities. In academic institutions and entrepreneurship support centers, there is a lack of methodological tools considering complex variables from social and environmental perspectives, hindering the application of systemic thinking in business creation.The research addresses the central question: How can we encourage the use of systemic thinking to mitigate risks for budding entrepreneurs?The Flourishing Business Canvas (FBMC) emerges as a solution to this situation. FBMC is a collaborative visual tool for designing business models suitable for the 21st century, focusing on interdependencies between businesses, society, the environment, and the economy.To address this, the FBMC model was employed and complemented with a validation process through the design of co-learning workshops, initially targeting research seedbed members. Additionally, a booklet with characters was created for easy dissemination, and methodological tools were integrated into the workshops to promote systemic thinking among young entrepreneurs.In essence, our seedbed has used a qualitative approach to analyze the impact of workshops on business models for two groups initially, targeting high school students and another group of four budding entrepreneurs. From these two exercises, it was highlighted that a comparison revealed the achievement of each participant in integrating essential elements into their presentations, such as recognizing stakeholders, environmental variables, and key concepts to validate their models from financial, technical, and market perspectives.In conclusion, the research underscores the importance of FBMC and systemic thinking in shaping early-stage entrepreneurs, demonstrating the effectiveness of workshops in enhancing business models and considering key aspects for their comprehensive viability.

Abstract Name: The Unheard Voices of Al-Intifadah Al-Shabaaniyah: An Exploration of the 1991 Uprising and America's Betrayal Through the Testimonies of Iraqi Participants Residing in America

This thesis delves into the often-overlooked 1991 uprising in Iraq, a significant early instance of resistance against Middle Eastern dictatorship. Rooted in the experiences shared within Michigan's Iraqi community. Focusing on southern Iraq, the thesis investigates the catalysts and mechanisms that enabled oppressed individuals under Saddam Hussein's Ba'athist regime to unite and rebel. Through extensive oral history methodologies, this research engages with diverse survivors—mothers, youth, and children—across various southern Iraqi cities. Their narratives unveil the hardships endured before, during, and after the rebellion.Remarkably, despite oppressive conditions and violent impediments, the southern Iraqi populace achieved a formidable mass uprising. This accomplishment, however, was overshadowed by the conspicuous absence of support from the United States. This lack of intervention facilitated the dictatorship's prolonged grasp for twelve more years, leading to grievous loss of innocent lives, human rights violations, and civilians confronting Saddam's brutal rule unaided. The aftermath of Saddam's retaliatory assault resulted in an estimated 30,000 to 60,000 civilian casualties in the South. The survivors of this tumultuous event carry lasting scars—PTSD, depression, and anxiety—echoing the trauma they endured.This thesis endeavors to illuminate this uprising's significance by amplifying the voices of its survivors. By listening to these accounts, it seeks to provide a comprehensive perspective on the events, shedding light on a pivotal historical moment that profoundly impacted the lives of those involved.

Abstract Name: Determining the impact of stress related on plant root microbial community dynamics

Interest in space exploration has been rising over the past decades. Growing plants healthily in space is a necessity of space missions due to its importance for astronaut's life. Plants provide nutrients to the space crew and help refresh the air through oxygen production. Furthermore, they provide crucial psychological support to astronauts during long space missions, which makes them essential for Mars and Moon missions. Plants are exposed to stresses in space that are not present on Earth, like microgravity and space radiation. Plant-associated microbiome has gained attention due to its potential for improving stress mitigation in plants, providing nutrient and growth benefits. Although the importance of microbial communities for plant health is well-studied, the impact of space-related stresses on plant-associated microbes has not been investigated. In this project, we explore the plant-root microbe interactions under space-associated stresses. Brachypodium distachyon and Setatia viridis plants, inoculated with a bacterial synthetic community, will be grown in lunar regolith, a mimicry of lunar soil. Plants will then be evaluated for their growth. Furthermore, bacterial growth in the lunar regolith will also be assessed. We expect our outcomes to create a genetic roadmap of how space-related stresses affect plants and their root microbiome.

Abstract Name: Chest X-ray Interpretation with Visual Question Answering in Medical Diagnostic

In medical diagnostics, this project aims to revolutionize chest X-ray interpretation usingmedical visual question answering. The goal is to streamline radiological evaluations, providingquicker and more consistent results for patients. Traditional methods relying on individualradiologists may lead to inconsistencies and delays. Our solution integrates object detection,Natural Language Processing (NLP), and stacked attention networks, enabling users to upload achest X-ray, pose related questions, and receive accurate predicted answers.Our image preprocessing pipeline resizes input images and questions before passing themthrough an attention layer. This attention mechanism allows the network to dynamically focus onspecific regions of the image, simulating a radiologist's attention to particular areas in an X-ray.Leveraging a dataset of 329 chest X-rays, we meticulously organized resulting question-answerpairs, question IDs, answer types, X-ray image locations, and annotations into a structured JSONfile.Our system, integrating object detection, stacked attention networks, and a diverse dataset, hasshown promising results. We observed adaptability in question answering and enhanced accuracywith the inclusion of a stacked attention network. In the future, we plan to address potentialbiases and improve performance, we plan to add a new dataset for brain tumors. Additionally,we'll apply bias mitigation techniques to account for abnormal images in both chest and brainX-ray datasets. This approach aligns with our commitment to developing a powerful andadaptable system for medical image interpretation.Integrating AI into radiology addresses the variability in human interpretations, evidenced bystudies showing disagreement among experienced radiologists. Built on a diverse dataset, oursystem aims to reduce discrepancies and enhance diagnostic accuracy. This research underscoresthe potential of combining computer vision and NLP to transform medical diagnostics, withongoing efforts to provide healthcare providers and patients with more reliable and expediteddiagnoses in the medical field.

Abstract Name: Comparative study of the impact of Nitrogen and Oxygen on Argon vs. Helium plasma

Dielectric Barrier Discharge (DBD) plasma is a well known non-intrusive method for healing and sterilizing wounds. The plasma jet consists of a working gas like helium or argon, that is ionized when high voltages are applied, which may vary from 5-10 kV (10-40 kHz). Once the plasma jet exits the torch, it entrains surrounding air to generate reactive oxygen and nitrogen species (RONS) essential for rapid wound healing. Identifying and quantifying RONs in the plasma will assist us to optimize the wound healing and wound sterilization process. This research takes an emission spectrum from an emitting plasma jet and uses emission spectroscopy (HR4000CG-UV-NIR) to analyze oxygen and nitrogen emission lines. When adding Nitrogen and Oxygen to Argon plasma, there were visible differences in the emission spectrum. In the case of 0.1% nitrogen addition, lines from N2+ SPS appeared in the spectrum whereas no new emission lines resulted as 0.1% oxygen was added. It was found that N2+ SPS lines intensity was heavily dependent on the applied voltages that varied from 7 kV to 13 kV. Particularly N337 and N357 N2+ SPS lines were monitored that increased in intensity by almost 700% as the applied voltage was increased by 86%. Preliminary corresponding study for the helium plasma is under progress and new results are being analyzed. Further

investigation will provide a thorough comparison of the impacts of nitrogen and oxygen additions in both helium and nitrogen plasmas. Final presentation will include comprehensive results from this research.

Abstract Name: CDKN2A/B Homozygous Deletion in IDH-Mutant Glioma Promotes Vascular Formation in Vitro

Isocitrate dehydrogenase (IDH)-mutant gliomas comprise an incurable group of grade 2-4 brain tumors with limited treatment options to date. Though IDH-mutant gliomas have a better prognosis than their IDH-wildtype counterpart, as tumors evolve to grade 4 designation the survivability is particularly discouraging at only 3-5 years, and moreover IDH-mutant tumors most commonly present in young adults. A hallmark of molecular evolution to grade 4 IDH-mutant glioma is acquisition of the homozygous deletion (HD) of CDKN2A/B, which encodes the cell cycle regulators p14ARF, p15INK4B, and p16INK4A. However, little is known about the deregulated biologic pathways that occur coincident with CDKN2A/B HD and there are no molecularly targeted therapies for these tumors to date. We therefore sought to investigate the functional impact of CDKN2A/B HD by generating tet-inducible re-expression vectors for p14, p15, and p16 in grade 4 IDH-mutant PDX models. From a cohort of 42 image-guided intratumor biopsy specimens representing 13 IDH-mutant patient tumors we identified several candidate genes/pathways differentially expressed across CDKN2A/B status including regulators of embryonic development, extracellular matrix organization and regulation of vascular processes. Using our IDH-mutant glioma PDX lines we then investigated the functional role of p14, p15, and p16 in models of angiogenesis. While conditioned media (CM) from the cell lines did not impact endothelial cell proliferation, we found CM from lines with re-expression of p14, p15 or p16 effectively hindered the formation of capillary like structures compared to parental lines. Overall, these data support a role for enhanced angiogenesis in the progression of IDH-mutant gliomas to aggressive grade 4 tumors and support further study of these pathways for novel therapeutic target identification.

Abstract Name: Exploring the "Gymcel" Phenomenon: Social Media Narratives and Identity Formation within the Manosphere

This study investigates the “Gymcel” subculture within the manosphere, focusing on societal and media influences that may contribute to its emergence. “Gymcels” are characterized as incels (involuntary celibates) with an obsessive focus on bodybuilding, potentially leading to extreme measures such as steroid use. This study contributes to the broader field of social identity and subculture studies by specifically focusing on the

“Gymcel” phenomenon, an area that remains underexplored in academic discourse. By analyzing narratives on social media platforms, including Reddit, Instagram, TikTok, and YouTube, this research aims to uncover the societal pressures and factors influencing “Gymcel” identity formation. Employing Collective Identity in Online Groups Theory, the study will explore shared practices, values, and beliefs within the “Gymcel” community. This study expects that factors such as social isolation, body image concerns, cultural influences, and mental health challenges play significant roles in shaping the “Gymcel” identity. This research seeks a deeper understanding of this subculture and its implications for social identity and behavior in the digital age.

Abstract Name: The Nightlife in Cairo: Who protects, who is protected, and who is entertained?

After an exchange semester in Paris, four female students at the American University in Cairo decided to go out to a nightclub to have a good time, meet some friends of both genders and compare this space to the one they had in Europe, away from family restrictions. After contacting the destination venue to make a reservation, they learned the conditions for entering the place: the number of females in the group must be greater than the males, the Facebook accounts of all attendees must be sent, any type of head covering is not allowed unless it is a turban, and everyone must pay the minimum charge at the gate. Cairo is a diverse, cosmopolitan city that attracts tourists from all over the world and is inhabited by thirty million people of diverse nationalities and backgrounds. One of the most important features of Cairo recognized in popular culture and common knowledge is the bustling nightlife that appears in cinema, television and advertisements to encourage tourists to visit Cairo to enjoy music, belly dancing and good service. During the last ten years, after the unstable political and economic conditions that Egypt went through and capitalism completely tightening its grip on the lifestyle, the rules of entertainment in nightlife changed and became restricted to a specific class with certain restrictions. If one seeks to have a good time, one must follow a series of rules that spaces have come to impose for “protection.” Through fieldwork and emerging as a participant-observer in these spaces, this paper seeks to investigate the alleged meaning of protection. An attempt will be made to answer the question: Who are the people to be protected in Cairo's nightlife? Who is responsible for this protection? Are the protections being promoted merely a pun on class and gender biases?

Abstract Name: Life and Works of Abram Games: The Official War Poster Artist of World War II

Abram Games is a British designer that made over 100 posters for the War Office’s Public Relations Department during World War II. His posters relied heavily on the use of clever imagery, rather than words. His philosophy is one of simplicity, to make a simple design well enough to reflect the maximal meaning of the message a poster may be conveying. His expertise shines brightest in his war poster designs. His careful

selection and precise execution of imagery was instrumental in his design success. His typographical choices were simple and minimalistic. This allowed imagery to guide the eye within his design. As in his thinking, if there is interest within the poster themselves, that will naturally draw out interest for the written message. Games was very successful in drawing out the emotion of his audiences and inspired both criticism and patriotism through his work. A few of his posters were taken out of circulation due to controversial messages or choices in imagery. His skill and expertise in design is still very admirable within those posters, even if they were not approved to be sent out to the public. Posters weren't the only thing he succeeded in. Games' skills in logotype, typography, and product design are also seen with high regard, and he stands as influential within the world of design, both then and now. His methods and designs are still admired by many in the present day. He paved the way for future designers, not only through his work, but also within his teaching, writing, and mentorship. Toward the end of his career, technological advancements grew. He encouraged young designers to remember the basics of traditional poster design. He also encouraged them to move forward, make mistakes, and learn how to transform their work into digital media.

Abstract Name: BODPOD GS: Derivation of Body Fat Correction-Equations

Background: The value of information collected by an instrument and/or equipment is dependent upon its degree of validity. Practitioners, researchers, and clinicians should verify the accuracy of instruments and equipment prior to disseminating information to their clientele. Purpose: To derive a body fat correction-equation that will provide results equivalent to the applied Gold Standard obtained from the BOD POD GS. Methods: Two hundred females and 134 males (Age = 21.8±6.8 and 22.5±8.0 years), underwent percent body fat (%BF) assessments via four methods (BODPOD GS, Hand-Hand BIA, Foot-Foot BIA1, and Foot-Foot BIA2) in a randomized sequence to mitigate sequence bias. Pearson correlation determined interrelationships, paired sample t-tests assessed mean differences, and linear regression facilitated equation derivation. Sex-specific analyses were conducted for all procedures. Results: Mean BODPOD GS %BF values were 22.6±6.9 for females and 14.9±6.3 for males. Systematic underestimated values for Hand-Hand BIA, Foot-Foot BIA1, and Foot-Foot BIA2 were -3.0, -2.2, and -1.2 for females, and -2.1, -2.9, and -0.2 for males, with all mean %BF significantly different from BODPOD GS except for males using Foot-Foot BIA2 (14.7±5.0; p=0.68). Correlations ranged from 0.73 to 0.75 for females and 0.52 to 0.66 for males. Female correction-equations to estimate BODPOD %BF were a) -2.556 + (1.246*Hand-Hand BIA), b) 1.542 + (1.03*Foot-Foot BIA1), c) 4.156 + (0.878*Foot-Foot BIA2). Male correction-equations to estimate BODPOD %BF: a) 2.02 + (1.0*Hand-Hand BIA), b) 3.670 + (0.935*Foot-Foot BIA1), and c) 5.784 + (0.62*Foot-Foot BIA2). Conclusions: The investigation revealed moderate to moderately high correlations and statistically significant mean differences. Except for Foot-Foot BIA2 for males, all other body composition equipment systematically underestimated the BODPOD GS. Practitioners, researchers, and clinicians can use these correction-equations in the field to derive equivalent percent body fat values to the BODPOD GS.

Abstract Name: Dignified Community Resource Center Design for the Homeless, Hungry, Impoverished, and In-Need

Food and housing insecurity are growing pandemics in the United States. Annual reports show that homelessness has increased each year across major American cities. In 2021, the number of Americans considered to be “in poverty” was 37.9 million, or 11.6 percent of the entire population in the country. More than 1 in 10 people are below the poverty line and struggle to access core necessities for living, including food, clothing, and shelter. With the added burden of inflation and the increasing food and housing costs, the need for community support continues to grow.Case studies and survey data provide additional evidence for this growing need for community support, what users of resource centers need most, and what existing facilities may lack. Principles of wellness and theoretical precedents, including color psychology and Abraham Maslow’s Hierarchy of Needs, also inform this project's design approach.The purpose of this project is to apply principles of wellness and hospitality design to create an elevated, enriching community resource center for the homeless, hungry, impoverished, and in-need. This center provides access to food, hygiene facilities, mental health services, community engagement events, and skill-building opportunities. One of the primary design goals is to avoid the othering effect of utilitarian design. Instead, this design aims to provide access to more than just necessities. It should also create an inspiring, dignified experience that can more effectively empower users on their path towards self-sufficiency.For the growing financially vulnerable population, lacking secure and consistent access to life’s fundamental requirements injures hope and spirit. This research project will determine how to overcome these challenges through effective community support, services, resources, connection, and dignified design.

Abstract Name: Investigating the Effects of Pregnancy on the Freshwater Mussel Lasmigona costata's Gut and Gill Microbiomes

North American freshwater mussels (family Unionidae) have a direct role in improving water quality. They filter microorganisms (plankton, protists, and bacteria) and particle detritus from water. The gut microbiome is the community of microbes within the gastrointestinal tract, and it performs critical functions for a host’s metabolic and digestive capabilities. Gut microbiomes can vary within and between species as a result of many factors, including the environment in which they live, the food they eat, and the host’s physiology. Pregnancy is characterized by maternal adaptations that are necessary to create a hospitable environment for development. Microbiota varies throughout life, from infancy to old age, in reaction to external stressors and changing physiological states. However, relatively little is known about the gut microbiome and how it works in mussels. I anticipate exploring more into this by comparing pregnant and nonpregnant between of a species of mussel to see if the eubiosis varies. A microbiome includes bacteria, archaea, and microscopic eukaryotic organisms (e.g., fungi and protists) living together in a community. Environmental factors like pH, temperature, and available resources select for specific microbial members; therefore, microbiome

community composition can change across a host's body and its species' range. In humans, this includes a change in the microbiome community of the gut and vagina; however, little is known about maternal changes in the microbiome of the ecologically important freshwater mussels. Here we investigate the bacterial community of the mussel species Lasmigona costata across two locations within the Licking River system, looking at both the gill and gut microbiome of gravid and non-gravid mussels. We plan to further explore this area by incorporating more mussel species in the future.

Abstract Name: Determining the role of gut microbiota in the production of ROS by Periplaneta Americana hemocytes

The impact of the gut microbiota on the development and function of the host immune system has been assessed in mammalian systems using germ-free and gnotobiotic animals, primarily mice. However, this relationship remains incompletely defined in insects. The American cockroach (Periplaneta americana) has a relatively complex gut microbiome compared to other insects and is an excellent model for such studies. With the recent development and optimization of germ-free protocols for the American cockroach, this system now provides a unique opportunity to investigate the interaction of the gut microbiome and the innate immune system. Insect immune cells, called hemocytes, have been characterized primarily through microscopy, leaving a knowledge gap regarding the specific functions and relative abundance of different hemocyte subsets. To first address this knowledge gap and better characterize the immune cells of the cockroach, we have employed flow cytometry and functional assays. With these approaches, we can isolate and identify hemocyte subsets based on lectin-binding capabilities and their specific functions (I.e., production of reactive oxygen species). Our studies demonstrate that a subset of granular hemocytes from conventional cockroaches produce ROS when stimulated with LPS with activity peaking within one hour of stimulation. We will additionally utilize cell sorting and microscopy to gain a fuller understanding of hemocyte morphology and individual functionality. These studies will serve as foundational knowledge for future studies, providing the necessary baseline immunological characterization in conventional P. americana for comparison to germ-free P. americana. This comparison will provide unique insight into the role of the gut microbiome in host immunological development and function.

Abstract Name: Understanding Engineering Undergraduate Students' Engagement with Research

This study delves into the exposure and interaction of undergraduate engineering students with research opportunities to show its impact on their academic development and future careers. Undergraduate research holds value by providing opportunities to students for hands-on-application, innovation, critical thinking, problem solving, personal growth and many more skills. Despite this, there is a void in the amount of research undergraduate students participate in while in school and this study aims to determine what causes this gap.Through a mixed-method approach consisting of surveys and interviews of undergraduate engineering students, this study assesses their current landscape when dealing with research at their local university. Findings show different patterns of engagement which were influenced by things such as program structures, institutional support, personal circumstances and motivations, along with internal perceived relevance towards career goals. Therefore, this research utilizes the experiences of a diverse group of engineering students, guaranteed by including multiple grade levels in the university, along with various areas of study in the University's College of Engineering.The research also finds there is an emphasis on the role of Professors in guiding motivation towards personal research along with a lack of knowledge fueling a decline of participation in undergraduate research programs for majors where the curriculum didn't encourage students to do so. Supportive environments, mentorship programs, and clear marketing of accessible research opportunities were the biggest roadblocks to engineering students when pursuing opportunities in Engineering research. Thus, recommendations arising from the results of this research include integration of research opportunities into the undergraduate curriculum, development of mentorship programs to facilitate student engagement in research, and increased promotion of collaborative research projects between faculty and undergraduates through faculty members and University Staff.

Abstract Name: Optimization of a Rapid and Efficient Method for Ginsenoside Extraction Abstract

American ginseng (Panax quinquefolius L.) is one of the most commonly used medicinal herbs worldwide. The ever-expanding market for and research into the benefits of American ginseng has perpetuated the necessity for more practical and efficient extraction methods. Common methods require extensive processing times and the unfortunate degradation of heat-sensitive ginsenosides (saponins). This study's goal is to develop a more efficient extraction method with decreased processing times which will also allow for the increased procurement of saponins and rarer ginsenosides. Traditional and novel methods such as Codex Standard Method, Japanese Pharmacopeia (17th Edition), United States Pharmacopoeia (40th Edition), European Pharmacopoeia (9.0 Edition), Chinese Pharmacopoeia (2015 Edition), and Ultrasound-Assisted Extraction were tested and compared using American ginseng roots. Ultrasound-assisted extraction with direct sonication using a probe horn was further tested by using varying parameters (sonication times including 15 min, 30 min, 45 min, 60 min, or 120 min and solvents including N-Butanol, Methanol, or 10% Methanol). After completing extractions, High-Performance Liquid Chromatography (HPLC) was used to analyze 11 different ginsenosides (Rg1, Re, F11, Rg2, Rb1, Rb2, Rb3, Rc, Rd, Rg3, and Rh2) in the samples. The sonication method had the highest extraction rates for ginsenosides F11, Rb1, Rb2, Rb3, Rc, Rg2, Rg3, Rh2, and overall, but the United States Method had higher extraction rates for targeted Re, Rd with

equivalent results in the extraction of Rg1. Our study demonstrated that the optimized ultrasound-assisted extraction method allowed for a higher total ginsenoside extraction rate while the United States Method had higher contents for targeted ginsenosides, Re, and Rd.

Abstract Name: Optimizing Nutrient Uptake: Understanding Cost Functions of the FUN Model through Innovative Cost Parameter Analysis

This study explores the cost functions of the FUN model, which aims to optimize the amount of carbon used when plants acquire their necessary nutrients from the soil to maximize nitrogen and phosphorus uptake while minimizing the carbon cost, more specifically, the complex relationship of cost parameters belonging to the cost of nitrogen and phosphorus uptake functions by Arbuscular Mycorrhizal and Ectomycorrhizal fungi with the goal of understanding nutrient cycling better. As a part of the methodology, this study presents three dimensions of sensitivity analysis done to the cost parameters; additionally, this study also examines outcome variations by graphing observed versus modeled data using linear regressions. When analyzing the cost of resorption of leaf phosphorus, increasing the kR cost parameter decreased the R2 value, while the model for nitrogen remained stable in the first dimension. Holding one cost parameter constant while changing the other in the second dimension increased the model's sensitivity to changes in both phosphorus and nitrogen. Switching the cost parameter being held in the third dimension yielded similar findings, highlighting the model's sensitivity to changes. The observed versus modeled graphs showed some exciting results; as the 'kR' value increased, the model's predictions became lower than actual values, with a larger residual spread; this caused an unexpected pattern and introduced uncertainty in the predictions, with a more negative bias and increased RMSE. This study aligns with and builds upon previous research in the field, emphasizing the need to perform sensitivity analysis further to enhance predictive accuracy.

Manal Alshamrani

Abstract Name: A Longitudinal Study of Hemopexin in Patients with Left Ventricular Assist Devices

Heart failure remains a global health challenge, with 26 million people diagnosed with terminal heart failure, where 90% of adults face a daunting prognosis within 10 years. Left Ventricular Assist Devices (LVADs) have emerged as life-saving interventions, addressing the scarcity of donor hearts by providing continuous blood circulation. However, the clinical benefits come at the cost of poorly understood complications, such as bleeding, thrombosis, infections, and pump malfunction, attributed to changes in hemodynamics and increased fluid shear stress.This longitudinal study focuses on the potential of hemopexin (HPX) as a predictive biomarker for adverse events in LVAD patients. HPX, a scavenging protein responsible for mitigating the effects of hemolysis, has shown significant variations in levels pre- and post-LVAD

implantation. Blood samples were collected from a cohort of 34 patients at baseline, discharge, 1 month, and 3 months post-discharge, utilizing a commercial Enzyme-Linked Immunosorbent Assay (ELISA) for quantitative HPX measurement.Analysis revealed that, on average, HPX concentrations were lower than reported normal values, with a notable drop at 1 month post-discharge. While no statistically significant difference in HPX levels was observed between patients with and without complications in this interim study, a trend of increased HPX concentrations was noted in patients experiencing clinical events. This study, powered for 250 patients, suggests the need for continued research to enhance statistical power and delve into potential associations between HPX levels and patients' CBC data, exploring correlations with red blood cell count, hemoglobin, and hematocrit.By expanding the cohort and conducting separate analyses for different LVAD types, our study aims to unravel the intricate relationship between HPX dynamics and LVAD-induced complications. Understanding the underlying mechanisms of HPX changes could pave the way for developing diagnostic tools and therapeutic interventions, ultimately improving outcomes for LVAD patients worldwide.

Abstract Name: Silica Replacement and Engulfment in Limestone; Currant Gap Detachment fault, Nye County, Nevada

Silicification in and adjacent to faults commonly appears as quartz veins and as replacement for carbonates and/or other lithologies. Petrographic data from rocks along the Miocene-Pliocene Currant Gap Detachment (CGD) raise the possibility that a significant portion of silicification begins as isolated quartz crystals that nucleate and grow in primary pore spaces of carbonate. Such crystals may later form veins along zones of weakness and/or enhanced primary permeability. Thin section investigation of partially silicified carbonate rocks in and adjacent to the CGD reveals extensive networks of quartz veins surrounded by carbonate and isolated euhedral quartz crystals. The isolated quartz crystals ($\leq$ 0.5 mm) have cores of often densely-packed primary (5 μm up to 30 μm) carbonate grains, called “matrix cores” because the carbonate grains are similar to those of the matrix surrounding the quartz. In addition, some veins also contain (25 μm up to 300 μm) euhedral quartz crystals with matrix cores. Acid dissolution of limestone yielded a residue of isolated euhedral quartz and intact quartz micro-vein networks. Scanning Electron Microscopy (SEM) reveals cavities in the crystal surfaces that are similar in size (5 μm up to 30 μm) to the grains of carbonate seen in the matrix cores. This indicates that the cavities seen in the SEM imaging resulted from quartz grains that did not completely grow around the carbonate grains, allowing for the acid to take effect on the partially covered grains. Angular to sub-rounded cavities occur both in isolated quartz crystals and in those found in the aforementioned intact micro-vein networks. These observations show that isolated quartz grains and quartz grains in at least some veins share the same origin: they nucleated in pore spaces surrounded by primary calcite grains, and eventually grew to engulf those grains. Such crystals did not originate in fluid-filled fractures.

Abstract Name: Relationship Between Hypertension and Measures of Depression at 10 Years After Traumatic Brain Injury

Research Objectives To examine the association between hypertension and a measure of depression at 10 years post-traumatic brain injury (TBI) and observe how hypertension in individuals with TBI may affect the chances of developing depression. Design Longitudinal study with analysis at 10 years post-injury. Setting Traumatic Brain Injury Model System (TBIMS) data collected from University of Alabama at Birmingham (UAB). Participants 142 participants with moderate to severe TBI who received inpatient rehabilitation following acute care at UAB with baseline, Year 1 and Year 10 data collection time points. Interventions Not applicable. Main Outcome Measures The National Health and Nutrition Examination Survey(NHANES) item related to hypertension was collected regarding if and when hypertension was diagnosed. The PHQ-9, a questionnaire assessing incidence and severity of depression was administered to participants at follow-up. Additionally, covariates such as age at time of injury and overall household income were collected from participants or their family members. Results Sixty-three patients reported having a diagnosis of hypertension prior to injury. At 10-year post-injury follow-up, the relationship between hypertension and the PHQ-9 score was significant ($p=0.020$) while accounting for the covariates of age and income (ANCOVA, one-way analysis of covariance; $F=5.565$). The mean PHQ-9 score for patients who reported having hypertension was 5.67 ($SD=5.691$) (indicating mild depression) whereas the mean PHQ-9 score for patients who did not have hypertension was 4.16 ($SD=4.584$) (indicating minimal depression). Conclusions The relationship between hypertension and depression was statistically significant at 10 years post-injury. Patients who had a diagnosis of hypertension pre-injury were more likely to score higher on the PHQ-9, even after controlling for age and household income.

Abstract Name: Plasma-assisted Destruction of Polystyrene Nanoplastics

Microplastics have been found in an estimated 30% to 90% of water sources and have a range of potential health effects whose full impact is still unknown. These microplastics enter our water systems in a variety of ways. It is postulated that these particles serve as sorbents for organic contaminants and pathogenic biofilms, which pose a risk to drinking water quality. These microplastic particles may further degrade by means of chemical such as natural oxidants to yield nanoplastic particles. Due to their sizes, they may cross the blood brain barrier. Literature reports that advanced oxidation processes (AOPs) can serve as effective methods for the decomposition of various organic contaminants, but research in the degradation of nanoplastics is limited. AOPs are an area of interest because reactive oxygen species (ROS) from these processes have high oxidizing power to breakdown organic materials. This work focuses on reporting our use of a falling-film plasma reactor to destroy polystyrene nanoplastics in water (98% removal), which has proven to be an effective method. Furthermore, this work aims to reveal the kinetics of nanoplastic particle degradation and characterize major reaction products through the course of the remediation process.

Abstract Name: Exploring flavors of edible ants: A path to sustainable gastronomy and consumer acceptance

Edible insects are gaining popularity as a sustainable protein source, owing to their low environmental impact and high nutritional value. However, solely emphasizing the environmental and health advantages might be insufficient to encourage widespread acceptance. Investigating the flavor profiles of edible insects holds the potential to shift marketing strategies towards hedonic-focused campaigns that will be more successful in boosting consumer acceptance. Certain insects are already considered delicacies. For instance, Formicine ants are utilized as a sour flavoring agent in some cultures, and chicatana ants are highly favored in Mexican cuisine. To explore the flavor profiles of these edible ants, the volatiles of black ants (Lasius niger) and chicatana ants (Atta mexicana) were analyzed using headspace solid-phase microextraction and gas chromatography-olfactometry-mass spectrometry. Our study revealed distinctive odor profiles for different ant species. Black ants were characterized by a pungent, acidic, and vinegary smell primarily due to their high formic acid content, a secretion from their venom glands. Additionally, numerous Dufour gland alkanes such as tridecane, undecane, and pentadecane, known to act as alarm pheromones, were detected in black ants. In contrast, chicatana ants exhibited nutty, roasty, woody, and fatty notes. Unlike black ants, chicatana ants did not contain formic acid. Instead, they had alarm pheromone 4-methyl-3-heptanone and trail pheromone 2,5-dimethylpyrazine. The fatty aroma of chicatana ants was probably attributed to their abundant presence of aldehydes such as hexanal, octanal, and nonanal. Understanding these flavor profiles is essential for creating appealing insect-based products that can overcome disgust-based aversions associated with insect consumption.

Abstract Name: Exploring the Impact of Parental Mobile Device Usage on the Early Language Environment

The purpose of this study is to measure the prevalence of mobile device usage of parents of young children and to explore the impact of mobile device usage on the quality of the child’s home language environment. This will require collecting data from both child and parent. We know that the more a child is exposed to an environment rich with language, the more a child's brain develops. This is because environments rich with language promote more conversational turns, which are non-cry sounds made by the child after being spoken to, which will then lead to more brain development. Conversational turns will be measured through the usage of recorded vest that will be worn by the child throughout their daily activities, which will record langauge

sounds spoken to the child and by the child. The data collected from the recorder vest will then be processed into daily data charts which are ready for analysis. On the parents' side, mobile device usage will be measured through data collected from weekly diaries. These diaries will be completed once a week for four weeks and will include questions surrounding the amount of time a parent is engaging with their mobile device. Screenshots of mobile device usage data will also be collected through the weekly diary. Through analyzing the correlation between the number of conversational turns between the child and caregiver and the prevalence of mobile device usage, we aim to see understand the relationship between these variables. We hypothesize that higher levels of mobile device usage will corerspond to a lower quality and quantity of conversational turns.

Abstract Name: Naturalistic Observations of Interpersonal Gratitude: Relative impact of modeling vs. diffusion of responsibility

This naturalistic study has been comparing the differential behavioral influence of two notable psychological science theories—observational learning and diffusion of responsibility. Observational learning predicts individuals will take cues from the actions of others and model relevant behavior observed. In contrast, diffusion of responsibility predicts that people will be less likely to take responsibility for the welfare of another person if others are available to actively care. This field study has been observing expressions of interpersonal gratitude between drivers and passengers on campus buses. For three semesters, undergraduate researchers have been recording whether passengers thank bus drivers as they exit the bus and note whether such a "Thank you" is influenced by the drivers exhibiting a prosocial comment (e.g., by saying "Have a nice day!"). Our researchers have been recording other relevant variables, including the number of passengers exiting at the same time, passenger position within the group who verbalizes gratitude, the weather, the temperature, the day of the week, and the time. A behavioral analysis is ongoing and comparing the impact of observational learning vs. diffusion of responsibility. To date our observations have indicated that a kind remark from the driver significantly increases expressions of gratitude from exiting passengers. While 68.8% of 5,347 passengers followed a driver's kind remarks with a "Thank You," those passengers exiting after a passenger expresses gratitude were less likely to express gratitude, supporting diffusion of responsibility over modeling or observational learning. When the driver does not verbally express prosocial behavior, only 31% of passengers will thank them. However, when the bus driver expressed a prosocial remark to a group size of two departing passengers and the first passenger did not offer a positive reply, the second passenger expressed gratitude on 57.1% of the 28 occasions. Naturalistic behavioral observations are ongoing and additional findings will be reported.

Abstract Name: The Relationship between Acculturative Stress and Depressive Symptoms

Higher levels of acculturative stress are associated with higher depressive symptoms. The pressures for acculturation (to take on the norms and culture of the receiving society) and enculturation (to take the norms and culture of native culture) may become chronic stressors and increase the risk of depressive symptomatology. This study adds to this literature by examining the effects of acculturation and enculturation on depressive symptoms and investigating differences by race/ethnicity and gender.Participants (22.4 ± 4.5 years; 70% women, 28% men, 2% LGBTQI; 42% Latinx|e, 15% white, 37% Asian, 2% black, 4% Indigenous, PI, and mixed race) were N=412 students from a public university. The analyses included descriptives, bivariates, and multivariate linear regressions. We run a multivariate linear regression to investigate the effects of acculturation and enculturation (the Multidimensional Acculturative Stress Inventory - MASI) on depressive symptoms (Center for Epidemiologic Studies Depression Scale – CESD-10), controlling for demographics (age) and other stressors (perceived financial situation, first-generation student, and immigrant generation). We examined Acculturation (or Enculturation)*Race/Ethnicity*Gender interactions.We found significant differences in depressive symptomatology by gender (Women=24.0; Men=21.5; t=-4.95, p<0.0001). Acculturation (β= 1.21, p=0.011) and enculturation (β= 1.01, p=0.022) stress were significantly associated with depressive symptoms in crude regression models. After adjusting for demographics and other stressors, Asian women in the high category of acculturative stress had higher depressive symptoms (β= 8.49, p=0.023) compared to male and female students in the low acculturative stress, males in the high acculturative stress, and white, Latinx, and Black and indigenous women in the high category of acculturative stress. Our findings indicate that female Asian students with high levels of acculturative stress are at a greater risk of reporting depression symptoms. Our findings highlight the need for targeted mental health programs in higher education to identify and support students at higher risk.

Abstract Name: Motivations, Barriers, and Outreach Initiatives in Promoting Short-Term Study Abroad Participation Among California State University Long Beach Students

According to the 2021-2022 IIE Open Doors Report, 65% of U.S. college students who studied abroad went on short-term programs. However, there has been little research into the motivations driving this population and potential barriers that might limit student participation. This project explores the motivations and barriers guiding California State University, Long Beach (CSULB) students in their decisions to pursue short-term study abroad programs, filling a notable gap in the existing literature. This study takes a dual-method approach involving surveys and interviews with CSULB students, faculty, and staff. Data was analyzed to identify patterns and themes. Preliminary results indicate the importance of financial constraints, employment, and safety concerns as barriers. At the same time, there is a relatively low cost of short-term compared to long-term programs as well as opportunities for personal and professional growth, and cultural exploration emerge as key motivators for various types of study abroad programs. These results can help

universities and colleges develop targeted outreach initiatives addressing these factors to increase participation and can work towards making their short-term study abroad programs more inclusive, accessible, and beneficial for all students, regardless of their socioeconomic background.

Abstract Name: Comparison of radiation emission among electronic devices: Ipad, Earbuds, and Laptops

There have been warnings about an increase in health problems including brain cancer in connection to cellphone use. This has led to scientists implementing guidelines to reduce the effects of radiation exposure from technology. The World Health Organization has published guidelines on safe public EMF exposure levels. The range is currently 28-61 V/m. WHO considers the maximum public exposure level for TV and computers screens at an operating distance to be 10 V/M. They state that this value is for the public and does not necessarily apply to specific requirements of individuals. In this project, we wanted to measure the radiation exposure of iPads, AirPods, and a laptop to assess the danger from exposure. Beyond quantifying, we compare the RF radiation from different devices. Using an Acoustimeter we measured the RF from an electronic source at different distances; we took measurement when the devices are in use and off. Our results show that the radiation emission from devices such as iPads, laptops, and AirPods are within the recommended range, whereas AirPods outside their case are shown to emit the highest radiation.

Abstract Name: Investigating the Role of PACE Transporters in Antibiotic Resistance and Susceptibility

The emergence of antibiotic resistance poses a substantial public health threat, necessitating a deeper understanding of its mechanisms. Bacteria make use of active efflux to expel antimicrobials and lower the intracellular concentration to survivable levels. To do this, multidrug resistance transporters use the proton motive force as the energy source to pump out toxic compounds. This study investigates the role of PACE transporters in antibiotic resistance and susceptibility. It was recently discovered that a related family, the Small Multidrug Resistance (SMR) transporters, can perform different types of transport depending on the specific substrate. Most interestingly, these different types of transport can cause resistance or enhance susceptibility (Spreacker, 2022). We hypothesize that PACE transporters will also be able to perform multiple modes of transport, leading to either susceptibility or resistance. We cloned and expressed three PACE transporters from Pseudomonas aeruginosa (PaPACE), Francisella tularensis (FtPACE), and Acinetobacter baumanii (AceI) in Escherichia coli and performed growth assays and resistance/susceptibility assays. We observed that strains expressing FtPACE or PaPACE exhibited significant resistance to methyl viologen, a

common substrate of multidrug efflux pumps, while AceI displayed limited resistance to this substrate, highlighting variance among PACE transporter specificity. PACE-expressing strains were susceptible to acriflavine, challenging our traditional understanding of multidrug transporters, but supporting our hypothesis that PACE transporter are functionally promiscuous like the SMR transporters. The study deepens insights into membrane transport processes and substrate specificity by multidrug transporters, providing a basis for future development of interventions against antibiotic resistance.

Abstract Name: Determining the Influence of Macrophage-specific Osteopontin on Intramuscular Fat in the Dystrophic Muscle Niche

Duchenne muscular dystrophy (DMD) is an inherited degenerative muscular disease caused by loss-of-function mutations in the DMD gene, which encodes for dystrophin. Dystrophin, a protein found near the membrane of muscle cells (sarcolemma), is responsible for maintaining membrane integrity by linking the muscle cell cytoskeleton to the extracellular matrix. Without functional dystrophin, the sarcolemma is prone to ruptures that lead to chronic cycles of muscle degeneration and regeneration. The long-term consequence of this cycle is the replacement of muscle fibers with extracellular matrix (pathological fibrosis) and intramuscular fat. Previous studies done by the Spencer Lab have identified Osteopontin (Spp1) as a regulator of DMD pathology and have shown that a global knockout of Spp1 mitigates fibrosis and increases muscle strength in mdx mice, a model for DMD. Spp1 is expressed in various cell types, so, accordingly, we aim to understand how specific sources of Spp1 affect DMD progression. To start, the Spencer Lab generated a macrophage Spp1 conditional knockout (MϕcKO) mouse line using Cre recombinase to study one of the most prevalent sources of Spp1, macrophage-derived Spp1. We observed the disappearance of two novel stromal cells, Lifr and Procr positive stromal cells, after the ablation of macrophage-derived Spp1. The increased expression of adipogenic genes in these stromal cells may suggest that they play a role in intramuscular fat accumulation, a hallmark of DMD pathology. To explore this further, oil red o staining was done to understand how Lifr and Procr positive stromal cells may affect intramuscular fat. Analysis of intramuscular fat deposits in our experimental and control groups shows a trend of increased intramuscular fat deposits in mice lacking macrophage Osteopontin compared to control mice. This trend is also observed in older mice and indicates that macrophage Spp1 may play a role in exacerbating the DMD pathology.

Abstract Name: CrAInium: Implementing Artificial Intelligence on MRIs to Revolutionize Brain Tumor

Analyses

Intracranial Neoplasm, commonly known as a Brain Tumor, is an abnormal mass or growth of tissues in the brain, one of the most complicated parts of our body. This research study focuses on developing and implementing Artificial Intelligence in developing models to enhance the precision and efficiency of Magnetic Resonance Imaging (MRI) analysis to address the pressing need for expeditious and accurate medical diagnostics. We evaluate and compare the performance of seven distinct machine-learning algorithms in identifying brain tumors: Convolutional Neural Networks (CNNs), Random Forest Classifier, Support Vector Regression (SVR), Gradient Boosting Classifier, Gaussian Naive Bayes (GaussianNB), XGBoost Classifier, and K-Nearest Neighbors Classifier (KNeighborsClassifier).We use a dataset of MRI scans, each labeled as benign or malignant, and further classify them into different kinds of tumors such as glioma, meningioma, pituitary, and no tumor. Evaluation metrics, including accuracy, precision, recall, and F1-score, are employed to assess the models' performance in terms of precision and accuracy. By enhancing diagnostic accuracy and expediting the dissemination of critical information, our models attempt to improve the efficiency of healthcare services, benefitting patients and medical practitioners alike.

Abstract Name: Model Studies to Guide Cleanup of Clandestine Methamphetamine Labs: Developing Reliable Controls

The number of homes in the U.S. condemned after the discovery of clandestine methamphetamine labs (“Clan Labs”) is growing. Clan Labs are found in residential dwellings, motels and hotel rooms, garages, barns, automobiles, etc. After law enforcement and first responders remove quantities of hazardous materials, further remediation must be done by property owners. Protocols for proper remediation have not been sufficient in protecting occupants from health and safety problems arising from high amounts of residue. Properties can be cleaned of nearly all lingering amounts of methamphetamines; however, the residual amounts of the different substances used in the production of the drug are still apparent. The decontamination process for chemical residues varies, and it is unknown which type of cleaning is the safest and most effective. This study explored new approaches for the best remediation process for Clan Labs. Precise amounts of a modeled methamphetamine compound on different nonporous sample-building surfaces (e.g., stainless steel, ceramic, glass) go through the remediation process of surface cleaning. Laboratory instruments, such as UV-VIS spectroscopy, gas chromatography, and computational statistical analysis, determine the percent of surface residue recovery. The immediate goal of the study is to understand the chemical properties and surface reactions that dictate whether a particular cleaning method is effective.

Abstract Name: Automated Black Soldier Fly Incubator using Internet-of-Things and Computer Vision

Black Soldier Fly Larvae (BSFL), Hermetia illucens, have proven to convert organic waste into cheap and high-quality animal protein feed and residue frass fertilizer (a mixture of digested biowaste, larval feces, and chitin-rich exuviae) for soil enrichment while addressing the dual problem of mismanagement of organic waste and climate change. People have already discovered the benefits of these flies and are using traditional approaches to rear them. However, BSFL is difficult to rear due to its sensitivity to external conditions such as temperature, humidity, lighting, and rearing medium. Rearing them in a natural environment may sometimes lengthen their lifecycle as well as affect the by-products of each stage. Therefore, in this document a system that automates the regulation and control of ambiance in a Black Soldier Fly (BSF) farm using Internet-Of-Things as well as monitors the health of produced larvae using Computer Vision is proposed, designed, and developed. Results after testing the developed proposed system support the viability of the automated system in Black Soldier Fly rearing, with the mechanical subsystem showing structural integrity, the system effectively maintaining optimal environmental conditions (temperature: 27-32°C, humidity: 60-70%, light intensity: 100-400 lux and organic waste moisture: 60-70%) and the system demonstrating energy efficiency by its ability to changeover promptly between electrical grid and solar power.

Abstract Name: Post-Polymerization Modification of Branched Polyglycidol

The post-polymerization modification of polyglycidol is of great interest for the synthesis of novel polymeric biomaterials. We present the synthesis of novel ratio-controlled amino-oxy and keto functionalized branched polyglycidols. The biocompatibility and chemospecificity of the amino-oxy functional group make it particularly well suited for applications in bioconjugation, drug delivery and tissue engineering. Amino-oxy functionalized branched polyglycidol can serve as a critical building block for the synthesis of innovative biocompatible degradable hydrogels that are injectable. Ratio-controlled amino-oxy functionalized species were obtained by controlling the ratio of N-hydroxy phthalimide to the hydroxyl groups attached to the polyether backbone. A similar strategy was utilized to obtained ratio-controlled keto functionalized branched polyglycidols. This unique feature will allow for the tailoring of this branched PEG-like structural motif for the synthesis of novel biomaterials with tailored biochemical and biomechanical properties

Abstract Name: The Effectiveness of the Short Compassion Strengths Course Modules on First Semester Nursing Students' Compassion Scores

Purpose: This student-led study measured the impact of the Short Compassion Strengths Course (SCSC) modules on first-semester nursing students' compassion scores.Background: The 2021 American Association of Colleges of Nursing (AACN) Essentials require baccalaureate nursing students to demonstrate compassionate care. Although the importance of compassion in quality care is well-established in the literature, effective programs and best practices for formally teaching compassion are less understood and understudied. Early engagement in targeted interventions that foster compassion prior to caring for patients and measuring their progress as compassionate caregivers can accelerate students' progress in incorporating this core value into their professional identity. Durkin (2022) developed the Short Compassion Strengths Course (SCSC) modules based on his Compassion Strengths Model to foster nursing students' compassion in England. Student compassion scores in Durkin's study significantly increased (p=.001), yet the SCSC modules have not been employed or studied in the United States. Measuring compassion scores over time provides data regarding SCSC module effectiveness and provides a mechanism for both students and faculty to assess progress in applying compassionate care concepts as they transition into clinical practice.Methodology: First-semester nursing students completed nine SCSC compassion modules embedded into a didactic course prior to starting hospital clinicals. Using the Bolton Compassion Strengths Indicators (BCSI) survey, students' compassion scores were measured three times: before and after completing the nine modules and after completing clinicals. Data collection was completed in November 2023, and analysis will be completed in December 2023. Using SPSS, a RANOVA will analyze changes in compassion scores across the three timepoints.Expected Findings: It is hypothesized that students' compassion scores will increase at each timepoint. If effective, findings will drive data-driven curriculum decisions regarding the SCSC modules. Next steps include a longitudinal study measuring compassion scores across the curriculum.

Abstract Name: Experimental Characterization of a Bifacial Solar Panel at Various Operating Conditions

Most solar panels are highly inefficient, with even the most expensive ones converting less than 25% of the sunlight that falls on them into usable energy. Bifacial solar panels are a new way to improve the solar panel efficiency by absorbing some of the sunlight that reflects off of the nearby ground. The current work is looking to measure the increase in voltage produced by solar panels when they are bifacial as compared to monofacial. Experimental work was performed on a commercially available solar panel (JJN Solar 200 Watt Bifacial PV Panel). The objectives of the experiment included monitoring the efficiency of the panel as a function of incident solar flux and ground reflections from the back side. For this purpose, various background surfaces were employed including grass, room tiles, aluminum foil, and sand. For each case, the short-circuit current and open-circuit voltage of the panel were obtained, and IV characteristics were plotted to measure the fill factors and measure the efficiency of the solar panels. 8 K-Type thermocouples, calibrated using the standard method, were attached to different points on the panel, and an automated 8 channel data logger was used to record the temperatures to monitor the temperature's effect on the IV characteristics. For indoor experiments, four halogen light bulbs were used to simulate sunlight. When testing outdoors, the experiment was conducted at various times of day to vary the incident flux over the panel surface. Among

different ground reflectors, aluminum foil was found to give the highest increase in the solar panel output (~1 percent) followed by the sand, concrete, and grass. Highest surface temperature reached up to 50 degree Centigrade that deteriorated the overall efficiency of the panel by (2-3) percent. Full results will be presented in the conference.

Abstract Name: Understanding the Role of Phosphorylation in RNA Binding Protein Function

RNA Binding Proteins (RBPs) play a crucial role in regulating alternative pre-mRNA splicing and, in turn, dictating the cellular proteome. Polypyrimidine tract binding proteins PTBP1 and PTBP2 are paralogous RBPs that share 74% primary structure identity and regulate alternative splicing of pre-mRNA gene transcripts. Despite their similarity, the paralogs regulate different sets of target exons, which plays a critical role in neuronal development and maturation. Previous studies discovered that PTBP2 is distinctly phosphorylated in the unstructured N-terminal and Linker regions to a greater extent than PTBP1. We determined that PTBP2 distinctly phosphorylated residues are conserved in lower species, indicating an important role in PTBP2 function. The N-terminal and Linker regions share less sequence identity between the paralogs compared to the RRMs. Thus, we hypothesize that linker region phosphorylation plays a role in the neuronal-specific splicing activity of PTBP2. Our proposed experiments are to test this hypothesis. First, we used recombinant DNA technology to create phosphate mimic aspartate mutants of PTBP2 phosphorylated residues. Alanine mutants that cannot undergo phosphorylation serve as controls. We are currently assaying these mutants in vivo in mouse neuro-2A cells to test for protein expression via Western Blotting and splicing activity on PTBP2-regulated exons via reverse-transcription PCR. Results from this study will determine the role of phosphate modifications in PTBP2 splicing activity and determine whether phosphorylation plays a role in dictating the distinct splicing activities of related RBPs in a gene family.

Abstract Name: Distribution of Dahlia Mosaic Virus in Tubers

Dahlias are in high demand by florists and have been increasingly grown by Utah cut flower growers in the last few years. Growers have been trying to acquire dahlia tubers that are virus free which is very difficult. Dahlia Mosaic virus (DMV) is widespread in commercially available dahlia tubers. Recently, growers from across the country have been sending dahlia samples to the Utah Plant Pest Diagnostics lab (UPPDL) with symptoms of stunted growth, mosaic patterns on leaves and color breaking for testing after receiving

conflicting results from other testing facilities using different testing methods. The UPPDL uses conventional PCR, gel electrophoresis and when needed DNA sequencing to determine if a plant is positive. Some testing facilities claim the inconsistent results come from uneven distribution of DMV in tubers. This research project determines the distribution of three strains of DMV in individual dahlia tubers. Tubers were cut into one-inch segments, DNA was extracted and PCR with strain specific primers conducted. The results show that all three strains of the virus are evenly distributed throughout the tuber. This indicates that it does not matter from which part of the plant a sample is taken. The variation in results from different testing facilities may be attributed to potential different testing methods with varying test sensitivity.

Abstract Name: The effect of neuron death in the amygdala on aggression in green anole lizards

The green anole lizard (Anolis carolinensis) is seasonally breeding, with dramatic behavioral, physiological, and morphological changes between the breeding and non-breeding season. It is known that across different seasons, there is a change in the number of neurons within the amygdala, such that there are more neurons during the non-breeding compared to the breeding season. This is a region in the brain that is shown to play a major role in behavior, especially aggression. This study sought to see the impact of induced neuron death on aggressive behavior in this species. To induce neuronal death within the amygdala, stereotaxic brain surgery was performed on each of the lizards during the non-breeding season. These procedures locate and target small areas in an organism such as the brain, via a three-dimensional coordinate system. A small incision was drilled through the skull to the brain and the amygdala was injected with either vehicle control (saline) or staurosporine (100 nl), which is a neurotoxin that induces cell death through intrinsic apoptotic pathways, via a Hamilton syringe. After injection, the opening was sealed with petroleum jelly, and the lizard recovered for three days. Aggressive behavior was assayed pre- and post-surgery using 15-minute resident-intruder behavior tests. The lizards were allotted 5 minutes of acclimation to the cages before the intruder was added in with the resident and behaviors video recorded. Behavior recordings are currently being analyzed by an observer blind to condition using BORIS software to determine if there are changes in behavior pre- and post-surgery. This information will help us better understand the relationship between neurons in the amygdala and their influence on the behavioral differences seen in green anole lizards.

Abstract Name: Exploring Forms of Communication within Professional Organizations: Member Preferences

for Receiving Information

As large professional organizations seek to adapt to an ever-changing society, the need to adapt information should also change. To involve members of a professional organization, one should best understand the preferences of its members. The current research project aims to better understand the preferences of members of the Council for Undergraduate Research (CUR)'s Education Division for receiving information. Following online classes during COVID-19 and the rise of those working from home, many faculty and instructors have learned to use a variety of communication tools to receive and disseminate information to colleagues and their students (Cosco, 2015). As professional organizations have seen a generation shift in membership, both the methods to disseminate information and the language used to share information may need to change (Rowan-Kenyon et al., 2022). Many academics and other professionals utilize social media to engage with others in their field, though research to understand professionals' social media use has not been extensively studied (Jordan, 2023). The current research will first analyze websites of professional organizations to determine how organizations disseminate information to members. Then, researchers will survey division representatives to determine how they disseminate information to members. These methods will be analyzed for themes. Finally, researchers will email members a social media preferences survey tool (Attitudes Toward Thinking and Learning Survey, Galotti et al., 1999), with demographic questions to determine age. An analysis will be conducted to determine preferences for receiving information. Results will then be analyzed using correlational analysis to determine differences in preferences related to age and membership.Researchers expect to determine new methods of disseminating information to professional organization members. Researchers hope to determine whether multiple methods for disseminating information should be utilized based on generational preferences. These results will be shared with members of professional organizations to improve their communication with members.

Abstract Name: Detecting Estrogen Pollution in the Stones River Waterways using the Yeast Estrogen Screen (YES) test of "Saccharomyces cerevisiae"

Estrogen is a steroid hormone, most well-known as being associated with the female reproductive system. Estrogen is used in the dairy and livestock industry as a muscle enhancer and used to increase growth rates. Once in the environment, estrogen enters the estrogen transmission chain, and the effects have been connected with disruptions in waterway ecosystems. This study aims to identify the levels of estrogen pollution for each site at the Stones River Watershed. Using the Yeast Estrogen Screen (YES), Saccharomyces cerevisiae was scientifically engineered to carry one DNA (either ERα or ERβ) sequence and two estrogen-responsive sequences (ERE). The ERE controls the reporter gene, lac-Z, which encodes for the enzyme β-galactosidase, and in the presence of estrogens, is secreted. The lysis buffer contains chlorophenol red-β-D-galactopyranoside (CPRG). When cleaved by β-galactosidase, it produces a colorimetric product. This study distinguishes a practical way to identify said pollutions and promotes a better understanding of what estrogen pollution can do towards biodiversity. The study also confirms why testing our local Stones River Watershed is very important, as it improves our ability to protect against threats towards biodiversity and possible contamination.

Abstract Name: Genetic structure of Daphnia populations within and among lakes

Natural selection and gene flow are processes that affect genetic variation in populations and the ability of populations to evolve in the face of environmental change. These processes also determine the extent to which populations of a given species may become genetically distinct from one another. Environmental heterogeneity promotes selective conditions favoring certain genotypes in different habitats resulting in genetic differences between or within populations. Conversely, gene flow due to migration and interbreeding introduces alleles from one population to another and causes greater genetic homogeneity. The species investigated in this study is Daphnia pulicaria, a freshwater zooplankton. Daphnia usually reproduce asexually, but can switch to sexual reproduction and the production of resting eggs when conditions in their environment become poor. Sexual reproduction generates genetic diversity enabling populations to have evolutionary flexibility. Gene flow in Daphnia populations can occur when individuals move between lakes, via dispersal of resting eggs among lakes, or via “migration from the past” when resting eggs hatch from the sediment “egg bank” of given lakes. In this study, we examined the extent to which D. pulicaria populations were genetically structured within lakes and among lakes in close proximity to each other (in northwestern MN). Daphnia were sampled at several depths at two locations for each lake. Water depths sampled differed from each other in temperature and dissolved oxygen conditions, and were therefore different habitats to which particular genotypes may have been adapted. Of the five lakes sampled, three contained D. pulicaria. We found those three populations to be allelically polymorphic for both allozyme loci tested (GPI and PGM). We discovered that there was genetic differentiation within lakes implying that selection was operating differently at different depths, and we found even greater genetic differentiation between populations in different lakes, implying that gene flow among lakes is limited.

Abstract Name: The Restoration of a 19th Century Boxwood

The School of Music at Montana State University owns a 19th century boxwood clarinet that is in a state of disrepair; my project involves researching the history of the clarinet, learning how to repair it, and getting it restored to playing condition. With today’s technology, it is easy to look up and listen to a performance or demonstration on one of these instruments, but I believe it would be more beneficial to have hands-on experience with such an instrument. I decided that I would look into the instrument further to gain a greater understanding of it, and once I had a general knowledge of the instrument and a better understanding of what needed repair, I would begin looking for someone capable of fixing it in keeping with historic preservation practices. Building on former student Karen Johnson’s project gave me a general idea of its historical context. My oboe studio professor suggested I call the American Musical Instrument Society; I contacted them to see if they would be able to help me with my project. I also consulted local instrument repair specialist Ken Decker about his ability, expertise and interest in restoring the clarinet. My hopes are that he will be capable of repairing it back to playing condition, and it will be able to be demonstrated in period ensembles by faculty

and students for years to come. I also plan to submit my research project for our campus research celebration and undergraduate research journal.

Abstract Name: #IrelandIsFull: A Content Analysis of Irish Discourse on Ukrainian Refugees in Social Media

Since the beginning of the Russian invasion into Ukraine, thousands of Ukrainians have migrated to Ireland. This study is about how Irish citizens have framed Ukrainian refugees immigrating into Ireland in social media. I conducted a content analysis of 200 different posts from the social media application of X. I analyzed the posts for framing techniques and categories used to describe the immigrants. In many cases, Ukrainians were framed as “burdensome” and “a problem”. Prominent categories used to describe the refugees were “user”/”freeloader”, “intruder”, “victims” and “humans”. This study provides new insights to how immigrants are framed in social media.

Abstract Name: El Desierto: Queer Geographies of Chicanx Identity in Arturo Islas’s The Rain God

Though much scholarly thought has focused on the inherent liminality of Chicanx identity, little has been said about its geographic genesis—the desert borderlands of the U.S. Southwest. This region, culturally significant to indigenous groups and, as I argue, to Chicanxs, operates as a literal and metaphysical space of identity-making in which Chicanxs negotiate their position as the colonial product of mestizaje, the intermingling of white Spaniards and Indigenous peoples. Arturo Islas’s semi-autobiographical novel, The Rain God: A Desert Tale (1984), delineates this disaggregated socio-ecological landscape where the desert drives a particularly Chicanx longing for historically denied filial relationships, what Eugenia Cotera and María J. Saldaña-Portillo term mestizo mourning. Through an exploration of the estrangement experienced by Miguel Chico Angel, the queer Chicano protagonist and Islas’s fictionalized counterpart, this study extends mestizo mourning to relationships between the human and the non-human desert landscape, locating the family as a microcosm of Chicanx alterity. In unveiling the dual mourning of Chicanxs—for family and land, a place and a people to belong to—this study considers the thematic resonances of death to expose the interplay between Chicanx mourning and the geographical landscapes that intertwine the living and the dead. Ultimately, I seek to map a novel ecological imaginary of the desert borderlands that moves beyond the common perception of this region as a mere transitional space between Mexico and the United States, redefining it instead as a significant site of Chicanx subjectivity, embodying both its liminal and contentious nature.

Abstract Name: Swimming Against the Current: Oreochromis Niloticus Xenografts as Ultraviolet-Resistant Burn Dressings

This study compared Oreochromis niloticus (Nile Tilapia) xenografts to simulated split-thickness skin grafts (STSG) under varying ultraviolet (UV) exposure levels with an aim to assess the xenografts' UV resistance as a burn treatment. Recently developed by Dr. José Emaciel Lima Junior, these xenografts have successfully treated severe burns due to their high type I collagen levels that prevent scarring and facilitate burn site recovery. Though already considered as efficacious as human donor grafts and more flexible than porcine grafts, their UV resistance remains understudied. To address this gap, this study conducted a photochromic colorimetric analysis comparing meshed porcine skin (simulating the industry-standard STSG) to an Oreochromis niloticus xenograft. Both types of graft were placed on UV test cards and exposed to full-spectrum UV lights, starting with a control trial at 0 SPF (Sun Protection Factor) and gradually increasing to 100 SPF. As expected, UV exposure levels decreased as SPF increased for both grafts. However, the Oreochromis niloticus xenografts demonstrated a consistently lower range of UV rays throughout the trials. Findings suggest that the new fish skin-based therapy may offer superior protection to burn patients' damaged tissues even under varying sun exposures. Consequently, the field of medicine could potentially benefit from using the novel xenografts in treating severe burns. Nevertheless, confirming the results of this simulated study requires additional research in the form of pre-clinical mouse studies and clinical human trials with subject observation.

Abstract Name: Examining the Leaky Pipeline of Black PhD Professionals: How Networks and Racial Climates Impact Career Advancement in Sociology

There is an underrepresentation of Black professionals in higher education, which is an inequity that can lead to a lack of social justice, support systems, and retention of students of similar backgrounds. This study examines roadblocks and inroads that exist for Black PhD professionals working in academia. The research questions addressed are: (1) How do pathways and networks shape the advancement of Black sociologists in the academy? (2) How does racism and/or roadblocks interfere with advancement? The emphasis was placed on factors that perpetuate a phenomenon known as "the leaky pipeline" where Black professionals are not able to advance in their careers. Black PhD professionals (n=51) answered a series of questions in a survey that yielded quantitative and open-ended qualitative data. The survey was conducted over the course of one year, (July 2021-July 2022) with two six-month checkpoints (December 2021 and July 2022) to assess data collection progress. The data gathered gives insight into the participant's networks, how they experience the racial climate in their work environment, and how their network shaped their advancement. We expect to find correlations between participants' networks and their advancement in academia as well as a drag to their advancement related to the racial climates at the institutions where they work.

Abstract Name: Variation in Offspring Sex Ratio in American Kestrels

Grassland bird populations in North America are experiencing significant declines, including American kestrels (Falco sparverius), whose populations have been declining since the 1970's. Studies that examine population dynamics and causes of declines are important for directing conservation activities. Population metrics such as reproductive effort and sex ratio of offspring are useful for understanding population dynamics. Birds may facultatively adjust their clutch size and the sex of their offspring in relation to resource availability in their home range. High quality habitats may result in larger clutches and variation from 50:50 sex ratios, typically in favor of the larger sex (females in kestrels). Sex ratios can also vary depending on timing of breeding. We assessed reproductive success and structure of a natural population of breeding kestrels in west-central Pennsylvania during May – July 2023. We monitored 50 nest boxes for breeding activity and recorded date of clutch initiation, maximum clutch size, hatch date, brood size, nestling sex ratio, and the number of fledglings in eleven breeding attempts. Clutch size ranged from two to five eggs (mean = 4). Nest failure rates were high; only five nests survived to fledging and 17 kestrels were recruited into the local population. Sex ratio per brood ranged from 33% to 80% female and earlier nests had a higher proportion of female nestlings. Overall, brood sex ratio did not depart from 50:50. Our results suggest equal breeding for the next breeding season, but low nest success rates signal a struggling population. There may also be an increase in resource availability earlier in the breeding season due to earlier nests being predominantly female. Considering the decline of kestrels in Pennsylvania, our results suggest conservation action for this species is necessary in our region.

Abstract Name: Reading Between the Lines: Regimental Records of Black Soldiers in the Civil War

The myth of the nation of the United States is a set of narratives, legends, and stories that help coalesce national identity around shared perceptions of the significance of those narratives, legends, or stories. The memory of nearly 180,000 Black soldiers who served in the Union Army during the Civil War has been marginalized for much of the 160 years since the Civil War ended. Out of over 2,000 Civil War monuments on the National Register of Historic Places, only 24 are dedicated specifically to Black soldiers. Utilizing the 100th Colored Infantry Regiment Records, 1864, at the University of Kentucky Libraries Special Collections Research Center, research will explore how these records help create a counter-narrative of the Civil War that centers the lives of these men within the conflict. These records, used in conjunction with soldier letters, autobiographies, secondary sources, photographs, and memorials, enable a greater understanding of the vital role these soldiers played in the Civil War. This is a study on narrative change and the power of archives to help understand the lived experiences of marginalized people. Using folkloric theory and the concept of the myth of the nation, this project utilizes muster rolls, records of effects, and furlough notices to document day-to-day activities of Black soldiers serving in Nashville, Tennessee in the summer of 1864. This project

demonstrates the ability of archival work to center the lives of these men within narratives of the Civil War, and social justice, in the United States today.

Abstract Name: Little Boxes, Big Impact: The Use and Collection of Matchbox Art

Known now only through those who collect it, matchbox art is often an overlooked part of the history of graphic design. When matchboxes were invented, there was nothing special about the label, but as the print industry expanded, matchbox labels turned into art. Using matchboxes for commercial art was developed by countries like Japan and Sweden, soon followed by the U.S. and Britain. During WWII, matchbox labels were used not only for practical purposes but for war propaganda and public service announcements. Countries and businesses used this item that every household owned, to send a message. With the invention of the disposable lighter in the 1970s, matches became obsolete, but now, through phillumenists (matchbox label collectors), we get to see and learn about the impact that matchbox art had on the world and how it helped move forward graphic design.Keywords: Matchbox, Matchbox art, War Propaganda, Phillumenist

Abstract Name: Visual Impairment in Ethanol Treated Zebrafish Larvae Evaluated Using a Novel Optokinetic Response Apparatus

Fetal alcohol syndrome (FAS) encompasses various physical, visual, and cognitive abnormalities resulting

from high concentrations of alcohol exposure during pregnancy. Zebrafish (Danio rerio) and mammals both have conserved genes for visual system development and share a cone-dominant vision that makes results more comparable than studies done with rodents. As a result, we sought to use the zebrafish as a model organism for comparative visual acuity experiments. Ethanol (EtOH) exposure during embryonic development can lead to various developmental abnormalities, including physical impairments that affect visual acuity, as observed in the optokinetic reflex (OKR) in this experiment. OKR, a reflex that stabilizes the visual field during motion, can be observed in zebrafish starting at 4dpf (days post-fertilization) when a high density of cones, similar to human eyes, is present in the central retina. Our lab sought to test how ethanol affects the development of OKR using an inexpensive, custom-designed OKR platform that utilizes light to test for quickness of response. Our custom-built OKR apparatus can rotate clockwise and counterclockwise which serves as an excellent tool for further investigating the underlying mechanisms and potential interventions for visual impairments. Zebrafish embryos were exposed to EtOH at 24 hpf (hours post fertilization), when they have undergone significant morphogenesis of the eyes. Our results showed that 0.5%, 1.0%, and 1.5% EtOH treatments impaired the OKR of the zebrafish larvae, significantly reducing eye saccades with increasing EtOH concentration compared to the control fish that were not exposed.

Abstract Name: Genetic Engineering in Dairy Cattle to Better Fit the Environment

Genetic engineering, specifically in dairy cattle, has provided many beneficial uses which has not only impacted the farmers but the industry as a whole. There is also an argument that many people in the public would assume that it is harming the cattle, when in reality there are substantial benefits such as a faster rate of production, offspring, and potentially disease-free cattles. This research is based on literature review and in this presentation, we will show how genes can be expressed to select for desired outcomes, such as the improvement of milk production, physical health, welfare, resistance to diseases such as mastitis, and the offspring phenotype such as hornlessness and physical characteristics. Through the use of genetic engineering, a solution was found for the black spots, which absorbs more solar radiation than a cattle could handle, this ultimately leads to heat stress, affecting the cattles overall milk production and impacting their offspring. Another example when looking at this from a safety level perspective is the use of dehorning of cattle. Cattle with horns affects the daily lives of workers as it would cause severe injuries and more hospital costs. It also contributed to the cattle themselves as many would harm themselves in the pens leading to less comfort. It is important to know that genetic engineering has been providing good results as research has shown that people are in contrast to this technology for a variety of reasons. Through strategic genetic engineering approaches, there is a high chance of cattle not contracting diseases and also increasing the industry's income from milk production as its protein, calcium, and vitamin D levels have also improved. The purpose of this research was to not only educate the public but important in the development and future in technology of the dairy industry.

Abstract Name: The Voices We Hear – Effect of Cognitive Bias and Gender on Digital Voice Assistant Shopping

Digital Voice Assistants have evolved into recommendation agents assisting users in online shopping by supporting decision-making and facilitating the search and selection of products and services. These assistants can also lead to gender stereotyping and cause cognitive biases that influence customers' purchasing behavior. This study specifically examines the potential of digital voice assistants as recommendation agents in terms of gender bias and social proof. A multidisciplinary protocol involving a scenario-based survey and a neuroscientific experiment are used to answer this research question. In the male digital voice assistant survey scenario, prior experience is more important for women than for men. For the female digital voice assistant scenario, perceived usefulness has a greater impact on purchase intention for men than women, whereas women's attitudes are more relevant than men's. Implicit association measures suggest that digital voice assistants are perceived as informative, and they indicate the presence of gender stereotypes that reinforce the opposite attraction hypothesis for digital voice assistants and participant gender. Facial expression analysis and galvanic skin conductance support these findings and show significant changes in customer attention and arousal. Most importantly, digital voice assistants' recommendations outweigh traditional social proof heuristics in customers' product selection. Keywords: Behavioral Economics, Digital Voice Assistant, Gender, Neuromarketing, Technology Acceptance Model, Voice Commerce.

Abstract Name: Do Strength Fibers cause more Soybean Production?

Efficient food production is vital within farming. Out of the many crops made not only in America, but in the world, soybeans pose many benefits in terms of consumption. Soybeans have a vascular system that causes production and analyzing could help us alter growth yield for the better. During research we examined cross sections of vascular bundles and wanted to focus our study on fiber cells; strength fibers that help with structure of branches to produce high fruit yield within the plant. We found that through image analysis, strength fibers do not correlate with increased seed production, but other tissues within the plant may such as water conducting xylem or turgor producing pith. This is important because we will be able to research what exactly increases growth yield and in the long run help soybean producers as well.

Abstract Name: An Analysis of Educational Disparities Perpetuated by Prevailing Classroom Management Practices

Alarming data shows notable differences in how students of color and students with disabilities spend less time in the classroom due to discipline and are at higher risk of being suspended without educational services. The research delves into the enduring influence of classroom management practices on the educational quality received by these marginalized groups, with the primary objective of analyzing current practices perpetuating educational disparities and their implications. Examined classroom management through three dimensions: teacher’s personality, teaching, and discipline. Identified implicit biases as pervasive influences on all dimensions. Argued that exclusionary discipline not only fails to address student concerns but also hinders the development of appropriate behavioral and communication skills. Recommends systemic training on diversity, equity, and inclusion to raise awareness and rewire preconceived attitudes. Practical suggestions include enhancing diversity and representation for a “racial match”, incorporating diversity into the curriculum, and implementing varied learning styles and differentiated instructions. These measures aim to capitalize on individual strengths, fostering an environment where students of color and those with disabilities feel heard, represented, and integrated into the educational community.

Abstract Name: Evolutionary Origins of Mate Jealousy: Dichotomies due to biological sex, sexual orientation, and sexual identification

Evolutionary psychology postulated that males should be more disturbed by sexual infidelity than emotional infidelity, given paternity uncertainty and the risk of not passing on one's genes. On the other hand, females should be more disturbed by emotional infidelity because, during the era of evolutionary adaptedness (EAA), males controlled all the resources, without which offspring could not be nurtured and one's genes would not survive. Emotional infidelity may lead to the male leaving and taking his resources with him (Buss, 1992). The survey literature is contradictory on this question, so we propose to take physiological (GSR) measures. Galvanic skin response (GSR) is measured while participants listen to audio recordings and picture scenarios involving emotional and sexual infidelity (along with neutral stimuli). We hypothesize that cis, hetero males will have a ratio of GSR responses to sexual and emotional infidelity greater than 1.0 when listening to scenarios of sexual infidelity relative to emotional infidelity, reflecting greater distress to sexual infidelity. Conversely, cis, hetero women should have a ratio of responses of less than 1.0, reflecting greater distress to emotional infidelity. Since homosexual men have feminized brains, and there is indirect evidence that lesbians have masculinized brains, we hypothesize that these ratios will be reversed in homosexuals, and will correlate with the Kinsey Sexual Orientation Scale. Finally, the ratios of transsexual individuals will be calculated, although we do not have an a priori hypothesis.

Abstract Name: Framing Climate Change: A Comparative Study of Climate Change Framing in State-owned and Independent News Media in Russia

This study conducted a comparative analysis of how climate change is framed in state-owned versus independent news media in Russia, focusing on RT International and the independent news source Moscow Times. The findings revealed differences in framing between the sources: RT portrays climate change as primarily non-local, emphasizing temperature increases and vague natural disasters, while the Moscow Times presents it as a global issue with statistically significant consequences. Both sources employ framing techniques to either support or criticize governments.

Abstract Name: Evaluating the Performance of Various Wood Biochars as Supercapacitor Electrodes

Energy storage devices such as supercapacitors typically rely on activated carbon derived from nonrenewable sources such as coal and petroleum. Biochar, charcoal produced from the pyrolysis of biomass, serves as a renewable alternative. Future research demands more information about the performance of different biomasses as biochar when used as activated carbon in energy storage devices. This study explored the performance of biochars derived from four different species of wood: Boxelder, Buckthorn, Bur Oak, and Green Ash. Although these four species, sourced from Minnesota, are all hardwoods, they have distinctive microstructures and thereby different specific surface areas. Wood samples were pyrolyzed using a Top-Lit Updraft Gasifier before undergoing potassium hydroxide chemical activation in a tube furnace. Activated carbon was then used in the fabrication of supercapacitors as electrodes. The supercapacitors were tested by undergoing 250 charge/discharge cycles to simulate their lifecycle. They were analyzed by three primary metrics: specific capacitance, cycling stability, and internal resistance. For instance, Bur Oak supercapacitors have achieved excellent results reaching a specific capacitance of 105.6 F/g, and a cycling stability of 98.59% over 250 cycles. Comparing this to a device created with commercially available activated carbon that has a specific capacitance of 102.0 F/g, and a cycling stability of 94.17%, as well as qualitatively determining that wood biochar supercapacitors achieved a lower internal resistance, it is apparent that wood biochars can outperform commercial activated carbon. This study assesses the performance of biochars derived from the four wood species and provides insight into correlations between wood microstructures and their applications for supercapacitor electrodes.

Abstract Name: Alkynyl Iodide-Based Halogen-Bonding with Isocyanides to Improve Utility

Isocyanides are utilized in synthetic chemistry and are used in multicomponent reactions such as the Ugi and Passerini reactions, but their pungent odor limits their utility. Halogen bonding was found to quell the stench of isocyanides while retaining their original properties, in particular, halogen bonds were formed between iodo-pentafluorobenzene and isocyanides. We are interested in expanding the repertoire of halogen-bonded isocyanides and so have investigated alkynyl iodides, a class of halogen bond donors. We used FOPT calculations with a STO-3G basis set to compare the halogen bond lengths and complexation energies of our proposed scheme, 4-iodoethynyl-nitrobenzene and 2,6-dimethylphenyl isonitrile (3.908 Å and -0.90 kcal/mol), to that of a co-crystal from the literature: iodo-pentafluorobenzene and 2,4,6-trimethylphenyl isonitrile (3.987 Å and -0.29 kcal/mol). Then, we synthesized 4-iodoethynyl-nitrobenzene to co-crystallize with 2,6-dimethylphenyl isonitrile. On the halogen bond donor, the strong polarizing effect of the sp carbons and the electron-withdrawing effect of the nitro group polarize the iodine atom to become electrophilic. Our hypothesis is that alkynyl iodides would suppress the odor of isocyanide due to halogen bonding.

Abstract Name: The Role of the Neurotransmitter Acetylcholine in a C. elegans Cell Migration

The linker cell (LC) is a leader cell for the long-range migration of the developing C. elegans male gonad. In the L4 stage, the LC migrates along the ventral bodywall of the animal in close proximity to the ventral nerve cord, which contains cholinergic–muscarinic and nicotinic– neurons that release the neurotransmitter acetylcholine (ACh). We previously found that excess ACh induced by the drug aldicarb causes the LC to reverse its migratory direction from the normal posterior-facing to anterior. We show here that the LC uses nicotinic receptors acr-15, acr-16, and lgc-9 to respond to ACh. We also used time-lapse microscopy to capture z-stack images of the migrating linker cell as it reversed in response to excess ACh over the span of two hours and 30 minutes, reflective of the regular migratory LC timeline. The bullet-shaped LC is always polarized towards the direction of migration with the cytoplasm in front and nucleus in the back. We measured directional change by tracking the position of the cytoplasm relative to the nucleus as the LC reversed directions in recorded z-stack images. There were clearly at least three specific stages by which reversal occurs—posterior facing, ventrally facing, and anterior facing. The LC always rotates clockwise towards anterior facing, with the ventral facing as an intermediate step in reversal. We propose a model that increased levels of ACh lead to stronger adhesion and polarization of the LC towards the ventral bodywall, causing the initiation of the turn. This may then result in the follower cells overtaking the LC, resulting in the LC completing the reversal.

Abstract Name: "What Can I Do About It?": Climate Anxiety in College Students

Climate change presents increasingly worsening global social justice issues. Along with the environmental and economic effects of the changing climate come a variety of personal stressors. Mental health practitioners have noted a growing number of patients expressing distress due to environmental issues. This distress, known as climate anxiety, is a relatively new topic and thus has been used in multiple contexts with varying definitions. It is a topic of relevance to sociologists as well as mental health practitioners. Understanding climate anxiety will aid in promoting action to combat climate change. This research examines the existing literature on climate anxiety, specifically in college-age individuals in preparation for a future study measuring it in the student population of Middle Tennessee State University. Research studying climate anxiety in college students is of particular importance as they represent emerging professionals and scholars who will shape the future of climate policy. Limited research on climate anxiety in college students exists, but a study by the Yale Program on Climate Change Communication showed that Gen Z and Millennials have higher rates of climate anxiety compared to older adults. Existing research has found a negative relationship between climate anxiety and positive mental health in teens and emerging adults. The aim of this article is to provide an overview of research about: (a) ways that climate anxiety has been defined, (b) existing measures of climate anxiety, (c) the relationship between climate anxiety and pro-environmental behavior, and (d) climate anxiety and overall mental wellbeing.

Abstract Name: The Howard Movement: Collective Action Framing Amongst Howard University Student Protestors

Using the sociological comparative historical approach and primary source analysis of The Hilltop Student Newspaper, I make two arguments: first, that student protestors through instrumental collective memory anchoring, use collective action frames as well as framing dynamics and processes to influence collective action. Second, although these two protests occurred twelve years apart, the processes have ensured the continuity of a singular continued social movement unified by what I term the "collective Howard student memory and identity". Through informing The Hilltop Student Newspaper staff writers and public media, Howard University's 2021 #BlackburnTakeover Protest and September 4th, 2009 protestors claimed the administration was responsible, held rallies, and drew on past protests. Furthermore, they create slogans, unify with the faculty and staff as well and encounter internal and external disputes to frame the events in a manner that benefits their campus protests's objectives. This research expands the literature on social movement theory, collective memory, collective identity, and framing by exploring collective memory and identity on a singular college campus across time as well as providing insight into how student protestors construct campus movements.

Abstract Name: Effect of Toxoplasma gondii Infection on Amyloid Plaque Accumulation and Microglial Activation in an Alzheimer's Disease Mouse Model

In the United States, roughly 6.5 million people have Alzheimer's Disease (AD), a disorder characterized by clinical symptoms of memory loss, difficulty concentrating, and a decline in ability to make judgements and decisions. It is also characterized pathologically by the accumulation of beta-amyloid plaques and neurofibrillary tangles. This project aims to explore how Toxoplasma gondii affects AD pathology in Arctic mice, an AD mouse model.Toxoplasma gondii (T. gondii) is a foodborne parasite that is able to infect most warm-blooded animals. It does not typically present with life-threatening symptoms and it has been found to evade complement mediated lysis. Data from our collaborators show that infection of T. gondii in the 5xFAD mouse model of AD resulted in reduced plaque pathology 6 weeks post-infection that was accompanied by increased microglial activation. Immunohistochemistry (IHC) techniques (anti-Iba1 staining for microglia) and thioflavin staining for amyloid plaques were used to see whether a second AD model, the Arctic mouse, would have the same results. Since C5aR1 has been reported to be activated upon T. gondii infection, the responses of the Arctic mice with and without C5aR1 receptors (C5aR1KO) were compared to determine if

the presence of C5aR1 contributes to plaque reduction. Finally, mice were infected with T. gondii at either 6 weeks or 12 weeks before perfusion to determine how long after infection the effects on plaque pathology are maintained. Preliminary results show that Arctic mice that were infected with T. gondii had a decrease in amyloid plaque pathology and an increase in microglial activation 6 weeks post-infection. The absence of C5aR1 had no effect on these measures. However, this suppression of plaque accumulation appeared to dissipate 12 weeks after infection, suggesting control of the infection limits microglia activation and thus clearance of amyloid in the Arctic model.

Abstract Name: Racial & Economic Disparities in NYC's Public School Athletic League

The Public School Athletic League (PSAL) is the oldest and largest sports league in the United States, serving New York City Public Schools' approximately 1.1 million students. In nearly 70 years since the Brown vs. Board of Education (1954) lawsuit, New York City student-athletes won a class action lawsuit based on gross racial disparities in the New York City Department of Education (DOE). In majority Black and Latinx schools, students had access, on average, to 7 PSAL teams. In non-majority Black and Latinx schools, students had access to over 29 PSAL teams. As a part of a settlement of this lawsuit, the DOE implemented the Shared Access Program with the intent to increase access to sports teams by creating new teams for students from schools of close geographical proximity to participate in. However, over three years after its implementation this study explores how effective such programs are in addressing the root causes of racial disparities in the DOE. Based on the Shared Access Program's targeted approach based on disparate school districts I will conduct qualitative research using ethnographic observations comparing neighborhoods with the largest disparities, in order to ask pertinent questions to neighborhood stakeholders. The neighborhoods selected for this study were from four distinct districts, all of which are part of the Shared Access Program. We anticipate finding environmental features that help us understand the nature of inequality, rooted in the neighborhoods, that goes beyond what the Shared Access Program attempts to address. This raises the question of how much, if at all, the program can lead to significant changes regarding poverty.

Abstract Name: Curriculum Validation and Effectiveness Measurement of Entrepreneurship Education at Musashino EMC

This study aims to uncover the current state, challenges, and distinctive features of entrepreneurship education at the undergraduate level in Japanese universities, with a specific focus on Musashino University

Entrepreneurship Faculty (Musashino EMC), which actively implements entrepreneurship education at the undergraduate level in Japan. Japan has recognized the importance of startup creation, evident in the establishment of the "Startup Development Five-year Plan" in 2022. In this context, entrepreneurship education has emerged as a crucial factor in fostering startup initiatives. Musashino EMC defines entrepreneurship as "a mindset of stepping out and creating new value based on high aspirations and ethics, without fear of failure. This mindset is deemed indispensable for fostering startup creation in Japan. Despite the growing emphasis on entrepreneurship, the provision of entrepreneurship education at the university level in Japan remains limited. Moreover, there is a notable lack of comprehensive measures to assess the educational impact and the development of effective methodologies related to entrepreneurship education. This study examines the curriculum at Musashino EMC and investigates its educational effectiveness through questionnaires and interviews. The purpose is to utilize the curriculum framework adopted by Musashino EMC and to determine how each curriculum contributes to enhancing students' entrepreneurship. As a result, it will become clear how the curriculum at Musashino EMC fosters entrepreneurship, and the current status, issues, and characteristics of entrepreneurship education as a leading example. It will also reveal what curriculum elements can foster entrepreneurship. This study aims to contribute to the discussion on the future of entrepreneurship education.

Abstract Name: Is this you? Foucauldian Ethics in Multifactor Authentication

Multifactor authentication (MFA), which was in use as early as 1994, is a system used to verify user identity during the login process to increase security and deter hackers. Today, MFA requires a user to prove their identity by way of their knowledge, through a password or one-time code; their possession, through a physical key or USB; or their inherence, through biometrics like a fingerprint or an eye scan. While the sign-on method has proliferated in recent years, little if any research has been done in relation to its ethical implications as a surveillance technology. In his scholarship on discipline, Michel Foucault writes of surveillance as “an architecture that would operate to transform individuals.” MFA is one such method of surveillance — various forms track users’ location data, common usage and login hours, and biometric information — that is changing its users. Through autoenrollment, employers and other organizations have implemented MFA in a way that requires users to sacrifice privacy in order to gain protection. In my presentation, I will apply Foucauldian ethics to show how MFA violates the definitions of privacy and security, and in doing so, diminishes our autonomous self-concepts. As a part of our daily lives, the routinization of MFA surveillance is changing the way we perceive ourselves and our ability to act with independent power.

Abstract Name: NASA LU ROCKON 2023

In 2023, the Langston University NASA RockOn team, comprised of five members, will build a real sounding rocket payload and launch it on a two stage Terrier-Orion rocket into outer space. Our project manager will lead our team by 1) Scheduling of the rocket launches, agenda, and other events. Maintain inventory of workshop and create acquisition and requisition reports. 2) Understand the chemical makeup of the rocket materials and their molar masses. Analyze data collected by using properties of atmosphere and matter to determine temperature, pressure, speed, and acceleration. 3) Understand Rocket history 101, the center of pressure, and center of gravity, design & build a rocket, rocket motor, payload, and recovery system, and coordinate launch missions. 4) Using an Arduino minicomputer to create a hardware/software system (payload) to collect data. Store data on an SD card for analysis. 5) Document the progression of the project by way of photos, video, oral presentation, and written work.

Abstract Name: Restorative History and Community Led Narrative Change on Maryland’s Eastern Shore

This project, completed over the summer of 2023 focuses on bringing the local history of Maryland’s eastern shore to light through a community led process of preserving and making accessible their history. Through conducting archival research and becoming involved in the community at Salisbury I worked with the City of Salisbury, the University of Maryland, Eastern Shore, and the Maryland State Archives. Working in close partnership with the Maryland State Archives, I was able to find documents that were relevant to our investigation around lynchings in Maryland, most notably in the cases of Garfeild King and Wright Smith. It was previously believed that the first secret investigation by a private firm was commissioned by governor Philips Lee Golds-borough following the lynching of King Johnson in Brooklyn Maryland in 1911. These newly uncovered 1898 correspondence with the Pinkerton National Detective Agency investigation establish this investigation as the earliest known secret investigation by a private firm in Maryland. These findings further solidify the precedent of Maryland using private firms to commission secret investigations and also demonstrate significant financial investment by the state with receipts showing significant costs for the investigations in 1898.

Abstract Name: Testing the efficiency of membrane enzyme truncations for medicinal in-vitro systems using E. coli

Malaria is a highly infectious disease affecting an estimated 249 million people in 2022. The primary

treatment for Malaria is artemisinin, which is isolated from the plant Artemisia annua. However, the affordability of this treatment, especially for countries in the Global South, is a significant concern due to two main challenges: the low extraction yields of artemisinin and its infrequent harvest. To address this issue, our lab uses well-established metabolic engineering strategies to increase artemisinin content in planta. One approach involves understanding key enzymes in the artemisinin biosynthetic pathway and enhancing their capacity for catalysis. To achieve this, we currently use E. coli as our model system to produce recombinant enzymes from this pathway. Our focus is on Cytochrome P450 (CYP450), responsible for synthesizing artemisinic acid—a precursor of artemisinin—and its redox partner, Cytochrome P450 Reductase 1 (CPR1). Both of these enzymes pose a challenge for expression in a prokaryotic system due to their native binding to endoplasmic reticulum (ER). These proteins are inserted into the ER membrane by its hydrophobic N-terminal anchor. Due to this domain, they bind to the plasma membrane when expressed in E.coli and make it difficult to purify the proteins since they form many inclusion bodies (accumulation of unfolded protein) during extraction. Truncating the transmembrane domain was demonstrated to produce a soluble CYP450 and CPR1 for optimal expression conditions in E. coli and better purification. I aim to further that research by testing the efficiency of multiple truncation expression constructs that are created using Gateway Cloning. The production efficiency of these truncated enzymes will be analyzed using SDS-PAGE, a technique for protein separation. This solution not only addresses immediate challenges but also contributes to our overarching goal of understanding in-vitro mechanisms of artemisinin biosynthesis to enhance enzyme production in planta.

Abstract Name: All-Optical Image Denoising Using a Diffractive Visual Processor

Image denoising, an inverse problem aiming to eliminate noise/artifacts from input images, serves crucial roles in fields like computational photography, medical imaging, and remote sensing. Current image denoising methods often come with significant latency and computational burden. Our paper introduces an analog diffractive image denoiser operating optically and non-iteratively. These characteristics enable it to function at the speed of light and consume minimal power, only requiring a small amount for input illumination. The denoiser comprises passive transmissive layers with tiny phase modulation features optimized through deep learning. These features scatter the optical modes corresponding to noise characteristics away from the output image field of view while preserving modes related to the object features of interest. The training occurs for an arbitrary illumination wavelength λ, allowing the realization of a physical network spanning <250λ for any chosen wavelength without retraining. In a proof-of-concept experiment, our denoiser was demonstrated to operate at the terahertz spectrum. Our results exhibit the efficient removal of salt-and-pepper noise and spatial artifacts associated with image rendering from input phase or intensity images. Additionally, it achieves an output power efficiency of approximately 30-40%. Due to their speed, power efficiency, and minimal computational overhead, all-optical diffractive denoisers can revolutionize various display and projection systems, such as holographic displays.

Abstract Name: Characterizing the Role of Lynx2 Following Chronic Mild Stress

Cigarette smoking is the leading cause of preventable disease and death in the United States. Nicotine, the psychoactive constituent from tobacco, is responsible for the reinforcing properties of smoking. Adult smokers who attempt to quit, may relapse within the first few weeks as result of discomfort from stress. Lynx2, a negative allosteric modulator of nicotinic acetylcholine receptors (nAChRs), is enriched in brain regions associated with stress regulation and nicotine reinforcement. Thus, our studies aim to characterize the mechanism by which lynx2 may impact stress related behaviors. To address this, we implemented a chronic mild stress (CMS) protocol including several different conditions (nesting removal, water deprivation, damp bedding, cage tilt, continuous light, and white noise with predator odor) with both wild-type (WT) and transgenic lynx2-knockout (TG) mice. Following the CMS protocol, both CMS and control mice underwent a social interaction test and a nicotine conditioned place preference (CPP) paradigm. We hypothesized that in the social interaction test, CMS mice would spend less time in a chamber containing a novel mouse in comparison to the control group, with WT mice exhibiting greater time spent in the chamber compared to TG mice. In addition, we hypothesized that CMS conditioning would exacerbate the preference for the nicotine-paired chamber in both WT and TG mice compared to the control group as assessed in nicotine CPP. Overall, our studies suggest a potential interaction where lynx2 significantly interacts with stress exposure to alter social behavior in mice. In conclusion, our studies illustrate a role for lynx2 in nicotine cessation and stress exposure.

Abstract Name: Comparing Differences in the Endpoint of Mutations Between Ancestry Groups

Differences across genetic ancestry groups have been observed in the rate and genomic location of somatic chromosomal alterations (mCAs) detected from sequencing of blood tissues from donors without cancer. This project sought to determine whether there are differences in the frequency of somatic copy number mutations that span entire chromosome arms compared to those with endpoints within a chromosome arm, which would indicate a double strand break during generation of the copy number change. A double strand break (DSB) occurs when the sugar-phosphate backbone of the DNA molecule is split between two neighboring nucleotides. This type of DNA damage can be caused by environmental agents such as ionizing radiation, ultraviolet light, chemical compounds, diet, smoking, and air pollution. The driving hypothesis behind this project is that differences in mutation rate, if present, stem from variations in DNA-damaging factors or genetic susceptibility across ancestry groups. Determination of differences in mutation frequency across European American (EA), African American (AA), and Hispanic American (HA) groups (clustered based on genetic similarity) was accomplished through the development of python scripts to identify breakpoints from

somatic copy number changes. These were then sorted across two categories: Endpoint at chromosome arm boundaries and endpoint within the chromosome arm. The results of this analysis indicate that there are no differences across genetic ancestry groups in the frequency of inferred somatic copy number changes arising from double strand breaks. Our findings support the notion that genetic and environmental drivers do not lead to differences in DNA double strand breaks across these groups; however, further validation is warranted in additional cohorts.

Abstract Name: Mechanisms for Microbial Regulation In the Presence of Amphetamine

Amphetamines (AMPHs) are effective psychostimulants used to treat neuropsychiatric disorders such as attention deficit hyperactivity disorder (ADHD). Much of the published data shows reciprocal communication between the microbiome and the brain. In a recent study using Drosophila as a model system, it was demonstrated that Fusobacterium nucleatum (F. nucleatum) enhances behavioral responses to AMPH (hyperlocomotion, sexual drive, and drug preference) through secretion of butyrate, inhibition of histone deacetylases, and upregulation of expression of DA transporter (DAT). This increased expression of DAT leads to non-vesicular DA release (DA efflux), in response to AMPH, translating into enhanced AMPH-induced behaviors. This provides evidence of a role for imbalances in the microbiome (dysbiosis) in the pathogenesis of AMPH use disorders and supports previous work, in mice, demonstrating that administration of antibiotics reduces AMPH-induced hyperlocomotion, conditioned place preference, and sensitization. The mechanisms by which AMPH affects F. nucleatum abundance are not known. Preliminary data demonstrates that AMPH does not directly alter F. nucleatum growth rates, but instead increases biofilm formation As biofilms protect anaerobic F. nucleatum colonies from environmental oxygen, and F. nucleatum colonization enhances host responses to AMPHs (including preference for AMPH), the ability of biofilm inhibition was tested for a decrease in host responses to AMPH. F. nucleatum adhesins are known to facilitate formation of multi-species biofilms with the aerobic bacteria Streptococcus mutans (S. mutans). After confirming that co-cultures of F. nucleatum and S. mutans enhance the presence of AMPH, a dependence for AMPH was tested for by co-colonizing F. nucleatum and S. mutans bacteria. Additional pharmacological inhibitors that exhibit an inhibition of AMPH-enhanced biofilm formation were then tested. It was anticipated and was found that aerobic environments block co-culture biofilm formation. This is significant because biofilms provide a major route to tolerance and resistance for bacteria, especially to agents such as antibiotics.

Abstract Name: Updated Molecular Dynamics

Aptamers are single-stranded nucleic acids that behave similarly to antibodies in that they bind to certain target molecules. The main difference being that aptamers can be synthesized in lab (in vitro) while the main synthetical pathway to create antibodies often includes some sort of biological element (in vivo). Additionally, some research suggests that aptamers may have tunable properties and might generally be more chemically resistant than antibodies. This makes aptamers a subject of interest for various biochemical applications. Our chosen aptamer is the malachite green aptamer (MGA), which binds to its target molecule, malachite green (MG). Malachite green is an organic molecule mainly used in dyes and fungicides. Molecular dynamics (MD) simulations are a computational method to model desired systems that has been used in complement with experimental methods. We focus on using MD simulations to generate models of how MGA behaves in water—in the unbound state and while bound to malachite green. Specifically, we aim to determine the mechanism through which MGA binds to malachite green. It has been reported in previous studies that an “induced fit” method is the main way MGA binds to MG. In other words, the structure of MGA is only loosely determined before binding and undergoes a reorganization of structure while it is binding to MG. Previous computational simulations have been done on this same system before. Though the advancement of technology and develpment of new software has made it possible to take an updated look at this system. Comparing the updated simulated bound and unbound states helps us understand the possible differences in flexibility and stability between both states. This in turn, could point to certain behaviors that could explain the mechanism we seek to understand.

Abstract Name: Effects of Perceived Health of Hair on Attractiveness Ratings

Attractiveness is likely a combination of evolutionary and cultural factors, which makes identifying features that contribute to attractiveness an important topic of debate within the field of psychology. The current study assesses how perceived hair healthiness influences perceived attractiveness. Hair density and diameter has been shown to have a strong influence on perceived youth, health, and overall attractiveness due to hair health being indicative of hormonal changes related to age in women (Fink, et al., 2016; Matz & Hinsz, 2018). It was hypothesized that (H1) for images of women, the higher the health rating of hair, the more attractive a participant would be rated. Additionally, we predicted that (H2) the higher the estradiol levels of the photographed woman, the higher the perceived hair quality. Participants (N=37) used the computer program, SuperLab, to rate grayscale images of hair on hair healthiness (5-point scale) and another group of participants (N=55) rated on overall attractiveness (7-point scale). The results of the study did not support H1 (r=0.08, p=0.31) nor H2 (r=-0.15, p=0.84); no significant correlation was found between hair health and attractiveness nor estradiol levels and ratings of hair health. Understanding factors that influence perceived attractiveness helps further guide research to identify features relevant to analyze when using attractiveness as a research measure. Because the results of our study are not consistent with other studies of hair health and female hormones, and hair and attractiveness, we plan to further explore the conditions for these three conditions to be related.

Abstract Name: Sexuality and Mental Health Part Two

Previous research (Arnold et al., 2023) has indicated an association among mental health disorders, sexual orientation, romantic orientation, and gender identity. However, these studies have examined the relationships in the context of the overall LGBTQIA+ community without considering specific mental health disorder groups. Therefore, the objective of this research was to expand on these findings by investigating the relationships among different sexual orientations, identities, and specific mental health disorder categories. To explore these relationships, a comprehensive 100-question survey was designed. The survey included questions about demographics, mental health, sexual orientation, sexual identity, discrimination, and catch questions used for data validation. The survey was administered using Survey Monkey and distributed through Prolific.com. Participants were required to meet specific criteria, including being 18 years or older, US citizens, and proficient in English. Out of 1045 registered participants, data from 999 individuals who completed the survey and provided consent were analyzed. The preliminary data analysis resulted in significant correlations among sexual orientation, romantic orientation, gender identity, and various categories of mental health disorders, as expected. Among specific significant correlations (p. = < .01) identified were those between (A) schizophrenia diagnoses and transgender male identity, (B) non-binary identity and trauma/stressor-related disorders, and (C) questioning of sexuality and institutionalization for mental health disorders. This research revealed a better understanding of the relationships between mental health disorders and LGBTQIA+ affiliation. Instead of merely examining the global relationship between mental health and sexuality, associations between specific sexual orientations and certain mental disorders were identified. However, more research into the links between specific mental health issues and specific sexual orientation should be performed. Additionally, other lifestyle factors may undoubtedly have a significant influence on mental health. Identifying these factors and the links may provide a better understanding and treatment of mental disorders.

Abstract Name: The World's Leading Countries, And Their Perspective On Artificial Intelligence

Artificial intelligence (A.I.) has always been a topic of debate, however more recently so. Most of the world's leading countries have invested billions of dollars into the A.I. industry. It has become so popular that we unknowingly use it in our daily lives ranging from: answering machines, search engines, to speech recognition apps. A systematic research was conducted using JSTOR and Google Scholar. Eight research

articles were used to collect data on artificial intelligence and government policies. Politics plays a massive role in the development of A.I. and how it will be implemented by a country's respected government. The results from this paper showed that a vast majority of countries have implemented guidelines regarding the creation and use of artificial intelligence. Countries' have their own regulations on A.I.and these regulations differ based on the countries' economies and governments. The United States has invested billions of dollars into artificial intelligence, China has invested 150 billion, Russia 12.5 million, and determining the EU's total investment cannot be conclusive as Brexit had an impact on the total budget for A.I. The project's goal was to determine the perspective world's leading countries have on artificial intelligence, countries' regulation and implementation of artificial intelligence. Every government should integrate policies, ethical guidelines, and resources into artificial intelligence since it might affect the economy of the country.

Abstract Name: FLUORESCENCE STUDY OF MAGNESIUM OXIDE AND MAGNESIUM HYDROXIDE NANOPARTICLES WITH GRAM-NEGATIVE AND GRAM-POSITIVE BACTERIA

Previous studies found that magnesium oxide nanoparticles (nMgO) had antibacterial effects against two Gram-negative and three Gram-positive bacteria, and magnesium hydroxide nanoparticles (nMg(OH)2) were antibacterial against Staphylococcus epidermidis. Currently, the specific mechanisms are unknown, but several have been suggested in previous studies. Understanding these mechanisms may lead to their potential in a clinical setting, for example, with surgical implants to aid in postoperative infection mitigation. To identify these antibacterial activities, fluorescence dyes have been integrated into studies involving bacteria exposed to nMgO or nMg(OH)2 to identify suspected mechanisms. These may include Gram-negative bacteria membrane permeability, Gram- negative and Gram-positive plasma membrane depolarization, reactive oxygen species detection, and the effects of reactive oxygen species. Observing fluorescent dye reactivity will reveal if nanoparticle activities include one or more or these mechanisms in bacterial cells. Results of this study are expected by the end of April 2024. Overall, this study will give further insight into the nature of nMgO and nMg(OH)2 effects on bacteria and will aid in downstream research involving nMgO and nMg(OH)2.

Abstract Name: RACE-ASSOCIATED DIFFERENCES OF INFLAMMATORY PROFILES IN TYPE 2 DIABETES

Type 2 Diabetes(T2D) is an inflammatory health disparity, which presentation and progression is known to be exacerbated in some races more than others, such as African Americans(AA). Reports have shown that the presence of inflammatory molecules like Th-17 cytokines (IL-17A, IL-17F, IL-21, and IL-22) are associated with type 2 diabetes. However, most of these results come from non-diverse cohorts, neglecting the characteristic inflammatory status of T2D in diverse populations. We hypothesize that there are differences in the inflammatory profiles in AA with T2D compared to white Americans. To test this hypothesis, we took blood samples from the AA and white American cohorts and analyzed their plasma samples using Luminex. Luminex is a laser-based instrument that we used to measure the expression of 53 cytokines between our racial cohorts. Our data analysis involved uni and multivariate analytical approaches. The univariate results showed that out of the 53 cytokines evaluated, 4 (eotaxin, IL-27, M-CSF, MCP-1) were significantly different in terms of them being expressed at a higher amount in the white cohort over the AA cohort. Out of these cytokines, MCP-1 and M-CSF are associated with acute inflammation while IL-27 is known to inhibit TH-17 differentiation. These findings suggest that the AA cohort may be less susceptible to develop an acute inflammation response and be impacted by an increase of TH-17 cyotkines, indicating a more severe inflammatory status. For the multivariate analysis, cluster generation was done using the gap statistics and k-means method. There were no significant differences in these clusters between races and sex groups. Overall, we conclude that there are racial differences in the inflammatory profiles in our diverse cohorts. In the future, control groups (non-T2D and pre-diabetics) and other confounding variables will be included to evaluate further differences in T2D inflammatory status.

Abstract Name: Canvases for Expression: Redefining Pediatric Prosthetics and Societal Stigmas Through Themed Expression and Airbrush Artwork

Vuillermin et al. estimate 5 in 10,000 children have a limb difference, with many rejecting prosthetic devices. Unsatisfactory cosmetic appearance contributes to this rejection. Prosthetic limbs often try to replicate human anatomy but can fall victim to Mori’s Uncanny Valley, where robotics with human likeness are correlated with distaste. This research proposes a design scheme to address prosthetic rejection due to cosmetic appearance, offering children a platform for personal expression.New artistic effects were explored for clinical trial applications to enhance patient expressivity. Within current trials, participants design interchangeable cosmesis on a 3D-visualization web-interface. The design scheme is then elevated with a focus on artistic elements of the cosmetic's form, color, and shape. User involvement is imperative to the satisfaction of the product and process. Automotive-grade airbrush techniques are used to apply artistic finishes to the cosmesis, which are then magnetized onto the novel prosthetic arm. This creative research

aims to uplift children with limb differences and enable them to express themselves. The research will adapt following participants' feedback, with preliminary data indicating that participants feel confident while wearing their cosmetics.Exploring new artistic effects, two cosmeses were created to showcase vibrant expressions reminiscent of princess gowns. The first sleeve follows a triadic color scheme using iterations of value and chroma of the primary colors. Following David Kessler's color system, harmony appears with pink, blue, and yellow being dominant, non-dominant, and accent colors, respectively. Vibrancy, saturation, and composition enhance the angular topology, creating an energetic and playful experience. Furthering this expression, a new black-light effect will create visual dynamics in black-lit environments. The second sleeve follows an analogous color scheme ranging from yellow-orange to blue-green, complementing a new light-sensitive color-shifting paint, providing visual interest in simplistic topography. Integrating these new artistic effects expands opportunities for personal expression within prosthetics.

Abstract Name: Microfabricated Silicon Filters for Shape-Based Separations

Separation by shape of similar-sized particles requires innovative filtration methods with potential benefits to fields such as biomedical diagnostics, environmental testing, and additive manufacturing. Through microfabrication processes including photolithography, reactive ion etching, and anisotropic wet etching of single crystal silicon wafers, we produce precision filtering microchips with 3-dimensional pore geometries customized to pass or trap particles based on their shapes. This pore structure can be exploited for the separation of micro- and nanoscale objects such as bacteria, viruses, prions, and microplastic contaminants. A stereolithographic resin printer is used for its feature precision capabilities in the manufacture of a microfluidic cell that houses the silicon filter and permits forward, reverse and cross-flow filtration. We describe microfluidic principles, fabrication processes, and proof-of-concept tests for shape-based separations.

Abstract Name: Assessing the Pathogenic Role of APOE4 Genetic Risk Factor of Alzheimer's Disease in 3D Brain Organoids

Apolipoprotein E4 (APOE4) is a prominent genetic risk factor for Alzheimer's Disease (AD) and is associated with 3-12 times greater risk of developing AD. Human induced pluripotent stem cell (iPSC) technology allows us to derive patient-specific 3-D brain models that recapitulate features of human brain tissue structure, providing a tool to study early pathogenic mechanisms and disease-related phenotypes. The exact mechanism of how APOE4 affects specific neuronal cell types, and their relevance to AD risk, is unknown. Recent studies show that there is increased maturation in specific cell types which may contribute to AD risk. To investigate the role of APOE4 on various neural cell types, we generated two types of iPSC-derived cortical organoids, human cortical organoids (hCO) that are enriched in excitatory neurons and human subpallial organoids (hSO) that are enriched in inhibitory neurons. We compared cellular phenotypes of iPSC-derived hCO and hSO from healthy (APOE3) control organoids, the non-risk allele, to AD patients (APOE4) organoids. Across all time points, we observed a significant decrease in the size of APOE4 organoids in both hCO and hSO. In hCO, we observed a trending increase in proliferation and a significant decrease in cell death in the early time points. In hSO, there is a significant increase in the proliferation and growth of neurons and progenitors in the early time points, but there is also a significant increase in cell death in the later time points. These results are consistent with the notion that APOE4 leads to increased maturation of cells and APOE4 has a differential effect on neuronal cell subtypes, which may contribute to AD risk. Further examination at later points is needed to understand the full extent of the influence of the APOE4 allele on AD pathology on cortical organoids.

Abstract Name: "Automatic Brain Tumour Detection: An Enhanced SSD Algorithm With SIFNET Architecture and Shap and Lime CNN Explanations"

In medical diagnostics, the significance of automatic brain tumor detection cannot be overstated, especially when comparing it to error-prone manual methods. By discerning subtle patterns and abnormalities in MRI images, automated techniques empower healthcare professionals to identify brain tumors in their initial stages, facilitating prompt intervention and treatment. Despite the current research showing good accuracy, challenges persist in achieving precision for irregularly shaped tumor identification and ensuring interpretability. To bridge this research gap, we propose an automated brain tumor detection technique using the SSD (single shot multi-box detector) algorithm. We have adapted the model by applying transfer learning to the existing approaches utilizing an enhanced SIFNET (self-attention interaction fusion network) architecture with SSD framework on a larger dataset for more accurate object classification compared with existing research. Models tailored to small testing datasets are the focus of the present research. We propose to expand the reach of our model to a dataset of larger variety and size. We have integrated LIME CNN and SHAP CNN explanations for interpretability and increased transparency of the model, a pioneering move in automated brain tumor detection that has not been explored before. To determine whether the results of the research are reliable and helpful, we also intend to collaborate with oncologists.

Abstract Name: Online Education: Increasing Accurate Prediction of Adaptability After Online Education

The recent pandemic/Covid-19 adversely impacted our education system where in-person mode of education was replaced by online education. Students' adaptability in online education emerged as an issue that still needs attention. We hypothesize that by incorporating AI/Machine Learning techniques, students' adaptability level predictions can improve online education. Additionally, we plan to oversample some of the minority cases, to make up for the data being unbalanced. In this work, data from Kaggle was borrowed to develop machine learning models. The data from Bangladesh included thirteen important features including age, gender, educational level, institution, class durations, internet and network type, devices, load-shedding, IT-related-studies, and financial conditions. A total of 1205 students from academic institutions were involved. The availability of IBM platform made it possible to use multiple algorithms to develop predictive models. In this work, Snap SVM classifier, Gradient Boosting Classifier, and Logistic regression with and without enhancements were employed. In our previous work presented at SSCUR 2023, the accuracy of various models was found at moderate levels below 80 percent. However, in the current work, the data was manipulated to make it balanced; the algorithms after this gave an accuracy 5 percent higher than the previous case. In each algorithm, significant features percentage contribution to model predictions were noted. The feature importance for SVM classifier without oversampling was found to be 100% for financial conditions, and 92% for class duration. The corresponding values for the SVM classifier with enhancements were similar, with financial condition being 100% and class duration being 63%. In both cases, similar results from the other two algorithms were obtained with slight deviation. ROC curves, F1 score, and confusions matrices were obtained for a comparative discussion. A full discussion on machine learning results including methods to further improve the accuracies will be included in the presentation.

Abstract Name: It Takes Two to Tango: Positive Student and Instructor Affect Supports the Success and Persistence of a New Pedagogical Tool

A growing body of literature shows that student-centered pedagogical tools enhance student learning and experience, yet widespread curricular transformation has not necessarily followed. This is likely because successful curricular transformations require buy-in from both students and instructors. Consequently, much effort has been expended to explore the extrinsic and intrinsic barriers to instructor buy-in for such changes, including their perceptions and experiences. The long-term incorporation of these tools in classrooms is likely to be limited if either the instructors or students fail to recognize the student benefits or lack confidence in the efficacy of a given tool/approach. Two-stage collaborative group exams (CGEs) are a student-centered pedagogical tool involving students working together in groups to complete the same or similar assessment after first attempting the assessment individually. This study explores the effects of large-scale adoption of CGEs across all levels of a biology curriculum at a medium-sized private university. The alignment between student and instructor perceptions and experiences with CGEs was evaluated through surveys with quantitative and qualitative data recorded from 834 individual students and 10 participating instructors,

respectively. Additionally, students' performances on individual exams and CGEs were used to estimate and compare performance gains across the academic semester. Our data indicate that the perceptions and experiences with CGEs were generally aligned between students and instructors. CGEs improved exam performance, and students overwhelmingly reported decreased exam anxiety, positive group dynamics, and enhanced perceived learning. The majority of instructors adopting CGEs reported similar positive perceptions and experiences, while also expressing the intention to continue using CGEs (or similar assessment strategies) in the future. These results support the ideas that 1) the student benefits of CGEs are seemingly universal and 2) mutually-positive experiences for instructors and students are likely to increase the success of curricular transformation and persistence of new pedagogical tools.

Abstract Name: Obstacles to Intra-Africa Trade

This research explores the critical obstacles to intra-Africa trade, with a particular emphasis on the challenges posed by inadequate hard infrastructure. Despite Africa's potential for increased regional trade, various factors, including limited road networks, insufficient electricity supply, and inadequate logistics facilities, have hampered the continent's intra-regional commerce. The study draws from various resources, including reports from the African Development Bank (AfDB), World Bank, Asian Development Bank, and the United Nations Economic Commission for Africa. Using a comparative approach, it examines successful infrastructure projects and initiatives in other regions to glean insights applicable to the African context. From the Øresund Bridge in Europe to the East-West Economic Corridor in Asia, these case studies provide valuable lessons for Africa. The research aims to underscore the vital role of well-planned and executed infrastructure development in enhancing trade and proposes strategic directions for improving Africa's intra-regional trade infrastructure.

Abstract Name: Straighten Your Hair- It's More Professional, Exploring the Relationship Between Black Hair and Professionalism

From racial discrimination to wage gaps, workplace discrimination is a significant and pressing issue. According to Omri Ben-Ari, racial discrimination in professional settings are often difficult to detect, as the employer's inability to hire/promote an individual on account of race is nearly impossible to assess (Ben-Ari, 2011). While identifying the racial discrimination may be difficult, socially, implicit biases and perceptions of people of color have become normalized (James, 2019). Traditional hair styles like braids, afros, or dreads have socially been deemed unprofessional while straight hair has become the standard for what a professional should look like (James, 2019). In addition, new research suggests that the lack of people of color in

professional settings have normalized what “professional” actually looks like, making the small number of black people appear unfamiliar and therefore unprofessional, too (Henson, 2020).Beyond this, other research has found that this issue scopes beyond aesthetics. In researcher Bridges' sociology study, statistically, African Americans were found to be least likely to graduate high school and college due to high dropout rates (Bridges, 2017). While there are many factors for this, Bridges highlights that the systemic barriers in place for black people has inhibited this minority group from even reaching the interview stage, contributing to the perception that black aesthetics lack sophistication and professionalism (Bridges, 2017). This present research seeks to explore the relationship between African American hair and perceived professionalism. Specifically, what factors aid in the perception that Black aesthetics are unprofessional, and how does the education system influence this, if at all?

Abstract Name: The Influence of Organic Amendments on the Heat Capacity of Soils

The heat capacity of soil is an important thermal property influencing heat storage and transfer, impacting greenhouse gas emissions, seed germination, plant transpiration, and contaminant dynamics. This study explores the modification of soil heat capacity following the incorporation of organic amendments, aimed at enriching soil organic matter and enhancing soil health and fertility. We specifically investigate the changes in soil heat capacity before and after the addition of various organic amendments, such as humic acids and biochar. The excess heat capacity was determined by the difference between measured values against theoretical predictions based on the mixture rule. This approach facilitated a comparative analysis of the magnitude of excess heat capacity across four distinct soil samples, each treated with different amendments.

Abstract Name: Enabling AAV-based in vivo Perturb-seq

Human genetic studies have tied neurodevelopmental disorders to ‘risk genes’, where inherited or de novo genetic variants significantly increase one’s likelihood of developing these disorders. Several Autism spectrum disorder (ASD)-risk genes have been identified, yet most of their molecular mechanisms remain unclear. In vivo Perturb-seq combines clustered regularly interspaced short palindromic repeats (CRISPR)-based gene editing and single-cell RNA sequencing (scRNA-seq) to enable elucidation of these mechanisms across diverse cell types. We can knock out many genes simultaneously in various cells within the prenatal

brain and individually sequence postnatal, developed cells' transcriptomes. We can therefore examine each gene's role across cell types, providing greater insight into their molecular logic. In vivo Perturb-seq requires lentiviral vectors to deliver gRNAs, which have limited in vivo transduction efficiency, thus impacting the scalability of Perturb-seq. Adeno-associated viral (AAV) vectors have higher efficiency with less immunogenicity. However, unlike lentiviral vectors, they are unable to integrate into the host genome, leading to low expression level of gRNA and dampened perturbation effects and capture in the scRNA-seq. My project addresses this fundamental challenge by boosting gRNA expression in AAV-based in vivo Perturb-seq via a separate transposase piggyBac (hypPB), which integrates the transgene into host cell genomes, stabilizing and enhancing expression. To demonstrate enhanced expression via hypPB, embryonic brain targeting AAV vector containing a transposon with fluorophore was co-injected alongside AAV-hypPB in E14.5 mice and analyzed via immunohistochemistry at P7. With hypPB co-transduction, I found the number of fluorophore-positive cells were 2.2-fold greater. To demonstrate enhanced gRNA expression, I transfected the vectors in vitro and analyzed the gene expression via RT-qPCR of extracted RNA. gRNA expression increased by 4.2-fold as hypPB-based genomic integration enhanced expression. Our research thus significantly enhances in vivo Perturb-seq's efficiency, providing a modular platform to understand the molecular intricacies of genes.

Abstract Name: Genetic Analysis of the Invasive Barn Owl Species Tyto alba Through DNA Barcoding

Barn owls, as avian predators, exhibit nocturnal behavior and inhabit diverse ecosystems worldwide, spanning Australia, Europe, Africa, and North America. These avian species are distinguished by their capability for silent flight, exceptional visual acuity, and superior auditory prowess, facilitating proficient prey localization even in low-light conditions. DNA barcoding, a scientific methodology utilizing DNA sequences for the identification and classification of species, serves as the primary tool in this study to ascertain potential genetic variations within the invasive barn owl population (Tyto alba) introduced to the Hawaiian Islands during the 20th century. Before sequencing, DNA extraction, polymerase chain reaction (PCR) utilizing cytochrome oxidase subunit I (COI) primer, and gel electrophoresis were carried out to confirm the successful amplification of 45 owl breast tissue samples. Sequence analysis, facilitated through the blue line of DNA Subway, was employed to discern polymorphisms within the species. Among the 45 samples sequenced, 29 yielded sequences of high quality. Analysis of these sequences implies the potential presence of specimens from two barn owl species, Tyto alba and Tyto furcata, within the Hawaiian samples. Polymorphisms were also identified within certain samples. This study provides valuable insights into the genetic diversity of the introduced barn owl population, contributing to our understanding of the evolutionary dynamics and ecological implications of invasive species establishment in different environments.

Abstract Name: Understanding the Social Determinants of Health in Accessing Sickle Cell Disease Care Services in Southern Minnesota.

Rural residents of the southern Minnesota region represent 63% of the total number of individuals with sickle cell disease in the state. Among these, nearly half report issues related to public transportation and problems related to nutritional access as cornerstone impairments of pursuing care. Geographically isolated treatment centers only further problems related to transportation access. The goal of this study is to provide a model of patient need/access versus geographical region. As a part of this regional summary, data collected through a literature review in tandem with comparison data provided by the Olmsted County REC and Minnesota Sickle Cell Coalition systems were used to isolate the greatest Social Determinants of Health (SDOH) impacting the rural sickle cell population; sighting transportation and nutrition access specifically. A proposal for further statistical evaluation of patient trend data was developed, utilizing EPIC as the primary software charting system for which discharge trend data would originate. The statistical validity of the proposal was evaluated and adjustments to specified data were made. A trend summary for patient data was compiled to provide a quantitative comparison to the previous qualitative study to verify the impact of transportation and nutritional access in patient care outcomes. The study results can be used to inform future policy development related to public transportation and food supply in supporting the health of rural southern Minnesota.

Abstract Name: Ikko Tanaka: Fusing the East and West

Ikko Tanaka is celebrated in contemporary art critiques for his ability to blend. His impact on the global art world is undeniable, as traditional imagery meshed with mass consumer culture of the West was his main subject. This study of his work will be focused on his ability to bridge cultural barriers while creating a visual language that was understandable to a broad range of audiences. This exploration into Tanaka’s body of work will compare and contrast typical designs of the late 20th century for further context into his popularity. Furthermore, the combination of analyses on Tanaka’s artistic background, the images selected, and the aesthetic mainstream choices of both the East and West will conclude that he is one of Japan’s greatest graphic designers.Keywords: design, woodblock, posters, Pop Art

Abstract Name: Women’s Artistic Memory: Andean Textile Practices

This study explores the aesthetic and technical development of Andean textiles over the course of Spanish colonization. Some scholars have and continue to argue that the excellence of indigenous tornesol techniques formed as a direct result of European contact. This study instead analyzes how the colonial setting acted as a global platform for indigenous cultural memory. Cloth was a significant cultural tool in Pan-Andean communities which was drastically altered at the behest of the Spanish Crown and the Catholic Church. Constructs of race, gender, and religion implemented in the “New World" changed the gendered nature of many forms of work, such as weaving. Under the hierarchical nature of colonial-run textile production, Spanish authorities created workshops and imposed regulations which exploited Indigenous women’s mastery of textiles and removed them from religious spaces. Women were ordered to make clothing for priests, colonial officials, local elites, and European exports. Thus, benefitting the Spanish colonizers as they profited from the highly sought-after textiles. This research is based on the formal examination of pre- and post-colonial textiles originating from the Andes region in South America, oral histories from indigenous peoples, and scholarly sources on the topic such as the writings of historian Denise Arnold. This study will conclude that textile practices were passed down among Indigenous women and their creativity and skill culminated in the cloth that shimmers in the sun, tornesol.

Abstract Name: The rail link between the State of Utah and the Republic of Kyrgyz Republic

Railroads have played a significant role in the development of Utah, connecting the state to the rest of the country, and facilitating economic growth. The first transcontinental railroad was completed in Utah in 1869, which led to an increase in transportation, commerce, and settlement in the state. The railroad made it easier to transport goods and people and allowed Utah to become a hub for mining and agriculture. Similarly, the construction of a new railroad in the Kyrgyz Republic will have a significant impact on the country and the region. The proposed railway will connect Central Asia to China and Europe, providing a faster and more efficient means of transportation for goods and people. This will likely lead to increased economic activity, job creation, and improved living standards for the region. However, there are also potential drawbacks to consider, such as environmental concerns and the displacement of communities along the route. It is important for the government and stakeholders to carefully consider the costs and benefits of the railway and ensure that it is implemented in a sustainable and equitable manner. In conclusion, the impact of railroads on Utah and the potential impact of the proposed railway in Kyrgyz Republic demonstrate the importance of transportation infrastructure in shaping economic development and social progress.

Abstract Name: Remembering Owen: Exploring How TikTok's Algorithm Can Facilitate Cyber Abuse

For my presentation I will provide an ethnographic account of how TikTok's moderation algorithm helps facilitate cyber-abuse on its platform. I will focus on the story of Owen, a transgender man who's abusive former boyfriend used TikTok's moderation features to further control, isolate, and tyrannize him online. After leaving a physically and emotionally abusive relationship, Owen developed a following on TikTok in order to make meaningful social connections and eventually met a new romantic partner named Lee, another TikTok user who developed a relationship with him through the social media platform. Unfortunately, Owen's abuser discovered Owen's TikTok account and recruited several of his friends to simultaneously report Owen's videos as content that violate TikTok's community guidelines. Per TikTok's moderation algorithm, once an account is reported enough times it is permanently erased from from the platform and the owner of the account banned from TikTok permanently.Such eviction from social media is known as deplatforming. Through deplatforming Owen's abuser weaponized TikTok's moderation algorithm and deprived Owen of the relationships he made online, isolated him, and emtionally hurt Owen via this virtual platform, a dynamic referred to by Elisa Giaccardi and Liedeke Plate as cyber-abuse. This unfortunate dynamic eventually proved too much for Owen and he committed suicide in May of 2022. This tragedy must call into question both the TikTok algorithm and the nature of deplatforming. TikTok's algorithm must be amended in order to prevent such weaponization by malicious actors. Additionally, deplatforming must become a more commonly recognized form of cyber-abuse.

Abstract Name: Perceptions of Therapist Notetaking

This study attempts to further the research on whether a therapist taking notes during a therapy session affects the perception of the therapist. Notetaking is often a part of therapy, yet there are few studies on how it affects therapy. The studies that do exist each reach different conclusions on the effect of notetaking on perceptions. The current study attempts to determine if perceptions of the therapist's credibility/expectancy and empathy are affected by notetaking. Credibility and expectancy were found to correlate highly so they were combined into a single variable named skill. Videos of graduate student therapists are paired with audio from APA therapy sessions to provide an authentic therapeutic experience. It was planned for the data to be analyzed with a two-factor repeated measures ANOVA but due to an order effect being present, a between-subject design is currently being used. The results will be used to make inferences on how notetaking affects client perceptions. The results will provide information on whether the therapist's notetaking affects how observers perceive the therapist. Preliminary analysis of the available data indicates that notetaking is perceived positively in both the skill variable and the empathy variable. This result is different from the few studies that do exist on the research topic.

Abstract Name: Endogenous metalloprotein activators of pain sensing neurons in Drosophila melanogaster

The Bellemer lab seeks to investigate the cellular and molecular factors that influence nociceptor sensitivity. For my research project, I will investigate an endogenous metalloprotein (EM) as a direct protein activator of nociceptors—specialized sensory neurons that show preferential transduction of noxious stimuli. While many proteins act as inflammatory mediators that sensitize nociceptor ion channels via intracellular signal cascades that result in post-translational changes to the ion channels, this remains disparate from any endogenous protein directly activating nociceptors. We will use RNAi knockdown via Drosophila husbandry in order to drive the depletion of our target EM in resulting progeny, allowing our experiments to compare EM lacking and EM having larvae. Baseline thermal and mechanical nociception behavioral assays will be shown to demonstrate whether EM depletion affects baseline nociception in EM knockdown, wildtype, and genetic control larvae. Further, nociception in larvae sensitized from UV/tissue injury will be tested behaviorally to clarify if there are certain physiological conditions in which metallothionein acts on nociceptors. Lastly, putative patch clamp electrophysiology recordings may be shown to elucidate which ion channels our target EM may be acting on.

Abstract Name: Art as a Tool for Processing Trauma: Global Similarities in Commemorating the COVID-19 Pandemic

Our Mellon-founded project, Creativity in the Time of COVID-19: Art as a Tool for Combating Inequity and Injustice, explores how populations are using creative outlets to foster healing and beginning to push back against the systemic inequities exacerbated by the COVID-19 pandemic. In gathering stories of how individuals turned to creativity to get through the pandemic, this project has culminated in a digital and physical exhibition that explores how the shared space of collective artworks (and memories) may pave a path towards envisioning a more just future. Creativity, broadly defined, has allowed people across cultures and identities to memorialize their experience of the pandemic and honor the loved ones they have lost. We have collected hundreds of survey responses in which most respondents indicated grief, anxiety, and stress, but also expressed hope for the future and pride in their identities. Many of these responses come from people worldwide; however, it was noticed that people often processed the pandemic in a similar way, despite their wide-ranging geographical locations. Through our survey submissions, we aim to better understand the

thematic similarities across the various art mediums people utilized during the pandemic. While analyzing patterns in pandemic-era artwork from across different countries and cultures, we found that common themes emerged such as self-portraits, data processing, and commemoration of loved ones. Self-portraits often reflected common feelings of isolation and confusion despite the wide range of people creating them. The loss of loved ones became more common in the wake of the pandemic and is thus shown across many art pieces. Despite the differences in individual circumstances, using art as a method of processing trauma is a collective experience that is not isolated to a specific culture.

Abstract Name: The Use of Transparent Geomaterials in Geotechnical Engineering Modeling

Geosynthetics are human-made polymeric products with diverse applications in geotechnical engineering, including reinforced soil retaining structures, foundations, and encased stone columns. To understand the mechanical behavior of geosynthetics as they interact with the surrounding soil, geosynthetics could be tested in the lab in surrogate transparent soils that allow direct visualization of geosynthetics as they deform under loads. Such tests have significantly improved the understanding of how geosynthetics behave underground. Additionally, opaque soil particles can be seeded in the transparent soil medium to allow direct visualization of soil particles as they displace in the vicinity of geosynthetics. However, in some geotechnical engineering applications, geosynthetics may obscure soil particles that need to be monitored. This research experimentally evaluates the practicality of using products that can model transparent geosynthetics in geotechnical engineering lab experiments. A comprehensive review of the pertinent literature was completed which assisted in devising the experimental program. A number of transparent soils have been created in the lab, including transparent sands made of fused quartz submerged in a mixture of mineral oils of a matching refractive index to that of fused quartz. A few product candidates were used to simulate transparent geosynthetics. The experimental program involves the evaluation of soil and geosynthetic transparency and transparency depth for various mixtures of oil types and ratios.

Abstract Name: The Effects of Physically and Affectively Exaggerating Hand Gestures on L2 Mandarin Tone Production

Hand gestures are ubiquitous in second language (L2) learning (Gullberg, 2006), but they play only a limited role in helping novice learners produce Mandarin speech (Zheng et al., 2018). However, learners with greater experience in Mandarin may derive more benefit from gestures (Danesh & Shahnazari, 2020). Given the tight coupling between gesture and L2 speech (Li et al., 2020), the accurate production of gestures is crucial. Moreover, previous research suggests that teachers' enthusiasm enhances L2 learning (Keller et al., 2016). Building on this work, this study explores how physically and affectively exaggerated gestures facilitate Mandarin tone production in intermediate learners. Participants will watch three video conditions: speech alone (S), speech+gesture (SG), speech+gesture+emotion (SGE). In the gesture conditions, a native speaker will use exaggerated hand gestures to map the contour of the tones, while the SGE condition will add enthusiastic facial expressions. Participants will imitate what they hear and see in each condition. They will be video recorded to measure the accuracy/enthusiasm of their gestures. To determine tonal accuracy, acoustic analysis of fundamental frequencies will be conducted.Based on studies showing that intermediate learners have greater motivation in L2 learning contexts (Danesh & Mohammadtaghi, 2020), the SG and SGE conditions should increase tone production accuracy compared to the S condition. Based on work showing that enthusiasm keeps students motivated and engaged in learning (Keller et al., 2016), the SGE condition should increase accuracy compared to SG. If the SG and SGE conditions enhance tone production accuracy, we can conclude that gestures and emotions improve phonetic pronunciation of words for intermediate learners. Thus, co-speech hand gestures help students more than research previously perceived. This is not only important for expanding scientific knowledge of multimodal learning but has practical benefits in helping L2 students according to their current proficiency level.

Abstract Name: Agent Based Modeling of Immune System Response to SARS-CoV-2

To investigate the human immune response to SARS-CoV-2, we develop an agent-based modeling (ABM), a novel computational approach that describes the actions and interactions of autonomous agents to understand the behavior of a system and what governs its outcomes. In contrast to a compartmental model based on differential equations (DE), the ABM simulates variables as moving, interacting agents constricted by a pre-defined spatial environment and, thus, captures their spatial movements in the context of COVID-19. In this project, we first apply ABM to understand the dynamics of a simple COVID-19 model. Then, we extend it to consider a complex model that includes more critical components such as innate immune cells and cytokines present in COVID-19 patients. Our ABM results would not only validate but supplement the predictions of our previously developed DE model, which will enhance our understanding of the COVID-19 dynamics and inform potential therapeutic treatments. More broadly, our model could be used to identify several therapeutic targets that would provide hypotheses to be tested clinically, thus, serving as a foundation for the development of evidence-based therapeutic strategies.

Abstract Name: Synthesis of Diphenylpyraline Derivatives

For centuries the brain has been studied to uncover its complexity. Researchers from psychology, biology, chemistry, etc. have been interested in connecting the brain and behavior and understanding neurochemical pathways. More recently, the effect of illicit drugs on the brain has been researched extensively. The dopamine transporter (DAT) is one of the main sites in the brain where addictive drugs such as cocaine and methamphetamine bind. Previous research has shown that cocaine and diphenylpyraline (DPP), an antihistamine, have similar effects in terms of increasing dopamine (DA) in the synapse. The mechanism of action involves these compounds blocking the DAT and hence, the reuptake of DA from the synapse into the presynaptic terminal. Importantly, DPP does not block the DAT as well as cocaine. Additionally, some analogs of DPP, (WSS-X), present low affinity in comparison to cocaine while others were superior. Our work involves improving the synthesis of these analogs for further biological testing. Through S N 2 coupling reactions, dehydration synthesis, and metal-catalyzed reactions, we aim to not only improve on the synthesis but also determine which molecules would serve best as molecular probes to help with unraveling the complexity of the dopaminergic neuronal system. This research will help to create radiotracers for PET imaging in order to further our knowledge of the brain's DA neurotransmitter systems and maybe open the door to improvements in therapeutic treatments, especially in the area of addiction research. Hence, toxicity studies are also critical when designing compounds. Herein we report our current findings.

Abstract Name: Photocatalytic Ability of Titanium Coated Gold Nanoparticles

Metal-semiconductor photocatalysts have shown an increased ability to transfer electrons in recent studies. The premise of our research is that the injection of hot electrons into the TiO2 conduction band will result in the system becoming more catalytically active. Based on this, we hypothesized that the presence of ALD or sol-gel deposited TiO2 on plasmonic AuNPs will enhance charge separation/transfer, therefore increasing the photocatalytic activity of AuNPs in the visible region. To test our hypothesis, TiO2 was deposited onto 3nm, 10nm, and nanorod nanoparticles and their photocatalytic activity was observed using UV-Vis spectrophotometry. This poster discusses how the presence of deposited TiO2 affects the charge separation/ transfer of gold nanoparticles, therefore increasing their photocatalytic activity. Additionally, we discuss difficulties identifying nanoparticles of increased photocatalytic activity due to aggregation of some of the gold nanoparticles. The results revealed several issues related to working with TiO2 coated nanoparticles. Our main challenge was the fast charge recombination. Another complication we've encountered is the aggregation of our samples, where difficulties finding viable concentrations for both TTEAIP and AuNP, for example, have led to the aggregation of the AuNP during the coating process. Based on our results, more testing is needed in order to more accurately determine the photocatalytic ability of TiO2 coated

nanoparticles. Further steps will include filtering out the large aggregates in order to separate the coated nanoparticles from the non-coated particles. However, as of our current research, we have concluded that aggregated liquid phase-coated TiO2 is not applicable for photocatalysis.

Abstract Name: Historical Injustices and Contemporary Challenges: Examining The Medical Exploitation of Black Women.

In the early 1900s, Dr. J. Marion Sims, known as the ‘father of modern gynecology,’ performed medical experiments on enslaved Black women without their consent or anesthesia. He used enslaved Black women as test subjects for his surgical techniques, which he later used to treat wealthy white women (Equal Justice Initiative, 2019). Historically, Black women have been subjected to medical exploitation and mistreatment by healthcare institutions. They have been used as test subjects without consent for the sole purpose of advancing medical knowledge. Despite medical procedures being an integral part of the healthcare system, there is a significant disparity in the quality of healthcare provided to people of color, especially Black women. From the unrestrained medical experiments done on enslaved people to the infamous Tuskegee Syphilis Study, forced sterilization, and the unauthorized use of Henrietta Lacks' cells, there is an undeniable need to confront past transgressions to pave the way for ethical medical practices for the future. Today, Black women still suffer at the hands of medical professionals as they are often ignored when they are in pain, especially during pregnancy and childbirth. Research shows that Black women are two to three times more likely to die from pregnancy-related complications compared to White women (Petersen et al., 2019). This paper will examine the history of medical exploitation of Black women in the United States. The research will include examples of unethical experimentation, forced sterilization, mistreatment during childbirth, racism present in healthcare today, and the medicine that has derived from slavery in the US. It will also engage in questions related to Black women's gendered racism in comparison to White women (Chinn et al., 2021), contemporary unethical medical practices towards Black women, and the lack of accountability for doctors.

Abstract Name: A Continual Analysis of the Impact of the Trash Trout Catchment System on the Waterways within the Walnut Creek Watershed

Trash entering our waterways either intentionally or unintentionally has a negative impact on the quality of aquatic life, plants, and humans in the surrounding area. In this study, we are monitoring the impacts of trash on Little Rock Creek located within the Walnut Creek Wetland Center in downtown Raleigh. This area has a history rich in environmental injustice, resulting in a lack of stewardship of the land. Over the years many environmentally questionable practices were used in the area of the watershed, such as the introduction of dense rubber tires into streambanks; something momentarily useful as an erosion control measure, but having long-term impacts on the presence of water quality through the leaching of toxic chemicals into nearby creeks. Additionally, many plastic products enter the waterway from downtown stormwater drainage pipes, increasing the presence of synthetic material in the water. As a method of combating this ongoing trash issue, Sound Rivers, a non-profit organization, embedded a “Trash Trout” Catchment system at the center. Weekly measurements of basic water quality parameters such as pH, conductivity, dissolved oxygen, nutrients, and turbidity will give us a better understanding of the form of pollution that causes changes in the data observed. In addition, monthly biological testing of total coliform and E. coli is performed to monitor changes throughout the project. In addition to other testing sites (upstream and downstream) from this location of measurements, we can analyze how significant the collection of trash is by observing the changes pre- and post-trash removal. By analyzing these preliminary findings, conclusions can be drawn regarding the effectiveness of this system on the overall condition of the waterway. These findings will be helpful in concluding beneficial engineering and placement adjustments to be applied to the system.

Abstract Name: Investigating the Neural Networks of Learning in Drosophila melanogaster

The mushroom body of Drosophila melanogaster is a structure in the brain that is necessary for learning, but much of how it functions remains unknown. In this model organism, D. melanogaster’s mushroom body neurons, known as Kenyon cells, and input projection neurons have connections that are random and biased —in which some projection neurons connect with Kenyon cells more than others—allowing the fly to potentially prioritize the learning of particular odors. Theoretical and experimental approaches were taken to investigate the functional consequences and characterizations of these biases in order to understand the biological role they play for the fly. With a computational model of the D. melanogaster olfactory system, how biased connectivity to the mushroom body influences its ability to form associations with various odors and distinguish between similar odors was explored. Experimentally, the morphological features of olfactory circuits were characterized with low to high connectivity rates to the mushroom body, allowing us to see the unique features in these circuits that are beyond the different connectivity rates. Through a combination of immunohistochemistry and confocal microscopy, high-quality images were generated of these different neuronal olfactory circuits and their morphological qualities, such as the number and volume of boutons they project to the mushroom body. Altogether, these findings demonstrate how neural connectivities behind learning shape the representation space in D. melanogaster and impact its learning outcomes.

Abstract Name: Assessing the Efficacy of Polyrhythmic Music in Attention-Based Therapies through Electroencephalography(EEG) Monitoring

Understanding the brain's response to polyrhythmic music has been a potential avenue of research to treat neurological conditions, such as attention deficit disorders. The brain's rhythm processing involves neural entrainment, wherein oscillatory neural frequencies align with the structure of the beat in an anticipatory fashion, as if to predict the beat and allocate neural resources accordingly. This study aimed to explore the primary question of whether polyrhythmic music (involving two simultaneous, overlaid rhythms) may play such a role in neurological attention therapies. An electroencephalography (EEG) device measured neural responses in the frontal regions of the brain using Power Spectral Density(PSD). Participants, first, listened to a polyrhythmic melody and were instructed to copy a passage, to understand the extent of the music's effects on motor coordination, attention to detail, and concentration. Afterwards, participants were instructed to copy down a passage while listening to a non-polyrhythmic melody and finally with no music played. Results showed comparative increases in frontal beta waves and decreases in frontal theta waves between the three iterations with regards to PSD and word count, indicating an increase in focus when the polyrhythmic music was played. There was also a dramatic decrease in the Theta wave to Beta wave ratio(-0.14) in polyrhythmic playback as compared to non-polyrhythmic playback(-0.03) and silence(0.1). We expanded the original findings from 8 participants to 20 participants and this has shown interesting results in comparison to prior iterations of the study. This study demonstrates that polyrhythmic music may be a viable avenue in exploring the treatments of those with neurological conditions.

Abstract Name: Exploring the tension between Division 1 College Tennis and the Professional option in Tennis

What's the difference between pursuing a career in professional sports or choosing the college option? In the era of expanded student NIL rights, the distinction between the two paths is less clear than it once was. This project explores the question by focusing on the sport of tennis. Unlike professional team sports, tennis is an inherently individual one, and the choice between going pro or attending college is often unclear and involves substantial risk. It can take years to accumulate enough qualifying points for a player to enter a tournament on the ATP tour, requiring a substantial financial investment with no guarantee of any return. Using statistical data from the National Collegiate Athletics Association as well as interviews with aspiring, current, and former players, the project seeks to tell the stories of current tennis players going through the decision making process while also examining the issue in historical context through discussions with former players, coaches, and tennis journalists. No common story exists--in some instances, such as former longtime pro John Isner, a player has spent all four years in college; in others, as with new pro Alex Michelsen, the player forgoes college altogether. The project also explores themes of class (does the expense of pro tennis prevent players without wealthy parents from having a chance?) and race (given the underrepresentation of Black players at the highest ranks of tennis, should colleges focus more on expanding the pipeline?). The focus on tennis provides a specific way of exploring broader questions about the intersection of sport and society. And I also discuss my opinion on what is the best option, in general, for individuals to take.

Abstract Name: Cross-Cultural Perceptions of Child Abuse and Parenting Practices

Culture impacts many aspects of life including parental disciplinary practices and views of children. Acceptable forms of discipline and treatment of children vary across cultures. However, the US has a robust system of laws governing the treatment of children and identifying certain behaviors as child abuse. Given the cultural diversity in the US, it is important to examine potential cultural differences in child-rearing practices and child discipline. What may seem like an appropriate form of discipline in one culture, might be seen as abusive or neglectful in others. Despite the US demographics including a large proportion of immigrant families, there is little cross-cultural research on differences in parenting practices. This study aims to fill the gap in cross-cultural parenting research. One thousand students from a large Hispanic-serving institution in the southeast were recruited for participation (83% females). They were asked to rate vignettes describing parental practices on a scale from 1 (not abusive or neglectful) to 3 (very abusive or neglectful). Data collection is complete, and analysis is beginning. It is expected that there will be differences between cultural groups, specifically, Caucasians will be more likely to rate parenting behaviors are abusive. It's also expected that Hispanics have very high severity ratings for physical abuse, but lower for emotional abuse. Asians are expected to have lower severity ratings for abuse than the previously mentioned cultural groups. Lastly, African Americans are expected to have the lowest severity ratings for abuse from any of the groups. It is also expected that there will be a consensus amongst cultures when it comes to acts of sexual abuse, with all cultural groups reporting sexual behavior toward children as abusive. Finally, while the sample for parents is small (n=117), it is also expected to rate differently than those who don't have children in their lives.

Abstract Name: Take a Ballot: Can Transnational Theatre Foster Political Efficacy in Women of Color?

This research examines whether transnational theatre fosters political efficacy in women of color. Research shows the history of disenfranchisement of women of color; even today, upper-class, white males have the greatest access to opportunities to ignite their political efficacy– like theatre– in the United States. The gap in research fails to examine how, and if, transnational theatre affects women of color's political efficacy. This research begins to close the knowledge gap by analyzing theatre's role in fostering political efficacy, in order to explore avenues for building a more equitable and democratic society. This research utilizes a case study analysis of two female playwrights from opposite sides of the U.S. border– Sor Juana Inés de la Cruz (1648-1695) and Estela Portillo Trambley (1926-1998). As a playwright in former New Spain (i.e., current-day Mexico), Sor Juana represents the originator of transnational theatre, having authored plays outside of the

United States. Estela subsequently authored a biographical play about Sor Juana's life. I anticipate finding Sor Juana's work inspired Estela to engage in political activities considered not typical of women of color in the United States. I explore Estela's political consciousness through documented knowledge of her political radio show "Stella Says," interviews with Estela, and thematic analysis of her plays. By utilizing primary source documents of Estela's at the University of Texas at Austin's, Benson Latin American Library, I am analyzing themes-particularly those regarding female empowerment and political expression-explored by Estela in her theatre practice. I will connect Estela's multiple political actions to a level of heightened internal political efficacy. This research opens a dialogue regarding the lingering effects of colonialism, how women of color continue to be affected, and how academics, political scientists, and theatre practitioners may acknowledge historic wrongdoings by looking to the future of political engagement through theatre.

Abstract Name: The Relationship of Undergraduate Stimulant Abuse to Adulthood Substance Use

A disturbingly high number of students sell or give away their ADHD-related prescriptions. These coveted stimulants are the second most highly used drugs among undergraduates. While medicinal for legitimate patients, stimulants are controlled substances with a dangerous addictive potential. Yet, there is a hole in the literature examining the long-term consequences of their routine abuse on university campuses. This study investigates how stimulant abuse as an undergraduate may foster adulthood substance abuse. Data was sourced from peer-reviewed journals in the field of psychology. Stimulant-using and nonusing stimulants were compared. Data from students with genuine ADHD diagnoses was incorporated for context. Demographics, social organizations, motivation, drug/alcohol use, behavior profiles, and baseline neurological dysfunction we all considered. The research revealed that stimulant abuse is highest at competitive colleges. The most likely culprits were white, Greek life-affiliated students. With no indication of lower intelligence, the overwhelming motivation was desire to offset self-inflicted educational hurdles caused by frequent binge-drinking, marijuana use, and cocaine use. Intentional polysubstance use was common. Alarmingly, when stimulant abuse persisted past college, a tendency developed to escalate other drug choices to ones more highly lethal and addictive than before. Compared to their nonusing peers, stimulant-using students scored higher on impulsivity exams and lower on behavioral control and self-regulation tests. Together, these findings suggest a generally elevated predisposition for addiction among stimulant users. In the context of America's prescription drug epidemic and with colligate substance use record high, this topic is of the utmost concern. Additionally, nonprescription stimulant use raises serious questions about academic and subsequent professional integrity; usage rates have swollen into double-digits at medical and dental schools. Given that stimulants are typically used as an academic coping mechanism, additional research should target how this common practice during youth may foster dangerous drug or alcohol-related coping methods during adulthood.

Abstract Name: Incorporating Gels in Microbially Produced Calcite Precipitation to Decrease Time in Shale Core Sealing

Microbially induced calcite precipitation (MICP) is a process through which Sporosarcina Pasteurii hydrolyze urea during growth, then, in the presence of calcium, produce calcite. This mineral production has been used to seal fractures in shale rock columns with a goal to apply it in unconventional oil and gas wells to reduce methane emission. In the summer of 2023, I conducted research at the Center for Biofilm Engineering at Montana State University to seal cores using MICP. One downside of this sealing method is it requires many injections to effectively seal a fracture. The goal of this project is to improve the sealing time of MICP of rock fractures by incorporating gels in the growth medias of S. Pasteurii. The incorporation of gels will increase the viscosity of the medias, ideally containing the mineral reaction within the fracture to reduce the need for multiple injections. Two gels, guar gum and sodium alginate, were tested for bacterial growth inhibition in a preliminary growth study, then an ideal additive and concentration of such additive was determined. This additive will then be implemented in a flow-through injection core sealing experiment, following protocol from a previous core sealing experiment. The results of this flow through experiment will then be compared to results from my previous research to determine effectiveness of gel addition.

Abstract Name: O-GlcNAc regulation and expression of subunits of cytochrome c oxidase

The post-translational modification of proteins by O-linked N-acetylglucosamine (O-GlcNAc) is a dynamic and reversible process that plays a crucial role in the regulation of various cellular functions such as transcriptional regulation, cellular signaling, and metabolism. The addition of O-GlcNAc is catalyzed by the enzyme O-GlcNAc transferase (OGT), while its removal is facilitated by O-GlcNAcase (OGA). Cytochrome c oxidase (COX), is a key enzyme in the mitochondrial electron transport chain, and vital for cellular energy production. Our recent studies have shown potential regulatory role for O-GlcNAc regulation of COX level which may impact mitochondrial function and pathogenesis of neurodegenerative disorders such as Alzheimer's disease (AD). This study is aimed to investigate the acute and chronic impact of pharmacologically increasing O-GlcNAcylation using the OGA inhibitor Thiamet G (TG) on the transcriptomes of mouse brains starting at 1 month of age. We hypothesize that elevated O-GlcNAcylation in response to TG decreases the expression of subunits of cytochrome c oxidase. Subunits that are being considered to look at include COX1, COX2 and COX3 which make up the catalytic core of the enzyme. Along with many other subunits, other things that will be looked at is assembly factors such as Cox14, Cox19, and any other enzymes that may have a significant role in COX. We are investigating this using real-

time RT-PCR and Western blot analyses. We anticipate that this study will help establish the how O-GlcNAc impact COX level and activities.

Abstract Name: Revolution of the Heart: An Interpretivist Analysis of the Reverse Shift in American Teen Pregnancy Policies

Teen pregnancy policies in the United States underwent a fundamental shift from 1978 to 1996. During the Clinton administration, a series of teen pregnancy policies were passed that focused on morality-addressing initiatives, such as abstinence education programs and punitive laws for unemployed or out-of-school minor parents on welfare. This was a stark contrast to the first federal teen pregnancy policy of 1978, which called for increasing social services and welfare for minor parents. Theories that conceptualize the U.S. as a secular state expect to see a gradual shift from morality-centric policies to resource-centric policies as states become more secular due to human rights universalism replacing religious values within the public policy sphere. This paper addresses the question: why did U.S. teen pregnancy policies undergo a “reverse shift” from the Carter administration’s resource-centric policies to the Clinton administration’s morality-centric policies? Using poststructuralist discourse analysis, this study maps a series of representations about minor parents and the causes of teen pregnancy across five fundamental teen pregnancy policies and finds that a gradual change in language surrounding teen pregnancy began taking place in policy documents during the end of the Carter administration and set the tone for the Clinton administration’s more morality-centric policies. The paper also challenges the conceptualization of the U.S. as a secular state by drawing upon secularization theory and locating a transformation in official discourse surrounding women, families, and morality toward the end of Carter’s presidency. Its results may be used to better understand the current partisan divide over the purpose of reproductive health education in U.S. schools.

Abstract Name: Political Ideologies and Mobilities of the LGBTQ Community in the United States

Utilizing surveys, this research explores the connection between an area's political ideology and LGBTQ individuals' perceptions of safe neighborhoods while thinking of places to live. During the 1970s, LGBTQ individuals gathered in urban neighborhoods to protect themselves from society's discriminatory behavior. However, recently, they have been seeking to move beyond these historic residential patterns, though the reasons for doing so remain uncertain. Some explanations considered economic and cultural factors, but this research focuses on the impact of political ideologies on their residential decisions and imaginaries. We know that LGBTQ people are now moving to more heteronormative spaces and not restricted to queer-specific spaces. However, we do not know to what extent political ideologies influence their decisions when

perceiving safe places to live and navigating unfamiliar environments. I hypothesize that cities with more prominent liberal ideologies are more attractive to LGBTQ individuals because liberals now tend to create more favorable and supportive policies for the LGBTQ community. The findings of this research are important to the LGBTQ community as they can make informed decisions about friendly and safe neighborhoods to relocate to, especially with the decline of gay-specific neighborhoods.

Abstract Name: The need for regulations in Wilderness Therapy

Wilderness Therapy is a practice to help adolescents disconnect from the world around them to help with mental disorders, severe behavioral issues, and substance abuse. Wilderness therapy started in the 1940s during the war when German educator, Kurt Hahn, noticed that the newer young sailors had been struggling not having enough strength to bear the open sea. He developed Wilderness Therapy as a way for young boys to develop strength and character to build their self-esteem. It has developed little from having this rugged 'survival of the fittest' experience for these young adults and they are not getting the benefits they need from it. There have been numerous reports of neglect, abuse, and death. The first reported death was in 1970 at an institution which was the start of Wilderness Therapy; the most recent report of death was in July of 2023. There needs to be more accountability for these institutions and regulations. There needs to be regulations on the local and the federal level. I hope bringing a call for regulations to the federal level will get more cohesiveness to it avoiding anything being swept under the rug. The primary purpose of my research is to bring forward previous research that has been done and bring in my own opinions about what else we can do to make the changes that are needed. This research will bring the history of Wilderness therapy, the negative impacts it has caused, what the benefits are, and the potential they can get if we have the regulations to make it more beneficial to those who attend.

Abstract Name: Dioxygen Reactivity of Synthetic Fe and Ni Models of Dioxygenase Enzymes

Enzymes that contain a metal-centered active site (metalloenzymes) are highly selective and efficient catalysts. Ring-cleaving dioxygenases are an important class of metalloenzymes that use dioxygen (O2) to cleave the aromatic and heterocyclic rings of metabolites and xenobiotic pollutants. While the majority of these enzymes feature a nonheme iron active site, examples with other transition metals (Mn, Co, Ni) have been reported. The design of synthetic complexes that mimic the structure and reactivity of ring-cleaving dioxygenases can provide a better understanding of enzymatic catalysis. This presentation will describe the

preparation of Fe and Ni complexes that model the substrate-bound active site of aminophenol dioxygenases (APDOs). Both sets of complexes have been characterized with X-ray crystallography and NMR spectroscopy. Importantly, exposure of the Fe-based complexes to O2 results in oxidative cleavage of the aminophenolate ring, thereby replicating the enzymatic reactivity. Reaction of the Ni complexes with O2 does not yield ring-cleaved products; instead, the aminophenolate ligand is oxidized to a Ni-bound radical. Multiple spectroscopic techniques were used to analyze intermediates observed during the O2 reactions. The results shed light on the role of metal ion identity (Fe vs. Ni) in controlling the catalysis of metalloenzymes that activate dioxygen.

Abstract Name: J. Edgar Hoover: Tyranny Within the Federal Bureau of Investigation

During the course of the 20th century, we witnessed the most notorious FBI director who unleash countless campaigns and investigations onto black leaders through most of the Civil Rights Movement. J. Edgar Hoover over his five-decade career delt with Communism, Civil Rights, and anarchist terror attacks. When it came to black leaders Hoover employed unethical and illegal crusades against figures like Bayard Rustin, Malcolm X, Paul Robeson, Thurgood Marshall, Black Panther Party, and most famously Reverend Martin Luther King Jr. Hoover's ruthless campaign against King was sparked by a fear of Communism however, as shown in internal FBI documents was made aware of no Communist tie or infiltration into King's Movement. Hoover illegally surveyed King from the start of the movement up until his assassination in 68, which led to Hoover trying to discredit, dimmish, and destroy King's name and popularity. Once Hoover failed to find any tie to Communism, instead of backing off King Hoover doubled down and started to target King's personal life. This entailed illegal surveillance of King trying to expose his extramarital affairs and the 1964 FBI suicide letter. Scholars like Beverly Gage, Lerone Martin, Curt Gentry, and Paul Letersky all bring explanations for Hoover's questionable actions within his career. This paper is meant to further their research and pinpoint the motivations for the endless targeting of King. Hoover's paradoxical battle with the immorality of King's personal life while keeping the white supremist status quo of the Jim Crow era. Expanding our knowledge of a complex history of an infinitude of immorality within Hoover's almost century long career and battles with race, conspiracy, and morals.

Abstract Name: A Medieval MeToo: Christine de Pizan's Feminist Pastourelle

In 2006, Tarana Burke founded the #MeToo movement to provide resources, support, and guidance for women who had been sexually assaulted. Since its inception, #MeToo has evolved from a small, grassroots organization to a global phenomenon dedicated to raising awareness of sexual assault, coercion, and the

importance of consent. Yet grappling with the imbalances of sexual power is unfortunately not new: Christine de Pizan's Dit de la Pastoure [Shepherdess's Tale], is emblematic of what I am calling the medieval #MeToo movement. This poem challenges the popular pastourelle genre, which traditionally depicts a brief conversation initiated by a man who flatters, harasses, and often rapes a woman in an idyllic country setting. By contrast, Christine's radical and proto-feminist narrative shifts to feature a woman narrator and her perspective, and it epitomizes Christine's polemical contributions to early feminist theory. In this thesis, I argue that pastourelles and the Dit de la Pastoure in particular expose men's "chivalric" or "courtly" flattery of woman as part of a pattern of control over women's bodies. I deploy the innovative method of "contrapuntal reading" (developed by Edward Said) to place Christine's poem and #MeToo survivors' stories into conversation as a way to illuminate the exploitation of women's bodies and women's ultimate potential to reclaim authority over their bodies and over their stories.

Abstract Name: Frankenstein's Symbolic Eco-Feminist Agenda

This presentation discusses the theme of ecofeminism embodied in Mary Shelley's Frankenstein and its significance. Ecofeminism maintains that men's domination of nature and women led to ecological crisis and gender inequality. The author argues that Shelley illustrates this theme through her use of symbolic characters in Frankenstein. Through Victor (Frankenstein himself) and his creation ("the monster"), Shelly conveys both the patriarchy's abuse of technology and its ignorant manipulation of nature. Similarly, through the three main female characters (Frankenstein's mother, his fiancée, and the housemaid) and their submissive and unequal relationship with Victor, Shelley demonstrates that in the society that men represented power, strength, and rationality, women were under men's mental oppression and lose their self-consciousness of pursuing their own lives. The author contends that Shelley's use of symbolism in Frankenstein further illuminates the novel's ecofeminist agenda: the synchronicity between how one treats the nature and how one treats women in society. Thus, she intends to warn us that if humans continue to be obsessed with scientific exploration at the cost of sacrificing nature, humans may not be able to build equal relationship between two genders, and we humans might be even destroyed by ourselves. So from an ecofeminist lens, the author maintains that the novel functions as a cautionary fable warning against patriarchal "domination" of the natural world: a vital lesson for our current era of climate catastrophe and environmental struggles due to humans' over-dominance on nature.

Abstract Name: Terahertz Analysis and Harmonic Characterization of Antiferroelectric Crystal 2-

triflouromethylbenzimidazole (TFMBI)

Interest in using terahertz time-domain spectroscopy (THz-TDS) to characterize biological samples has recently increased as the low wavelength radiation can measure bond vibrational frequencies without denaturing samples. Simultaneously, interest has grown in understanding the connection between the structures and dynamics of organic antiferroelectric crystals and the ability of these materials to store electrostatic energy. Our objective is to understand hydrogen bonding intermolecular interactions present in the antiferroelectric crystal 2-triflouromethylbenzimidazole (TFMBI) and how they affect this material's vibrational spectra and dynamics. To examine these properties, we use THz-TDS and fast Fourier transformation (FFT) methods as implemented in commercial software. Following measurements of the THz transmission spectra of TFMBI sample grown through re-crystallization processes, we use periodic density functional theory (DFT) calculations to assign vibrational spectra of TFMBI in the region between 0.5 and 2 THz. Our analysis shows that the main peaks in the measured spectra correspond to low-frequency vibrational modes consisting of pseudo-rotational motions of both molecules within the material's unit combined with intramolecular ring distortions. These results have critical implications into the study of quantum mechanics in molecular crystals as the harmonic frequencies predicted by DFT calculations cannot capture anharmonic behavior of the vibrational dynamics with the hydrogen-bonded crystalline framework of TFMBI, which may help researchers understand how imidazole-based molecular pack into pharmaceuticals and react within biological subjects.

Abstract Name: Alpha-Gal Testing for Americans with Coronary Artery Disease: A Model for Earlier Median Diagnosis of AGS in the Southeastern United States

The tick-borne Alpha-gal syndrome (AGS) has gathered increasing attention in the southeastern United States as α-Gal sensitization has trended upwards in recent years. The AGS epidemic began with the publication of twenty-four cases in 2009, and over 34,000 Americans were diagnosed by 2019. Those presenting with undiagnosed AGS have demonstrated an increased risk for developing premature coronary artery disease (CAD), allowing for AGS to be underreported and/or misdiagnosed. Although national CAD mortality rates have fallen from 2009-2017, data suggests stagnation in rural CAD mortality, whereas a decline persists in metropolitan regions. This research identifies a correlation between AGS and premature CAD through a detailed literature review of works published from 2011-2022 regarding AGS, food allergy, and CAD. The databases CDC, NIH, and AHA were referenced extensively in this study. This research offers a model checklist for providers to reference during AGS diagnosis, which includes lesser-known symptoms, comorbidities such as premature CAD, and post-diagnosis steps. A standardized procedure for diagnosing AGS may benefit both AGS and CAD trends in the southeast United States. Further research and proofing is required for the possibility of a more formal and specified checklist that could be implemented nationwide and internationally. Keywords: tick-borne disease, alpha-gal syndrome, α-Gal sensitization, premature coronary artery disease, cardiovascular disease, food allergy, southeastern United States

Abstract Name: Priming Effects of Divorce Experience on Photo Gaze Patterns

This study was an examination of priming effects on participant gaze patterns after viewing divorce scenario videos. Priming effects were studied with three eye tracking technology trials per participant. Each trial had participants watch one of three stimulus videos selected in a randomized order before viewing 100 slides of facial photos and silhouettes. After the three trials, participants were given a demographics form to complete which allowed us to gather basic information (age, gender, college year) as well as parental marital status information. Demographics were kept anonymous, only tied to an anonymous participant number to allow for the data to be compared with the demographics information. We hypothesized that the priming video (mom blame, dad blame, and no blame) shown would produce priming effects for gaze pattern depending on the gender of the parent mentioned in the video. There were statistical tests conducted that included all thirty-three participants whose data was collected. Another set of tests were conducted with just fourteen participants who retained at least fifty percent of their data from the eye tracker. The participants who were removed from the analysis had less than fifty percent of usable data either due to technology malfunction or another unidentified confound. We found that our results suggested potential implicit biases surrounding gender but did not suggest an interaction between the video manipulations and gender. If this study were to be recreated in the future, an implicit associations test would be valuable to include before the eye tracking portion of the study.

Abstract Name: The Role of Genetics in Post-Cerebrovascular Accident Impairments

Cerebrovascular accidents (CVAs), commonly known as strokes, represent a significant global health burden with substantial morbidity and mortality. While risk factors for stroke are well-established, the role of genetics influence the occurrence and severity of side effects following a CVA remains an area of growing interest. Genome-wide association studies (GWAS) have become instrumental in identifying genes involved in complex multifactorial diseases and other medical conditions. This study investigates genetic factors of stroke susceptibility as well as side effects in individuals who have experienced CVA. Electronic health records and genomic data from participants in large, diverse All of Us Research Program data resource analyzed using R in a Jupyter Notebook environment. A GWAS was performed on short-read whole genome sequencing data using Hail. Evidence suggest potential association between gene mutations with increased risk of ischemic stroke and diseases that correlate to stroke. Gene mutation such as TREX1 are in individuals with conditions known as retinal vasculopathy, cerebral leukodystrophy. ACTA2, COL4A1 gene mutations result in integrity of blood vessels, particularly in the small vessels of the brain with aneurysms affecting the vessels that supply the brain. Secondary genes have connections to other diseases like atherosclerosis. Genetic factors shown via results measures the relativity of statistical finding to be pursued further in genes. The GWAS method involved the examination of genetic variaSpetion from ClinVar across the entire genome

in a large cohorts (254,388) of individuals with and without CVAs. The approach allowed for the identification of single nucleotide polymorphisms associated with the risk of stroke. (Gene: C7K43 SNP rs39471494 P-value: 2.18E-08, Gene: OKL37 SNP rs80535217 p- Value: 1.85E-10, Gene: BLO71 SNP rs58671438 p-Value: 9.29E-10). Further work to better understand the environmental contribution to stroke occurrence and post-stroke complications, which may lean to precision preventions and treatment measures that can help all patients.

Abstract Name: Forensic Taphonomy

The goal of the research was to look at the taphonomy of animal bones to be applied in a forensic context, with the main focus being the marks scavengers leave or don't leave. To conduct the research the first step was to find an area with a lot of wildlife activity by using a trail camera. Once the area was chosen, the lower legs of a wild boar carcass was set up in front of the camera to capture the different types of animals that scavenge. Once there was little to no soft tissue remaining on the bones, they were taken from the site and the soft tissue was removed using the maceration process. With the bones clean, marks were found on the iliac body that are consistent with turkey vulture marks. The results on the bones line up with the videos captured on the trail camera. The study was conducted in Atascadero, California in the month of November. The weather also impacted the research including the rate of decay and the maceration. The camera was able to capture 902 videos of the chosen site, with 704 of the images being centered around the wild boar sample that had the bones recovered. The camera also provided evidence for how many times a scavenger or carnivore was at the site, giving information about the infrequency that they come into contact with the bones and leave marks. A background is provided for the animals captured on video. If provided with more time, avenues for future research could include, leaving the bones out for longer to see what further scavenging would happen, if any root growth would occur, how the continued drop in temperature would affect the activity.

Abstract Name: Role of HNF4alpha in Subacute Liver Injury and Subsequent Regeneration

Following acute liver injury, hepatocytes and biliary epithelial cells regenerate to restore the hepatic mass. However, subacute or chronic liver injury impairs this mechanism, resulting in delayed or loss of regeneration. Hepatocyte nuclear factor 4 alpha (HNF4α) is a key hepatic nuclear receptor that plays an important role in proliferation and differentiation during liver regeneration. This study investigated the role of

HNF4α in regulating liver regeneration after subacute liver injury. Wild-type (WT) and hepatocyte specific HNF4α knockout (HNF4α-KO) mice were given choline-deficient and ethionine-supplemented (CDE) diet to induce sub-acute liver injury. To study mechanisms of subacute liver injury, WT and HNF4α-KO mice were fed a CDE diet for one week. To study regeneration and recovery, WT and HNF4α-KO mice were fed one-week CDE diet followed by a one-week recovery period on a normal chow diet (recovery model). Blood and liver tissue samples were obtained to determine liver injury, liver cell proliferation, and hepatic gene expression. WT and HNF4α-KO mice showed significantly higher liver injury after one week of a CDE diet. qPCR analysis revealed that the CDE diet significantly induced inflammation markers, fibrosis markers, and proliferation markers in HNF4α-KO mice only. Further, progenitor cell marker Epcam was upregulated in HNF4α-KO while Sox9 expression was greater only in WT mice. In the recovery model, CDE diet-induced inflammatory, fibrosis, and proliferation markers were significantly downregulated in HNF4α-KO mice during recovery. Progenitor cell markers Krt19 and Epcam showed significant decreases in HNF4α-KO mice whereas Sox9 expression decreased in WT mice during the recovery period. These data suggest that the CDE diet enhances liver injury, inflammation, and fibrosis in HNF4α-KO mice as compared to the WT mice. Recovery after the CDE diet ameliorates these effects and promotes regeneration.

Abstract Name: Muted Group Theory, Linguistic Censorship, and Marginalization in Higher Education Settings

This paper will explore the impacts of linguistic censorship within higher education settings, such as student affairs; Diversity, Equity, and Inclusion (DEI) offices; and university programming on marginalized students. In Muted Group Theory, Edwin and Shirley Ardener (1975) discuss how non-dominant cultural groups are excluded from the creation of language by the dominant group. This limits the ability of these groups to speak about their own experiences, as the dominant culture does not provide models of communication that reflect them. Non-dominant groups are forced to create their own language to describe their experiences, which is seen as less valid and is policed and challenged in education, literature, government, research, and healthcare spaces by the dominant group. This paper will review existing research and demonstrate the importance of representation in language for marginalized groups and the negative impacts of censorship and language regulation on students in higher education. Future research is needed on the current trends of linguistic censorship in higher education settings for their impact on community engagement, education outcomes, retention, graduation, and wellbeing of marginalized students.

Abstract Name: Perceptions of Therapy Among the Latino Community

Although previous research has examined the stigma around mental health in the Latino community and how that correlates with the underutilization of mental health services (Kouyoumdjian et al., 2003), the research is 20 years old and needs to be further studied. Previous research has also shown that when compared to other ethnic groups, Latinos have greatly underutilized mental health services (Chang et al., 2013) while being at high risk of experiencing mental health issues such as depression and anxiety (Willerton et al., 2008). The current study examines the association between the negative stigma surrounding mental health in the Latino community and their underutilization of mental health services while also examining whether there is an association with depressive or anxiety-related mental health symptoms. It is hypothesized that Latinos are less likely to attend therapy compared to other ethnic groups due to the negative stigma surrounding mental health within the Latino community. The current sample consists of 42 participants aged 18 or older from the Raleigh area. Participants completed a survey on their perceptions of therapy, the Beck Depression Inventory (Beck et al., 1996), and the Beck Anxiety Inventory (Beck et al., 1961). For this study, therapy is defined as meeting with a counselor privately regarding one's personal issues being faced. To examine the association between participants' perceptions of therapy and their depressive and anxiety symptoms, correlational analyses were performed. Participants' perceptions of therapy were unrelated to symptoms of depression ($r(42)=-.17$, $p=.269$) or symptoms of anxiety ($r(42)=-.16$, $p=.319$). At this point in data collection, an insufficient number of Latino participants have been recruited to adequately test the hypothesis. Due to this, additional participants will be recruited to test the hypothesis. This will include translating the surveys into Spanish in order to increase the number of Latinos recruited.

Abstract Name: Historical Trauma and the Bosnian Genocide

While the field of psychology is adequately equipped to assess and treat ethnic conflict, thus far, its application to this international crisis has consisted of the analysis of political and governmental reactions. This discipline could be incredibly useful for addressing this deadly social ill, particularly in contexts where ethnic conflict has prevailed for multiple generations. A theory adequately fit to begin this pursuit is that of historical trauma, which emerged as recently as thirty years ago as a psychological and sociological concept used to understand the lasting effects of colonization, genocide, and ultimately ethnic conflict on the physical and mental health of American Indian and Alaskan Native (AIAN) peoples. From a clinical perspective, historical trauma draws on ideas of intergenerational trauma and PTSD. Although the theory was initially developed to describe the Native American experience, its place in academia has broadened, allowing its use to apply to any historically marginalized or oppressed ethnic group. Could this concept, then, be used to describe the traumatic effects of the multigenerational experience of ethnic conflict? In this academic research, I will utilize data from psychological literature to qualitatively synthesize the ethnic cleansing of Bosniak Muslims in the Bosnian War of 1992-1995 and the concept of historical trauma. I hypothesize that this project will reveal the connection between extreme traumatic experiences and aggressiveness, as transmitted intergenerationally through parental and communal means, serves to reinforce and maintain historic ethnic conflict within the Balkans, extending as early as the Ottoman Empire to ethnic tensions in the present. Through this pursuit, I hope to contribute to my future goal of creating a theoretical clinical model for understanding ethnic conflict that can be applied on a global scale, including current crises like that of Israel and Palestine.

Abstract Name: Regional Heterogeneity of CNS Glial Response in a Translational Model of Type-1 Diabetes

Type I diabetes (T1D) is an autoimmune disease where T-cells destroy insulin-producing β cells, leading to insulitis and hyperglycemia. The non-obese diabetic (NOD) mouse, a common model of T1D, experiences immune responses leading to T1D pathogenesis. Experimental autoimmune encephalomyelitis (EAE), a murine autoimmune disease, is inducible through myelin oligodendrocyte glycoprotein immunization in these mice. Mice develop severe EAE and shortly experience a disease pattern resembling relapsing-remitting multiple sclerosis due to T-cell infiltration and myelin degradation. The goal was to determine how T1D impacts glial response and synapses in the central nervous system (CNS) and to analyze differences in regional responses. We hypothesized that the metabolic dysfunction in T1D and inflammatory pathways degrade synaptic integrity and oligodendrocyte number but increase astrocyte response in the CNS, as will be evident through a diminished expression in both Olig2 and Synapsin I (SYN1) and increased glial fibrillary acidic protein (GFAP) expression. Tissue from NOD/Lt mice and CD-1 (control) mice were used for DAB immunohistochemistry (IHC) assays for an oligodendrocyte marker (Olig2), an astrocyte marker (glial fibrillary acidic protein, GFAP), and a synapse marker (Synapsin I, SYN1). Light microscopy and image analysis were conducted. Average area percentages and cell counts were graphed and analyzed by t-test. $P \leq 0.05$. Decreased cortical staining for SYN1 and increased staining for GFAP in the rostral corpus callosum was present in NOD mice. Decreased Olig2 staining in the dorsal column and decreased GFAP staining in the whole spinal cord and white matter were present. Staining in other brain and spinal cord regions were not significant. The corpus callosum, cortex, and spinal cord seem most vulnerable to metabolic dysfunction induced in the T1D model. For a better understanding of differential responses, further analysis of glia and synapses in the spinal cord on a regional level may be beneficial.

Abstract Name: Air-jetting based bioprinting of alginate droplets for human stem cell encapsulation toward biomanufacturing of pancreatic islet organoids

The transplantation of biomanufactured pancreatic islet organoids has shown promising results towards finding a treatment for Type-1 diabetes. However, the process for generating consistent and robust derivations of mature organoids from human pluripotent stem cells (hPSCs) is challenging. The primary focus of this

research is to explore the application of air-jetting droplet printing in combination with alginate-based hydrogels that house hPSCs. We developed a custom alginate droplet generation system by integrating a syringe pump system with a 3D-printed air-jetting adapter. We conducted comprehensive studies to investigate and validate the design and configuration of this system, as well as parameters for droplet generation. We were able to establish a consistent and replicable bioprinting technique for generating uniform, spherical blank alginate droplets with a small diameter (<500 μm). Our research has since been centered on understanding the impact of the addition of hPSCs to the bioink and other various modifications to our printing process on the characteristics of the alginate droplets. Our primary objective is to enhance the replicability of these droplets, ensuring uniform quality and optimal performance in the bioprinting procedure. To achieve this, we have conducted several analyses, including monitoring the longevity of the alginate by observing its viscosity changes over time, evaluating droplet reproducibility by examining images that recorded the speed of droplet production, assessing how different concentrations of solutions used during the production process can produce better droplets, and investigating the most effective methods for mixing cells and alginate to achieve superior outcomes. By gaining insights from these investigations, we aim to develop a more precise and reliable bioprinting technique, ensuring consistent and high-quality hPSCs containing droplets that contribute to the successful biomanufacturing of pancreatic islet organoids.

Abstract Name: The Entertainment Industry and Its Effects on Desensitization and Romanticization of Mental Health in College Students

With the entertainment industry as prevalent in people's lives as it is today, it is no wonder there is a positive correlation between exposure to entertainment and mental health issues. In research on the association between suicide statistics and the release dates of the show, there has been a strong correlation between suicides immediately after the release of an episode or whole season (Reidenberg et al., 2020). This study aims to determine the impact of the entertainment industry on the desensitization and romanticization of mental health in college students. The researcher hypothesized that there would be a positive relationship between exposure to the entertainment industry and desensitization and/or romanticization in college students. A researcher surveyed undergraduate students (N=100) at a Christian university. Screen Time Behavior Questionnaire (STBQ, Bandiera et al., 2020) and Public Perception of Mentally Ill People (Mushtaq et al., 2015) were measured. The researcher also created a unique scale to measure the romanticization of mental health. Correlations and simple linear regressions were used to analyze the data in this study. This study's findings revealed a significant relationship between the entertainment industry (measured by screen time behavior) and desensitization, including blame and immorality. There was no significant correlation between the entertainment industry and romanticization. Some future studies should include social media application usage and personal history with mental illness, as those can also impact the results.

Abstract Name: Higher recognition accuracy for biographical information of racial in groups compared to racial out groups

The cross-race effect (CRE) is the likelihood of more accurately remembering faces of your racial in-group (same-race faces) compared to your racial out-group (other-race faces). While this effect is well established, it is unclear whether better memory for same-race faces extends to better memory for biographical information of those faces. It is also possible that the CRE is mitigated by providing biographical information for same-race and other-race faces, in that more information could lead to better processing of faces. In addition, 132 White Participants were introduced to eight faces paired with either long or short biographical introduction. In addition, faces equally varied by race (i.e., Asian, Black, Latino, and White faces) and gender wherein two racial groups were male and the other female with counterbalancing. Participants then studied 48 distractor faces. Recognition memory was tested by presenting the eight introduced faces and 48 distractor faces intermixed with an equal number of new faces. Participants indicated whether they remembered seeing each face. A second test phase had participants identify which faces they were introduced to by picking four faces from an all-male and all-female grid of 16 faces. To recognize that a face has been seen before only requires a feeling of familiarity but identifying the specific context in which the face was encountered requires higher memory processes. Analysis found remembering which faces participants were introduced to was noticeably more difficult than recognizing whether they previously saw those faces. The CRE was more prevalent when participants had to recall which faces were given introductions compared to recognizing whether a face was seen before. Moreover, participants remember information about White faces more accurately than Black and Latino faces. Findings showed that participants' recall for careers and faces of those paired with short bios were significantly better than those paired with long bios.

Abstract Name: Beyond the Melody: Corridos Tumbados and Their Impact on the Perception of Women in Mexican Society

Gaining popularity in 2019 with the release of singer Natanael Cano's innovative album "Corridos Tumbados", a new generation of corrido was born that mixed the already present gangsta rap and trap movement in Los Angeles with the old generation corrido framework. Some common themes found in corridos are el amor, which usually exhibits a beautiful woman whom the protagonist wants to conquistar (conquer); el desamor, a man who is heartbroken by a beautiful woman; and el éxito, those who have overcome difficulties and have now found fame. These themes comprise the selection of songs for the present investigation, both prevalent in more traditional corridos (which I refer to as "Old Gen Corridos") and corridos tumbados (or "New Gen Corridos"). This research will compare lyrics found in select New Gen and Old Gen corridos based on popularity and the presence of the aforementioned themes. Through an analysis of the main tropes and traditions found within the songs and music videos, along with current gender studies theory, this investigation will show the similarities and differences between how the two types of corridos represent women, and the role these women play within the songs. This will also be analyzed in correlation with the generational gap between the two types of corridos, along with their respective stigmas. Through this investigation, we can start to understand how the victimization and consumerism of women directly correlate

with the generational divide in Mexican society, and how the messages found within may carry more similarities than differences.

Abstract Name: Franklin College and the AIDS Epidemic

Beginning in the early 1980s, the AIDS epidemic in the United States produced lots of misinformation, stigmatizing the LGBTQ community. Conservative policymakers and national leaders did not respond very positively to the crisis.My research contributes to the existing historical scholarship of the epidemic by focusing on the response of a small liberal arts institution in the Midwest, Franklin College. Historian Bradford Martin, who analyzed the effects of Ronald Reagan's presidency, and Kathrine Cummings, who studied histories of discrimination against gay communities in America, provide the broader context for my research.The research then investigates how Franklin students, the administration, and campus organizations reacted to the AIDS epidemic. It also examines the extent to which the campus formed activist groups and/or spread false narratives about the disease. My research uncovered that many students at Franklin College initially shared many of the biases toward the AIDS epidemic that existed in the national discourse in the mid-1980s. However, through the efforts of faculty, staff, and student activists, Franklin College students increasingly countered larger trends of homophobia and embraced greater acceptance towards the LGBTQ community than was found elsewhere in the state and nation. My research depends upon the Franklin College archives and its collection of student newspapers, which contain frequent columns of student life and campus activities throughout the 1980s and 1990s. Additionally, an oral history with a critical campus advocate also contributed to my work. My research concludes that Indiana was mostly a conservative state, and Franklin College went against the norms and advocated for the AIDS crisis. AIDS activism at Franklin College continues to shape our present health and wellness efforts on campus.

Abstract Name: Investigating the effects of relationship quality on cortisol levels during pregnancy and postpartum by ethnicity.

Altered levels of cortisol (a biological marker of stress) during pregnancy are associated with poor maternal and infant health outcomes. Prior studies have explored the role of ethnicity on cortisol levels throughout pregnancy. Specifically, Latina and African American mothers are shown to have altered cortisol patterns that may lower their resiliency against stressors. However, few studies have examined whether factors such as the quality of the relationship with one’s partner affect cortisol levels during pregnancy and postpartum. The current study examined whether relationship quality is associated with salivary cortisol levels and if ethnicity

influenced this relationship during pregnancy and postpartum. The sample was comprised of 97 low-income pregnant women (71% Latina, 18% African American, 4% non-Hispanic White, 7% Asian American or mixed race), most of whom were married or living with a partner (77%). During the second trimester of pregnancy and at three months postpartum, relationship quality (ENRICH) was assessed through self-report and saliva was collected four times in one day (waking, 12pm, 4pm, and 8pm) to assess total cortisol produced (AUC). Regression analyses showed that mothers who reported more relationship satisfaction had lower cortisol levels (p<0.5). A non-significant trend was found for African American mothers, with higher relationship satisfaction being associated with higher cortisol levels during pregnancy. This differs from the general trend of lower prenatal relationship quality being associated with higher cortisol levels. At three months postpartum, lower relationship quality was associated with higher cortisol levels, with African American mothers producing the greatest cortisol levels (a non-significant trend). These results suggest a protective role of relationship quality on daily cortisol levels after pregnancy. To promote maternal and infant health, interventions should focus on improving relationship quality during pregnancy and postpartum. Future studies should investigate the mechanisms that contribute to the different experiences of African American mothers.

Abstract Name: Old Taylor and Old Overholt Whiskey Brands' Marketing Strategies: Balancing Heritage and Modern Consumer Engagement

The worldwide whiskey industry, valued at 80 billion dollars a year, is vital to Kentucky's economy and the financial well-being of the Commonwealth depends on how this historical distilled spirit is domestically and internationally marketed. Balancing heritage and modern consumer engagement, Old Taylor and Old Overholt whiskey brands have deployed marketing strategies into cultivating long lasting customer relationships to maintain their presence in the liquor market since the 1800s. Despite challenges such as Prohibition, evolving consumer tastes, and ownership changes, these brands have preserved their essence and competitiveness in the market over the years. To understand the methods behind their enduring success, this study examines the Old Taylor and Old Overholt whiskey collection, 1895-1944, at the University of Kentucky Libraries Special Collections Research Center. The collection contains business and marketing materials documenting the history, evolution, and cultural significance from these renowned whiskey brands from 1895 to 1944. Through this analysis, valuable insights into historical marketing practices within the whiskey industry emerge, allowing for meaningful comparisons with modern marketing campaigns. However, the significance of this research extends beyond the whiskey industry. In a rapidly changing market characterized by technological advancements and evolving consumer preferences, understanding the role of continuity and heritage is crucial for success as it reflects the uniqueness of their brand. Effectively balancing heritage with modern consumer engagement strategies is essential for businesses to remain competitive and connect with a wide range of consumers. In this context, this research offers a relevant exploration of brand heritage and its impact on customer relationships.

Abstract Name: Implementation of Flexner Report on Delegitimization of Black Providers to Understand Presence of Doulas

The increase in maternal mortality has disproportionately affected Black women. It has become evident that doulas may be beneficial for mothers, as they are able to enhance maternal care. However, doulas are not commonly used. The Flexner Report, written by Abraham Flexner in 1910, changed the standards of medical education throughout the United States, in which medical schools still use today. Identifying the underlying reasons for their limited use is critical to enhance maternal care. This study aims to investigate how doulas may be used to alleviate current health disparities in maternal care by examining the Flexner report, specifically with regards to the medical education of Black students and women. In a comprehensive literature review of peer reviewed sources, this study explored historical maltreatments against the Black population, the delegitimization of Black maternal providers, the benefits that doulas offer, the perceptions that maternal care providers have towards doulas, and the standards of education for doulas. This study examined the experiences of maternal providers and doulas working together and investigated potential reasons on why doulas may not be as accepted as other medical professions or incorporated institutionally. Findings indicate that historical medical maltreatment, such as the Tuskegee Experiment and Eugenics Movement, have contributed to current health disparities, such as an increase in Black maternal mortality. In addition, doulas are able to serve as advocates, some maternal care providers have negative perceptions of doulas, and doulas are found to pursue certification for various reasons, such as being perceived as legitimate to other maternal care providers. As a result, through a set standardized education, doulas may be implemented into the healthcare system, effectively addressing health disparities.

Abstract Name: Improving Discharge Instruction Among People with Language Barriers in the Emergency Department

PurposeThe diverse population in the United States often encounters language barriers in healthcare, which can be problematic and lead to adverse outcomes. The purpose is to compare traditional and technological interpretation modalities for patients with limited English proficiency (LEP) by using a quasi-experimental approach. The goal is to identify the most effective communication modality, ultimately improving patient outcomes and satisfaction while preventing potential deaths.MethodsThe study was conducted at Arrowhead Regional Medical Center (ARMC) Emergency Department (ED). The study comprises two surveys - one administered after the initial assessment and another before the patient is discharged. The study will include 200 total participants between 18 and 60 years of age, indicating Spanish as their primary language.ResultsThe study may anticipate greater patient satisfaction, health outcomes, and discharge

instruction comprehension through the use of technological interpretation modalities, such as video-based interpretation and google translate.ConclusionsThe findings indicate that the usage of technological interpretation modalities for patients with LEP is critical for discharge comprehension and better health outcomes. To minimize ED admissions and increase cost efficiency, technological modalities should be prioritized versus traditional forms, such as in-person and phone-based interpretation. Hospitals and healthcare institutions adopting this as a common practice would establish a streamlined ED admission process to treat more patients in less time.Policy Implications include advocating for expansions and improved access to translation services and resources by increasing the number of interpreters and video devices for interpretation, providing educational materials printed in the preferred language, and standardizing translation services.

Abstract Name: Adinkras: an exploration of Supersymmetry and Graphs

When Describing the equations that make up supersymmetric physics, things can get very complex and be a challenge to work with. One tool that is useful in the study of these equations is called an Adinkra. Adinkras are graphical representations of the math that describes supersymmetry. Using an adinkra allows study of the relationship between different particles in supersymmetric gauge theory. Seeing a graphical representation allows one to visualize patterns that form in the relationships. For example, particles arrange themselves into structures that may be familiar to us, most notably N dimesional cubes. These structures also behave in the same patterns as self correcting code. The use of adinkras in studying these relationships allows one to better visualize and communicate what is happening under the surface of complex algebra. This helps make the study of supersymmetry both more accessible and intuitive.

Abstract Name: The Aftermath of Intimate Relationship Inventory-21

IntroductionRecently, the field of psychology has shown a growing awareness of the significance of understanding the emotional ride individuals experience after ending their relationships. The Aftermath of Intimate Relationship Inventory -21 (AIRI-21) has recently been made a crucial resource to measure people's experience after a committed relationship. This study seeks to explore by examining the AIRI-21's utility in assessing psychopathological aspects of social anxiety, suicidal behaviors, depression, and revenge. Methods A total of 424 undergraduate participants were given five self-report measures: The Aftermath of Intimate Relationships-21 (AIRI-21) to examine experiences after a committed relationship, The Multidimensional Revenge Attitude Inventory-21 (MRAI-21) to analyze types of revenge, Patient Health Questionnaire-9

(PHQ-9) to evaluate mental health, specifically depression, Social Anxiety Questionnaire-30 (SAQ-30) to detect anxiety in social settings, and the Suicidal Behavior Questionnaire-Revised (SBQ-R) to determine past and potential suicidal behaviors and thoughts. ResultsThe internal consistency analysis of the scale scores for all measures consistently exceeded the 0.8 threshold, which indicates that questionnaires can be considered reliable for the study. Using Pearson's correlation analysis, the AIRI-21 demonstrated discriminant correlations under 0.3 throughout the scales. The correlations between AIRI-21, and the SBQ-R, were found to be below 0.16, meaning suicide behaviors and aftermaths of relationships don't have a strong relationship. However, emotional distress and MRAI's revenge rumination dimension had the highest correlation overall with 0.34, which indicates a slight yet discriminant association between these variables. In addition, SAQ-30, PHQ-9, and AIRI-21 had an overall low correlation of 0.2, signifying that these two aspects also don't strongly influence each other. DiscussionThe findings imply that post-intimate relationships experiences offer a unique perspective on psychopathology and its constructs. The AIRI-21 is a crucial tool for understanding people's post-committed relationship experience and gaining a better comprehension of the complex relationship between these factors.

Abstract Name: Saturday Morning Live: Student researchers and a structured public audience

Pedagogy that requires undergraduate research is a skill that often includes critical thinking, investigation, disciplinary writing, document design, and the work is often prepared for an audience of one—the professor. Also, it is common for students to provide final presentations or to display visuals for a disciplinary audience of one—the classroom. The limited audience, common for academia, reinforces what Francis Bacon observed, "The Idols of the Cave consist of conceptions or doctrines which are dear to the individual who cherishes them, without possessing any evidence of their truth." Rather than increase a student's limited understanding of their work based on a confined traditional classroom, two faculty designed Saturday events, "The Gallery" and "CapCon" for the Fall and Spring terms. The focus is on student presentations of research findings because as Vico reminds us "It is in tune with the opinions of the audience that we have to arrange our speech. It often happens that people unmoved by forceful and compelling reasons can be jolted from their apathy and made to change their minds by means of some trifling line of argument" (p929). Students not only learn how to design an argument-presentation, they positively experience first-hand and immediately, the impact their words have on their audience which emphasizes what Gloria Anzaldúa noted "A lack of belief in my creative self, is a lack of belief in my total self and vice-versa—I cannot separate my writing from any part of my life. They are one." Each event includes a series of Infographic presentations and special attention to seniors and interns whose presentations include questions from a senior professor directly. While similar to a symposium or a conference, the differences include low cost, structured feedback, and a format that is appealing for faculty and students alike. We will include core principles for adaptation.

Abstract Name: The Intergenerational Transmission of Intensive Parenting Beliefs among Contemporary Mothers

This study investigates the transmission of intensive mothering beliefs across generations and how contemporary mothers redefine, reclaim, or discontinue these dimensions in their parenting practices. Intensive mothering refers to a parenting ideology that emphasizes the idea that mothers should devote significant time, energy, and resources to raising their children despite its association with adverse mental health outcomes such as anxiety, depression, shame, and guilt.Early research has primarily focused on the transmission of parenting behaviors across generations. Studies indicate that parents tend to emulate the parenting behaviors they experienced in earlier generations. Family relationships, maternal well-being, and social support significantly mediate the transmission process. Adverse childhood experiences can negatively impact infant development, further underscoring the importance of understanding the complex factors that shape parental behavior.While numerous studies have investigated the transmission of parenting behaviors, few have specifically focused on the intergenerational transmission of intensive mothering beliefs. This study addresses this gap by examining the transmission of intensive mothering beliefs through a cultural lens. It considers the ways contemporary mothers reconcile intensive mothering discourses in their own parenting practices.Interviews were conducted with 26 mothers to examine their experiences and perceptions of motherhood. The analysis focused on discussions of intensive mothering, cultural factors influencing the transmission of intensive parenting behaviors, and the factors leading contemporary mothers to redefine, reclaim, or discontinue intensive mothering dimensions.The thematic analysis explored the influence of family as culture in navigating norms and values, particularly in the context of intensive mothering. It also examines the impact of past experiences on current mothering practices, the changing landscape of parenthood, and the challenges mothers encounter in reconciling societal expectations.The findings contribute to understanding intergenerational transmission of intensive mothering, the cultural factors that influence parenting practices, and how contemporary mothers navigate this ideology in their parenting practices.

Abstract Name: A Qualitative Study of In-School Support for LGBTQ+ Students

Research suggests that LGBTQ+ students experience higher rates of bullying and harassment due to their gender identity in school (Moe et al., 2015). Therefore, the need for schools to create a positive school climate and provide interventions for these students is imperative. This study aimed to understand the effectiveness of these interventions from the perspective of adjustment counselors. This study followed

Moustakas's methods of transcendental phenomenology and semi-structured interviews to collect data. The sample consisted of seven adjustment counselors interviewed on their usage and perceived effectiveness of in-school supportive interventions for LGBTQ+ students. Five themes surfaced (e.g., open and accepting climate, policies, professional development, therapeutic support, in-school community). These results echo existing research that adjustment counselors play a supportive role for LGBTQ+ students in schools. Participants describe the importance of having in-school supportive interventions accessible for students, school staff, and families as they attribute these as central for a positive and accepting school climate for LGBTQ+ students. These findings contribute to the research base on LGTBQ+ student success in school and suggest that schools could better support such students through professional development on LGBTQ+ topics for school personnel and an integrated curriculum for students.

Abstract Name: Mentoring Matters: Impact of Partnership on the Success of Programs, Mentors and Trainees

Responsive mentorship of novice researchers in science, technology, engineering, mathematics and medicine (STEMM) has been well-documented to result in many positive benefits, including increased self-efficacy and persistence of trainees in their chosen field of study. The question of how to effectively and inclusively mentor undergraduate researchers is, however, not as well defined in the literature. During this presentation, we will explore the transformative impacts of mentorship on student-led research. Program directors/administrators from the Division of Diversity, Equity and Educational Achievement (DDEEA) at the University of Wisconsin-Madison will share current mentoring methods that have been shown to be effective in supporting students, especially those from historically marginalized backgrounds, among a variety of research disciplines. Mentored undergraduate researchers from DDEEA programs will also share the impacts of the mentorship they have received, highlighting specific mentoring techniques that have individually motivated and inspired each scholar. Collecting effective and culturally-responsive mentoring strategies and styles in a concerted manner and providing models of effective implementation will allow for STEMM mentors and trainees to support each other towards the creation of supportive environments where researchers and research programs flourish.

Abstract Name: Queer and Transgender Representation in Mary Shelley's Frankenstein

There are several potential ways in which the relationship between Victor and the Monster can be interpreted in Mary Shelley's Frankenstein. Some critics believe that they portray a more 'maternal relationship' while others view their bond as a symbol for the 'creator and his creation'. However, it is worth considering how the behavior and mindsets of these characters' depict queer struggles and transgender representation. When looking at their perception of themselves, each other, and the world around them from this perspective, there are numerous important factors to analyze. A few of these issues include Victor's reaction to the Monster's creation as potential suppression of homosexuality as well as his polarized perception of the novel's male and and female characters. Furthermore, the negative treatment of the Monster by a shallow, oppressive society introduces parallels between transgender feelings of isolation and the sensation of 'otherness' he feels as a result of being outcast for his appearance. Addressing these topics will not only further my argument that Frankenstein portrays queer representation, but it will also deepen the novel's meaning and present a strong message to a marginalized community. Victor's internalized homophobia through his horrified, disgusted response to the Monster's creation would become an outlet for the sexual tension and self-loathing experienced by many queer individuals. Additionally, how the Monster was negatively perceived and outcast by others can be appreciated as an allegory for the rejection and segregation of transgender people in today's society. Approaching Frankenstein from this perspective demands an alternative angle to be considered which would make the novel more impactful, memorable, and relevant to thousands of readers.

Abstract Name: The Futurama Theorem: Solving Mind-Swapping Variations Using the Symmetric Group

In the television series Futurama, a character creates a machine capable of swapping the minds of two people. However, the machine was faulty in that once a pair swaps, they can not swap back. If a group of people permute untraceably amongst themselves, can the swapping be undone with the introduction of characters who have not used the machine? Keeler's theorem tells us it can with the introduction of two people who have not used the machine. Recently, J. Elder introduced the variation of a mind permutation machine that can cycle n people under the restriction that once a permutation is done, none of the permutations in the subgroup it generates can be used. Elder solves this problem for the cases in which n is prime and when n is even. We pick up where she left off, generalizing her proof to the case where n is odd. We introduce an additional restraint: that no two cycles can permute the same n people. Using well known results on the alternating group allowed us to find all possible situations a group of people could get into using the machine. Analyzing these findings allowed us to solve the problem for all n. We go on to study the optimality of the case where n equals three and introduce a more optimal algorithm. We further explore a variation on a machine that cycles an infinite amount of people, showing unexpectedly that finitary permutations can be undone in just two swaps using this machine. This work was funded by the CC-REU NSF REU grant (DMS-2050692).

Abstract Name: Flow Imaging Microscopy and Machine Learning Analysis to For Finding the Root Cause of Protein Aggregation

Therapeutic proteins in the form of monoclonal antibodies (mAbs) are becoming increasingly used in the medical field. However, the various stresses that these mAbs may encounter between manufacturing and their injection in patients can cause protein aggregation and subsequent particle formation. The negative implications of particle formation are safety concerns and the loss of drug product potency. Thus, it is imperative that particles formed during manufacturing are closely monitored. Previous works used thousands of images of particles captured using flow imaging microscopy (FIM) to train convolutional neural networks (CNNs) to monitor changes in collections of images of proteinaceous particles. These changes were induced by an obvious imposed stress condition (e.g., peristaltic pumping). However, it is unknown whether stable, pre-formed proteinaceous particles are affected by more subtle stresses, such as time. In this work, we use supervised and unsupervised CNN techniques to monitor the stability of proteinaceous particles generated from subjecting mAb solutions to a stirring stress after an incubation period in a refrigerator. Machine learning models were first trained on particles obtained immediately after the applied stir stress. The trained models were then applied to FIM images unseen by the CNN models during training, obtained after incubation in the fridge over the course of 24 weeks. Initial results of the project have not shown any significant changes in particles over 8 weeks. The results of this work will inform future efforts in machine learning based particle analyses on the effects of an incubation period on protein particles following an applied stress and test the sensitivity of machine learning algorithms to be able to detect minute changes in collections of images.

Abstract Name: : Leveraging Large Language Models for Structuring and Querying Unstructured Data

This research project delves into the application of Large Language Models (LLMs) to efficiently structure unstructured data and facilitate information retrieval through natural language queries. The study focuses on harnessing the power of LLMs to enhance the comprehension of web data by leveraging their contextual understanding and language processing capabilities.The project adopts a practical approach by utilizing Python and the OpenAI API to develop a Flask application. The application is designed to scrape data from the Buffalo State webpage, and using LLMs, transform the unstructured information into structured formats. This innovative approach enables the comparison of different structuring techniques, shedding light on how LLMs interpret and organize data.Key components of the research include the implementation of a systematic process that integrates the OpenAI API key to fetch data from a specified webpage URL. The data is then processed and structured in various ways to facilitate meaningful comparisons of results. The goal is to discern the nuances in how LLMs read and interpret information, providing insights into their strengths and limitations in handling diverse types of data.By employing natural language queries, the research assesses the

ability of LLMs to comprehend and respond to user-generated questions based on the structured data. This methodology not only contributes to the understanding of LLMs' natural language processing capabilities but also explores the potential of these models in creating user-friendly interfaces for information retrieval.The findings from this research contribute to the growing body of knowledge on the practical applications of LLMs in structuring and querying unstructured data. The developed Flask application serves as a valuable tool for testing and evaluating LLMs in real-world scenarios, offering a foundation for future advancements in natural language understanding and data processing.

Abstract Name: Vaccine Hesitancy in the homeless population of Marin County: is COVID any different?

COVID-19 booster hesitancy amongst different populations is a continuing public health issue. Within Marin County, individuals experiencing homelessness are not receiving their booster vaccination in spite of receiving the primary series of the COVID vaccine. Hence, there is a lack of research that reveals the barriers and motivation as to why individuals experiencing homelessness in Marin are facing hesitancy towards the COVID-19 booster. In this qualitative study, the researchers will interview clients of the Ritter Center. Semi-structured interviews will be conducted with individuals ages 18 and older, currently experiencing homelessness, and speak English. Voice recorded interviews will be transcribed through Otter.ai and interviews not recorded will be hand transcribed by the researcher at the time of the interview. Once transcribed, the interviews will then be coded and divided into common themes using Dedoose. Based on preliminary results, thematic analysis reveals three main themes for the barriers and motivations to remaining unboosted amongst those experiencing homelessness: non-accessible services, prior COVID-19 infection, lack of vaccine promotion. Non-accessible services manifest as difficulties accessing booster vaccine services as it may be a common barrier which will reduce their efforts to receive the booster. Prior COVID-19 infection or experience appears as a theme when individuals have contracted COVID-19 prior to vaccinations that will negatively affect their motivations. Lack of booster vaccine promotion was reported when the participants were unaware or not given opportunities to learn about the booster. The themes of non-accessible services, prior COVID-19 infection, and lack of vaccine promotion are expected to be common amongst the interviews held which suggests that these recurrent experiences have led individuals experiencing homelessness to remain unboosted. Public health intervention can increase accessibility and offer more education services to further promote COVID-19 vaccination efforts to individuals experiencing homelessness.

Abstract Name: Sex-Specific Associations Between Brain Structures and Anxiety Symptoms in Preadolescent Children

Background: Pediatric anxiety symptoms are more prevalent in females than males. This study aimed to look at how sex influenced the association between brain structures and anxiety symptoms in children. The amygdala is a critical region in the threat detection network and is related to psychopathology risk. The rostral anterior cingulate cortex (rACC) and orbitofrontal cortex (OFC) regulate amygdala activity. Thus, we hypothesized that larger amygdala, but smaller regulatory regions would be associated with increased anxiety symptoms differently in sexes. Methods: We recruited 59 children (age 9 years, 35 females) from an urban population of Detroit, MI. T1 -weighted structural images were acquired using a 3T Siemens MRI system. FreeSurfer was used to reconstruct images by segmenting white- grey matter surfaces and parcellate brain structures. Self-reported anxiety symptoms were collected using Behavioral- Assessment System for Children (BASC- 3). PTSD symptoms were measured two years following initial visit using UCLA-Reaction Index Scale. Analyses were stratified by child sex.Results: We found that right amygdala volume was positively correlated with increased anxiety symptoms (r=.52, p<.01) in females, but not males, even after co-varying for intracranial volume. On the other hand, OFC and rACC thickness was associated with decreased anxiety symptoms (r= -.41, p<.05; r= -.44, p<.05 respectively), in males but not females. Both sexes with larger amygdala predicted greater PTSD symptoms in the future (r=.41, p<.01), even after controlling for additional anxiety symptoms. Discussion: Our findings suggest that sex may influence the association between brain structures and anxiety symptoms. Larger threat sensitivity regions associate with female but not male anxiety symptoms. Thicker regulatory cortical regions may have protective effects in males but not in females. Importantly, larger amygdala may be a biomarker to predict future PTSD in both sexes. These sex specific structural findings show neural markers of psychopathology.

Abstract Name: Clinical Outcomes and Patient Satisfaction of Platelet-Rich Plasma Injections in Regenerative Aesthetic Medicine

The skin, being the largest organ, plays an important role in defense and survival due to its inherent ability to repair and renew itself. With the notable progress in medical care and nutrition, there is an increasing imperative to devise innovative approaches aimed at enhancing the process of cutaneous healing. The field of medicine is currently experiencing rapid progress in the direction of developing procedures that are minimally invasive or non-invasive, as well as treatments that can expedite the healing process. These advancements aim to minimize the negative impact on patients' health and enhance their ability to regain normal bodily functions, leading to an improved quality of life (QoL). Regenerative medicine is a growing interdisciplinary domain within biomedical research that seeks to restore, regenerate, and substitute impaired tissues and cells. Platelet-rich plasma (PRP) is an emerging therapeutic modality in the field of regenerative medicine, which has garnered considerable attention for its capacity to facilitate and expedite tissue healing processes. Regardless of the existence of various conventional therapeutic approaches focused on wound healing and growth factors, the utilization of innovative treatments continues to pose a clinical challenge. There is an ongoing pursuit of regenerative therapies to reduce the burden on healthcare systems. For these reasons, the current study seeks to examine the field of regenerative skin wound healing, with a specific focus on the use of platelet-rich plasma as a cost-effective and safe therapeutic intervention that enhances the overall quality of life for patients. The present study utilizes a semi-structured interview format to evaluate

the following: (i) whether platelet-rich plasma (PRP) therapy improves clinical outcomes in the field of regenerative aesthetic medicine; and (ii) whether platelet-rich plasma (PRP) therapy and patients' quality of life (QoL) are positively correlated.

Abstract Name: Data Seriation Techniques with Average Repelling Distance in the Tree-penalized Path Length Method

Understanding the structure of data allows for many aspects of data analysis. Data ordering, otherwise known as data seriation, is a useful tool that helps to understand the data structure better. For example, one can use an ordering of data obtained by a seriation method to reorder the rows and columns of the distance matrix. Then visualize the data structures using heat maps of the matrix to understand the data structure. Obtaining a good ordering is crucial in this process. In this study, we try to improve a seriation method, called Tree-penalized Path Length (tpPL), which was shown to produce orderings that keep clusters of data together and have short path length, along with other merits. We introduce a new dissimilarity measure, Average Repelling Distance (ARD), and use it to construct two new distance matrices. We use the matrices and tpPL to produce orderings of 39 datasets and visualize them via heat maps of reordered distance matrices. We then compare the obtained orderings with those of tpPL, Optimal Leaf Order (OLO), and Travelling Salesman Problem (TSP) seriation methods using two numerical criteria. Although our work is contained within the field of data seriation, our new distance matrices may potentially be useful to other fields that use distance matrices in data analysis.

Abstract Name: Mapping Hybridities of People, Places, and Projects to Strengthen a Model of Sustainability from the Margin

Favelas are increasingly being recognized as sources for new models of sustainability and resilience. The Sustainable Favela Network (SFN), a network of community leaders from over 127 favelas in and around Rio de Janeiro, generates and shares these models through in-person and digitally mediated gatherings. In 2018 and 2021, these projects were added to the Sustainable Favela Network Map, serving as a platform showcasing diverse sustainability initiatives that enable members to connect around shared objectives, experiences, and goals. To visualize how the culturally and contextually relevant ideas of sustainability travel, we interviewed community leaders from ten favelas in and around Rio de Janeiro, to explore their relationship to the network and how their work fits into the conceptual understanding of sustainability. The term favela, and the territories they refer to, have often been contested. As such, we asked community leaders

how they define their communities. We used ArcGIS Pro to visually represent the interconnections between Sustainable Favela Network members and to highlight how ideas of sustainability travel across networks. From our findings, we aim to better understand the practices for community-based participatory mapping that provide heuristic and practical approaches for strengthening collaborations and networking amongst various grassroots sustainability initiatives.

Abstract Name: Autism Screams: Exploring Opinions, Definitions, and Social Injustices of the Autistic Community

Since the early 1900s, Autism Spectrum Disorder, also referred to as ASD, has been feared, stigmatized, and often kept behind closed doors. Multiple social factors and misconceptions have been spread throughout the United States, causing the experience of Autistics to be erased and demonized. The anti-vaccination movement and orginazation such as Autisim Speaks have rapidly silanced the true experinaces of Autisitics, allowing fear to be the foundation of our sociatal understanding around ASD. This restricts Autistics from self-advocating, finding independence, and receiving respect within their day to day lives. The infantilization of adult Autistics creates systematic, educational and social injustices by preventing Autisitc-led advocacy. This study aims to shed light on the neurodiversity paradigm, which views Autism not as a defect or deficit, but a valuable human perspective that can be utilized to accelerate our collective knowledge. In addition to the rapid spread of information surrounding Autistic experiences throughout the COVID-19 pandemic, Autism diagnosis have spiked over the past decade. Centering and examining queer, BIPOC, and female Autistic experiences continues to open a plethora of new symptoms and skills within the Autistic community. This study will examine these factors and advocate for a redefinition of ASD in medical, mental health, social, and sociatal enviroments.

Abstract Name: Net Nitrification Rates with Soil Depths in an Agricultural Peatland

Agricultural croplands emit one-third of global greenhouse gas emissions. Globally many croplands are peatlands, wetlands that contain soils with high amounts of carbon. Although they are excellent sources of vegetation and agricultural production, major greenhouse gases are released at these sites. Our study sought

to measure the change of nitrate concentration over two weeks from soils of varying depths to estimate net nitrification rates in the Sacramento-San Joaquin Delta, a source known to emit large amounts of nitrous oxide. Our trend analysis encapsulated a five-step procedure using a soil probe, potassium chloride extractions (nitrogen mineralization), a soil incubator, and a SEAL Analyzer. After testing soils from depths, our findings showed that nitrification rates decreased as soil depths lowered. These findings help us understand the correlation between soil depths and their biogeochemical compositions to help further understand the best conditions to promote nitrification. Further studies are needed to simplify the approach to minimize disturbance and calculate samples closer to real-time.

Abstract Name: Mapping of Microplastic Concentration in the Pearl River Estuary in China and the Indo-Pacific Humpback Dolphins (Sousa chinensis) Population

With the purpose of determining where the concentration of microplastic contamination in the Pearl River Estuary in China is located and the population area of the Indo-Pacific humpback dolphins (Sousa chinensis), a critical literature review was conducted with a focus on data sets from research studies conducted from 2018 to 2021. Previous research has shown that industrial clothing factories such as Shien, located near the Pearl River Estuary, are releasing microplastic-contaminated wastewater into the river. In order to identify if Pearl River Estuary Sousa chinensis populations are located in areas of high microplastic concentrations, a literature review was conducted to identify if both overlap. Research by Mai et al. and Li et al. identified the specific area of the river where microplastics are abundant. Further research by Zhu et. al. and Chen et al. identified the location of Sousa chinensis populations. Experimental findings from Zhu et al.'s research showed microplastics were ingested by sampled individuals. A map was created to find a correlation between microplastic and Sousa chinensis location. The results indicate an overlap in the location of both microplastics and Sousa chinensis. Further research should focus on identifying the environmental threat and adverse effects of microplastic ingestion by Sousa chinensis.

Abstract Name: The Effects of Finasteride on the Parity Rates of Female Drosophila Melanogaster

Finasteride has been tested for and is known to treat male pattern baldness and benign prostate hyperplasia; however, the drug could treat female pattern baldness and polycystic ovary syndrome with the proper testing and investigation. The current database on the effects of finasteride on the female reproductive system is largely unknown and divided. This study aims to investigate the effects of finasteride on the female reproductive system using Drosophila melanogaster as the model organism. The female flies in this study were fed human dosage equivalents of 0.5 mg, 1 mg, and 5 mg of finasteride, with a control group of females who consumed no finasteride. Over the course of three trials, the female Drosophila were allowed to mate with undosed male Drosophila and after 24 hours all of the flies were removed from the vial after they laid their eggs. For two weeks following fertilization, the vials were checked every 8 hours and adult flies were removed. Adult Drosophila were counted, sexed, and frozen at -80°C to preserve their RNA. This study predicts that the results will indicate that finasteride will negatively impact the reproductive abilities of females and their male offspring. A follow-up study will be conducted using an RNA sequencer to investigate changes in gene expression among experimental groups. These results will help contribute to the research body that may ultimately be used to help determine treatment protocols for female patients suffering from pattern baldness.

Abstract Name: The Mechanistic Association between Cognition and Alzheimer’s Disease using Machine Learning Methods

Since its discovery in 1906, Alzheimer's disease has been the most common form of dementia. More than six million Americans aged Sixty-five and older live with Alzheimer's disease, making it more important than ever. As a result, it is critical to identify the predictors responsible for the onset of the disease. The purpose of this analysis is to investigate the role of biological factors in determining the severity of cognitive impairment. To evaluate which biomarkers were most significant, we used machine-learning techniques to examine the relationship between cognition-related markers and levels of cognitive impairment. We investigated the Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset which we parsed through various cohorts. Our study consists of a variety of disease markers, including performance-based neuropsychological scores, apolipoprotein E (APOE) genetic status, and demographic details such as age and level of education. Our prediction was that cognitive exams would provide the greatest statistical significance. We ran rigorous statistical hypothesis tests in all aspects of our inference, in addition to quantifying predictor effects. Analysis in our study indicated that the Clinical Dementia Rating sum of Boxes and the Mini-Mental State Exam linked with thresholding of disease progression. Furthermore, the joint effects of risk factors and cognitive tests were highly associated with the likelihood of further progression of cognitive impairment. Given the alarming rate at which Alzheimer's disease and other dementias are growing, further research is needed to evaluate the roles of biomarkers in accurately tracking disease progression for patients and those at risk for cognitive impairment.

Abstract Name: Understanding the effect of estradiol treatment on the development of the pre-optic brain area in green anole lizards.

Sex differences in forebrain morphology arise during development and are often linked to hormonal changes. These dimorphisms frequently occur in regions related to reproductive behaviors. Steroid hormones, such as testosterone and estradiol have important roles in vertebrate development by producing sex-specific structures, including the copulatory system and areas of the brain. The overall goal of our experiment is to examine the effects of estradiol on the brain and copulatory system development. Specifically, this study focuses on the preoptic area (POA) of the brain. This region exhibits sexual dimorphism, with males displaying a morphologically larger preoptic brain area compared to females. Previous research establishes estradiol as having a role in masculinizing the POA in rats. Although, these findings have been displayed in rodents, there is no further research of estradiol effects on the preoptic brain area in other vertebrates such as green anole lizards (Anolis carolinensis). We hypothesize that estradiol masculinizes the POA in green anole lizard development, therefore we anticipate that female lizards treated with estradiol would exhibit an enlarged POA, resembling the size of a male POA. To address this hypothesis, we treated lizard embryos with either estradiol or vehicle control and collected tissue after hatching. We previously utilized PCR on genomic DNA to determine the sex of the hatchlings. We are currently sectioning brains to examine POA morphology of the hatchlings treated with estradiol or vehicle control to see if there are any effects of hormones on brain development. The growing understanding of estradiol in green anole lizards will promote a better prediction for how estradiol treatment could affect brain morphology in other vertebrates.

Abstract Name: The Coca-Cola Bottle

The Coca-Cola bottle has been around since 1916, and it serves a far greater purpose than just a bottle. This particular bottle is without a doubt one of the most iconic designs in the history of product packaging. Its unique shape and timeless appeal have made it instantly recognizable around the world. It was modeled after the shape of the Kola nut, which gives it its ergonomic shape. The bottle's shape has become an iconic symbol of Coca-Cola, reinforcing the brand’s identity and making it stand out from others.

Abstract Name: Brain-eating amoeba rescue-of-infection model using drug combinations

In the United States, 157 documented cases of primary amoebic meningoencephalitis (PAM) have been recorded between 1962 and 2022. In the 60 years since the first reported case, only four patients have survived; a 97.5% fatality rate. The causative agent responsible for the highly fatal infections, is the free-living, single-celled parasite, Naegleria fowleri— or the “brain-eating amoeba.”The aquatic thermophiles are opportunistic pathogens that inhabit a wide range of environments; from poorly maintained pools, moist sediment, rivers, lakes, etc. Exposure to N. fowleri invasion is reliant on direct contact with a host’s upper nasal mucosa, and the active parasite. Rapid deterioration of neural tissues occurs shortly after infection.Today, there is no universally accepted treatment plan for treating PAM infections. The CDC has recommended an empirical approach to treatment, and suggests utilizing combination drug-therapies. Suggested drugs include Amphotericin B, Azithromycin, Fluconazole, Miltefosine, and Rifampin.To better understand and evaluate the effects of these drugs on N. fowleri, a rescue-of-infection model was applied to test the efficacy of single and combination-drug treatments, at various time points. The model utilized an immortalized HeLa cell line that was infected with the amoebae until roughly 50% cytotoxicity was observed. The rescue stage commenced with drug additions, and HeLa cell metabolism, and apoptosis levels were monitored using fluorescence viability assays and caspase-3 enzyme detection systems.Drug combinations that included Rifampin and Amphotericin B, provided the greatest protection for human Hela cells against N. fowleri infections. Data collected from this model provides deeper understanding of Naegleria fowleri pathogenicity. This knowledge will aid the development of more reliable and efficient treatments for this devastating infection.

Abstract Name: Calculating Spatial Accessibility to Primary Healthcare Providers in Yucatán, Mexico

This poster examines spatial accessibility to primary healthcare facilities in the state of Yucatán, Mexico by employing the Two-Step Floating Catchment Area (2SFCA) method. Access to primary healthcare plays an important role in enhancing overall health outcomes, especially due to preventative care measures. 2SFCA is used to first calculate a provider-to-population ratio using network analysis, and then aggregate these ratios within population catchment areas. The end result is a spatial accessibility index, which is a valuable metric to evaluate relative spatial accessibility of population points to primary healthcare locations. This research helps quantify accessibility, with potential applications aiding in policy development and service planning, ultimately resulting in improved health outcomes for the population.

Abstract Name: Smart Drone Technology for Disaster Rescue in Complex Environments

In disaster-stricken areas marked by extensive destruction caused by earthquakes, individuals often find themselves trapped amid debris and structural collapse. Navigating these perilous terrains poses significant risks and consumes valuable time for rescue teams. This research introduces an innovative approach to address these challenges by proposing a novel drone technology designed to adapt its dimensions mid-flight, thus enabling efficient navigation through complex environments. This unique drone incorporates experimental "4-D" printing materials that can dynamically respond to external stimuli, allowing for unprecedented adaptability during its mission. Specifically, the drone's arms are constructed from thermoplastic polyurethane, which reacts to heat stimuli at the arm's base, facilitating mid-flight shape changes. This transformative capability enhances the drone's maneuverability in confined spaces, while the integration of 4-D printing minimizes wing components, reducing overall costs and resource requirements.

Abstract Name: Drips and Divides: A County-Level Exploration of Water Quality and Equity

In October 2023, Michigan prosecutors announced that they were no longer pursuing criminal cases against public officials in relation to the Flint Water Crisis, which began in 2014 when the city changed its municipal water supply source from Lake Huron to the Flint River, causing water distribution pipes to corrode and leach lead and other contaminants into municipal drinking water. Flint, Michigan experiences higher-than-average levels of poverty---in 2021, 35.5% of its population lived below the poverty line compared to the national average of 12.6%. In addition, 56.3% of Flint's residents are black, compared to 13.6% of the U.S. population.This research project investigates the interplay between poverty, race, and water quality violations at the county level in the United States. Our study utilizes county-by-county data on socio-economic factors and water quality violations from the Environmental Protection Agency's Safe Drinking Water Information System (SDWIS). The primary objectives include assessing whether disparities exist in water quality violations based on poverty levels and racial demographics and examining the potential implications for environmental justice policies. Statistical analysis techniques, such as correlation, regression, and spatial analyses, will be utilized, allowing for a comprehensive understanding of the complex relationships shaping water quality across diverse communities.

Abstract Name: The Connection Between Self-Isolation and Mental Health in College Students

Self-isolation has been understood to be detrimental to a person's mental health. Multiple studies have found a significant relationship between anxiety and depression, and self-isolation. The present study explores the effect of loneliness from self-isolation on mental health in college students. In this study, loneliness was measured with UCLA's Revised Loneliness Scale. Depression was measured with the Center for Epidemiologic Studies Depression Scale (CES-D). Anxiety was measured with the Generalized Anxiety Disorder 7-item (GAD-7) scale. The sample included 107 full-time college students from a Christian university. A t-test, a one-way ANOVA, and a multiple regression analysis were conducted to analyze the data. The findings in this research revealed that perceived loneliness significantly predicted depression, (b2 = 0.35, p = .012). The more perceived loneliness was associated with an increase in depression controlling for anxiety in college students. In addition, there was no statistically significant difference in loneliness between males and females (t = -2.001, p = .783). Results also showed that the school year was significantly associated with loneliness (p < .05). Loneliness was significantly lower among juniors (M = 2.32, SD = 1.12) than seniors (M = 3.03, SD = 0.97). The findings emphasize the need for society and university institutions to recognize the impact of loneliness on mental health in college students. Furthermore, future implications address the need to understand how perceived loneliness can be decreased among college students.

Abstract Name: Comparing Genotype and Phenotype of Antibiotic Resistance Profiles of Staphylococcus Aureus Isolates from Cystic Fibrosis Patients

Cystic fibrosis, CF, is a genetic condition that affects an estimated 160,000 people worldwide . This project studies Staphylococcus aureus, S. aureus, a bacteria that is commonly present in cystic fibrosis patients. Specifically, the project is attempting to identify if there is variation between the expected and observed phenotype in regards to antibiotic resistance. Resistance is tested by exposing the S. aureus to six antibiotics commonly used to treat CF and analyzing the growth of the bacteria. A MIC assay is used to find the minimum inhibitory growth concentration (MIC) for each antibiotic and to determine if the S. aureus is resistant or sensitive based on clinical laboratory standards. The data is compared with the genotypes of the collected isolate to identify if there is a variation. So far, the data collected in this experiment indicates that variation is present and using the genotype of Staphylococcus aureus may not be a useful technique when determining treatment plans for CF. Clinicians utilize genetic testing to determine which antibiotic should be

used to treat CF, but literature on S. aureus has shown that the genes may be turned off/on which changes the observed phenotype. This shows that the treatment plan for CF may be ineffective and can be linked with the lack of clinical success in treating the condition. Therefore, our data can be used in conjunction with clinicians to help identify better ways to determine antibiotic resistance quickly in a clinical laboratory and best treat patients with these bacterial infections.

Abstract Name: Loggerhead (Caretta caretta) Disorientations on Gulf of Mexico Beaches

Sea turtles find the ocean by crawling towards the brightest horizon and moving away from sand dunes and large shadows. Their ability to find the ocean can be impacted by artificial light sources that illuminate the beach, removing natural visual cues. The Sea Turtle Conservation and Research Program (STCRP) at Mote Marine Lab has documented loggerhead (Caretta caretta) hatchling disorientations in Sarasota and Manatee counties, Florida, USA from 1989 – 2023 across five beaches that vary in size, building sizes, and population. Disorientation data were used to determine the primary hatchling disorientation direction, to quantify what caused the most disorientation events, to determine how moon phase impacts the number of disorientation events, and to identify how many hatchlings disorient from those that emerge from their nests. When disoriented, hatchlings crawled southeast across all beaches, with most attracted toward condominium building lighting. Moon phase significantly affected the number of disorientations that occurred, with the most events occurring during the fourth quarter of the lunar cycle. While the percent of hatchlings from each nest is roughly the same on every beach, the number of disorientation events is dominated by Longboat Key. Additionally, the number of events on every beach is increasing independent of the increase in the number of nests on each beach.

Abstract Name: Estradiol Influences Memory Formation Via Prefrontal Cortex Mechanisms

This project aims to study brain estradiol synthesis and prefrontal cortex (PFC) activity in memory formation, aiming to understand and treat memory decline. Memory deficits often relate to PFC dysfunction, necessitating an understanding of its role during memory formation. The hormone 17-β- estradiol (E2) regulates synaptic plasticity, enhancing memory consolidation. However, its involvement outside the hippocampus, like in the medial prefrontal cortex (mPFC), remains unclear. Letrozole, blocking E2 synthesis, impairs cognition, leading us to hypothesize that E2 synthesis in mPFC is vital for object recognition

memory. Ovariectomized female C57BL/6 mice with mPFC cannulas underwent behavioral testing in an open field box. Letrozole or vehicle was infused post-training. Testing with a novel object revealed impaired memory consolidation in letrozole-infused mice, indicating E2's essential role. We used fiber photometry to measure neuronal activity during memory formation. Mice were habituated to an open field box in which behavioral testing took place. During the training phase, mice explored two identical objects for a cumulative total of 30s. Immediately afterwards, mice received an intra-mPFC infusion of letrozole (0.025 μg or 0.05 μg/hemisphere) or vehicle. During testing, one object was replaced with a novel object. The time spent exploring each object is measured, and increased exploration of the novel object indicates intact recognition memory. Letrozole-infused mice exhibited impaired OR and OP memory consolidation. Using GCaMP, we visualized intracellular calcium changes in mice expressing the indicator in the mPFC. Initial experiments infused jGCaMP7s [pGP-AAV9-syn-jGCaMP7s-WPRE (AAV9)] (Addgene) in the prelimbic region of mPFC (AP +1.9, DV -2.1, ML ± 0.3 mm relative to Bregma) and implanted optic fibers in the mPFC of anesthetized female mice, with ongoing analysis focusing on hormonal effects on mPFC calcium activity during object recognition. Increased mPFC activity in the SHAM group during object training and testing, aligning with E2's memory-enhancing effects.

Abstract Name: Mutation in the DAF-7/TGF pathway rescues dauer formation defects and changes gene expression in the brain of C. elegans.

In C. elegans, aging can be slowed by entering dauer diapause, a non-aging stage activated by inhibiting the DAF-7/TGF neuroendocrine signaling pathway, usually triggered by environmental stressors. In our laboratory, we discovered that unc-33 mutants could not form dauers in response to environmental stressors, but the mechanism behind this is still unknown. We hypothesized that mutating the daf-7 gene could rescue dauer formation in unc-33 mutants. To test this, we created unc-33;daf-7 double mutants and studied whether this new strain can produce dauers and inhibit the DAF-7/TGF pathway in response to environmental stressors. In brief, this study used synchronized young adults or dauers, in order to quantify dauer formation and examine the GFP expression driven by the daf-7 promoter. For the latter, we used the ksIs2 transgene, which codes for daf-7 promoter driving the expression of GFP. Results showed that under unfavorable environmental conditions, these animals produced dauers at similar levels as wild-type animals. Moreover, when we analyzed the activation of the DAF-7/TGF pathway, we observed that both daf-7 single mutants and unc-33;daf-7 double mutants showed GFP expression in ASI and ASJ neurons. More specifically, unc-33; daf-7 dauers and young adult hermaphrodites have an active daf-7 promoter in ASI and ASJ neurons. Additionally, daf-7(e1372) dauers and young adult hermaphrodites also showed an active daf-7 promoter in ASI and ASJ neurons. Taken together, this study supports the hypothesis that inhibition of the DAF-7/TGF pathway via the introduction of the daf-7(e1372) mutation is sufficient to rescue the dauer formation defects of unc-33 mutants. Last, the mutation daf-7(e1372) alone or in an unc-33 mutant background results in the activation of the daf-7 promoter in ASJ neurons, a feature underlying behaviors such as males seeking mates or hermaphrodites avoiding the pathogenic bacteria Pseudomonas aeruginosa.

Abstract Name: Analysis of the effect of real time geometric alterations on the motion of a self-diffusiophoretic bent rod

Microrobots, microscopic entities that can be used to accomplish biomedical and environmental remediation tasks, primarily use two modes of swimming: mechanical and chemical. Mechanical swimming involves altering the microrobot's geometry to induce motion, while chemical swimming employs reactive patches to establish a concentration gradient that the microrobot can move along via diffusiophoresis. In this work, we use slender body theory and mobility relations to assess how geometric asymmetry, surface activity, and hinge articulations affect the motion of a bent rod actuator. Using the intuition gained from trajectory simulations, we plan to explore ways to implement a control scheme that can determine the necessary parameters for a bent rod actuator to move along a predetermined trajectory. We determine the bent rod actuator trajectories in the zero Reynolds number limit using mobility relations. Mobility relations allow us to calculate the velocity of a bent rod actuator due to applied forces and torques generated through diffusiophoresis and hinge articulations. We first study bent rod actuator motion due to only diffusiophoresis. We find that the trajectories of the bent rod actuator are always circular. We then study the bent rod actuator motion due to only hinge articulations and find that the bent rod actuator trajectories trace circular arcs. The length of the arc is dependent on length asymmetry and the amplitude of the hinge articulations. We conclude by studying the motion of the bent rod actuator with both chemical and mechanical modes of swimming. The trajectories traced follow curved trajectories, where the specific shape depends on the geometry and flux profile of the bent rod actuator. Our findings offer valuable insights into the relationship between mechanical and chemical modes of transport at the microscale, presenting a new way for the rational design and control of microrobot motion.

Abstract Name: Stationary Lower-Body Movement System to Mitigate Muscle Atrophy in Spaceflight

Upon landing on Mars, astronauts need to possess the requisite muscle strength to exit the spacecraft, setup the habitat, and explore. Currently, NASA is evaluating the Miniature Exercise Device as a countermeasure to muscle atrophy for long-duration travel. Limitations exist in the implementation of lower- body

movements that target specific musculature. Thus, the addition of a supplementary device targeting these muscles is needed. To address lower limb atrophy during deep-space missions, we designed a compact, lightweight device that incorporates pneumatic principles and airflow restriction to provide varied resistance. The device was originally designed in three-dimensional modeling software (Solidworks Premium, Waltham, MA). Components included: a boot, leg brace, ball valvie, clevis mounting bracket, rod clevis end, and two double acting pneumatic cylinders. Testing included measurements of force, muscle damage during exercise, and finite element analysis (FEA). To measure the retraction and extension stroke, a force plate and cable machine was utilized, with a mean force for both, up to 537.9 N and peak force of 1,116.1 N. For exercise tesiting, ten sets of 10 repetitions (at 136 N) and 10 sets of 5 repetitions (at 538 N) were performed. Serum concentrations of creatine kinase, a biomarker of skeletal muscle damage, were measured via a blood sample before vs. after exercise. Greater muscle damage for an aerobic-only trained female (108 vs.324 U/L) vs. a physically active male (93 vs. 97 U/L) was measured. For FEA testing, at a constant amplitude of 293 N, run for 1 million cycles, the boot and bracket can withstand approximately 38,050 and 14 million cycles, respectively. Approximately 7.143% damage was incurred after 1 million cycles. In conclusion, we fabricated and tested a compact device that provides the capability for resistance and aerobic exercise countermeasures to address lower-limb muscle atrophy in microgravity, especially during long-duration spaceflight.

Abstract Name: Analysis of Pencil Graphite Electrodes for a Cheaper Alternative to Paraffin Impregnated Graphite Electrodes in Electrochemical Experiments

Pencil graphite electrodes (PGEs) are increasing in popularity due to their commercial availability and electrochemical characteristics in comparison to PIGEs (paraffin impregnated graphite electrodes) PIGEs are commonly used in certain applications, such as ion-transfer studies focused on modeling cellular membrane transport; however, there are disadvantages associated with them. PIGEs require purchasing graphite rods and preparing them through time-consuming fabrication steps. It is also difficult to determine if the paraffin has completely infiltrated the graphite pores. We describe the fabrication of PIGEs which are then tested using electrochemical techniques, namely SWV (square wave voltammetry) and CV (cyclic voltammetry) in solutions of potassium bromide, chloride, iodide, and ferricyanide. Contact angle and microscopic analysis were also performed on the PIGEs to confirm paraffin impregnation. The electrochemical data was then compared to SWV and CV data using PGEs to determine their utility in electrochemical experimentation. Initial results indicate that PGEs are electrochemically similar to PIGEs and can offer a cheaper alternative for electrochemical experiments. However, in some experiments, unexplained peaks in the analysis indicate possible electrode contamination. Further testing of leaching from PGEs and scanning electron microscopy imaging could help determine the cause of these unexplained results.

Abstract Name: The Evolution of the Mexican Healthcare System: Exclusion and Inequities

In the 1917 Mexican Constitution, Article 123 Section Number 14, health became an occupational right in which the employer paid for sickness and injuries, a right advocated in the Mexican Revolution. Despite this, it was not until 1943, with the creation of Instituto Mexicano del Seguro Social (Mexican Social Security Institute), that it became a reality. Following the creation of social security, other programs were established for federal workers (Institute for Social Security and Services for State Workers), oil workers (Mexican Petroleum Company), and the armed forces (Ministry of National Defense and Secretariat of the Navy). Even then, the new healthcare system was not for everyone, generally leaving out informal laborers. There were varying degrees of quality and access to healthcare within subsystems. In 1983, a more meaningful attempt was realized to include everyone and provide healthcare access for all Mexicans. A 1983 amendment to Article 4 of the Constitution added that "Every person has the right to health protection. The law will define the ways and means for access to health services and will establish the concurrence of the Federation and the federated entities in matters of public health…" This led to subsequent healthcare reforms in the hope of a quality, equitable, and efficient universal health system in Mexico. The reforms attempted to unite and improve the health sectors, such as the Sistema Nacional de Salud (National Health System), the Programa de Reforma del Sector Salud (Health Sector Reform Program), and Seguro Popular (Popular Insurance), but many increased divisiveness and inequality. By piecing together this long history of reform, this paper analyzes the overall strategy and effectiveness of the Mexican Healthcare System, specifically focusing on the more contemporary reforms from 1983 to 2003; ultimately concluding that the Mexican healthcare system remains divided and inefficient.

Abstract Name: Nutrition Literacy and the Consumption of Unhealthy Fats & Sugar-Sweetened Beverages Among University Students in the UAE.

The drastic increase in ultra-processed food and sugar-sweetened beverage (SSB) consumption is one of the greatest factors contributing to a global epidemic of non- communicable diseases and obesity. With the rising prevalence of obesity in the United Arab Emirates (UAE), nutrition education is one of the few strategies to bring about the lifestyle change among the youth. However, conflicting results exist in the literature on whether nutrition literacy leads to improved dietary behavior. As such, this study aimed to examine the association of nutrition literacy with the consumption of unhealthy fats and sugar-sweetened beverages among university students in the UAE. A cross-sectional study design with self-administered questionnaire was conducted on a sample of 409 university students in the UAE, aged between 18 to 30 years old, using a convenience and snowball sampling strategy. The mean nutrition literacy score of participants was found to be 37.8 ± 8 out of 55. There was no difference in nutrition literacy based on gender, BMI, emirate of residence, employment, monthly income, and degree level. However, marital status, nationality, age, and ethnicity were associated with nutrition literacy. The findings showed that higher nutrition literacy is associated with less percentage intake of fat ($p=0.004$), but daily cholesterol intake ($p=0.174$) and consumption of SSB ($p=0.058$) were not significantly associated with nutrition literacy. The findings suggest

that students translated their nutrition literacy in terms of reducing their total fat intake, but there was a gap between nutrition literacy and the consumption of sugar-sweetened beverages and daily cholesterol. This magnifies the importance of nutrition literacy in promoting healthy eating habits, while also underscoring the fact that more awareness campaigns or interventions regarding sugar-sweetened beverages are required. Further should examine the effective intervention strategies that reduce the intake of SSBs among college students with a representative sample.

Abstract Name: Erasing or Creating History: The Causes of Confederate Statue Removal

During the global protests that followed the killing of George Floyd by Minneapolis police on May 25th, 2020, protesters vandalized and tore down statues and monuments. Local governments and private organizations removed nearly a hundred Confederate Statues in 2020. There were over 700 Confederate statues and monuments in the old Confederate areas of the US at the end of 2021. With many Confederate statues still erected in public, one can wonder why some Confederate statues get torn down by protesters and governments while others remain. What determines which statues stay in the public eye versus those removed? In a set of case studies comparing twelve Confederate statutes, this paper explores whether high levels of conservative ideology led to statue retention and whether public prominence led to statue removal. The research was conducted by exploring secondary sources, including records of the statues' origins, newspapers, and voting records. The study of six removals and six retentions shows that the removal of a Confederate statue depends on the level of support for the democratic party in recent elections and high public awareness of the figure represented in the statue. Retained statues are regarded as local heroes without public prominence and are located in highly conservative counties. This preliminary study opens up the opportunity for a more systematic study in the future, discussing a trend of systemic injustice and the destruction of controversial art.

Abstract Name: Erasing or Creating History: Mapping Controversial Statue Removal

This study undertakes the comprehensive task of mapping and scrutinizing the removal of controversial statues across the United States. Its primary objective is to discern potential linkages between the elimination of these statues and anti-racist movements. The research methodology involves the meticulous compilation of a dataset encompassing statues removed between 2000-2023. This dataset covers details including geographical location, removal date, cited reasons, and any associated protests or activist efforts. Through a systematic analysis of patterns and trends within this dataset, the study aims to unearth correlations and potential causative associations between statue removals and the evolution of anti-racist movements. The

discoveries from this research endeavor are poised to yield profound insights into the intricate societal dynamics surrounding the elimination of controversial statues. Furthermore, it will illuminate the role played by anti-racist activism in influencing public discourse and the formulation of policies on historical representation. By shedding light on these intersections, this study contributes significantly to comprehending how historical symbols are contested, negotiated, and redefined in contemporary American society.It is important to note that despite exhaustive efforts, some instances of statue removals may not have been documented or accessible through online sources, and time constraints have limited the number of statues found. Additionally, the dataset is living and will continue to be updated as time passes but will not show in these results.

Abstract Name: Electromyographic Signal Processing in the Development of a Novel Bionic Rehabilitative Device

The development of a novel bionic device, the Biochair, addresses the significant societal challenge posed by rehabilitation for conditions like Osteoarthritis and post-stroke impairments, which affect millions in the United States. Traditional rehabilitative solutions, such as physiotherapy and robotics, often face limitations due to high costs and time constraints. The Biochair emerges as a cost-effective, efficient, and patient-controlled solution for rehabilitation exercises. It features two adaptable leg-holding support plates, controlled by an integrated system comprising an Arduino microcontroller, motor drivers, and stepper motors. These sensors are placed on the patient's quadricep muscle and are critical for detecting the minute electrical activities of skeletal muscles, which are then amplified and filtered to guide the device's movements. The amplification process is engineered to boost signal strength without introducing noise, utilizing high-precision amplifiers which is crucial in maintaining the fidelity of the EMG signals for accurate interpretation. The filtration of these signals is equally important, involving sophisticated band-pass filters that isolate relevant muscle activity frequencies from background noise. The EMG sensors, operating within a frequency range of 20 to 450 Hz and with a sensitivity threshold of 10 to 500 μV, are pivotal in detecting the subtle electrical activities of skeletal muscles. This integration of advanced EMG sensors and tailored signal processing techniques has resulted in a successful initiation of the system, with the chair demonstrating expected operation. The movement of the leg from a vertical (0 degrees) to a horizontal position (70 degrees) is effectively facilitated by the Biochair. The Biochair not only enhances the efficacy of rehabilitation exercises but also holds the promise of making rehabilitative care more accessible and user-friendly. Its development represents a significant advancement in assistive bionic technology, offering a novel solution that could benefit millions with mobility impairments.

Abstract Name: A Cross-Regional Machine Learning Study to Enhance Predictive Accuracy in Forest Fire Analysis

Forest fires pose a significant environmental challenge globally, leading to substantial loss of wildlife and millions of acres of forest cover and wildlife loss. This study presents a comprehensive machine-learning analysis of forest fire factors in two distinct geographical locations, Algeria and Portugal. The data, sourced from the UC Irvine dataset repository, encompass several critical features contributing to forest fire risks. The study's methodology involves an in-depth examination of data spanning with key variables including temperature, relative humidity, wind speed, rainfall, and various indices from the Fire Weather Index. The analysis was conducted separately on datasets from Algeria and Portugal. The machine learning models selected, Snap Boosting Machine and XGB Classifier, achieved an impressive accuracy of approximately 99% for the Algerian dataset. In contrast, the model's performance on the Portuguese dataset was notably lower, with an accuracy of around 60%. This discrepancy could be attributed to the skewed distribution of the output variable towards 'no fire' cases in the Portuguese dataset. To enhance the robustness of the findings, the two datasets were merged, resulting in a combined dataset with similar and balanced features. The combination of data led to a significant improvement, with the accuracy of the predictive model increasing to approximately 71%. Notably, variables such as temperature and relative humidity emerged as prominent factors(100% and 45%, respectively) in determining fire likelihood. To further assess the impact of combining the datasets, a comparative analysis of the ROC Curves before and after the merge of the dataset was conducted. In conclusion, this study sheds light on the critical factors influencing forest fires in different geographical contexts and demonstrates the efficacy of combining datasets to improve machine learning model performance. The findings have significant implications for predictive modeling in environmental studies in the context of forest fire risk assessment.

Abstract Name: Implementing Image Processing Tools to Control Plasma Jet Scanning Trajectories Over Wounds

The acceleration of wound healing relies on the utilization of reactive oxygen and nitrogen radicals (RONS), which can be supplied by exposing the wound surface to an impinging DBD plasma jet. In order to scan wounds, a 2D traversing system housing a DBD plasma jet operating at voltages 5-10 kV (10-40 kHz) was developed. In the current study, we optimized the operation of the traversing system by precisely controlling its scanning area, focusing exclusively on a wound image. To achieve this, MATLAB libraries were employed to image the wound surfaces and demarcate the wound boundaries using a rectangular box. An image processing program was developed and offered the flexibility of automated boundary setting or manual control using a cursor to mark the final boundaries. Subsequently, the coordinates of the rectangle were transferred to the 2D traversing system software to guide the plasma jet to the targeted wound area. Images at various stages of healing, displaying distinct color contrasts between normal skin and the wound, were utilized. The programming steps included reading the image, converting it into RGB color space, creating a binary mask for red pixels, and determining the maximum and minimum row and column indices of the red pixels. The boundary box was then overlaid, and the size and orientation of the box were adjusted to fully cover the image. Within the marked wound area, a zigzag path pattern was generated to ensure comprehensive scanning by the plasma jet. Finally, the coordinates of the box were determined and relayed to the microprocessor controlling software to accurately position the plasma jet over the targeted wound area.

The details of the image processing and 2D control of the traversing system, along with a video, will be presented.

Abstract Name: "Examining the Impact of Historical Legacies on Contemporary Anti-Americanism in Latin America"

The Latin American region is often cited as a prime example of historically rooted and deeply embedded opposition to the United States. In theory, the extensive record of American foreign policy interference and the suppression of state sovereignty provided grounds for historical legacies tied to these events to ingrain themselves in national culture. There is a rational assumption that is frequently made that individuals who witnessed American intervention first-hand could be marked by these experiences. This thesis aims to explore whether historical legacies are indeed a significant predictor of negative evaluations of the U.S. By exploiting cross-country variation in the years and types of cases of American meddling, this study tests the empirical significance of the relationship between legacy effects and anti-Americanism at the individual level of analysis. Based on the existing literature, we would expect those who received more exposure to intervention to express stronger anti-American attitudes. To quantify the potential effects, ordered logistical regression analyses are conducted at both the regional and country level using data from Berger et al. (2015) on cases of CIA intervention and public opinion data from the 2020 Latinobarometer survey. Interestingly, the results show that exposure to intervention is a significant predictor of anti-Americanism, but not in the expected direction. The analyses in this study indicate that individuals with less exposure tend to rate the U.S. more unfavorably than individuals with more exposure. Subset analyses and results are further discussed.

Abstract Name: Mantled howler monkeys modify activity and spatial cohesion in response to seasonality

Climate change shifts seasonality, increasing the length of dry seasons across various habitat types which decreases precipitation, consequently impacting wildlife who rely on stable seasonal patterns. Howler monkeys in tropical rainforests rely on consistent seasonality for food. We investigated mantled howler monkeys' response to seasonality at La Selva Research Station, Costa Rica by comparing their activity and spatial cohesion across seasons. We predicted that howler monkeys would rest more, feed less, and locomote less during the wet season compared to the dry season, due to increased nutritional resources. We also predicted they would be more spatially cohesive during the wet season as greater food availability precludes the need to spread apart to obtain resources. We collected data on howler monkey activity and spatial cohesion at La Selva using instantaneous focal sampling during the dry season (November 2018-February 2019: 225 hours of behavioral data) and the wet season (May-June 2022 and 2023: 376 hours). As expected, monkeys spent significantly more time feeding in the dry season (14.1%) than the wet season (7.9%), although they spent more time locomoting in the wet season (6.3%) than the dry season (4.8%). As predicted, the mean distance between nearest neighbors was higher in the dry season (2.8m) than the wet season (2.5m). These results suggest that lower nutritional yields of dry seasons require increased feeding to meet energy requirements while high yields of the wet season allow energy expenditure on locomotion to search for preferred foods. The wet season's resource abundance allows howler monkeys to be more spatially cohesive due to the decrease in competition for resources. Since many primate species rely on stable seasonality, these results suggest that primates across the tropics will likely need to modify their activity and spatial cohesion patterns as climate change continues to increase the length of dry seasons.

Abstract Name: An Overview of the Main Components Implemented in Effective Teacher Professional Development Programs for Computer Science Educators

Recent research findings concerning the rates of different demographics' enrollment in higher education STEM programs suggest there continues to be a prevalence of Latinx underrepresentation, specifically in Computer Science. Therefore, as an attempt to locally tackle the low rates of Latinx college enrollment in the field of Computer Science, the CS4SA (Computer Science for San Antonio) teacher professional development (PD) program was developed. CS4SA is intended for in-service secondary teachers interested in

becoming certified to teach Computer Science and develop initiatives that will prompt their respective students to become interested in CS with the aim of increasing Latinx college enrollment among a large, urban, predominantly Latinx public school district in South Texas. Moreover, the program prepares teacher participants to become advocates for and leaders of CS education through an intensive year-long Programming and Culturally Responsive Teaching (CRT) Bootcamp with an emphasis on computer programming fundamentals using the Java programming language. This literature review focuses on the program's approach towards implementing effective teacher PD which was achieved through seven main components: content focused material implemented throughout the program, incorporation of active learning, support for collaboration, use of models of effective practice, coaching and expert support for teacher participants, offering of feedback and reflection forums, and sustained duration. These components were most commonly noted across several report findings regarding effective teacher PD for Computer Science educators and were all incorporated into the CS4SA program. This literature review provides an overview of the program's implementation of effective teacher professional development and highlights how the program aided teacher participants in embracing CRT as well as shifting their teaching styles based on the learnings achieved throughout the program's duration. The findings of this literature review are expected to be discussed among the CS4SA team to further efficiently develop the program's structure for potential future cohorts.

Abstract Name: "Interrogating Whiteness in The Handmaid's Tale Franchise"

Margaret Atwood's 1985 novel The Handmaid's Tale depicts a future where the US government has been overthrown by a militarized totalitarian theocracy and the fertility of women is treated as capital. Atwood's novel is typical in that a white worldview masquerades as the universal human perspective. Calling attention to this aspect of Atwood's narratives denaturalizes the way white racial experience remains unracialized. This project contemplates the absence of non-white characters in The Handmaid's Tale. The treatment of women's fertility as capital was a cornerstone of American slavery, resultantly, in the Black female experience. Hulu adapted the novel into a television series in 2017 with a multiracial cast. However, the diversity remained cosmetic as the issue is that it casts people of color without including the racial implications involved in these instances. Toni Morrison's theory of American-Africanism critiques this action of white authors removing Blackness and/or the Black essence from events to universalize these events. Atwood continued this dystopian storyline in her 2019 novel, The Testaments, including Hulu's newly raced characters, with the same result. Analyzing the characterization of women in the franchise, I consider how the creation of dystopian/utopian worlds relies on the selectivity of racial representation to reinforce the white literary canon. My analysis contends that neither the Hulu adaptation's multiracial casting, nor Atwood's appropriation of racial diversity, displaces the white dystopia of her 1985 novel. "Interrogating Whiteness" will investigate the literary and cultural mechanisms by which whiteness persists as the dominant standard of aesthetic imagination. Examining The Handmaid's Tale as a literary, televisual, and cultural spectacle argues that the structure of white futurism resists genuinely inclusive discourses.

Abstract Name: From Fear to Safety: Unveiling the Safety Dilemma in Schools and the Quest for Solutions

In recent years, a growing number of students have grappled with feelings of insecurity in schools, facing challenges such as mental health issues, school shootings, and bullying. This surge in problems, particularly the increasing frequency of school shootings, has heightened concerns, generating a pervasive fear that has transformed the school experience into an apprehensive ordeal. Notably, 28 states, including Texas, permit teachers or school staff to carry firearms, adding a layer of complexity to the issue. Shockingly, guns have emerged as the leading cause of death for children in America since 2020, claiming the lives of 4,300 children in that year alone.This alarming situation prompts essential inquiries into the evolution of school safety measures over time, the effectiveness of 21st-century interventions in reducing violence, bullying, and cyber threats, and the existing gaps that urgently require attention. Our investigation focuses on key themes: cyberbullying, mental health in schools, and gun violence in schools. By scrutinizing these critical aspects, we aim to provide insights into the current state of school safety, evaluating the effectiveness of existing measures and identifying areas that demand targeted interventions. As students navigate an increasingly complex and challenging educational landscape, understanding and addressing these issues are paramount for fostering a secure and conducive learning environment.

Abstract Name: Developing an Optimized Clean-up Method and Contaminant Assay for Mass Spectrometry-based Proteomics

During proteomic studies, the build-up of detergent contaminants has been known to damage LC-MS (liquid chromatography-mass spectrometry) systems by washing away LC packing materials and contaminating MS instruments with polymers that are difficult to remove. These contaminants have been shown to reduce data quality as samples contaminated with sodium dodecyl sulfate (SDS), a detergent commonly used in cell lysis to extract proteins, showed a decrease in the quantity of peptides identified as well as retention time shifts during LC-MS analysis. Existing methods of testing for SDS and similar detergents include the ProFoldin NanoGram SDS Assay Kit and the Hayashi test, however, these techniques had relatively high limits of detection and required a large sample input. Due to these limitations, a new contaminant testing method, ContamSPOT, was developed that had higher sensitivity, used practical amounts of sample, and gave rapid results. This method was also shown to be simple, inexpensive, and able to flag multiple contaminants common in proteomics. The lower limit of detection for SDS was determined to be 0.0004% using ContamSPOT, a significant improvement compared to the 0.002% advertised sensitivity of the ProFoldin NanoGram SDS Assay Kit. ContamSPOT was further applied to quantitatively compare contaminant

removal of established sample clean-up methods, specifically SP2 (single-pot, solid-phase-enhanced sample preparation) and trap resins, previously observed to cause significant sample loss and ineffectively remove contaminants, respectively, to liquid-liquid extraction (LLE) with ethyl acetate, a proposed method of SDS removal. LLE via ethyl acetate was found to be a greener, less expensive, and more effective method of removing SDS from contaminated samples compared to SP2 and trap resins, as LLE removed 99% of 0.1% SDS while recovering 93% of peptides.

Abstract Name: Celebrating and Embracing Small-Town Americana: Taking a Step Away from Urban America

In a world increasingly affected by urban sprawl and industrialization, this artistic project delves into the celebration and encapsulation of the Small-Town Americana through eight landscape paintings in the Buffalo and Mohawk Valley Region. Done in oil paint in the Plein Air technique, each artwork strives to capture and highlight the authenticity and charm of these towns in hopes of striking nostalgia and mood within viewers. Four of the eight paintings were done at various historical locations in Buffalo, New York, like The Canalside, Riverworks, The Cobblestone District, and Glen Park. The remaining four were done in various towns and villages in the Mohawk Valley Region, like Herkimer, Schuyler, and Clinton. All of the paintings were completed through the method and process of plein air painting, the act of painting outside where the subject matter is in full view. Plein air painting implies site and time specific. This technique requires artists to work quickly and efficiently to capture the changing light, colors, and atmosphere of their surroundings. It is arguably the best way to capture a scenery for what it truly is in that moment. Inspirations and references for this project were taken from the American painters, Edward Hopper, George Inness, and Fairfield Porter. All three painted either rural or urban landscapes with great use of composition, mood, and atmosphere. Although Buffalo is deemed more urban compared to the counties in Mohawk Valley, numerous similarities are present when comparing the two. This series of landscape paintings not only celebrates the visual beauty of a small town, but also serves as documentation of the town's history, spirit, and community. As an artist who focuses on painting figures, this project allowed me to enhance my landscape skills, therefore making it beneficial for a professional portfolio.

Abstract Name: Exploring Peer Role Models' Influence on First-Generation College Students' Academic Success.

Over the past decade, undergraduate enrollment in U.S. post-secondary institutions declined by 15%.

Diverse, underrepresented student populations now exhibit greater enrollment in U.S. universities, prominently including Black, Latinx, and Asian individuals, along with a rising number of first-generation college students. Despite this, disparities persist in graduation rates between BIPOC and first-generation students compared to their White and continuing-generational student counterparts. Studies reveal that first-generation students face distinct challenges in transitioning from high school to college, compounded by socio-economic, ethnic, and identity-related factors. These difficulties contribute to a 23.5% overall dropout rate, significantly higher than continuing-generation students. Factors such as race, gender, and income intertwine with decreased persistence among first-generation students at 4-year institutions. While sociodemographic traits partly explain this disparity, they only account for a fraction of the issue compared to students with college-educated parents. This research aims to investigate the influence of peer role models on the academic success of first-generation college students. Understanding these dynamics, including the influences of nonparental role models, grit, self-efficacy, and academic motivation, is crucial in retaining and supporting this student retention within higher education. This study's focus on nonparental role models aims to shed light on an underexplored area of influence. By examining how nonparental role models relationships impact academic outcomes, this research seeks to offer insights into strategies that can support the success and retention of first-generation students, addressing disparities and fostering inclusive higher education environments. Keywords: first-generation college students, non-parental role models, college retention, grit, academic motivation, academic self-efficacy.

Abstract Name: Sunlight Photolysis of Nitrate in the Presence of Iron-Bound Organic Matter

In the Raff laboratory, one of our main focuses is atmospheric chemistry regarding air pollution. Two key pollutants are nitrogen dioxide (NO2) and ozone (O3), which constitute a huge majority of all air pollutants in our atmosphere. The rationale behind investigating these particular pollutants is due to the wide range of respiratory related illnesses associated with prolonged exposure to poor air quality, which can also result in death. Globally, over 99% of the world population inhabits areas that have high exposure to diminished air quality (World Health Organization). Although air pollution has been heavily researched for many years, nitrous acid (HONO) is another key contributing pollutant that is incompletely understood. For this reason, we conducted a study that explores the sources and mechanisms of HONO. Our hypothesis is that HONO production is enhanced when nitrate photolysis occurs in the vicinity of catechol and oxalate with iron.

Abstract Name: Do Demographic Characteristics Predict Creativity? An Exploration of the Relation between Creativity and Gender, Sexual Orientation, and Religion

The current study investigates the relation between creativity and demographic characteristics. Methodologically, we gathered survey-based data from a sample of 103 undergraduates from a large university in Southern California. These participants were asked to respond to a creativity question where they needed to write a short, original story, and also were asked to report their demographic characteristics, including gender, sexual orientation, and religion. A group of subject matter experts evaluated the short stories for creativity using a 1-5 scale; at least two subject matter experts evaluated each story. Results indicate that contrary to our hypothesis, there was no significant correlation between creativity and demographic variables. When interpreting the absence of a significant correlation between creativity and demographic characteristics, it is important to acknowledge the limitations inherent in this study. Implications and future directions will also be discussed.

Abstract Name: Role of FGF2 mRNA 5′ UTR in cap-independent translation initiation

The FGF2 gene encodes the basic fibroblast growth factor which controls cellular growth, proliferation, and cell signaling. Under normal conditions, FGF2 mRNA is translated via cap-dependent translation. However, under certain stress conditions, an internal ribosomal entry site (IRES) reportedly bypasses typical regulation switching to cap-independent translation. Cancer cells overexpress FGF2 ultimately leading to tumor growth. Mechanistically, the reported switch from cap-dependent to cap-independent translation remains poorly described. In order to understand the regulation of the FGF2 IRES under cellular stress conditions, we investigate the secondary structure using the SHAPE-MaP chemical probing strategy under different chemically-induced stress factors. Here we describe our experimental strategy and present a secondary structure model of the FGF2 mRNA 5′ UTR built using gently extracted total RNA from the A549 human lung carcinoma cell line. We observe a complex arrangement of nucleotides throughout the targeted region (nucleotides 2-426). We compare the cell-free SHAPE reactivity profile with reactivity data from live cells using reagents 5NIA. Prior studies show that FGF2 uses four upstream CUG start codons which are activated in transformed and stressed cells. We present our initial reports on stress-induced cells, where we compare SHAPE profiles to identify the effect of stresses such as hypoxia, nutrient starvation, and heat shock. We aim to elucidate structural mechanisms corresponding to the effects of stress on FGF2 translation control. Lastly, we describe a workflow for future experiments involving DMS-MaP, a strategy for direct nucleotide base-pairing analysis, and RNP-MaP, an RNA-protein interactomics strategy to study the influence of IRES-transacting factors under stress conditions.

Abstract Name: Short-Term Effects of a Prescribed Burn on the Soil Bacterial Microbiome in an Area Under Restoration for the Longleaf Pine

The longleaf pine (Pinus palustris Mill.) is a pyrophytic conifer that fronts one of the more endangered ecosystems within the Southeastern United States. This ecosystem is dominated by a matrix of herbaceous grasses and forbs in which pine trees are embedded, and which serve as propellants for fire, a necessary component and natural regulator for the ecosystem. While there is extensive knowledge on the importance of fire within the longleaf pine ecosystem, not much is known about the impacts of fire on the soil microbiome associated within this ecosystem. This study aims to investigate the immediate and short-term effects of a prescribed burn on the bacterial soil microbiome of a restoration area for the longleaf pine, located in the Piedmont region of Georgia. Soil samples from Paulding Forest Wildlife Management Area were collected from randomized plots before and after a prescribed burn (one day after, one week after, three weeks after, and two months after the burn) in spring of 2023. DNA was then extracted from samples using commercially available kits and concentrations of DNA extracted from soil were quantified using a Nanodrop spectrophotometer. DNA samples were sent to a commercial lab for the identification of bacteria. Pre-burn results indicate that Actinobacteria, Acidobacteria, and Proteobacteria dominate the soil microbiome. We predict there will be a noticeable difference in bacterial richness and a shift within the composition of the community of bacterial families within these phyla depending on the time since the burn. These analyses provide a connection between the soil bacterial microbiome of the longleaf pine and ecological succession after fire. This study is part of a longer-term study of the longleaf pine and its soil microbiome concentrating on the relationship between the different bacterial taxa, the above ground dominant herbaceous species, and environmental factors.

Abstract Name: Social and Ecological Determinants of Antimicrobial Resistance in Africa: A Systematic Synthesis of Epidemiological Evidences

BackgroundAntimicrobial Resistance (AMR) is one of the greatest global health problems posing a threat to human, animal, and environmental health alike. While the association between various factors and AMR is being increasingly researched, there is a substantial lack of understanding of the social and ecological determinants in developing nations. This review fills these knowledge gaps by synthesizing existing evidence

on the social and ecological determinants of AMR within the African population.ResultsTwenty-four studies were selected based on predefined criteria from PubMed. 54.16% (n=13) and 20.8% (n=5) of the studies reported on ecological and social determinants of AMR, respectively. Six (25%) studies documented both social and environmental determinants of antimicrobial resistance (AMR).The most commonly reported ecological determinants of AMR included water source contamination by drug-resistant bacteria either through irrigation systems for agriculture, storage for cooking, or farming practices. Of the social determinants analyzed, education level, individual knowledge, attitudes, and practices toward AMR, and community size were most closely associated. ConclusionOur review demonstrates the importance of social and ecological determinants of AMR among the African population. The findings reported in this review may be valuable to researchers, policymakers, clinicians, and those working in low-income countries to implement AMR prevention programs through a holistic approach.

Abstract Name: Non-Traditional Recumbent Tricycle Steering

This research focuses on developing a steering system for recumbent tricycles, specifically designed to improve accessibility for individuals with limited upper body mobility. The study evaluates various sensors to effectively translate human motion into precise steering control. A touch sensor, characterized by its 10° interval precision, was identified as the most efficient, providing quick response and high accuracy, while avoiding issues such as overshooting or settling time. This is in contrast to the joystick, which demonstrated excessive sensitivity and lower precision. The integration of mechanical engineering and computer science in this research presents significant implications for recreational therapy and accessibility. It offers innovative solutions that not only enhance the functionality of recumbent tricycles but also contribute to the broader field of assistive technology. The findings of this study can be used as a starting point in advancing the design of accessible recreational vehicles, emphasizing the need for multidisciplinary approaches to address mobility challenges and improve the quality of life for individuals with physical limitations. This research highlights the potential of adaptive technologies in creating inclusive environments and empowering individuals through improved access to recreational activities.

Abstract Name: Reimagining College Support: A Critical Exploration of the Impact of Grief and Loss on the

Experiences of International College Students

International student attrition is a rising concern in higher education given the various challenges that have arisen over the past couple of years (Donohue et.al, 2021). The onset of the COVID-19 pandemic, the racial justice movements, and the current social-political climate have significantly impacted our college students like never before (Borgstrom & Mallon, 2022). Of growing concern is the rising mental health crisis that is sweeping through higher education which deserves an urgent response, especially for international students navigating unfamiliar academic and cultural terrains (Lee et al., 2021). International students are currently facing dire financial constraints, food and housing insecurity, and many other challenges that further complicate their college experiences (Duke et al., 2021). For international students, their college transitions are considerably different from traditional students. Specifically, international students' college transitions are muddied by their various high school experiences in other countries, assimilation difficulties, and living sometimes hundreds of miles away from home. Further, the grief, loss, and trauma experienced by international college students during the pandemic warrant special attention as we contemplate the resources and support required for their successful matriculation and degree completion (Sirrine et al., 2021). The lingering remnants of grief and trauma from the pandemic continue to impact the college experiences of international students and their ability to successfully navigate their academic and professional goals. Hence, through this qualitative study, our research explores the lived experiences of international college students. Specifically, our research question investigates the extent to which grief and trauma resulting from COVID-19 have influenced the educational journeys of international students. The goal of this research is to provide an opportunity to explore and identify strategies for better supporting international students as they navigate the complexities of their academic journey, fostering an inclusive and nurturing environment that promotes their academic and personal growth.

Abstract Name: LASIK EYE SURGERY AND MENTAL HEALTH

Laser-Assisted in Situ Keratomileusis (LASIK) surgery is a widely performed refractive procedure aimed at correcting vision problems by reshaping the cornea, thereby improving light refraction onto the retina. Few studies have examined the potential relationship between LASIK eye surgery and patient suicide as pain post-surgery can lead to major depressive disorder (MDD) in patients in the United States. Although LASIK surgery is effective, there are certain potential side effects to be aware of, namely dry eye syndrome and neuropathic corneal pain. Individuals who undergo LASIK refractive eye surgery experience persistent ocular pain, potentially linked to neuropathic mechanisms, which may contribute to extended discomfort in some patients, that may lead to preoperative depression. According to American Academy of Ophthalmology they highlight that roughly 30% of LASIK patients experience dry eye symptoms post-surgery, peaking around three months and typically subsiding within a year. This literature review analyzes several studies evaluating contrast sensitivity changes post-LASIK using the CVS-1000E unit, Hospital Anxiety and Depression Scale (HADS) for emotional states, and Neuropathic Pain Symptom Inventory Modified for the Eye (NPSI-Eye) to assess ocular pain. These implications are crucial for both patients and healthcare professionals, mainly ophthalmologists to make an informed decision for individuals considering LASIK eye surgery. Patients should be aware of potential risks and how they may affect their mental health after the procedure. This study aims to investigate the possible link between major depressive disorder (MDD) and post-LASIK side effects such dry eye and neuropathic discomfort.

Abstract Name: Intersectional Influences of Experienced Stigma on U.S. Sex Workers

Sex work is a stigmatized occupation, as sex workers challenge societal and moral norms. Based on intersectional theory, we conceptualized sex work stigma (SWS) as shaped and exacerbated by overlapping marginalized identities. Thus, the first objective was to explore the consistency of experienced SWS across gender and sexual experience. Additionally, research indicates that there are four domains in which SWS originates: community, law enforcement, healthcare, and family. Although SWS varies across these domains, little is known about how gender and sexual experience impact each domain. Therefore, the second objective was to explore gender and sexual experience differences across each domain of SWS.A total of 494 U.S. sex workers completed the four-factor Sex Work Experienced Stigma Scale and a demographics questionnaire assessing gender and sexual experience. Results revealed a significant multivariate effect of sexual experience, such that those with any amount of same-sex experience reported greater SWS than did those with exclusively other-sex experience. In the healthcare subscale, men reported experiencing significantly more stigma than did women. Additionally, the interaction between gender and sexual experience was significant for the law enforcement subscale, such that men with same-sex experience reported greater stigma than did women with same-sex experience. No gender differences were identified among those with only other-sex experience.These findings indicate that sexual experience has a greater impact on experienced SWS among U.S. sex workers than gender, suggesting that when compounded with the stigmatized trait of engaging in sex work, sexual experience carries more weight than gender. Additionally, in the healthcare and law enforcement domains, multiple stigmatized identities resulted in heightened experiences of SWS, suggesting that those in positions of authority may treat sex workers differently based on intersectional identities. Implications for sex workers' well-being and avenues for healthcare and law enforcement sensitivity training will be discussed.

Abstract Name: Word Learning and Relational Reasoning in Typically-Developing Children and those with Autism Spectrum Disorder

The shape bias is a well-studied word-learning mechanism that young children use to extend novel labels to objects of the same shape, and children who develop this bias are able to learn object names more effectively during their first years of language development. Previous research has suggested that children with Autism Spectrum Disorder (ASD) do not develop a robust shape bias (Tovar et al., 2019) and that children with ASD may not depend on shape for word learning (Potrzeba et al., 2015). Other work has drawn connections

between word learning and more general reasoning abilities (Hoyos et al., 2016), but this link has not been investigated in a neurodivergent context. Here, we seek to (1) further document differences in shape bias between typically-developing children and children with ASD; and (2) examine the relationship between shape bias and relational reasoning across children expressing a range of behaviors associated with ASD. In the present study, 4-year-olds with and without a diagnosis of ASD will complete three tasks: a Relational Match-to-Sample task and a scene analogy task used to measure relational reasoning, and an object sorting task used to measure the strength of the shape bias. The Autism Quotient is a parent questionnaire which will determine each child's number of ASD-related traits. Correlational analyses will then be conducted between ASD-related traits, degree of shape bias, and relational reasoning performance in order to gain further insight into one particular aspect of children's noun learning and its relationship with abstract reasoning.

Abstract Name: A Multiple Regression Analysis of Health Care Access in Least Developed Countries

In a world of technological advances and breakthroughs in all aspects of life, healthcare is an area that has seen some of the greatest changes in the past century. For some, accessibility has increased and the ability to attain primary and specialized care has never been easier. However, others, specifically those in developing countries, have been somewhat left behind in these advances. Availability and accessibility to health care are vital to every person's existence, no matter where they live in the world. This research aims to quantify healthcare access in lower-income countries by analyzing the number of physicians and comparing them to different socioeconomic rates for 46 of the world's Least Developed Countries (LDC). According to the United Nations Department of Economic and Social Affairs, a country is considered an LDC by the gross national income of that country, the human asset index, as well as their economic and environmental vulnerability. The data in this research is being collected from the following sources; the World Health Organization, United Nations, World Bank, and Central Intelligence Agency. The information in this research is based on several factors present in each country including average income per year, median age, number of hospital beds per thousand, neonatal mortality rate, average years of education, and life expected from birth. Using multiple and linear regression, this data is charted and analyzed to ascertain any trends that exist between the number of physicians and the factors listed above.

Abstract Name: Urbanization and Community Forestry in Nepal: Assessing Changing Forest Dynamics and Livelihoods

Rapid urbanization is significantly altering the landscape of Nepal, particularly affecting forest dynamics and community forestry (CF). This study investigates the impacts of urbanization on forest-dependent livelihoods in Nepal, emphasizing the changing socio-economic dimensions of rural populations. The increasing replacement of forest-based products, like fuelwood, with alternatives such as LPG gas, necessitates an in-depth understanding of current and evolving dependency on CF. This study will assess the extent of livelihood dependence on forests by focusing on three primary dimensions within CF: cash income from forest products' sales, LPG usage, and fodder utilization. A 'forest reliance index' will be procured based on the parameters defining livelihood dependence on forestry, the index is designed by the varying degrees of dependence on CF among rural and peri-urban communities. Data were gathered through random sampling of twelve households in the peri-urban district of Kavre and a broader random sample from rural districts of Pyuthan and Salyan. Factors including district population size, travel distance between urban center and the Community Forestry User Groups (CFUGs), and population density will be analyzed to refine the forest reliance tool. Moreover, values and income households obtained from community forests are tested for systematic variance between urbanization and market integration.Expected findings from this study will be instrumental in future research, contributing to the assessment of environmental goods and services provision by CFUGs, understanding patterns of out-migration, land-use decisions, social capital dynamics, and the impact of external shocks like the COVID-19 pandemic. There were further insights suggesting adaptive community forestry policies, strategizing energy transitions, focusing on community capacity building, and tailoring interventions based on the unique characteristics of peri-urban and rural communities. By elucidating evolving social dimensions of CF and the associated livelihood options available to local populations, this research aims to guide the future trajectory of CF in Nepal.

Abstract Name: Copper Oxide Nanoparticles Induce DNA Damage in Endometrial Cancer Cells

Chemotherapeutic resistance across many types of cancer is one of the greatest complications to cancer therapy and results in few treatment options for patients plagued with this disease. The vital demand for innovative anti-cancer drugs and drug delivery systems arises from these issues, revealing the importance that research on anti-cancerous compounds has on effective care for patients. Endometrial cancer is the most common gynecological cancer worldwide and is commonly treated using carboplatin, a platinum-based drug. Carboplatin resistance and unequitable access to treatment for endometrial cancer patients validates the need for a non-invasive form of endometrial cancer therapy. It is proposed that copper oxide nanoparticles can be used as an alternative to carboplatin when encapsulated in a polymeric nanoparticle for use as a drug delivery system. Copper oxide nanoparticles pose the potential as an anti-neoplastic compound due to Cu2+ ions demonstrating the ability to induce reactive oxygen species leading to double stranded DNA breaks ultimately resulting in apoptosis. Through viability assays, endometrial cell lines all showed sensitivity to copper oxide nanoparticles; however, trends were not identified across all cell lines that were tested. Using this information, Western Blot analysis was used to identify specific expression levels of apoptotic proteins, DNA repair proteins, and protein markers when DNA is damaged. Western Blots involved the treatment of cells in 24-well plates with varying concentrations of copper oxide nanoparticles for 24 hours. Gel electrophoresis separates proteins and primary antibody complexes. The differences in the expression levels

of these proteins after cells are exposed to copper oxide nanoparticles can indicate the mechanism of toxicity within the different cell lines, ultimately explaining the differences in viability.

Abstract Name: Comparing Inhibitory Control: Emotional vs. Neutral Stop Signal Tasks

Response inhibition (RI; the ability to stop an unwanted ongoing response) has historically been studied utilizing only non-emotional stimuli. Current literature needs a direct comparison of RI using emotional vs. neutral stimuli. To better understand how RI is affected by emotionally charged, real-world conditions, compared to dry, neutral conditions we are implementing the traditional Stop Signal Task (SST; standard tool of RI assessment) along with an Emotional Stop Signal Task (ESST; modified version of the SST). In an online study, 250 participants will complete self-report measures of experienced symptoms relating to several psychological disorders and complete three Stop Signal Tasks: utilizing neutral stimuli (neutral face), utilizing emotional stimuli (angry face) of the same modality and context as the neutral face task, and a control task utilizing neutral stimuli (upward arrow). We expect to find a significant increase in stop signal reaction times (SSRT; the primary index of RI deficit in the SST and ESST) in the emotional condition, indicating more pronounced difficulty in RI. Error commission and omission rates thus far have been higher than expected overall, but more so with the emotional task than neutral, further indicating decreased inhibition ability in the emotional condition. We hypothesize a decrease in RI with participants reporting experiencing clinical symptoms compared to those reporting no symptoms, demonstrating larger deficits in RI when symptoms are greater in number and/or severity. These results would suggest that much of the previous work on RI using only the neutral SST, although in-depth and informative, can shed limited light on the true experience of people's inhibition abilities in the real world.

Abstract Name: Attention Networks and Attention Bias in Social Anxiety Disorder

Attention bias (AB) toward threat has been studied as a primary cognitive process underlying social anxiety disorder (SAD) with mixed results. Recent research suggests that AB is dynamic and fluctuating rather than static and stable, and the concept of attention bias variability has been proposed (ABV; Naim et al., 2015; Zvielli et al., 2015). Little is known about the relationship between attention networks and ABV in SAD.

This study aimed to examine the relationship between attention networks, AB, ABV, and SA symptoms. The 89 participants of this study and completed three SA symptom self-report questionnaires, as well as two computerized attentional tasks: A dot-probe task indexed an AB score, and the attention network task-short version (ANT-S), computed three attention network indices (Alerting, Orienting, and Executive Control). Additionally, two types of ABV indices were calculated using Zvielli et al. (2015) and Naim et al. (2015) approaches. The AB index was positively correlated with the two of the three SA symptom measures, and marginally correlated with the Orienting component of the ANT-S. Only the Orienting component of the ANT-S was correlated with SA symptom measures. While the two ABV scores were inter-correlated, they were not significantly correlated with SA symptoms. Findings demonstrate a positive correlation between AB and SA symptoms, confirming previous research that greater attentional vigilance toward threat is related to higher levels of SA. Furthermore, the Orienting component of attention network was positively associated with SA symptoms, indicating that the cognitive ability to selectively allocate attention toward certain stimuli is relevant to SA. ABV was not linked to the severity of SA, indicating that ABV may reflect a different aspect of higher-level attention control, as compared with the AB index reflecting attentional vigilance. More research is needed to establish how ABV is associated with existing AB indices and anxiety symptoms.

Abstract Name: Epoxyketone-Based Peptide Derivatives Are Highly Selective and Potent Inhibitors of the Plasmodium falciparum Proteasome

Malaria, caused by Plasmodium species, sickens nearly 250 million people globally and leads to 619,000 deaths yearly. Of these deaths, 77 percent are children under 5 years of age. New and more efficacious agents to treat this devastating disease are urgently needed. Here, the synthesis and activity of potent and highly selective epoxyketone-based inhibitors of the malaria parasite proteasome subunit are reported. Key to two of these compounds' activity is an inverted binding model through the introduction of a D-amino acid at the P3 position and a 2,4-difluorophenylalanine-based epoxyketone warhead at the P1 position. In an effort to assess and improve inhibitor half-life and pharmacokinetic profile, P4 capping components were varied, and beta-amino acids were introduced at the P2 and P3 positions. Pharmacology, synthetic schemes, expected outcomes, biochemical and biological data, as well as future plans will be discussed.

Abstract Name: Dietary selectivity in picoplankton capture by the sponges Xestospongia muta and Niphates digitalis

Suspension feeding is an essential feeding mode in the marine benthos, with roles in the cycling of organic matter and other nutrients that helps to support high species diversity on coral reefs.The ability of sponges to efficiently remove organic matter from numerous sources in the water column contributes to their roles in nutrient cycling and dominance on Caribbean coral reefs. In this study, we examined the temporal variability and species specificity of prokaryotic picoplankton capture by two dominant sponge species in the Florida Keys. Incurrent and excurrent water were sampled from individuals of Xestospongia muta and Niphates digitalis on three nonconsecutive days, and prokaryotic community composition was evaluated using 16S metagenetics. Analysis of these communities revealed a consistent dietary “core” of taxa consumed by both species, as well as additional distinctions between each species. These results suggest that sponges may target specific taxa within the picoplankton community, providing insight into individual species’ contributions to nutrient cycling on coral reefs.

Abstract Name: The Functional Dynamics of Cohesin in Living Cells

Cohesin is a protein complex within the nucleus of eukaryotic organisms that is involved in the structural maintenance of DNA and regulating gene expression. It is highly conserved and is made up of 4 protein subunits: SMC1, SMC3, SCC1, and SCC3. Important questions remain about how these subunits are localized in living cells and how dynamic they are compared to one another. Here we seek to visualize the functional dynamics of the individual subunits of the cohesin complex within budding yeast cells. The experimental practices of PCR, Gel Electrophoresis, and Transformation are to be used in order to image live yeast cells at single-molecule resolution. The expected results of the experiment include being able to fluorescently label the subunits to track and compare their dynamics in their environment. Our findings about cohesin in budding yeast cells will further inform experiments concerning complex organisms and how their cellular activities are organized in space.

Abstract Name: Housing Design for Cataract Visual Impairment

The project aim is to create a single-family house design to provide a family member suffering from a cataract vision impairment with enhanced accessibility, comfort, and aesthetic environments. The design purposes are to make comfortable and safe living spaces and accommodate all family members' needs and necessities by considering their occupations and daily lifestyles.A Cataract is a cloudy area in the lens of the eye, which can cause blurry or dim vision, sensitivity to light and glare, difficulty seeing at night, and seeing colors as faded or yellowish. As societal perspectives evolve, there's a growing emphasis on creating environments that accommodate diverse needs. Many case studies and research findings highlight how contemporary architects and designers are rethinking traditional norms and employing cutting-edge technologies to create more inclusive house design. For instance, voice-activated devices, tactile interfaces, and spatial recognition technologies can be integrated into house designs to provide users with greater ease of navigation.Based on the research findings, the design solutions of this project are controlled lighting throughout the home, along with rolling blinds to control natural light in the house. Also, kitchen cabinetry is push to open to create a safer and practical environment, cabinet colors and wall colors are contrasting colors for facilitated visibility. Another design feature is grab bars in necessary areas such as bathroom and shower. Lastly, a large open space and symmetrical floor plan was used for easy navigation throughout the home, using a logical floor plan connecting the primary bedroom next to the primary bath, following the primary closet and lastly the laundry room.In conclusion, this single-family house is an inclusive and enhanced home for anyone with cataract vision impairment.

Abstract Name: Knowledge, Opinions, and Perceived Barriers toward Research among Undergraduate CSULA students

Background: Research can present undergraduates with valuable tools and knowledge that can be used in future settings. This study aims to assess California State University, Los Angeles (CSULA) undergraduates' knowledge, opinions, perceived barriers towards research, and reasons for their lack of involvement in research.Methods: This cross-sectional study was conducted among the undergraduate students of CSULA. The required information was obtained through a self-designed questionnaire in Qualtrics. Participants were asked to answer 15 multiple-choice and 2 matrix-style questions on their demographics, knowledge, opinions, and perceived research barriers.Results: A sample of 49 students voluntarily participated in this study. 79.6% of participants were first-generation university students coming from their immediate families. To understand students' interest, we observed that 57.1% (n=28) of participants had not participated in a research study, and 77.6% (n=38) of participants were unaware of the campus research opportunities. General knowledge of research among students varied; however, it showed potential. Most students exhibited positive attitudes toward research, with 73.5% (n=36) of participants agreeing that research is interesting and beneficial for their future and 87.8% (n=43) understanding research's value. 44.9%(n=22) consider research stressful, and 40.8 (n=20) find that the uncertainty of starting research was a commonly perceived barrier. Conclusion: Our sample of undergraduates showed positive attitudes towards research, although students were nervous about starting research and finding research stressful, which were barriers to engaging with research. Therefore, students' positive attitudes towards research can be developed into better training systems.

Abstract Name: Pasta and Politics: A Taste of Culinary Xenophobia in Italy

Italy has become a common “landing country” for many European and Asian immigrants, creating a perception of invasion that has led to cultural reactionism masked in the reinforcement of “traditional cuisine.” For so-called traditional foods to endure, they must continually be reinvented, bearing different meanings and social values throughout time and space while accumulating rich, cultural baggage that serves as a powerful marker of identity in a given society. This project explores the role of traditional cuisine in Italian national identity and pride, and the subsequent historical culinary antagonism maintained in widespread attitudes toward ethnic cuisine in Italy. Through an analysis of primary and secondary literature, complemented by qualitative field observations in the Italian cities of Perugia and Modena, several instances of culinary discrimination are discussed within the political, social, cultural, and historical complexities of preserving tradition while also accommodating diversity, highlighting an interplay between nostalgia and xenophobia that we can almost taste. Key factors such as food legislation, the tourism industry, and evolving attitudes among young generations are considered to yield a dynamic picture of the current perceptions of ethnic cuisine in Italy. Despite lingering biases, there is hope for a future of culinary coexistence and integrative celebration of non-Italian foods in Italian culture, driven by young individuals’ openness to diverse tastes and traditions.

Abstract Name: How Apple Made Computers More Accessible Through Design

The computer company, Apple, created one of the first home computers that was accessible to a wide range of people. By utilizing user-first design and embracing simplicity, Apple created a product that virtually anyone could use. Apple employee, Don Norman, argued that simple design is easier for market consumers to understand. Designers, such as Susan Kare, implemented these ideas into the design work that made Apple’s graphics so appealing. It is difficult to fully appreciate these design choices that have become so commonplace and expected in modern computers. To create context as to why Apple was such an improvement on the technologies that came before, this paper will outline the history of the computer and the evolution of its design. This history will begin with punch card and terminal computers, move onto the computer mouse created by Douglas Englebart, transition into the research facility Xerox PARC who honed these ideas, and finally end with Apple’s adoption of the technology and their own version of improvements. The computer evolved from clunky mouse adaptations and confusing GUIs into the seamless usability that people have grown to expect. By outlining the history of this experimentation, it becomes clear what a vast improvement Apple made to the computer’s usability. Apple applied graphic design principles to a product whose aesthetics had never been considered important. By making the computer less enigmatic and more visually appealing, Apple created a product that people felt comfortable using. Apple’s changes to the computer demonstrate the power of design to fundamentally change how people view and interact with a product.

Abstract Name: Demonstrating Stellar Magnitude Using Lasers and Polarizers

Stellar magnitude can often be a difficult concept to visualize, as it is a non linear scale based on human perceptions of stars. Seeking to model this in a classroom setting, this paper details a physical demonstration of this concept of stellar magnitude. Said demonstration is achieved by taking Malus' Law, which states that for polarized light, passing through a polarizer effects the lights transmitted intensity according to the relation where Θ is the angle between polarizer and the plane polarized light. Because a difference of 1.0 magnitude correlates to a 2.512 difference in luminosity, we can use this relation in tandem with Malus' Law to generate a list of associated angles given IO is equal to one and I, the relative intensity, is equal to . Thus, we can show . From this equation we can set up the polarizers in front of the already polarized laser light with the angle of the polarizers set to the angle generated from the previous equation. This setup demonstrates the stellar magnitudes one through six as visual points of light. This demonstration has applications to both show students in heavily populated areas the visual appearance of stellar magnitude, and its setup can function as an opportunity to show the applications and physics of Malus' Law, Polarizers, and Laser light. Everything done has been achieved using PASCO equipment, which is common lab equipment found in many schools.

Abstract Name: From Tacos to Functions; Understanding Functions and Relations with Tacos Abstract

Intro to proof writing courses are commonly a students first look at logic and more abstract ideas. These concepts are extremely important but can be difficult to grasp. While some texts use venn diagrams for concepts with sets, there are few visualizations used outside of these and those that are tend to be abstract themselves. Our goal was to create effective visuals using graphic design techniques along with the psychology of learning to create images that will increase understanding of topics in intro to proof-writing classes. By using tacos as fun overarching metaphors it's easier to see the relationship between these more abstract concepts. This talk will focus on the images developed for functions and relations. The images use color coordination and typography rules to make the concepts visually stimulating and easy to comprehend. A cartoon-like aesthetic makes the images more welcoming for students. While these initial visualizations were drawn with Intro to Proof Writing courses in mind, I believe these visuals can help anyone who is interested in understanding fundamental concepts pertaining to functions.

Abstract Name: Planets in the Stars: The Line Between Inspiration and Stealing Through the Music of John Williams

Similarity is not equivalency. The line between stealing and inspiration in music is ambiguous and controversial. John Williams is a film composer who wrote music that created suspense in Jaws, wonder in E.T Extra Terrestrial, and adventure in the Star Wars franchise. The music within Star Wars rejuvenated the symphonic orchestra in film scoring, due to its grand and epic nature. However, scholars and fans alike have pointed out striking similarities in Williams' scoring to works of past composers, claiming that he was stealing the musical motifs, melodies, and even rhythms. Like Richard Wagner, Williams demonstrates his technical ability by creating "leitmotifs", for each of his characters that not only were unique in their setting, but were adaptable to the situation that they were presented in. Williams uses these motifs to create emotions and tell unique stories. When using similar rhythms to his predecessors, like Gustav Holst, Williams composed distinctive melodies in the foreground. He created tonality and form that had audiences humming his tunes when exiting the theater. Though similar in orchestration, Williams also created virtuosic colors that set out from the rest. Whether it is creating a piece that uses similar melodic lines, or even chord structure, in music, the transformation of previous composers' music is crucial to making a new and innovative piece. Williams adopted previous ideas and created his own style and mark on history.

Abstract Name: Investigating age retardation and metabolic dynamics regulated by metformin in Drosophila with multimodal imaging

Aging is a progressive deterioration of physiological functions associated with alterations of lipid metabolism. The convoluted mechanism of changing lipid metabolism renders complexity in the investigation of the role that lipids play during aging. Metformin, a biguanide drug used as a treatment for type 2 diabetes mellitus (T2DM), exhibits anti-aging effects through the inhibition of enzymes of the mitochondrial respiratory complex I, consequently activating the AMP-activated protein kinase (AMPK). Despite the prevalent prescription of metformin, the age retardation potential of the drug remains understudied, especially at the subcellular level. Unprecedentedly, we applied a multimodal optical imaging system of deuterium oxide (D2O)-probed stimulated Raman scattering (DO-SRS) and two photon excitation fluorescence (2PEF) microscopies to non-invasively visualize the spatiotemporal lipid metabolic dynamics and optical redox status in the fat body tissues of metformin-treated Drosophila. We observed that metformin significantly prolonged the lifespan of flies while reducing de novo lipogenesis through the upregulation of autophagy and fatty acid oxidation. Moreover, metformin not only rescued the flies from oxidative stress, but subcellular analyses of lipid droplets also revealed that metformin impacted lipid saturation. For the first time, our novel label-free molecular visualizing imaging technique demonstrates the ability to study metabolic activity in situ, providing the insights into the mechanism correlating the anti-aging effect of metformin to its regulation of lipid metabolism.

Abstract Name: "The Choice is Our Identity"

My work explores my identity as a Colombian-American artist. Growing up, I always felt trapped between American and Colombian cultures. I was born in the U.S and was raised in American culture but I have Colombian blood running through my veins. I always struggled with identity during my youth and still do to this day. I feel that growing up I have been so Americanized which is nothing I am ashamed of but makes me feel as if I am losing touch with my roots. Out of my family “lineage”, my family is the most Americanized in the sense that we all speak English and haven’t visited our motherland in years. I’ve had moments where my cousins tell me I am not Colombian enough because I barely speak Spanish, and moments where my grandmas, aunts, and family friends laugh and joke about me being so quiet because I struggle to communicate with them. My father became a U.S. citizen when he decided to join the military 28 years ago, and my mother just got her citizenship a few years back so she has broken “Spanglish”. How she feels about her English is exactly how I feel about my Spanish, and I feel this is something many individuals can relate to. For my piece, I wanted to make a self-portrait using oil pastels and acrylic paint in a variety of colors as it portrays the colors you see in Colombia within the streets and buildings. I also incorporated flowers, traditional foods, and the Colombian flag since it is a big part of our identities. With this piece, I felt inspired by the love I have for my roots and wanted to show it is something I will never give up and will take with me for generations of my family line.

Abstract Name: Perflurooctane Sulfonate Exposure Duration on Hepg2 Cells

Perfluorooctane sulfonate is a type of PFAS chemical that due to its health concerns has been phased out of production from 2000 to 2015. Although PFOS is no longer being produced, the chemical is still found in surface water and soil, so it is still an active health concern due to its long half-life, and bioaccumulation in humans. While the adverse effects of PFOS on liver health have been reported, limited research has investigated the relationship between PFOS exposure duration and hepatic cellular outcomes. The objective assess the effect of varying PFOS exposure duration on oxidative stress markers and lipid accumulation in HepG2 liver cells. HepG2 cells were cultured in William’s E medium on collagen coated tissue culture plate. Cultured HepG2 were exposed to PFOS at concentrations five concentrations over different exposure durations ranging from 48 hours to 96 hours. Oxidative stress markers including Reactive oxygen species production and antioxidant capacity were assessed. ROS was measured using 2',7'-dichlorodihydrofluorescein diacetate assay kit. Total antioxidant capacity was determined using a commercial Oxiselect antioxidant assay kit and uric acid served as standard. All experimental data were analyzed using

JMP software. Our results showed that duration of PFOS exposure significantly influenced oxidative stress levels in HepG2 cells. PFOS exposure at 24 hrs, and 48 hrs led to transient increase in ROS production. Exposure to high PFOS concentration at 96 hours resulted in sustained oxidative stress characterized by elevated ROS levels and decrease antioxidant capacity. PFOS duration was positively correlated with intracellular lipid accumulation. The study findings demonstrate the role of PFOS exposure duration in modulating oxidative stress and promoting steatosis. Prolonged PFOS exposure exacerbates oxidative stress and increased lipid accumulation indicative of steatosis. These preliminary findings emphasize the importance of considering exposure duration when assessing PFOS-related hepatic effect and therefore requires further studies.

Abstract Name: Development of a Temporal Space Debris Population Calculator

As more and more rockets, payloads, and satellites are being launched into space, the increased risk of Space Debris in the Low Earth Orbit is becoming a growing problem. This poses a risk to future launches as adjustments in mission control have to continuously be made in order to avoid any disasters that deal with debris collision. Furthermore, technology is limited to detecting space debris of only a limited range of size. To be able to plan safer future launch missions, the purpose of the research is to come up with a digital calculator that is able to evaluate the population of debris in the LEO (Low Earth Orbit) at a desired time stamp. The input can include a timestamp from the past, present as well as future. As an output, the population of debris in the LEO at that timestamp will be displayed. The output for the past and present input will be extracted from a compiled data from existing calculators, while the output at a future date input will be a prediction evaluated using a MOCAT model. To make the research efficient, the work is being conducted in two teams. Team 1 at Iowa State University is working on extracting data from several existing calculators such as SpaceTrack, Celestrek, and DISOSWEB. Team 1 compiles, arranges, and sorts the extracted data into a matrix and sends it to Team 2, working at the Massachusetts Institute of Technology. Team 2 takes the

compiled data and uses it to create a MOCAT model to create a simulation. This helps predict the possible number of debris in the LEO at a given time in the future. In collaboration, a calculator is created that is able to evaluate the population of debris at any given time - past, present, and future.

Abstract Name: CT segmentation on Indian Abelisaurid

The use of CT segmentation has been used widely in paleontology. Through segmentation of fossil scans we can look at bones not physically available to us, we can look at parts of the bone hidden in the interior of the fossil. For example, we can take a detailed look at an isolated tooth. In an actual fossil this tooth could be concealed by other parts of the fossil and would require possibly damaging the fossil to look at. Using segmentation, we can simply segment only the tooth, giving us a detailed 3D image of the tooth for research. To do segmentations we used software, 3D Slicer, using the newest version. Using a 3D slicer, we plan to segment the skull material of an Indian abelisaurid, Indosuchus. Originally described by Huene and Matley in 1921, Indosuchus has proven to be taxonomically difficult to classify, as its material was very fragmented. Indosuchus has an overlap of skull material with two others Indian abelisaurids, Rajasaurus and Rahiolisaurus, which were described in 2003. We believe that these three species may be the same, however Rajasaurus and Rahiolisaurus have no shared skull bones present. Indosuchus contains the bones that both the other species possess. Due to this we hope that Indosuchus can be the “Rosetta stone” for comparing these various species. We have scan data of Indosuchus material, which is why we are pursuing segmentation. We hope that through this comparison of overlapping material in these three species we can further develop our understanding of abelisaurid phylogeny.

Abstract Name: Attitudes Towards Mental Illness across Black and White College Students

This study examined attitudes toward mental illness across gender and ethnicity in a sample (N=73) of black (n=22) and white (n=51) undergraduate psychology students attending California State University, Fullerton (CSUF), located in Orange County (OC), California. Participants completed an online survey including the Beliefs Towards Mental Illness (BTMI) scale, which focuses on Dangerousness, Poor interpersonal and social skills, and Incurability. Hypotheses were that (H1) black v. white and (H2) male v. female students

would express less positive attitudes toward mental illness. H1 was partially supported. A significant difference in the predicted direction was found for Dangerousness ($F(1,72)= 7.392, p= 0.008$), whilst no significant differences emerged for Poor interpersonal and social skills and Incurability. H2 was not supported, with women perceiving the mentally ill as displaying Poor interpersonal and social skills ($F(1,72) = 11.331, p= .001$) more so than men, and no significant gender differences were found for Dangerousness and Incurability. Whilst only 2% of the OC population and 2.2% of the CSUF student population is black, black hate crimes comprise over 50% of reports. Many hate crimes are committed by those who blame mental illness for their actions, and with ethnic minority victims, this may increase negative views of those who suffer from mental illness. These findings may further illuminate ethnic minority communities of those suffering from mental illness and help to identify misperceptions of mental illness in these communities.

Abstract Name: Identifying Mechanosensing Pathways In Artery and Vein Endothelial Cells

Coronary artery bypass graft (CABG) surgeries redirect blood flow from an obstruction in a vessel in order to maintain correct blood flow with the cardiovascular system. CABG procedures typically use a graft from the saphenous vein or radial artery. 5-7 years after a CABG procedure saphenous vein grafts have a patency of 75-86%, whereas radial artery grafts have patencies of 90-98%. Reductions in vein patency are due to thrombosis, intimal hyperplasia, and atherosclerosis. However, on a cellular level, these changes could be initiated by mechanosensors (sensors on endothelial cell surfaces that detect changes in shear stress experienced by the cell). Thus we hypothesized that the differences between arterial and venous endothelial cell responses to fluid shear stress mitigated by mechanosensors could contribute to earlier venous patency reduction in arterial settings. To test this we constructed an experiment in which we could precisely control the levels of shear stress experienced by vein and artery endothelial cells and observe morphological changes in terms of cell elongation and polarity. This was done by using the IBIDI flow and orbital shaker machines to provide shear stress levels of 5 and 25 dyne to the cells. After cells had been underflow for 24 and 48 hours they were removed, fixed, and stained for GM130 (golgi), DAPI (nucleus), and VECAD (cadherin membrane marker) to conduct cellular polarization and elongation analysis using FIJI. In addition, a qPCR was conducted to determine gene expression differences between Artery and Vein Endothelial cells. It was determined that Arteries were able to polarize under 25 dyne and 5 dyne conditions while veins showed little polarization under 5 dyne. In addition, both KLF2 and KLF4 were found to be upregulated in Artery ECs under shear stress while the same was not the case in Vein ECs.

Abstract Name: Model Averaging Toolbox for Enhanced Climate Change Projections: Methodology and Implementation

Climate change modeling is a complex endeavor that requires the integration of multiple climate models and observations to enhance the accuracy and reliability of predictions. In this research proposal, we present a novel toolbox designed to facilitate the averaging of climate models, resulting in an ensemble of predictions. Our approach incorporates the Bayesian Model Averaging (BMA) methodology, along with other techniques, to address the challenge of model averaging and improve the precision of climate change projections. The proposed model averaging toolbox encompasses various techniques, including BMA (as utilized in the 5th National Climate Assessment), the Sanderson approach (as employed in the 4th National Climate Assessment), and the MSE (Mean Squared Error) methods. These techniques are utilized to estimate model weights, calculate model averages, and compare the predictions generated by the multi-model ensemble against observed data. Furthermore, the toolbox allows for the identification of optimal sets of model weights that can be utilized for post-processing. Notably, the toolbox includes a model independence estimation, an important metric that has gained prominence in recent model averaging methods. By utilizing the obtained model weights, researchers can evaluate the skill and independence of each climate model. Existing model weighting approaches often rely on predefined criteria to assess model skill and independence, which can limit forecast flexibility and accuracy. In contrast, our suggested toolbox offers users a wide range of alternatives for the model weighting problem, enabling them to effectively address diverse climate change investigations.

Abstract Name: MalDrone: An Automated System to Detect and Treat Malaria Mosquito Habitats

Malaria is a life-threatening disease transmitted to humans through bites of infected female Anopheles mosquitoes. It is prevalent in tropical and subtropical regions, and despite global efforts to control and eliminate it, malaria remains a public health challenge, with an estimated 247 million cases in 2021. Further climate changes in temperature, humidity, and rainfall have an impact on important factors that dictate the transmission of malaria. In 2023, the US recorded the first home-grown malaria cases in decades. Effective control strategies include larval source management at breeding grounds to reduce mosquito larvae, thus reducing the population of adult malaria mosquitoes. However, assessing and treating potential malaria mosquito habitats is difficult and costly. Project MalDrone aims to develop an automated system to detect potential larval habitats for Anopheles mosquitoes and deploy an automated drone to treat these habitats. It is known that malaria mosquitoes breed in vegetated bodies of water. We used hyperspectral data from Landsat-8 or Sentinel-2 to detect malaria habitats. We developed an automated system that could be updated every eight days to segment areas of aquatic vegetation within a specific area. From there, waypoints can be input into an automated drone, equipped with a variable-speed sprayer system, deployed to treat the habitats. Currently we are working on creating a solar based wireless power transfer landing pad as well as an automated refilling station for the larvicide. Maldrone has a huge potential to impact the health of millions worldwide due to its low-cost, easy-to-use, and efficient approach to detecting and treating malaria mosquito habitats, thus reducing the spread of malaria.

Abstract Name: Cybersecurity disclosure and internal control deficiencies

Cybersecurity disclosure has received a lot of attention in recent years following the release of the U.S. Securities and Exchange Commission's (SEC) cybersecurity disclosure guidance on October 13, 2011.1 This study aims to examine whether good internal controls and internal control deficiencies can improve cybersecurity at public companies. The purpose of this study is to examine whether good internal controls can improve the cybersecurity of publicly traded companies. The study focuses on the relationship between internal control deficiencies and cybersecurity disclosure. Also, this study provides recommendations to the management of listed companies on how to improve internal control systems and prevent cybersecurity incidents. Deficiencies in the internal controls of public companies are weaknesses and failures in internal controls - the policies, procedures, and systems in place to ensure the accuracy and reliability of financial reporting, safeguard assets, and prevent fraud and waste in public companies. In the fall of 2011, the SEC issued enhanced financial statement disclosure guidance. The guidance specifies that "the increased frequency and severity of cybersecurity incidents experienced by SEC registrants requires new disclosure obligations that focus on cybersecurity risks and actual cyberattacks." On March 9, 2022, SEC Chairman Gary Gensler issued a statement on mandatory cybersecurity disclosure for public companies, stating that cybersecurity disclosure should be ongoing and should be mandatory, which can help investors effectively assess the analysis to help public companies reduce losses. Based on the fact that the SEC has not yet passed the proposal of mandatory disclosure of cybersecurity information by listed companies, this project will study the relationship between cybersecurity disclosure and internal control deficiencies of the company, and put forward suggestions and management methods to help listed companies to improve their internal control system and cybersecurity information leakage.

Abstract Name: The Students Outside the Box

While students across the nation with learning disabilities rely on parents and administrators to create specialized education plans for them, there is a lack of individualization within programs and school systems. This study is an attempt to investigate the special education programs throughout the nation and how individualized programs can be implemented into school systems and benefit a student’s growth in the classroom. The researcher reviewed the literature on past special educational programs and their effect on student success, as well as the importance for a student centered education. Through the implementation of detailed and enhanced IEPs, along with customized educational plans limiting the removal of a student from

the classroom with their peers, the success of students with learning disabilities has been proven to increase. The researcher plans to deliver recommendations to educators and directors in special education on how to best place students with learning disabilities into the classroom setting while also effectively creating a personalized plan that delivers the services needed early enough to see the maximum amount of student growth. These results will be a good model for the future creation of educational plans as students with different backgrounds and needs come into the school systems.

Abstract Name: Investigation of a Novel Insecticide Target for the Control of Disease Vectors and Agricultural Pests, the Insect Type-B Muscarinic Acetylcholine Receptor

Insecticide resistance threatens the continued efficacy of compounds currently used to manage disease vectors and agricultural pests. Moreover, it is important that insecticides have high specificity towards the targeted species to protect the health of humans and the environment. We are investigating the insect Type-B muscarinic acetylcholine receptor (mAChR-B), a G-protein-coupled receptor (GPCR), as a potential target for insecticide development. Although approximately one-third of all pharmaceuticals have a mode of action involving GPCRs, few insecticides exploit these receptors as targets. Additionally, no commercial insecticide targets mAChRs, despite the success of compounds interacting with other components of the insect cholinergic system. It appears that the Drosophila melanogaster mAChR-B is pharmacologically distinct from mammalian mAChR subtypes; therefore, insecticides targeting the insect mAChR-B may exhibit low toxicity in mammals. To gain functional insight into the role of the mAChR-B in the insect nervous system, we performed electrophysiology of the central nervous system (CNS) in D. melanogaster larvae in which mAChR-B expression was decreased using in vivo green fluorescent protein interference (iGFPi), an RNA interference method targeting a GFP tagged receptor. Pilocarpine, an agonist of mAChRs, had a biphasic effect on CNS firing rate, where high concentrations (10 μM) increased firing rate, while low concentrations (0.1 μM) decreased it. Knockdown of the receptor with iGFPi curtailed pilocarpine's biphasic electrophysiological effect. Consistent with our electrophysiology results, iGFPi reduced the toxicity of injected pilocarpine in adult D. melanogaster. We are developing a heterologous expression system to screen small molecule libraries for chemistries acting at the mAChR-B. While we make use of D. melanogaster as a genetically tractable model organism, we hope to move our results into disease vectors and agricultural pests and ultimately develop the mAChR-B as a novel insecticide target.

Abstract Name: From Zero to Sixty: The rapid evolution of a comprehensive research program to recruit and retain diverse women in STEM

The Alverno College Mary Ellen Powers research fellowship program was inspired by a pioneering Milwaukee businesswoman who believed strongly in expanding access to STEM education to women from historically underrepresented groups. We began in 2015 with three students and one faculty mentor. Our formal program launched in 2018 with a Wisconsin Louis Stokes Alliance for Minority Participation grant and institutional support. Using awards from NSF, USDA, NASA, and private donor funding, we now support an average of 18 students per summer (2020-2023), about 10 faculty research mentors, administrators, and an evaluator. Our program is built around community-based research experiences that make use of partnerships with Milwaukee community organizations. We are unique in our focus on providing students with research experiences early in their undergraduate education. We recognize that not all students can participate in off-campus research so the program also includes research experiences customized for advanced students and helps them develop independent research. Our aims are to increase STEM identity, build confidence, and create competitive researchers ready for subsequent off-campus research experiences at RO1 institutes. Since 2018, we have supported 89 total student research fellows (63 unique student fellows) and participants have a 95% persistence rate in the college. We have built-in weekly lab meetings and a professional development curriculum. Students are required to present their work at an on-campus research symposium and we have developed a cohort model of travel that has been very successful in encouraging our student research fellows to attend and present their work at regional and national professional conferences. We will present our program model, how we scaled up and grew the program, data on STEM identity, our current work expanding the program to serve students entering college, and the opportunities and challenges we face as we work toward sustainability.

Abstract Name: Addressing the Impact of Sexual Education on the Mental Health of College Students

This research delves into the dynamics of sex education training in colleges within the Washington Metropolitan Area, examining both student perspectives as well as insights from professionals involved in sexual education programs. Acknowledging the interconnected nature of education and mental well-being, our investigation answers the question: to what extent does a lack of sexual education and misinformation

surrounding the topic lead to the declining mental health of youth in the Washington Metropolitan Area? The study is structured around two main components: the experiences of students who have undergone sex education training and the perspectives of professionals actively engaged in facilitating sex education programs. For the student-focused segment, the research addresses students' initial reactions to their college's sex education and consent training, evaluating the perceived helpfulness and comfort levels associated with the training environment. It further explores the impact of education on confidence in handling uncomfortable sexual situations, awareness of institutional resources for sexual misconduct, and attitudes toward discussing sensitive topics such as sex, sexual assault, sexuality, and gender expression. The professional-oriented section of the study investigates the structure and goals of sexual education programs within institutions, identifying potential shortcomings and evaluating student responses. Professionals' opinions on the effectiveness of the programs, including their preference for student-led instruction, are examined. The research also explores limitations within these programs and seeks suggestions for improvements without constraints. The ultimate goal of this study is to uncover what makes a quality sexual education for college students, with a specific focus on its potential impact on mental health. Through understanding the strengths and weaknesses of existing programs, we aspire to identify key factors that can enhance the overall well-being of students.

Abstract Name: Again & Again: Memorials in Wake of School Shootings

School shootings are a concept most Americans seem to be eerily familiar with. Gun violence is reported as the leading cause of death for children and teenagers. Despite the first major shooting occurring over 24 years ago, lack of gun control remains an ongoing issue. With policymakers refusing to enact change and others demanding the Second Amendment be upheld, the battle for reform remains never-ending. The massacre at Columbine brought cries for gun control into the light of mass media, in addition to publicizing the victim’s memorials. This study examines the memorials of Columbine, Virginia Tech, & Ulvalde as trauma sites, commemorated through powerful visual art to represent and remember those who have been lost to the epidemic of school shootings. This research is critical, considering the increasing gun violence in American schools.

Abstract Name: The Impact of Sex and Diet on the Development of Metabolic Syndrome

Introduction: There are many different diets that may contribute to the development of metabolic syndrome. Metabolic syndrome is a cluster of conditions that increase a person's risk of cardiovascular disease. One aspect of metabolic syndrome is insulin resistance, which affects 7.3% of males and 6.6% of adult females. Muscle comprises 40% of the average body mass and helps to control insulin sensitivity. Purpose: The purpose of this experiment was to determine how different diets alters the progression of insulin resistance in males compared to females. Methods: Mice were fed one of three diets; Control (20% fat, 20% protein, and 60% carbohydrates (18% sucrose), High Fat (45% fat, 20% protein, and 35% carbohydrates (18% sucrose), or High Sugar (60% carbohydrates (60% sucrose), 20% protein, and 20% fat. Glucose tolerance test was conducted at 0 weeks, 6 weeks, and 12 weeks. Fasting insulin was measured in a subset of animals at weeks 6 and 12, and HOMA-IR was calculated. RNA was isolated from the skeletal muscle and RT-PCR was run for Gult4 and Igf1 genes. Results: The male high fat diet group at 12 weeks had higher insulin, blood glucose, and HOMA-IR compared to all other groups. HOMA-IR was elevated in the HF males at 6wks, while no change was seen in the HS or female groups. There was no difference in gene expression of Gult4 and Igf1. Conclusion: These data suggest that females may be protected from insulin resistance regardless of diet, and it may be regulated independently of muscle Glut4 and Igf1 expression.

Abstract Name: Fueling Strategies in Ultra Trail Runners

It has been suggested that ultra trail runners may fail to meet hourly carbohydrate intake guidelines during training and competition due to improper knowledge around fueling for performance. Runners may experience pressures to maintain a low body mass, body dissatisfaction, belief that lower body weight improves performance, and lack of knowledge around fueling strategies. The consequences of this can include poor performance, increased gastrointestinal stress, and an increased risk of Low Energy Availability (LEA). PURPOSE: The purpose of this study was to examine self-reported fueling habits during training and competition in male and female ultra-trail runners. METHODS: Cross-sectional study where participants completed a Qualtrics survey including 45 questions. Questions subjects included: age category, self-classified runner type, weekly running mileage, primary race type, and carbohydrate intake practices during training and racing. Trail runners between the age of 18-40 (n=1,899; males: n= 510, females: n=1,445). Questions regarding carbohydrate intake during training and competition were compared to current evidence-based recommendations. RESULTS: 45.6% of male and 47.6% of female reported fueling with carbohydrates during their workouts. 47.5% of males and 45.2% of females reported sometimes fueling with carbohydrate during workouts. 7.1% of female athletes and 6.9% of male athletes reported not incorporating any carbohydrates into their workouts. 25.7% of male and 36.2% of female ultra-trail runners reported intentionally restricting their energy intake during easy training days. 35.9% of males intentionally train in a fasted state, while only 19.7 % of females reported training in a fasted state. CONCLUSION: General recommendations for carbohydrate consumption during exercise lasting 1-2.5 hours and > 2.5 hours are 30-60g/hr and 60-90g/hr, respectively. However, ultra-endurance and other elite athletes should seek individualized guidance from sports dietitians to ensure that they meet necessary energy requirements to avoid LEA, and subsequently reduce the risk of disordered eating.

Abstract Name: Exploration of Microbial Contamination and Antibiotic Resistance within Rochester, MN Community Farms

Our study explores potential fecal contamination and antibiotic resistance within agricultural soil in community gardens in Rochester, Minnesota. The significant presence of the healthcare industry due to Mayo Clinic may contribute to an increased prevalence of antibiotic resistance in the environment. Antimicrobial-resistant strains of bacteria can be found in most hospital waste, which can contaminate local soils. Hospital wastewater and wastewater from near-associated communities contain elevated antibiotic-resistant bacteria. Within Rochester, the wastewater is routed into the local waterways, which are further downstream used for irrigation. Additionally, the presence of animals within these community farms may further contribute to antibiotic resistance. Farm animals may be subject to antibiotic treatments, contributing to elevated antibiotic-resistant bacteria that get introduced into the environment via their waste. Antibiotic-resistant genes can be spread among bacteria through horizontal gene transfer if located on the plasmids, increasing the spread of antibiotic resistance. Our study focused on the agricultural soils of The Village Community Gardens, a local nonprofit aimed at food sovereignty and the provision of land and resources for culturally relevant food growth. We collected soil samples from three distinct garden plots. From these samples, we 1) compared microbial community counts and 2) investigated microbial antibiotic resistance for enrofloxacin, chloramphenicol, ampicillin, and spectinomycin. We anticipated that the soil collected from the farm with sheep actively walking about would contain the greatest antimicrobial-resistant bacterium. We were surprised to discover that the garden plots used for large-scale agricultural purposes contained the most antimicrobial resistance. The third plot was the oldest community garden housed centrally within Rochester on a church's property and contained the least observed antibiotic resistance. Ultimately, our findings will be informative to the public and our community partner, potentially leading to further investigation into the domain and changes in environmental policy and antibiotic stewardship in Rochester, MN.

Abstract Name: Calm Down: How to Improve Undergraduate Student Performance

In recent decades, undergraduate students are progressively experiencing more stress. It is reported that stress negatively affects students' academic achievement; however, the connection between the two is still unclear. There are a multitude of both perceived and physiological factors that can influence stress levels, such as depression, anxiety, and coping skills. The objective of our study was to identify these factors and their influences on undergraduate student stress and GPA. The study was conducted in a renowned, research-heavy university in the Deep South with a primarily white population. Participants were interviewed using validated tools such as the Perceived Stress Scale (PSS), Generalized Anxiety Disorder scale (GAD), Patient Health Questionnaire (PHQ), and the Brief COPE test at the start of the 2021 fall semester to assess perceived stress levels. Student GPA was also collected as a self-reported variable. Increased anxiety and depression were significantly correlated with increased perceived stress. Coping skills such as self-distraction, denial, behavioral disengagement, venting, and religion positively affected perceived stress, while active, instrumental support and acceptance decreased perceived stress. Student GPA was negatively modified only by those that practiced venting as a coping mechanism. University-reported GPA, rather than self-reported, should be used in future analysis. Further studies should be conducted to identify the most significant sources of increasing undergraduate student stress, specifically regarding students' coping skills.

Abstract Name: How AI can responsibly coexist with the profound aspects of the human experience emphasizing respect for human dignity and the complexity of human cognition.

Large Language Models such as ChatGPT, Claude AI, and others have the potential for incredible amounts of good, but their unleashing on the world has raised a multitude of social and ethical concerns. For, as yet, it cannot be guaranteed that the multifaceted nature of humans and the understanding of human cognition can be accurately implemented into large language models and artificial intelligence (AI). Indeed, given that the "hard problem" of human consciousness is still up for debate, the question of AI intelligence raises the stakes in terms of how we understand human subjectivity - especially in terms of empathy, ethics, and choice. This presentation advocates that educators in tech and AI development engage with philosophy of mind scholarship, given that the hard problem highlights the gap in our knowledge when it comes to explaining the subjective aspect of consciousness- this necessitates interdisciplinary collaboration. Indeed, human traits such as emotions, empathy, intuition and most especially, ethical reasoning, go far beyond mere data-driven decision-making. The emotions and thought processes humans experience are inherently unique, so attempting to fully recreate such complexities in a genuine manner may be a fool's errand. For instance, AI models programmed to have empathy do not have a choice whether to produce such emotions, so the true essence of such emotions have been stripped. My presentation will discuss how today's undergraduates in AI development need philosophical training - from René Descartes to David Chalmers - to understand the subtitles of human consciousness, empathy and ethical decision-making. Philosophical training will alert today's students in tech to the limitations of objective, third-person perspectives - and the subjectivity of real human experience which affects choice, empathy, and human interaction.

Abstract Name: Energy Efficient AI on Embedded Systems

Big data is becoming the future of the computing world and Artificial Intelligence (AI) is more widely used to process such data. It is impractical to always centralize the vast amount of data collected from certain applications to cloud servers, such as autonomous transportation and advanced manufacturing. Due to privacy concerns, limited network bandwidth, and response delay, there is an urgent demand to process the data where it is collected, for which AI on embedded systems is a promising solution. However, embedded systems lack the computing power required to run computationally intensive AI algorithms, such as deep neural networks. Some embedded systems are battery-powered and can hardly support complex AI learning in the long term. Using accurate low-power AI models becomes imperative to process large datasets, especially on resource-constrained devices such as smartphones, medical equipment, and industrial robotics. To address these challenges, our project aims to simplify the AI model training on embedded systems, while maintaining the desired model accuracy with Federated Learning (FL). FL trains AI models on decentralized embedded devices without exchanging the local data samples held by devices. The updated model parameters are sent from devices to the central server, where they are aggregated with the contributions from other devices to collaboratively train the global model. This iterative process continues, allowing the model to learn from diverse and distributed datasets for improved accuracy and generalization. In addition, this project investigates the scarcity of computing power and memory space in embedded devices to balance the tradeoff in model complexity, number of connected devices, and dozens of other factors to achieve efficient and accurate FL. Finally, a comprehensive FL testbed is developed to validate the proposed AI simplification methods, consisting of a central server and multiple embedded devices conducting image processing tasks based on the collected real-world data streams.

Abstract Name: Experimental Comparison of Simulated Decay Curves using Dice and Centicubes: Implications for Teaching Radioactivity and Half-life

Radioactive decay is taught in Kentucky high schools (NGSS HS-PS1-8), where students learn about nuclear properties and radiometric dating. Given that materials and experimental radiation equipment can be expensive, many analogical hands-on radioactive decay experiences have been proposed and described in the literature.Centicubes have been a common manipulative in elementary and middle school classrooms. Due to their availability, simplicity, and low cost, we propose a novel way to use centicubes to illustrate radioactive decay rates. However, by having unconventional surface features, it is not clear whether centicubes will simulate randomness like dice do.The study statistically examined the use of centicubes as a simpler, low-cost alternative to dice to teach radioactivity lessons in Kentucky. The researcher implemented acarefully controlled set of 20 trials each modeling radioactive decays with short, medium, and long half-lives with both

centicubes and dice. A Chi-square goodness-of-fit test compared their various exponential best-fit curves to empirically demonstrate the extent of their similarity.The researcher found that for the long half-life trials, while the dice curve was statistically similar to the expected one, the centicube curve was significantly different from both the expected and dice ones. For the medium and short half-life trials, all three curves were statistically similar. It was concluded that if teachers are interested in the decay curves and half-life estimates, then both centicubes and dice will provide them. However, teachers who are interested in accurately representing the randomness aspect of nuclear decay should use only the centicube's "flats" and "holes" decay modes. During the Spring 2024 semester, this study will be expanded by exploring the role of release height in the decay rates of the centicube "tip" decay mode, and by testing pseudo-centicube objects made with dice and small metallic spheres.

Abstract Name: Development of Scalable Manufacturing Processes to Improve Solar Panel Efficiency

In response to a growing demand for sustainable energy sources, the utilization of solar energy has increased. Within the US alone, solar capacity has increased at an exponential rate with an addition of 10.9 gigawatts (GW) in 2022 alone. While these solar panels enable the ability to harvest solar energy, their efficiency decreases as the temperature of the solar panel increases (loss of 0.5% in efficiency with a 1℃ increase). This decrease in efficiency has driven researchers to explore cooling technologies. One area of interest is the use of thin films to achieve passive cooling by infrared radiating into space. These thin films use micro/nanotextured surfaces that possess high emissivity in the atmospheric window while allowing visible and near-infrared light to the solar panel beneath. By reflecting wavelengths of light that solar panels do not use to generate energy, the overall surface temperature of the solar panel will be decreased. Previous researchers have been able to demonstrate a decrease in surface temperature by 4-14.95℃ using thin films for passive radiative cooling. However, the current manufacturing methods require high levels of precision, are expensive, and are not easily scalable. In this research, we demonstrate a low-cost, rapid, scalable manufacturing process for thin films using a manufacturing method known as forward roll coating. The photonic thin films are composed of a polymer base (PDMS) and SiO2 nanoparticles. These materials were chosen due to their high and mid IR emission, which refracts non usable light. Furthermore, the nanoparticle addition increases the viscoelasticity of the composite and enables the creation of a micro/nanotextured surface during roll coating. The surface topography promotes the thermal infrared radiation emittance. When facing direct sunlight in the summertime at noon, the manufactured coatings demonstrated a 3.5°C temperature decrease without a loss of solar panel efficiency.

Abstract Name: Towards the Generation of Learning Objects with Generative Artificial Intelligence

This paper describes an on-going research on the use of generative artificial intelligence (GAI) in generating learning objects. Learning Objects are digital or non-digital artifacts, which can be used, re-used or referenced to augment or enhance the learning process. Examples of these presentation slides, images, text, surveys, quizzes, and hands-on exercises. The unprecedented availability and capability of GAI tools in recent years brings us to consider how their technical capacities and abilities can bring about effective and useful learning objects. We first explore the published literature to survey the work that has been in the field of applied GAI to generate learning objects. Next, we provide a review of their technical features and closely look at the distinctive features of the tools used in various GAI models. The focus of this research is to develop a method of utilizing freely available GAI tools to expedite the generation of learning objects and to evaluate their effectiveness. Specifically, we seek to optimize the utilization of these AI-generated learning objects for active-learning applications and learning best practices.

Abstract Name: Deciphering Synergy: Pterostilbene and Dabrafenib in Melanoma Treatment

Melanoma, the most lethal type of skin cancer, is characterized by a BRAF mutation in nearly 60% of diagnoses. Dabrafenib is a current treatment option for patients with this mutation; however, resistance often develops within a few months of initiation. To enhance treatment effectiveness, combination therapy is frequently employed. This study seeks to augment the therapeutic impact by combining Dabrafenib with Pterostilbene, a naturally occurring molecule with inherent anti-cancer properties, through the utilization of A375 cells, a cell line known to contain the relevant BRAF mutation. Independently, we have determined Dabrafenib and Pterostilbene have IC50 values of 8 nM and 40 mM, respectively, in these cells. However, our data indicates a synergistic effect between Dabrafenib and Pterostilbene at concentrations of 2 nM and 25 mM, respectively. Future investigations aim to reveal the mechanism of synergy through a comprehensive analysis of the relevant cell signaling pathways associated with each molecule's mode of action. Additionally, our lab has synthesized a novel derivative of Pterostilbene, whose anti-cancer properties have not yet been characterized. Therefore, future studies will also aim to establish an IC50 for the novel Pterostilbene derivative and assess the potential synergy of the derivative in combination with Dabrafenib through the development of a combination index by utilizing isobologram analysis. By comprehensively characterizing the synergistic effects of Pterostilbene with Dabrafenib and utilizing novel Pterostilbene derivatives, this research contributes valuable knowledge to the field, paving the way for more targeted and effective therapeutic interventions in melanoma treatment.

Abstract Name: Genetic Variance and Predisposition for Angina Pectoris

Angina pectoris is characterized by chronic chest pain due to imbalances in myocardial supply and demand. Stress, pollution, climate and drug and alcohol abuse are environmental factors that may increase one's risk for developing this condition. Angina affects millions of people worldwide and the likelihood of developing angina increases with age. Failure to properly prevent, diagnose, and treat the condition has led to complications for many patients. Despite the prevalence of angina, little is known about the role genetics play in the condition. The purpose of this study is to look for genes that may contribute to the development of angina by conducting a genome-wide association study (GWAS) using a diverse population from the All of Us Research Program. Data analysis was preformed using R in a Jupyter Notebook environment while GWAS was performed using Hail. GWAS for a sample cohort of 50,689 study participants displayed one variant, rs373255264, with a p-value of 5.427x10-6. GWAS for full cohort of 245,388 study participants displayed one variant, rs6601018, with a p-value of 3.960x10-6. Both GWAS displayed outlier variants on chromosomes 5 and 20. No variants reached a significance threshold of 5x10-8 in GWAS of sample cohort, nor GWAS of full cohort of participants with angina as the outcome. This study suggests genetics may play a negligible role in the development of angina and environmental variables, such as stress, may be more important. However, the role of genes as modifiers of disease under specific environmental pressures has not been tested in this study and cannot be ruled out. A better understanding of gene-environment interactions and epigenetics in angina may lead to more personalized and effective treatments.

Abstract Name: Investigating the Effects of ARID1A Knockdown on Cardiomyocyte Differentiation

Congenital heart disease (CHD) is an umbrella term for heart defects that affect around 1% of births each year. Though CHD is the most common birth defect, little is known about the genetic cause due to a lack of experiential data correlating patient mutations to defects in heart development. Genes associated with the development of CHD are still being discovered. One gene, ARID1A, encodes protein ARID1A which is a bona fide tumor suppressor in cancer and plays a role in neural crest development. ARID1A was shown to have high expression in early heart development and decrease into adulthood, selectively controlling differentiation of second heart field cardiac progenitor cells into beating cardiomyocytes. We hypothesized that knockdown of ARID1A during human-induced pluripotent stem cell (hiPSC) differentiation to

cardiomyocytes, alters differentiation efficiency and cell state outcome. We employed hiPSC encoded with a doxycycline- inducible dCas9-KRAB cassette and guide-RNAs that targets the transcription start site of ARID1A. We will quantify changes in ARID1A expression using quantitative polymerase chain reaction (qPCR) to test the efficiency of the knockdown. We will evaluate differentiation by tracking a cardiomyocyte specific MYL7-GFP reporter by fluorescence- activated cell sorting (FACS). By establishing this line, we hope to further characterize the role of ARID1A in heart development.

Abstract Name: Mosques Through Different Lenses: Perceptions Across Cultures and Religions

This research project aims to explore the relationship between an individual's cultural and religious background and their perception of mosque architecture and experiences. Given the lack of understanding about the nature of mosques among non-Muslims, it is essential to investigate these perceptions to promote greater public awareness and interfaith understanding.The research methodology employs two approaches. First, it analyzes Nader Ardalan's work, "The Visual Language of Symbolic Form: A Preliminary Study of Mosque Architecture," to identify common architectural characteristics in mosques. This analysis is correlated with a survey to compare common elements of mosque architecture to respondents' associations with the elements incorporated in mosque architecture. It is expected that the elements that most individuals associate with mosques are likely those that are most common.Second, an online survey assesses the influence of cultural, ethnic, linguistic, and religious backgrounds on individuals' perceptions of mosques. The survey covers familiarity with mosques, statements about mosque experiences, and demographics. Statements regarding mosque experiences are derived from Lindsay Jones' book The Hermeneutics of Sacred Architecture: Experience, Interpretation, Comparison. Demographic questions include religion, ethnicity, and primary household language. Respondents are recruited through QR codes on the Utah Valley University campus, religious groups at universities, and online forums for diverse religious traditions. Responses from those who practice Islam are expected to align more closely than those from non-Islamic backgrounds.In summary, this research shows that some architectural features in mosques are likely to be universally recognized due to their commonality. It also highlights a strong connection between an individual's background and their understanding of Islam, mosque aesthetics, and expected mosque experiences. These findings can inform mosque design by promoting the use of recognizable architectural elements and can contribute to fostering interfaith awareness and understanding, ultimately supporting harmonious coexistence among diverse communities.

Abstract Name: How Financial Status Affects Food Decisions in Households of Marin City

This research addresses disparities in food decision-making among households in Marin City by examining their food spending habits after covering essential bills. Understanding how these households allocate resources for food is crucial for developing targeted interventions to improve food security and health outcomes. Utilizing qualitative methods, semi-structured interviews, this study explores the spending patterns and decision-making processes related to food expenditures among households in Marin City. The sampling method ensures diversity in income levels and family structures. Ethical considerations are prioritized, ensuring informed consent and confidentiality for participants. The study focuses on residents of Marin City,

specifically targeting low-income households with a median income of $76,148 and a poverty rate of 8.9%. Thematic analysis of interview data will reveal insights into the impact of food spending on nutritional habits and overall well-being. Recruitment involves collaboration with community organizations and social service agencies such as Marin City Community Center. Preliminary analysis reveals that food decision making is primarily done by the female head of the household. Her thought process depends heavily on income level, especially when fluctuations in income are severe, seasonality, and discounts available at the time of purchase. Further thematic analysis will uncover additional patterns in the data. In conclusion, this study seeks to deepen our understanding of food access disparities and spending behaviors among households in Marin City. By illuminating these insights, it aims to inform targeted interventions and policies aimed at addressing food insecurity and fostering better health outcomes in this community.

Abstract Name: Collaborative Reading in the Literary Humanities: Imagining Laboratories With Christa Wolf

Undergraduate research can accomplish much of what ungrading aims to do—metacognition and intrinsic motivation. Grades are never even part of the discussion. Projects naturally continue beyond the confines of the semester. No one is required to do it. The lack of punitive measures allows for risk taking and learning from mistakes. However, resources and infrastructure for undergraduate research in the Humanities is lacking. The lack of funding is an obstacle to be sure, but it isn't the only one. A culture of collaboration is also missing. Collaboration is rarely part of our scholarly training at any level. In order to collaborate, we need a co-laboratory. But the Humanities doesn't have much in the way of good models for labs. In an effort to create such a model, I have worked with undergraduate researchers through the McNair Scholars Program, the Undergraduate Research Opportunity Program, the Learning-Assisted Employment Program, and the Mellon-Mays Undergraduate Fellowship Program. All of these researchers and I have worked on projects related to the East German writer Christa Wolf. Studying the works of Wolf with undergraduate researchers offers a way to think about this problem because Wolf herself depicts and critiques practices of the lab sciences while also being very open about the study of human subjectivity and experience-laden prose. Wolf's writings not only constitute an interesting corpus to study, they also provide guidance for imagining the possibilities of collaboration in the Literary Humanities.

Abstract Name: Dueling Characters: Femininity and Identity in Dolores Prida's "Coser y Cantar"

Cuban-American playwright, Dolores Prida's play "Coser y Cantar"(1981), explores the story of a bilingual woman in New York City and how her self-perception evolves over the course of an extended monologue. The two main characters in the play are, in fact, the woman herself, both "She" and "Ella." These two

characterizations allow the protagonist to grapple with her own identity as she code-switches between both Spanish and English: while “She” mainly speaks English, “Ella” speaks Spanish. Research has focused on how the two characters reflect femininity and adhere to the societal gender roles set for them. This research delves into how these gender roles coincide with Prida’s use of “Spanglish” in the play. The display of femininity from She and Ella and their use of “Spanglish” exemplify cultural representations and expectations of women navigating both Latinx and American cultures. Through the application of linguistic and cultural theories of Spanglish, this research analyzes Prida’s use of “Spanglish” and the gender roles of the protagonists She and Ella to explore how although each self represents a different version of the same woman caught between two cultural expectations of herself, the feminine struggle is present in both.

Abstract Name: Integration and Optimization of Hybrid Renewable Energy Systems for Kentucky EV Charging Stations with PV and Green Hydrogen Energy

With the growing interest in adopting both commercial and residential electric vehicles (EV), the assessment of PV-powered EV charging stations is required to achieve energy sustainability in Kentucky. PV solar panels generate energy during the daytime and provide a clean, renewable energy source. However, due to the variable and intermittent nature of PV-generated power, integrating green hydrogen conversion with the excess PV energy is promising due to the higher energy density of hydrogen and ever-increasing lithium prices. Whenever we need to use the stored hydrogen, we could use hydrogen fuel cells to access the hydrogen. This way would allow clean energy to be used during the night-time.In this study, we investigated the feasibility of hybrid energy systems charging EV stations in Kentucky using PV and green hydrogen through Artificial Intelligence (AI) augmented simulations. Based on our past studies, we also predict the amount of PV solar energy and green hydrogen energy in Kentucky using Python and other AI tools. Predictions can be used with the average energy consumption to get the amount of excess energy that can be converted into hydrogen energy. The energy conversion efficiency would also have to be used to find out how many hybrid renewable energy systems are necessary to supply all the power in the sampling areas.Through electrolysis, we can use a hydrogen electrolyzer to produce hydrogen from water molecules. The excess solar energy would be used to power the electrolyzer, and the hydrogen produced would be stored. After that, we can use a fuel cell that stores hydrogen to provide electricity to the entire house. Using these such energy sources would still be clean and renewable, having much less influence on the environment than many other energy sources. It would maximize PV solar panel efficiency by reducing the amount of wasted energy.

Abstract Name: Betrayed by the Blue: Intimate Partner Violence and Institutional Betrayal by the Criminal

Legal System

Building on the research on institutional betrayal and the criminal legal system, this paper asks the question: What types of institutional betrayal do victims/survivors of intimate partner violence experience when they report to the police? Previous research documents a multitude of help-seeking behaviors that survivors of intimate partner violence engage in; most commonly they engage the criminal legal system (CLS). Thus, when this institution betrays the trust of those dependent on them by being negligent or prosecutory, this is called institutional betrayal. Considering historical and present shortcomings of the criminal legal system when pertaining to survivors of intimate partner violence, this research strives to elucidate and describe the types of institutional betrayal that victims/survivors of IPV experience when they report their abuse to the CLS. The analysis is based on in-depth interviews with 11 women impacted by intimate partner violence who sought help from the CLS. Four themes emerged: (1) indifference by criminal legal system actors (2) being criminalized by criminal legal system actors, (3) The benefits of 'insider status', and (4) Having to be "in the system" to use the system. It is crucial that we recognize the inconsistencies and mistreatment within our current criminal legal system in order to better protect and support victims and survivors of IPV equally and effectively. The paper concludes with policy recommendations that, if implemented, would reduce the institutional betrayal that victim/survivors experience at the hands of the CLS.

Abstract Name: Representation of Older Women in Horror Films

Older women in horror films and television shows are often portrayed as the villain with their age being their most frightening feature. This can be seen in newer horror media where the old woman has the more chilling scenes in comparison to their male counterparts, such as "The Visit," and the villainization of the Mother in "Barbarian." The theme of taking an iconic villain often portrayed as an older woman, and making a prequel where the character is younger has become a staple in the entertainment industry in recent years. This can be seen in Disney movies and the popular movie "X," with its prequel "Pearl." This paper will analyze popular horror media that demonstrates the ageism present in the film industry. It will apply the feminist theories of Kathleen Woodward and others in order to analyze the portrayal of older women in horror movies. As well as look back at historical examples to determine the origins of these patterns.

Abstract Name: Genetic Analysis of Circadian Rhythm and Cancer Correlation

Circadian rhythm is the internal clock that constitutes the basis for the sleep/wake cycle. The regulation of circadian rhythm works in a positive feedback loop with various genes, called canonical clock components (CCC) genes. The disruption of CCC genes can be caused by both genetic and environmental factors, leading to negative implications such as insomnia, sleep apnea, diabetes, and potentially cancer. As of 2007, the International Agency for Research on Cancer (IARC), declared circadian rhythm dysregulation due to night shift work a likely carcinogen after studies showed this abnormal schedule correlates to cancer development and progression. This study aims to elucidate the relationship between sleep disorders and the risk of cancer and explore the role of genetics in this relationship. To conduct this research, analysis was done on participants in the All of Us Research Program by analyzing individuals based on demographic and electronic health record data with the utilization of R in Jupyter Notebook. Hail was used to perform a genome-wide association study (GWAS) on a diverse dataset of 138,335 individuals with cancer diagnosis as the outcome. The findings indicate that there is a significant correlation between sleep disorders and cancer, based on the prevalence of having a sleep disorder and cancer (p-value = 2.2e-16), current age (p-value = 2.2e-16), and diagnosis first of a sleep disorder in comparison to diagnosis first of cancer (p-value = 8.265e-9). The top SNPs identified from the GWAS were Chr1:152355935; p-value = 6.008e-18, Chr3:15456835; p-value = 5.988e-17, Chr3:123348018; p-value = 8.595e-16, Chr12:132618993; p-value = 1.024e-16, Chr16:67436424; p-value = 5.160e-17. However, no significant hits were found around CCC genes. A greater understanding of the connection between sleep and cancer may lead to prevention measures personalized to the patient and more effective treatment options.

Abstract Name: Appropriate Preclinical Model of Radiation-Induced Pulmonary Injury?

Background: Standard of care for stage III NSCLC involves concurrent chemo-radiation therapy followed by immune checkpoint blockade. The radiation dose administered is 2 Gy a day, 5 consecutive days a week, for 6 weeks. Unfortunately, up to 20% of patients develop life threatening pulmonary pneumonitis/fibrosis. While a number of preclinical studies focus on related sequelae, the majority do not include chemotherapy or immune checkpoint blockade. Furthermore, the radiation protocols in these studies employ large single acute doses (eg.,16 Gy or larger). An important, unanswered question is whether fractionated irradiation also initiates an early inflammation response.Methods: A calibrated ionization chamber was used to establish the dose rate for a 300 kVp/10mA, X-ray machine. Mice were divided into cohorts: A) mice injected with vehicle, sham irradiated, and then injected with control IgG antibody; B) mice injected with vehicle, the thorax administered 5 Gy a day for 5 consecutive days, and then injected with control IgG antibody; C) mice injected with the chemotherapy agent carboplatin, the thorax administered 5 Gy a day for 5 consecutive days, and then once a week for 4 weeks injected with PD1 antibody. Other than the thorax, the remainder of the body was shielded with 3 cm of lead. 18F-FDG PET/CT imaging was used to quantify pulmonary inflammation response.Results: The 18F-FDG PET/CT analysis revealed that relative to control cohort A, mice in cohorts B and C did not experience an inflammatory response. Rather, there was a statistically significant decrease in the 18F-FDG signal, indicating a diminished presence of inflammatory cells. Conclusions: Early pulmonary inflammatory responses are dependent on the dose per fraction and the number of fractions administered to the lung. More research is needed to determine if large acute irradiation models are appropriate for studying radiation-induced pulmonary injury.

Abstract Name: ERGi-USU Selectively Inhibit ERG Positive Prostate Cancer through ATF3 mediated Ferroptosis

Introduction: Prostate cancer (PCa) is the second leading cause of cancer deaths among men in the United States.Approximately 50% of patients with PCa harbor an oncogenic TMPRRS2- ERG gene fusion in their primary tumor and35% of patients with metastatic castration resistant prostate cancers have the gene fusion. We have identified a potentsmall molecule inhibitor, ERGi-USU-6 salt derivative 7b, that selectively inhibits the growth of ERG positive tumor. Thissmall molecule inhibitor is also effective in inhibiting the growth of benign and cancerous mouse prostate organoidsexpressing TMPRSS2-ERG (ERG positive organoids). To gain insights into the cancer-selective properties of ERGi-USU-6salt 7b we evaluated pathways associated in ERGi-USU induced inhibition.Methods: The biological activities of salt derivative 7b, were assessed in hormone- refractory metastatic tumor derivedERG positive prostate cancer cell line, VCaP along with organoids. We monitored the pathways associated in themechanism of drug action through immunoblot assays and ferroptosis related analyses in response to 7b treatment.The normal primary endothelium derived HUVEC cells were used as normal control due to the normal endogenous expressionof ERG in endothelial cells including HUVEC.Results: Cell growth and immunoblot analysis indicated the inhibition of ERG positive prostate organoid upon ERGi-USU treatments resulting in the downregulation of ERG and RIOK2 protein levels. The cell cycle analyses, pathway mapping by protein assessmentand ferroptotic assays suggests that salt derivative 7b treatment inhibits the ERG positive prostate cancer through ferroptosisalong with RIOK2 inhibition.Conclusions: Our results showed that the ferroptosis inducer ATF3 gene is involved in the cancer-selective activity of ERGi-USU-6 salt derivative 7b. Further, based on our observations we hypothesize that ferroptosis, the iron-dependent form ofprogrammed cell-death, may be the mechanism of cancer selective activity of salt derivative 7b.

Abstract Name: Women’s Involvement in the Economy

The research asks what the barriers to global female participation in the formal economy are (because this sector offers more stability, regulated work hours, and higher pay) by analyzing ten variables affecting women’s abilities to participate in the workforce: mobility, workplace, pay, marriage, parenthood, entrepreneurship, assets, pension, and education, and governmental representation.The objective is to build a proposed model to help increase women’s economic participation. Eighteen different nations are analyzed based on their scores from annual reports by the World Bank which assesses laws and regulations on women’s economic participation. The research analyzes differences within and between regions in order to find a generalizable result. The literature review involved researching the population, gross domestic product, average annual wage, employment rate, long term unemployment rate, and labor force participation rate

among females and males within each nation. The research found that women's education rates and women's governmental representation are major factors affecting their economic participation.

Abstract Name: The Notion of Escapism in Anime and Catholicism

In this essay, I discuss the concept of escapism in anime culture and Catholicism in the United States. This comparison is made by examining the characteristics of “fandom” given that the fandom serves to construct physical or virtual communities based on common interests and activities. These virtual communities are reproduced through moral storytelling that recycles the same general principles, including supportable protagonists and easily understandable morals, and the use of specific imagery and aesthetics. The reproduction of these principles, whether through visual or written language, creates a market value of escapism a follower can achieve. The study is based on artistic examples referencing the King James version of the Bible, and anime Attack on Titan and Jujutsu Kaisen. The Bible and the two anime both have visual and thematic structures constructed by images. Imagery is fundamental to anime---there is no anime without images. In Catholicism however, imagery is one of the forms to present stories of the Bible, but they are not inherent to the Bible. This research is important in analyzing the sociological effect on our society in which we cling desperately to forms of storytelling. The storytelling is used as an escapist method to cope with the stresses of our society. This form of escapism is, comparatively to Catholicism, what qualifies anime as a modern pseudo-religion.

Abstract Name: We Bleed Red, White, and Blue: American Imperialism through National Colors of Central American Societies

Among the over two hundred established countries in the world, thirty of them have official national flags with the colors red, white, and blue, reflecting the colors of the US flag. Scholars discuss this phenomenon by focusing on the design, the availability of supplies (dyes) at the time of their design, the psychology behind color, or “globalization.” The question posed in this study is to what extent the use of white, red, and blue was each country’s choice or a result of the U.S. imperialism. To answer this question, I will utilize color studies and scholarly research on the national political histories of Puerto Rico, Costa Rica, and Panama between the 19th and 21st centuries. These three countries are well-known for U.S. interference disguised as allyship, with Puerto Rico continuing to be a U.S. unincorporated territory. I will argue that the use of red, white, and blue colors in national flags, while not necessarily indicative of the U.S. imperialistic agenda, reflects American expansionist ideology into the region.

Abstract Name: Endoparasites Induce Differential Hemodynamics in Mosquito Fish

Mosquito fish (Gambusia holbrooki) are commonly found in local freshwater habitats and are highly regarded as an effective biocontrol agent for unwanted mosquito larvae. While an effective biocontrol, G. holbrooki and many kinds of freshwater fish are afflicted by various parasites (e.g. Blackspot). Blackspot is a disease caused by Schistosome-like parasites (flatworms) such as Uvulifer ambloplitis. U. ambloplitis cercariae attach to the muscle tissue of the fish, transform into black spot metacercaria, and secrete a hyaline cyst around themselves. The host fish deposits black pigment around the cyst and the parasite is visible as a black spot. While it is understood that this parasite changes the behavior (reproductive and shoaling) of Gambusia, it is not clear how the Cercariae/Metacercaria life stage may sub-lethally affect other life history patterns. This project investigated the circulation rates of G. holbrooki with and without blackspot by observing red blood cells (RBC/min) within the central capillaries in the tail region of 40 total fish (30 without blackspot & 10 with blackspot) at 100X magnification. Results indicated a significant difference in RBC counts of fish afflicted with blackspot in comparison to G. holbrooki free of blackspot. This information can be used to better understand the physiological effects of blackspot on Mosquitofish and how its infestation may impact the fish’s ability to be an effective biocontrol.

Abstract Name: Work Smarter, Not Harder: Utilizing AI to Enhance Elementary School Lesson Plans

Lesson plans are created by teachers to guide the implementation of instruction to ensure the learning environment includes components of high-quality lessons such as; accommodations for children with special needs, technology, meaningful connections for students, a pacing guide, developmentally appropriate assessments, and much more. Creating high-quality student-centered lesson plans can be a difficult and time-consuming process for many educators, and having access to instantaneous planning tools could be a beneficial way to support teachers. The purpose and aims of this project were to investigate artificial

intelligence (AI) platforms built for teachers, analyze the tools they provide for educators, and synthesize the benefits and limitations of using AI for lesson planning. With the introduction of open AI like ChatGPT, the way many professionals utilize technology for job efficiency is changing, including for teachers. There is a strong correlation between teachers' competencies in creating learning environments and student performance, and open AI platforms built for lesson planning can be a tool that supports educators in creating engaging activities and positive environments for students. There is a lack of current literature on using AI in lesson planning in elementary school settings. Therefore, in this research project, we generated elementary school plans using identical keywords on different AI lesson-planning platforms and used qualitative document analysis as our research methodology to analyze the lesson plans generated by the AI platforms. In this session, we will explain the findings from the reflective document analysis, discuss how AI can be a useful tool for educators in planning engaging lessons and in building teacher capacity and self-efficacy, and identify that there can be some limitations like access, affordability, and planning for diverse populations.

Abstract Name: Predicting Serious Cardiac Events from Noisy PPG Signals Using Intelligent AFib Detection

Placing up to 6 million individuals at risk yearly, atrial fibrillation (AFib) remains one of the strongest undetected indicators of heart failure or stroke. A previously self-developed model—Pulse—was employed to detect AFib episodes from extremely noisy PPG signals—an optical metric of atrial oxygen saturation measured in smartwatches. The Pulse framework consists of transfer learning (transfer of weights for better weight initialization), dual tasking (simultaneous assessment of the two related tasks of signal quality and AFib detection for increased performance), and threshold verification (clustering signal segment predictions for confirmation of true AFib instance). Pulse achieved high precision (97.77%) and recall (98.08%). However, there is limited research exploring the use of PPG signals in predicting more life-threatening cardiac conditions (related to AFib) because the PPG waveform does not reveal significant cardiac medical developments. This research introduces a novel multi-model approach to reconstruct unbiased ECG signals from noisy PPG signals to predict multiple severe cardiac events (i.e. stroke, cardiac arrest, myocardial infarction, syncopal events, and transient ischemic attack). The framework consists of a convolutional denoising autoencoder (CDAE) to generate denoised PPG signals, a linear transform model to construct unbiased ECG signals from denoised PPG signals (ECGreconstructor), and a CNN (CardiacPredictor) to predict the risk of occurrence of various cardiac events by constructing 3D features of AFib events (detected by Pulse), heart rate variability (HRV), and the reconstructed ECG signals (from ECGreconstructor). The CDAE resulted in a loss of 0.46% in clean signal reconstruction. The CardiacPredictor CNN successfully utilized the reconstructed ECG signals and performed with an average of 87.78% recall and 92.38% specificity among all tested severe cardiac events. This comprehensive prediagnostic tool can be implemented in a wide array of smartwatches for real-time assessment of AFib events to alert patients of their cardiac health.

Abstract Name: Predicting and Optimizing Workers' Trust Toward Autonomous Vehicles in Manufacturing Plants

This study aims to model, predict, and enhance the human subject's trust regarding Human-Autonomous Guided Vehicles (AGVs) interaction in manufacturing plants. The integration of Automated Guided Vehicles (AGVs) in manufacturing is seen as a significant advancement, offering advantages such as flexibility, space efficiency, safety, and cost reduction. Thus, as AGVs are envisioned as essential to the future of manufacturing, establishing trust in these autonomous systems becomes crucial for their successful collaboration with human workers in factory settings. The research team constructed a 3D virtual manufacturing plant that will serve as the setting for the experiment. The team will conduct human-in-the-loop experiments to collect subject data from interacting with the AGV. During the experiment, the subjects will walk on an omnidirectional treadmill to provide the experience of walking around a manufacturing plant, and they will be given the task of moving a virtual toolbox in the virtual world. Participant eye gaze, location, headings, moving speed, and task completion time will all be collected during data collection. The participants will also be asked to rate their trust in the AGV. Overall, the team aims to collect data from 200 participants. Using the collected data, the research team will then develop and test algorithms to predict worker's trust toward the AGV. Additionally, the research team will perform statistical analysis to discover relationships between human worker's decision-making and their trust. The results from this analysis will then be used to develop an optimization framework to allow the AGV to adapt its behavior to the worker's trust.

Abstract Name: Genx Chemical Exposure Alters Mitochondria Membrane Potential and Function in HepG2 Cells

Per and Polyfluoroalkly substance (PFAS) have gained attention due to their persistent in the environemnet and potential health implications in humans. GenX is an alternative to the predominant PFAS types PFOA and PFOS. While the health effect of PFOA and PFOS have been studied, limited research exists on the impact of GenX exposure on cellular process. Mitochondria are vital organelles responsible for energy production and play a crucial role in maintaining cellular homeostasis. This study aimed to investigate the effect of GenX exposure on mitochondrial membrane potential and functionality. HepG2 cells were cultured in William's E medium (10% fetal bovine serum (FBS), and 1% Penicillin-Streptomycin) on Collagen coated plate. Cultured HepG2 at 80% confluence were treated with varying concentrations of GenX (10 nM, 50nM, 100nM, 1000nM) and untreated cells (control group) and were incubated (37oC, 5% CO2) at two exposure durations (48 hours and 96 hours). Mitochondrial functionality was assessed through several assays including measuring ATP production, ROS levels, antioxidants status and mitochondrial protein level. Membrane potential changes were monitored using JC1 fluorescent probe. All experimental data were analyzed using JMP software and statistical significance was at p<0.05. Our results showed a reduction in mitochondrial

functionality following GenX exposure at higher concentrations and 96 hours duration. The ATP production rate significantly decreased in PFOS (1000nM) exposed cells for 96 hrs than 48 hrs cells and control group suggestion impaired energy production. An increase in ROS production and reduction in antioxidant capacity were observed indicating potential oxidative stress. GenX exposure was significantly associated with decreased mitochondrial membrane potential indicating a potential disturbance in mitochondria integrity. These findings highlight the potential mitochondrial toxicity of GenX and potential impact on cellular health and overall homeostasis, and therefore warrants further investigation to elucidate the underlying mechanism of long-term GenX exposure on cellular and systemic health.

Abstract Name: Integrating Multiple Geophysical Methods to Investigate Groundwater Flow Direction at the Old Works Golf Course, Anaconda, Montana

The Old Works (East Anaconda) Development Area Operable Unit (OWDAOU) site is located adjacent to the town of Anaconda, Montana. Warm Springs Creek is the area's principal drainage, flowing east through the site. The site contains large volumes of milling and smelting wastes, fallout from smelter emissions, and other debris that originated from smelter operations at the Upper and Lower Works and the Washoe Reduction Works. The Environmental Protection Agency (EPA) placed this site on the Superfund National Priorities List in 1983 to address metals contamination in soils, surface water, and groundwater. Extensive investigations and cleanup activities have been performed over the past 40 years, including construction of the Old Works Golf Course in 1994. The golf course was built on top of mine waste capped by lime rock and soil, and waste materials were also incorporated into design features of the course. The study’s objective is to locate groundwater and groundwater flow direction at the Old Works Golf Course to provide guidance for groundwater remediation before it flows into Warm Springs Creek and then Upper Clark River. Induced polarization tomography (IPT) and seismic refraction tomography (SRT) were performed along three lines running perpendicular to a sloped surface at the site to identify potential groundwater flow paths. Preliminary results show three locations with potential north to south groundwater flows. These results will be used to determine locations for a more detailed self-potential (SP) survey with high special resolution to more accurately characterize the subsurface groundwater flow patterns. The self-potential survey will be performed in Spring 2024. The findings of the full study could inform further groundwater contamination investigation at the site and provide guidance for future groundwater remediation before it flows into the Warm Springs Creek.

Abstract Name: Liberty University & Lynchburg, Virginia: A Town Captured for Jerry Falwell

Jerry Falwell Sr. (1933-2007), host of the televangelist show The Old Time Gospel Hour and the founder of the Christian Right organization The Moral Majority, was a controversial figure from the 1970s up until his death in 2007. While being known as a leader in the Christian Right, Falwell also founded Liberty University, an evangelical institution located in Falwell's hometown of Lynchburg, Virginia. Since the beginning of the institution, Liberty University was meant "to capture" Lynchburg in the name of God. In his book, Capturing A Town for Christ, Falwell states in no uncertain terms that he is "determined to reach every person in town with the gospel." Today, it is clear that Falwell's goal has been achieved: Lynchburg has been "captured for Christ." When not buying stock in declining businesses to revitalize them, Liberty University hosts entertainment attractions like the Halloween attraction 'Scaremare' and their popular Snowflex Centre on top of Candlers Mountain. In A 'Biography" of Lynchburg, M. Andrew and David M. Holowchak rhetorically ask whether Liberty University will "eventually swallow up Lynchburg and make it an evangelical city of its own." Their passing inquiry is significant as it acknowledges what many scholars have overlooked: the growing implications of Liberty University's take over (capturing) of Lynchburg. I will show how well-known scholarly investigations into Falwell's legacy have consistently failed to connect the city of Lynchburg and Liberty University as part of his overall economic interests. By recognizing this codependency between Falwell, Lynchburg, and Liberty University, I contend that we can better understand how "capturing a town for Christ" also meant building a Christian empire for Falwell.

Abstract Name: Enhanced Bioactivity of Titanium Implants through Silicide-Bioglass Coatings

In recent years, the field of biomedical engineering has seen significant advancements in the development of biomaterials for implantable devices and tissue engineering applications. Titanium (Ti) and its alloys have gained widespread popularity due to their excellent mechanical properties, but they have low bioactivity (fusion with bone tissue). In this study, we propose a novel approach to enhance the bioactivity of Ti implants and integration of titanium within the human body by coating the titanium surface with bioactive glass, mediated by a titanium silicide layer. The experimental methodology involves depositing a silicide coating on titanium substrates using a combination of reactions with eutectic salts, a reducing agent (such as magnesium), and heat. Then, bioactive glass is grown onto the metals using a general sol-gel method. Analysis is accomplished using scanning electron microscopy (SEM) and X-ray diffraction (XRD) to assess the morphology, phase composition, and surface properties. We show that the interfacial silicide coating on titanium significantly enhances adhesion of bioactive glass, thus improving the biocompatibility of titanium, whereas bioactive glass has little affinity and cannot be grown onto bare titanium. The results of this study have the potential to contribute to the development of improved biomaterials for orthopedic and dental applications, where a strong and stable bond between the implant and surrounding tissue is crucial for long-term reliability and benefit.

Abstract Name: Russian Wealth and the War with Ukraine: Evidence from the Bank for International Settlements

This paper uses public bilateral deposit data released by the Bank for International Settlements to analyze the effect of the start of the Russia-Ukraine war in February 2022 on Russian wealth held abroad. I find a sharp increase in cross-border deposits held by Russian nonbank counterparties of over $22 billion, or 66%, from quarter 4 of 2021 to quarter 1 of 2022. This increase in deposits fully subsided by quarter 2 of 2022. I quantify the size of the spike in deposits and document the exemplary nature of the Russian spike, finding that $17 billion of the increase is attributable to Russian deposits held in the US. I then show that a spike in Russian deposits is not observable in other advanced economies that are known to have exposure to Russian counterparties, such as the UK, Germany, and Switzerland. I advance a few possible explanations for why the spike is only seen in the the US, and the implications of this finding for better understanding responses to the sanctions implemented by advanced economies in Europe and the Americas. There are also implications for the use of the BIS data to observe how wealth stocks respond to policy changes.

Abstract Name: Psychiatric Misdiagnosis of Women in the Early 20th Century: A Scientific Exploration

In the early 20th century, scientific perspectives regarding psychiatric care for women were shifting to a more factual and scientific basis. However, constructs of women's mental health remained shadowed with historical concepts like "hysteria" and "madness". The disparity in attitudes towards men and women's mental health seemingly created a large gap between diagnosis and treatments in each group. For example, doctors argued that "men are only rarely hysterical" and pushed for outdoor exercise, while women were instructed to strictly avoid all physical activity. In the time when the term hysteria is based on from the name of the uterus to which a woman's mental condition was attached, symptoms such as cramps, moodiness, or independence from the husband could all be classified as "hysteria." The amount of which this condition was misdiagnosed remains unclear.Using a scientific approach, this project will be formatted as an investigative podcast based on the archival collection Diary of an Unidentified Nurse, 1930s, at the University of Kentucky Libraries Special Collections Research Center. Focusing on the incidence of misdiagnosis, research will explore early 20th century diagnoses of female patients. Meanwhile, the podcast will contain interviews from experts in the field of psychiatry, shining a light on women's mental health regarding diagnosis and treatment. The purpose of this research is to mitigate bias while scientifically developing conclusions regarding a significant period of development of psychiatric treatment for women. The piece concludes with the enduring impact this history has on contemporary perceptions of mental illness in women today. This research contributes to unraveling any misunderstandings regarding women's mental health, providing insights that resonate with the evolving landscape of modern healthcare.

Abstract Name: Coping

Just after my 16th birthday, I entered the darkest period of my life. I've never been one to know how to deal with my emotions, and, in the past, had let them consume me to a point where I felt that I had lost my identity and value for life. Fortunately, I soon after discovered my passion for piano and creating music, using it as a way to express those emotions that I otherwise struggled to control. In this piece, I aim to highlight the power of coping through non-traditional outlets, specifically music, and how music can be incorporated into the world of visual art. I do this through oil painting on canvas, displaying a somber self-portrait, representative of my destructive emotional consumption, surrounded by a vibrant audio file visualization from an original composition. As sister mediums, music and visual art have always been very closely related, influencing one another time and time again. As a musical artist, now entering the visual art scene, I want to make it my goal to push the envelope of music's presence and importance in the art world. Utilizing the contrast between a grayscale portrait, and an incredibly saturated background, I hope to convey the severity of the role that music plays in my life, and I aim to continue exploring unique ways to incorporate music into future visual artworks.

Abstract Name: Machine Learning for Evaluating Disaster Tweets

This research explores the application of Natural Language Processing (NLP) in analyzing disaster related tweets to enhance crisis management efficiency. Utilizing a dataset of over 7,600 tweets, this study conducts a comparative analysis of three empirically well-known machine learning models: XGBoost, CatBoost, and Random Forest. We aim to determine which model most effectively classifies tweets into the disaster and non-disaster categories. The dataset underwent extensive preprocessing, including text normalization, stop word removal, and lemmatization. Feature extraction was performed using CountVectorizer of the scikit Python package, thus, tailoring the dataset into numerical format for our case study machine learners.The methodology encompassed a detailed configuration and hyperparameter tuning of each of the three models, followed by an implementation of a majority vote ensemble technique to potentially enhance predictive performance. The models were evaluated through stratified k-fold cross-validation (k = 5), focusing model evaluation on the following performance metrics: accuracy, precision, recall, and F1-score. Our empirical results indicated minor differences in the performance of the individual models, making them comparable to this dataset. The ensemble approach demonstrated a general, improved overall performance, with a performance score of about 80% for the F-1 metric.The study provides insights into the efficacy of different machine learning models in processing disaster-related social media data and underscores the potential of using ensemble techniques in the domain. The conclusion of our research has practical implications for enhancing disaster response and management strategies. The research contributes to the broader understanding of NLP applications in the data-centric exploration of disaster-related modeling and analysis. The uniqueness of our work is the novel combination of the three machine learners in an ensemble setting,

which to our knowledge, has not been done with this dataset. Future work will explore deep learning with the case study data and other datasets.

Abstract Name: The Romanticization of Human-Vampire Relationships: How 'Twilight' and 'The Vampire Diaries' May Prime Teenage Girls to Accept Dating Violence and Abuse

The first literary vampire can be traced back to 18th century Germany, with Johann Wolfgang von Goethe's poem "Die Braut von Korinth," but the stereotypical features of a vampire are traditionally accredited to Bram Stoker's Dracula. Modern vampires, such as Edward Cullen and Stefan Salvatore of the Twilight and The Vampire Diaries series respectively, have managed to win the hearts of teenage girls all across America with their sex appeal and charismatic nature. According to Bandura's Social Cognitive Theory, individuals learn new behaviors by modeling and imitating the actions of those around them. This comprehensive literature review investigates the connection between the human-vampire relationships in Twilight and The Vampire Diaries and teenage girls' acceptance of dating violence and abusive behaviors from intimate partners. This study aims to examine how both Twilight and The Vampire Diaries create popular modern vampire narratives that may promote harmful messages to female youth regarding future romantic relationships. This analysis of peer-reviewed studies finds that harmful gender stereotypes and literary tropes are used on both female and male characters, the vampires exhibit manipulative and predatory behaviors, and the idea of true love overpowers the abusive behaviors of Edward and Stefan in the eyes of young girls, possibly creating a link between sex and violence. The findings of this study display a positive correlation between exposure to media violence and acceptance of dating violence among teenagers, as well as a positive correlation between exposure to sexually-oriented television and both the acceptance of the sexual double standard and earlier sexual timing expectations in relationships. New vampire media is still being produced, so it is important to understand what messages are being portrayed to teenage girls and how exactly these messages are altering their values regarding love in heterosexual relationships.

Abstract Name: Recruitment Strategies of College Admission Counselors

My proposed research project is designed to identify strategies used by college admission counselors to recruit students, techniques utilized to identify and avoid bias, and ways to overcome barriers to student success, paying specific attention to social reproduction processes. I recently conducted semi-structured, open-ended interviews with five college admission counselors where participation was entirely voluntary. Each counselor belongs to a different racial and ethnic group and recruits in a unique region. During each interview, the counselor was asked a series of questions regarding their recruitment strategies of prospective

students in their designated recruiting region. They also elaborated on their reasons for wanting to recruit in their region, what their typical conversations consisted of, and how they ensure successful recruitment of students from diverse backgrounds. The interviewees were recorded with a digital voice recorder and a complete transcript will be produced from each interview. The final results obtained from the interviews will now be interpreted in my analysis through an open coding process using qualitative analysis data software.

Abstract Name: Chromatic Polynomial of Generalized Petersen Graph

A graph G is a set of vertices together with a collection of edges, in which each edge corresponds to a pair of vertices. Vertices which share an edge are called adjacent. A proper coloring of a graph is a function from the set of vertices into a finite set of colors such that any two adjacent vertices are assigned distinct colors. The number of proper colorings of a graph using k colors is denoted P(G,k) and given by a polynomial, called the chromatic polynomial of G. Some explicit formulas for chromatic polynomials of special cases of graphs exist. However, explicit formulas for most graphs are unknown. All other graphs rely on a recursive formula involving deletion-contraction, which is computable only in polynomial-time.Here we present a method for computing chromatic polynomials for a special class of graphs which only requires linear-time. We have applied our method to both cycles and Generalized Petersen graphs, in hopes of addressing a conjecture. We expect our method can be extended to the graph Cartesian product of a cycle with many other reasonable graphs. It is left to be explored whether our method extends to more general Tutte polynomials.

Abstract Name: Sorption of Anionic Dye Alizarin Red S from Solution by Carbonate Mineral Dolomite

The dye Alizarin Red S (ARS) is used in histology to stain and locate calcium deposits in tissue samples, and in geology to identify carbonate minerals in thin section. Improper disposal of excess dye solution imposes a threat on water supplies. This study explores the potential of one selected carbonate mineral (dolomite) for dye sorption, which would facilitate proper dye disposal and mitigate contamination risk. Additionally, decomposition products of dolomite, the result of temperature-related processes occurring at 800° Celsius (magnesium oxide and calcite) were utilized and tested for their sorption efficiency as well. This earth

material was chosen due to its availability and low cost in comparison to synthetic alternatives. This study is designed to determine the rate of ARS sorption under specific conditions such as varying initial concentration, ionic strength, temperature, and time. Samples were prepared in duplicate to verify accuracy and precision of resultant data. Data was collected primarily via ultraviolet-visible (UV-vis) spectroscopy analysis of supernatant solution, to quantify the amount of dye absorbed by the dolomite/ heated dolomite. X-ray diffraction (XRD) and Fourier-transform infrared spectroscopy (FTIR) were used as analysis methods for the mineral component of each sample. XRD and FTIR data is currently being analyzed and as such, results and conclusions are anticipated in the near future. From UV-vis spectroscopy analysis alone, heat-treated dolomite was shown to be more effective in the removal of ARS dye – it ultimately was able to absorb higher concentrations of dye than raw dolomite a majority of the time. Specifically, based on the Langmuir sorption affinity parameter, heat-treated dolomite showed an increase from 1 L/kg to approximately 40 L/mmol: 40 times increase in efficiency compared to raw dolomite. Funding for this research is partially supported by the Freshwater Collaborative of Wisconsin and a WiSys Spark Grant.

Abstract Name: Can You Catch a Conspiracy Theory?: Critical Thinking to Dispel Conspiratorial Belief

Conspiracy theories are defined as a secret plot designed by two or more powerful actors, most often associated with the government. They are considered misinformation to the media and have become a cultural phenomenon that can sometimes prove malicious in their intent. While having ideation of an alternate reality can help to rationalize and justify the powerful actors' behavior, conspiracy theories are corrosive in both society and personal relationships. Often being the cause of violence and contributing to the propagation of prejudice in society, Conspiracy theory ideation is becoming a growing public health concern, causing distrust for government, health professionals, and authority. Conspiratorial thinking has been shown to correlate with lower levels of education. However, we do not know the causes, and beliefs can be malleable as we learn critical thinking skills. In this study, researchers will be asking two questions: Is critical thinking able to dispel conspiratorial belief and, is there a correlation between conspiratorial thinking and a persons religious or political affiliations? To investigate these hypotheses, I have devised a pre-test and post-test study with an intervention exposing the experimental group to new critical thinking skills. First, all subjects will receive the Conspiracy Mentality Questionnaire, the Centrality of Religiosity Scale, and demographic questions such as political affiliation. Participants will then be given the 27-question Critical Thinking Toolkit. The experimental group will read critical thinking skills, while control group participants will receive a reading on study skills. After reading, all participants will receive The CMQ questionnaire again. We live in an age where technology can give misinformation, and it is up to us to decipher reality from conspiracy. This work can help determine conspiracy theory as a mindset. This research aims to understand how education assists in weakening conspiracy theories and how a conspiratorial mindset can be changed.

Abstract Name: Return to One-Year Follow-Up For a Longitudinal Research Study After Disclosure of Amyloid Scan Imaging Results

Purpose/Background: Disclosure of biomarker testing for Alzheimer's disease (AD) is increasingly common, yet little is known about the effect of learning these results. Positive amyloid PET imaging may indicate a diagnosis of AD for individuals with cognitive symptoms and indicates risk level of developing AD in others. For such individuals, longitudinal follow-up for assessment of possible progression is critical. This preliminary analysis examines the rate of return for follow-up visits after participants from a longitudinal study of AD learn their scan results.Methods:Sixty participants from an Alzheimer's Disease Research Center (ADRC) had amyloid PET Imaging and learned their scan result. Return for follow-up cognitive assessment was tracked by the ADRC. A Chi-Square test of independence was used to examine whether amyloid status was associated with return for a one-year follow-up at the ADRC.ResultsParticipants were 62% Male, 93% White and averaged 70 years of age. Diagnoses at scan were 15% cognitively normal, 35% mild cognitive impairment , and 55% dementia. Mini Mental State Exam scores averaged 24.63 (range 12-30). Just over half (53.3%) were amyloid negative and 46.7% were positive.Chi-square test indicated no significant relationship between amyloid result and return at one-year follow-up.ConclusionIn this sample there was no relationship between whether individuals learned that they had amyloid plaque and whether they returned for follow-up one year later. This indicates that knowledge of one's amyloid status does not seem to affect adherence to recommendations for continued follow-up. A limitation of this preliminary data is the high proportion of already known dementia participants as individuals with MCI or normal cognition might be more affected by a positive for amyloid scan result. Keywords: Biomarker, Alzheimer's Disease, Result Disclosure, Retention, Amyloid, PET Scan

Abstract Name: A Dance-Based Movement Intervention to Address Scoliosis in College Dance Students

Purpose: The purpose of this project is to examine if an integrated modern dance-based movement intervention could also be beneficial in reducing the Cobb angle in the participants spine, improve strength and flexibility, assist with pain, and increase overall mental well-being and compare it with a strict Pilates regiment. A dance movement practice that combines yoga, Bartenieff Fundamentals, and modern dance could be a unique and enjoyable way for dancers to not only address their curvatures, but practice what they love in a healing way.Literature Review (Background): Dancers with scoliosis are more prone to back and knee injury than non-scoliotic dancers as well as a doubled risk of sustaining dance injuries (Wong 2022). Pilates has been researched for its efficacy in decreasing the Cobb angle in patients (Kim and HwangBo 2016) and decrease lumbar and curve thoracic curves (González-Gálvez et al. 2020).Methods: This IBR approved project was a five-week movement intervention was composed of 20-minute interventions once a week. The participants were divided into three groups: Pilates Group, Movement Intervention group, and control. Cobb angle was be measured using a Scoliometer for pre-screening and post-screening. They also filled out pre and post questionnaires regarding daily pain, dance experience, and scoliosis history. They gave feedback of the interventions after they were done.Results Participants who were in the Pilates intervention and the

movement intervention noted a decrease in physical tension. Participants in the movement intervention noted a greater feeling of relaxation Participants in the Pilates intervention had a decrease in Cobb angle by an average of 0.89 degrees. Participants in the control group and the movement intervention group did not have any decrease of Cobb angle. Self-perceived rankings of daily back pain decreased by an average of 1, based on a 1-5 pain scale, in the movement intervention group.

Abstract Name: The Lived Experience of Medical Interpretation on Ad Hoc Interpreters: A Phenomenological Study

Purpose The purpose of this qualitative study was to better understand the lived experience of adults who served as ad hoc interpreters (AHIs) in healthcare settings. An AHI is defined as any untrained person who serves as a language interpreter for another person/group of people. AHIs are sometimes referred to as Language Brokers in the literature. Background Although many studies discourage the use of AHIs in healthcare due to the risk of translation errors, the use of AHIs remains common. Existing literature on the lived experience of AHIs is largely focused on children who often report feeling conflicted and uncertain about the role. This study explored how adults, many of whom also interpreted as children, described their experience serving as an AHI. Methods Semi-structured Zoom interviews were conducted and common themes analyzed. Participants had to meet the following requirements: AHI experience in a healthcare setting in the past 5 years, 18 years of age or older, Texas Woman's University (TWU) student/faculty/staff member, access to a Zoom-capable device, and sufficient English speaking skills for the interview. This study was approved by the Institutional Review Board (IRB) as an exempt study. Results The interviews revealed that participants felt motivated to translate rather than obligated to do so. AHIs reported that the experience differed based on their familiarity with the person they were translating for. Many participants who translated as children reported feeling more comfortable serving as AHIs as adults due to greater experience and maturity. Several participants reported that their pursuit of healthcare professions was heavily influenced by their service as an AHI.

Abstract Name: Trigonometry, Planar Geometry, and Location by Trilateration with Unknown Stations

The work presented here shows how triangles and trilateration can be used in solving both abstract and applied problems. Trilateration is the process of locating an object using distances to three known points or stations. Satellites and other devices are usually involved in such a process, which allows for applications as commonly used as GPS, GIS, etc. An issue arrives when the locations of, or even the distances between,

these stations are unknown. For example, a satellite orbiting the Earth will be moving, making it hard to locate. The work introduced here presents a solution to such an issue in the context of two open problems published by the New York State Mathematics Teachers Journal, proposed by Bernerd G. Hoerbelt. The problems involve three stations of unknown location. The solution presented here uses circles centered at the stations to find the intersecting point, similar to GPS trilateration, and uses various mathematical techniques, such as revolving substitution and solving fourth degree equations. Another open problem is from the American Mathematical Association of Two-Year Colleges, proposed by Michael Ecker. This problem involves creating a hexagon of a known side length, and then inscribing hexagons recursively inside of it, asking when the perimeter will meet a certain threshold. The solution presented here uses mathematical tools such as trigonometric identities, converting series from recursive to explicit expression, and solving exponential equations. This problem is more abstract in nature, but utilizes important mathematical tools. Both solutions involve the use of analytical reasoning as well as geometric descriptions and visualizations

Abstract Name: Subconscious Comprehension of Structural Forms: An Eye-Tracking Study

This research seeks to analyze if there exists an understanding of structural design principles among untrained humans. Building forms and styles have evolved since the earliest structures. For thousands of years buildings were limited by naturally occurring materials. Designs of those periods reflected the structural principles of those materials. In the last few hundred years technological advances have provided structural methods which radically altered how buildings can be designed. An example is the difference in column spacing between historic and modern buildings, where the former has much tighter spacing due to natural material’s spanning limitations.To analyze the understanding of untrained humans an eye-tracking study was conducted using A.I.-3M-VAS eye-tracking software. This technology utilizes artificial intelligence to graphically display eye gaze sequences, patterns, and durations of focus. The software reflects the first few seconds of eye-tracking, providing insights into subconscious reactions before a logical response is formed. Images of structural elements were designed digitally to reflect a variety of forms, maintain cohesiveness, and remove visual variables. Each image was individually processed through the software providing isolated results.The results of the study show consistent patterns of focus on locations of structural significance, such as bearing points, connections, and material loads. The consistency by which these concepts received focus concludes that there is an innate human ability to locate structural methods of building. Of note the structural forms which adhered to the limits of natural materials registered different eye tracking patterns than the modern manipulated material forms. The historic methods displayed even tracking throughout the structure, whereas the modern methods created hot spots at the points of greatest structural significance. The differences further emphasizes that untrained people are not limited to just understanding familiar structural forms. This will allow for further research on the physiological effects between form types.

Abstract Name: Impacts of Environmental Microplastics on Larval Behavior Using an Amphibian Model

Microplastics pollution is on the rise within the environment with microplastics being found in terrestrial environments, saltwater bodies, freshwater bodies, and drinking water. Oftentimes, animals either mistake microplastics for food or microplastics become embedded in food and animals end up consuming them. I will be studying how exposure to microplastics will affect animal behavior using Xenopus laevis tadpoles as a model. For this study, I exposed 15 Xenopus laevis tadpoles to 10 µg/L of 34-50 µm polyethylene microplastics and 15 Xenopus laevis tadpoles were used as a control group (i.e. not exposed to microplastics). After three weeks of exposures, I performed behavioral assays. To assess impacts on feeding, I withheld food for 48 hours. After 48 hours, I added food to the tank and recorded how long it took tadpoles to approach the food, amount of time spent eating, and number of times tadpoles returned to the food. After the feeding assay, tadpoles were fed regularly. Three days later, I performed behavioral assays to assess general behavior and responses to a simulated predator stimulus. Analysis of these behavioral assays is currently underway. I predict that we will see a change in how tadpoles respond to food because microplastics have been shown to impact the function of the digestive system. This work is important because microplastics have been a rising pollutant due to single use plastic and their improper disposal leading to increasing exposures across the globe.

Abstract Name: Degradation of Perfluorooctanoic Acid in Water by a Pin to Water Discharge Cold Plasma

This study focuses on the degradation of perfluorooctanoic acid (PFOA)-contaminated water by a Cold Atmospheric Pressure Plasma (CAP). Using PFOA as the choice of our contaminant is justified in today's ecosystem. PFOA is a "forever chemical" that does not break down easily and is toxic even at low levels, and its conventional treatment technologies such as advanced oxidation processes and activated carbon have scientific challenges. A 20-micromolar PFOA solution in conductive water was subjected to argon plasma at around 10 Watts in both positive and negative polarity respectively. The time of plasma exposure was varied from zero to two hours and the solution was analyzed with an LC-MS to quantify the percent degradation of PFOA over time using CAP. It was determined that PFOA degrades about 65% in an hour when CAP is run in positive polarity with Argon gas. The negative polarity trials provided evidence that about 40% of PFOA degrades in the same conditions mentioned above for positive. In the presence of a 1 mM solution of a surfactant cetyltrimethylammonium bromide, 75% of PFOA degrades in one minute in both positive and negative polarity. Scavenger experiments were carried out in both positive and negative polarity with a 7 mM solution of isopropanol, a scavenger of the H, and the OH radical. Results indicate an inhibition of PFOA degradation by around 55% in positive polarity and around 11% in negative polarity. This suggests that the H radical is most likely a probable species responsible for the degradation of PFOA as OH radicals are not supposed to be responsible for PFOA degradation as suggested in the literature. We will continue to probe similar scavenger experiments in the future to determine a specified pathway for degradation.

Abstract Name: How The Open-Access Model Impacts Viewer Relationship and Interaction: A Close Investigation of Different Visions: New Perspectives on Medieval Art

My research explores the momentum of the open access movement in academic publishing. According to Cornell University Library, open access is defined as “scholarly literature that complies with peer-review processes and maintains high publishing standards while remaining free of charge and carrying less restrictive copyright and licensing barriers than traditionally published works” (Suber, 2023). This paradigm shift from subscription-based to open access journals raises intriguing questions about the OA model’s impact on engagement, particularly within art history and the humanities, and how it compares given a cross-disciplinary analysis.My presentation will delve into the multifaceted landscape of open access publishing by using a case study approach centered on the open-access journal Different Visions: New Perspectives on Medieval Art, which is dedicated to medieval art history. By analyzing data obtained from the journal's website regarding site visits and interaction throughout time, the study investigates the spectrum of interaction facilitated by open access platforms. The use of this journal as a primary source offers insight into the nuanced dynamics of operating an open-access publication, along with the credibility of academic journals functioning under this model. My presentation also uses information from The Journal of Academic Librarianship as a baseline to discuss the varying types of open access publishing; specifically the different goals and functionality between gold and green open access. Referencing this source helps to better contextualize the case study within the larger field of open access journals used in art history. As academia navigates these transformations, understanding the implications of open access publishing becomes imperative for shaping the future of academic communication. This research uses a comparative lens, extending across publication models, to discern the model with the most successful interaction between publication and audience while further exploring the model’s influence on scholarly discourse.

Abstract Name: The Higher Education Crisis: The Latine Student Experience at Bridgewater State University

The rise of Latine students at Bridgewater State University (BSU) emphasizes the institute’s lack of resources and representation of Latine culture and identity. For BSU Latine students to succeed they need their voices heard and their needs met. Students are in desperate need of Latine mentorship, representation, and resources. To address this issue, the study conducted interviews with Latine students who attend or have graduated from BSU. These interviews consisted of questions about participant’s demographics and their BSU experience and support. The interviews revealed themes relevant to the Latine experience: intersectionality, Latine

identity, first generation, and mentorship and support. The students in this project discussed their want for more Latine faculty and staff and revealed their encounters with microaggressions and discrimination from BSU members. The participants in the study rated their overall BSU experience as positive but believed the institute could do more for their Latine population. Results from this study show the importance of listening to Latine voices and the steps needed for closing the educational gaps and for student success at BSU.

Abstract Name: Hit Me with Your Best Shot - Nursing Student Perceptions on Covid Risk and Vaccine Effectiveness Could Surprise You

Introduction - Cultural beliefs and misperceptions may lead to variable behavioral responses to COVID and vaccinations. Educators should not assume uniformity of nursing students' (NSs) perceptions regarding COVID. A better understanding of nursing trainee perceptions can inform educational interventions. Methods - A 44-question survey was distributed in September 2023 to students enrolled in a senior-level BSN (baccalaureate program in nursing) course. Then compared to surveys from the same time across Missouri, with urban and rural participants. The analytic plan included descriptive and bivariate statistics. Results - Ninety-one NSs and 371 other adults (OA) were surveyed. NSs were statistically more likely than OAs to trust CDC, FDA, and other government agencies (60.4% vs 37.5%; p<0.0006) and less likely to trust healthcare providers (47.3% vs 57.7%; p<0.07) for information about COVID and vaccines. The majority of NSs when describing vaccination status reported "they got vaccinated as soon as they could" (67.3%), while one-quarter of the NSs (24.2%) indicated they are more likely to wait and "see what happens to others." Few remain skeptical about the pandemic (4.4%) or "do not trust the system" (4.4%). About half of the NSs and OAs plan to get vaccinated in the future (58.2% vs 54.4%), but significantly more NSs were unsure of future vaccination (28.6% vs 15.6%, p<0.004). Both NSs and OAs reported being "not at all worried" about getting long COVID (59.3% vs 52.6%), despite NSs reporting higher risk of getting COVID (medium to high risk 72.5% vs 56.9%; p<0.006).Discussion - NSs were not uniform in their perceptions of COVID risk or vaccinations and were different than OAs. NSs may trust government sources more and providers less, which could impact effectiveness of messaging strategies. Based upon our results, COVID education for NSs should include risks for long COVID with the safety and effectiveness of vaccines.

Abstract Name: American Airpower: Historical Narratives, Museum Aircraft, and World War II in Asia

In 1984, the National Air and Space Museum announced its impending restoration and display of the Enola Gay, the B-29 Superfortress that dropped the atomic bomb on Hiroshima. This was the beginning of the well-known public controversy about which narrative to assign to this historic aircraft. Because no one could agree on which narrative to present, the display of the restored Enola Gay opened in 2003 as a bare exhibit containing a singular sign listing basic facts. The question of historical narrative and the observation that many times museums lack historical objectivity and nuance has been questioned globally. Beyond the analysis of the Enola Gay controversy, there is no research about public history narratives of American airpower in Asia as studied through museum aircraft. The question I ask is how and why have certain historical narratives been prioritized in U.S. museums, particularly aviation museums and those revolving around American airpower during World War II in Asia? This project seeks to analyze the unique limitations and strengths of aviation museums, noting their purpose to serve and educate the public through the display of aircraft as their primary educational tool. It also seeks to highlight the lesser-known narratives of World War II, as museums and academic narratives adopt an occasionally Western-centric, even American-centric perspective. As evidenced by the case studies of American airpower in Asia during World War II, museums do not prioritize historical objectivity and nuance due to space, time, and funding constraints. Museums deal with the difficult balancing act of providing adequate historical context and attracting visitors. The narratives attributed to the aircraft change over time, and not every narrative is told. The choice of historical narrative becomes a part of the collective national memory of World War II, and the aircraft serve as a powerful reminder of the war.

Abstract Name: Impact of the ActiveStep Perturbation Treadmill on Fall Prevention within Aging Populations

As the global population continues to age, promoting healthy aging becomes crucial for sustaining individual well-being and alleviating the burden on healthcare systems. One-third of adults aged 60 and above experience falls annually in the US, a serious concern for mobility and independence. Prior research highlights the correlation between a decline in neuromuscular function in older adults and an increase in fall risk. The purpose of our study was to determine the effect of perturbation training on fall prevention in older adults. Participants from rural Minnesota underwent two weekly sessions over the course of four weeks. They were harnessed on an ActiveStep treadmill designed to challenge and enhance their neuromuscular responses

to unexpected perturbations (slips and trips). The ActiveStep treadmill has five levels of difficulty which determine the magnitude of the perturbations. Comprehensive assessment metrics were recorded at baseline and again at post-intervention for balance, strength, fear of falling, and gait patterns. Furthermore, follow-up evaluations at six months gauged the intervention's impact on fall risk, indicating that participants experienced an improved awareness of falls. Overall, predictors of fall risks and reactions were examined through exploratory data and regression analysis. Our results show a marginally significant improvement in sit to stand ($p = 0.1$) and timed up and go ($p = 0.08$). Overall, there was a decrease in reaction time to slips and trips. However, the magnitude of the effect was dependent on the participant's age and the season in which their sessions took place. Our findings contribute to the growing body of knowledge on healthy aging and present a possible targeted intervention for preventing falls in older populations.

Abstract Name: AI and Robotic Energy: Integrating Generative AI for Advanced Drone and Robotic Manipulator Real-Time Control

Generative Artificial Intelligence (AI) has revolutionized the technological landscape, driving unprecedented advancements across numerous industries. Its applications extend beyond mere convenience, tackling complex, high-stakes challenges such as climate modeling, personalized medicine, and advanced materials science, addressing some of the most pressing issues of our time.Building on this momentum, this research harnesses the power of generative AI to steer robotic units, including Tello Drones and Elephant Robotics Manipulators. These robotic entities prove invaluable in innumerable settings. Drones, with their aerial prowess, excel in tasks ranging from intricate surveying of inaccessible terrains to swift delivery services. Meanwhile, robotic manipulators excel in precision-based activities, thriving in environments requiring meticulous attention like complex assembly lines and delicate surgical procedures.In this innovative synergy, generative AI, represented by models like ChatGPT, leverages advanced logic and prompt-training to make robotic technologies more accessible and practical for users with limited technical understanding. The project initially targets basic functionalities like autonomous mobility and object localization within specific areas, aspiring to support critical, life-saving missions like search and rescue operations under challenging conditions.A significant innovation of this research is its approach to real-time robotic manipulation, addressing the pressing need for instantaneous feedback and directives in applications involving drone mobility and manipulators. Traditionally, GPT models introduce prompt delays and communication lags, presenting substantial challenges in real-time scenarios. This research project counters these issues by implementing parallel networking and computational enhancements, including multi-processing and innovative task-queuing techniques.In summary, the research boosts robotic units' responsiveness to user inputs and environmental changes, ensuring swift, seamless operations. The research contribution includes significantly reducing communication and GPT prompt delays to meet the stringent demands of real-time applications. Furthermore, it boosts real-time operation capabilities through advanced computational performance algorithms and unique tasking processes, as detailed in the results section.

Abstract Name: Urban Stream Corridor Restoration Effects on Sediment Loading

Urbanization of stream ecosystems is known to increase sediment loading and change the physical and chemical characteristics of a stream, leading to decreased water quality and poorer aquatic and riparian habitats. This is often in response to channelization, runoff from impervious surfaces, riparian corridor degradation, drainage systems, and pollution found in urban environments. Urban stream restoration projects generally include riparian habitat and vegetation improvements as well as removing channelization features. The impacts of stream restoration in urban environments bear investigation as to the effects it may have on water quality in a watershed. Galloway Creek in Menomonie, Wisconsin is a small urban watershed (~1300 hectares) and is responsible for handling much of the collected runoff from the city. The stream has been a long-term study site for UW-Stout undergraduate researchers and faculty and has recently undergone reach-scale restoration projects to improve the riparian corridor vegetative community by removing invasive shrubs and planting native tree species. In this project, we examined turbidity, conductivity, pH, NVSS, substrate type, habitat assessment score, biotic index, and flow measurements from locations upstream or downstream of areas of restoration or channelization. Analysis of the data attempts to display trends that restoration projects may have on an urban stream like Galloway with the goal of better understanding the impacts of stream urbanization and the effectiveness of subsequent restoration projects. This information may be useful in advocating for awareness about water quality in our streams and watersheds as well as encouraging new restoration projects based on potential positive impacts on water quality in small urban watersheds.

Abstract Name: Psychological and Medical Significance of Chitterlings (Chitlins) in Southern Rural American Communities: Foods that Shape Traditions and Dietary Choices in the South

Chitterlings, commonly referred to as ‘chitlins”, is the Southern American delicacy that represents soul food and comfort. Comfort food/tradition is combined with culture, and culture incorporates food that has been cultivated by hands that have passed down generational legacies. Chitterlings were associated with the dietary habits and position in society of enslaved people in the Southern United States, particularly in the 17th to 19th centuries. The present study investigated how the methods used to prepare chitterlings, the historical link to slavery, the nutritional aspects of chitterlings such as the high content in protein but also the harmful nutritional aspects of chitterlings such as high levels of cholesterol and fat. As well as the use of preservation techniques used in chitterlings and the similarities of convenience and affordability in fast food. In addition to the alternatives to align the traditional cuisine without losing its cultural essence and other substitutes in terms of vegan soul food. This research used peer-reviewed research articles, books, and cultural blogs. The reviewed literature gathered data through focus groups, interviews, and surveys conducted at University of Alabama at Birmingham and more Southern American Universities (Southern America= South of the Mason and Dixon Line, the Ohio River, and the 36°30′ parallel), representing a variety of socio-economic backgrounds rooted in Black American descent. Results indicated that chitterlings were ranked as one the unhealthiest foods associated with African Americans through the Nominal Group Technique (NGT). African Americans in the South were reluctant of vegan soul food because of the taste, chitterlings required heavy salting and seasoning to allow the dish to become palatable, and chitterlings represented low-

socioeconomic status for Southern communities in the United States. Examine how socioeconoomic status influences diietary taste preferences, with regard to chitterlings.Keywords Chitterlings, Black American, vegan soul food, slavery, Southern rural America

Abstract Name: Analysis of Complex Sentences in Language Samples Obtained from One Frog Too Many and Frog Where Are You: Step 1.

The purpose of this project was to create a systematic, reliable rubric for using two of the Frog Stories from the Frog Story series to evaluate the percentage and type of complex sentence structures as part of a comprehensive language sample analysis for the diagnosis and treatment of children with developmental language disorders (DLD). Language sample analysis is a critical part of the assessment process by speech language pathologists (SLPs) for determining whether a child has a developmental language disorder. Elicitation of language from a child is often achieved by asking them to tell a story. One popular way that SLPs have obtained samples is to ask them to retell one of four popular wordless picture books from the Frog Story series by Mercer Mayer. This series involves the antics of a frog and his boy as they encounter different adventures. There is no rubric or “analysis key” associated with the stories leaving the SLP to decide how to use the information obtained from the story independently. This makes it hard to obtain reliable results over multiple time points for use in progress monitoring.In this project, a team analyzed two of the four Frog stories, One Frog Too Many and Frog Where are you, for its inclusion of specific complex sentence structures that should be present in oral and written language samples obtained from school-age children. These include complement clauses, reported speech, relative clauses, subordinate and coordinate clauses. The methodology for identifying the language parameters of interest, reliability in coding, and uses for the rubric will be described. The rubrics will be automated using a web application so clinicians can upload their child’s story and have them instantly scored, making their use in analysis more reliable and consistent.

Abstract Name: The similarities and differences in the effects of bacterial endotoxin lipopolysaccharide (LPS) on synaptic transmission at glutamatergic synapses.

The endotoxin lipopolysaccharides (LPS), secreted from Gram-negative bacteria, has direct effects on synaptic transmission independent of systemic secondary cytokine responses. High concentration of LPS

(500 µg/mL) from Serratia marcescens increased synaptic efficacy at glutamatergic synapse at the crayfish neuromuscular junction (NMJ) but depressed synaptic efficacy at glutamatergic synapse at the larval Drosophila NMJ (N=12 for each; P<0.05). Both preparations resulted in transient hyperpolarization (N=6 for each; P<0.05). At the Drosophila NMJ, quantal responses and evoked excitatory junction potentials (EJPs) decreased in amplitude, and it appears that postsynaptic glutamate receptors are blocked. However, this is not the case at the crayfish NMJ despite the receptor subtypes at both NMJs being pharmacologically classified as quisqualate receptors. The hyperpolarization appears to be due to transiently activating K2p potassium channels at the Drosophila NMJ since doxapram blocks the LPS response (N=6 for each; P<0.05). Doxapram is a therapeutic compound used clinically to improve respiratory drive of carotid bodies by blocking the pH sensitive K2p channels (TASK subtypes). Doxapram (10 mM) depolarizes the larval Drosophila muscle in all preparations (N=6) but not as substantially for crayfish muscle (1 to 10 mV) for all preparations (N=6). Doxapram at the crayfish NMJ does not cause the NMJ to spontaneously fire action potentials as it does at the larval Drosophila NMJ. Doxapram does not block the LPS response on glutamate receptors in Drosophila but does block the hyperpolarization induced by LPS. Investigations at the crayfish NMJ is still underway. Perhaps doxapram will be able to be used to block the LPS direct responses during Gram-negative bacterial septicemia.

Abstract Name: Sex Difference in Stress-Induced Increase of Epithelial Permeability in the Mouse Colon

The intestinal inner lining is made of epithelial cells held together by tight junctions that prevent harmful or foreign material from entering into the body. Stress has been proven to increase intestinal permeability, contributing to the development of irritable bowel syndrome (IBS) and other gastrointestinal diseases. IBS is more common in females, but prior studies have been inconclusive on finding a link between biological sex and increased intestinal permeability. The aim of this research was to explore the role biological sex has in stress-induced increased epithelial permeability in the mouse colon. Mice were divided into four groups (5/group): control male, control female, stressed male, stressed female. Animals in the stressed groups were restrained for 1 h/day for five consecutive days. Control animals were kept in their home cages and did not experience restraint. Following the final restraint/control session, the proximal and distal colon were removed. The mucosa/submucosa preparations were mounted to the Ussing Chambers. The transepithelial resistance (TER) was recorded continuously as a measurement of paracellular permeability. FITC-inulin and horseradish peroxidase (HRP) were added to the luminal chamber to measure paracellular and transcellular permeability, respectively, across the colonic epithelium. The results showed stress caused a significant decrease in TER in the female proximal colon and in the male distal colon. Stress also increased FITC-inulin flux in the proximal and distal colon of female mice but had no effect in male mice. Stress increased HRP flux in the proximal colon of both male and female mice but had no effect in the distal colon of either sex. These results suggest female mice are more susceptible to increased paracellular intestinal permeability than male mice. Understanding how stress affects intestinal permeability differently between male and female may lead to the development of sex-specific treatments to reduce the symptoms of gastrointestinal distress.

Abstract Name: Music Preference, Personality, and Gender as Predictors of Resilience

This study sought to identify predictors of resilience in undergraduate students. Previous literature revealed connections between resilience, personality, music preference, and gender. For instance, there was a significant relationship between resilience and personality; specifically, a negative correlation was found between resilience and neuroticism/emotional stability as well as a positive correlation between resilience and both conscientiousness and openness to experience. Additionally, personality has also been shown to relate to music genre preference. Music is known to aid in coping with trauma, regulating mood, and reducing stress– all of which were factors discovered as important in building resilience. The current study also investigated the relationship between gender and resilience based on literature indicating a possible connection between gender and coping mechanisms. In consideration of the aforementioned literature, the following hypothesis was proposed. The Big Five personality test scores (openness to experience, conscientiousness, neuroticism/emotional stability, extraversion, and agreeableness), music genre preference scores, and gender would predict resilience scores. To test this hypothesis, The Big Five Personality Test Short Questionnaire (BFPTSQ), the Brief Resilience Scale (BRS), and the Short Test of Music Preferences — Revised (STOMP-R) were administered. One hundred sixty-five (N = 165) undergraduate students participated in the study. The participants were students of all classifications from mathematics, choir, history, and science classes. Upon IRB approval, instrument packets and consent forms were administered in classrooms with the permission of the professor. Participation was voluntary and confidential. The collected data was analyzed by a multiple regression analysis using SPSS software. It was found that neuroticism/emotional stability and a preference for unpretentious music were significant predictors of resilience. No other variables predicted resilience scores. Limitations included the homogeneity of the sample, and future researchers were advised to include more sample diversity.

Abstract Name: Submerged Fermentation of Ganoderma tsugae Mycelium for the Production of Exopolysaccharides

Ganoderma tsugae, commonly known as the hemlock reishi, has historically played a significant role in Eastern traditional medicine. Notably, Ganoderma species are known to have medicinal properties for potential commercial use including cholesterol reduction, lowering blood pressure, antivirals, and antitumor therapies. To fully capitalize on these medicinal benefits for commercial use, the Ganoderma mushroom and its potential therapeutic metabolites, including biologically active polysaccharides, must first be produced at scale. One promising approach is to employ stirred-tank bioreactors for the submerged fermentation of mushroom mycelium. The goal of this project is to maximize biomass and polysaccharide production from the submerged fermentation of G. tsugae mycelium. Experimental variables included media formulations and enrichments, temperature, pH, and agitation. Mycelium cultivation involved growing G. tsugae on Potato Dextrose Agar (PDA) plates, which were then used to inoculate liquid cultures in baffled shake flasks. After a two-week shaking incubation, liquid cultures were then used to inoculate 2 and 4-liter stirred-tank bioreactors. Samples were taken every 2-4 days and assayed for biomass, reducing sugars, and total polysaccharides. The highest biomass and polysaccharide production was observed in a lactose-based media with a constant temperature of 28°C, pH of 5.5, and an agitation of 120 RPM. These optimized parameters resulted in a peak biomass yield of 6.4g/L and a peak polysaccharide yield of 1.7g/L.

Abstract Name: A Radial Basis Function Neural Network for Classification in Smart Grids

Introducing technology into systems inevitably amplifies the susceptibility to malicious attacks and security breaches, a concern notably pertinent in the context of Smart Grid (SG) systems. Through integrating Internet of Things and intelligent devices into the conventional electrical grid, SG systems enhance efficiency but introduce security risks, including potential financial losses, power disruptions, data tampering, cascading failures, and erosion of trust. Mitigating these risks and promptly discerning potential attacks rank high on the priority list. To address this, we propose the implementation of a Self-Organizing Map (SOM) for data clustering and dimensionality reduction, utilizing its innate capacity for unsupervised learning, adaptive feature extraction, and topology preservation. Subsequently, the output of the SOM serves as input to a Radial Basis Function Neural Network (RBFNN), responsible for classifying data clusters into distinct attack types. The SOM-RBFNN algorithm will be applied to real-time power grid data obtained from the Mississippi State University and Oak Ridge National Laboratory. These datasets are grouped into 3 sets: Multi class, Triple class, and Binary, where the distinction is in how an event is classified. Development and testing of the SOM-RBFNN algorithm was done in Google Collaboratory using MiniSom and sklearn libraries. This algorithm is rigorously assessed and tested against other standard algorithms using the accuracy measure. The experiments using our SOM-RBFNN algorithm averaged 94% accuracy on the binary class data set.

Abstract Name: Synthesis and Characterization of a Heterometallic Copper Thallium Hydride Cluster

Metal hydrides have been a continual topic of research and development over the last 50 years due to their ability to catalyze complex molecular rearrangements and redox reactions. Thallium hydrides, however, are exceedingly rare and remain a relatively unexplored metal hydride. It was only in 2018 that the first thallium hydride complex was reported, and there have not been any developments since then. In efforts to synthesize this rare class of metal hydride, treatment of Cu6H6(PPh3)6 with TlOTf (OTf=trifluoromethanesulfonate) was performed to create [Cu6TlH6(PPh3)6][OTf]. We hypothesized that this cluster contained thallium hydride bonding and through structural characterization verified the presence of thallium hydride bonds and, successfully isolated the second of this rare class of metal hydrides. Characterization included: NMR spectroscopy, mass spectrometry, and X-ray crystallography. This project aims to provide a reliable synthesis, isolation method, and characterization of the copper thallium cluster.

Abstract Name: Brilliantly Black: Success and Resiliency in Predominately White Spaces (PWI)

In predominately White educational spaces, Black students are isolated and lack belonging. Despite this challenge, higher educational spaces remain an essential catalyst for success within the Black Community. Black students have not only persevered but excelled in predominately White spaces. This study is an analysis of qualitative comments generated from TikTok, a popular social media platform. The creator of the TikTok video is a current student of a predominately White institution (PWI) who sought advice and support while navigating this tumultuous environment. The project Resilience and Black Brilliance (R&B) highlights the marginalized perspective of Black collegiate students and showcases the many expressions of Black students and alumni. The narrative will be told through a presentation. This presentation will contribute to the body of scholarly knowledge and increase the understanding of the complex and dynamic relationships between Black students and the academy. The greater understanding provided by this presentation will highlight the role intentional inclusivity initiatives and academic community support play in the Black educational experience.

Abstract Name: Melia azedarach and Its Endosymbionts

Melia azedarach, commonly known as Melea or Chinaberry, is a plant valued for its antimicrobial properties and used as a remedy for various ailments. Several studies show that all plants form symbioses with microbes known as endophytes. Although endophytes can be neutral and under certain conditions, parasitic, they are mainly known for their beneficial symbiotic relationships with plants. Although M. azedarach is a medicinal plant, its endophytic diversity and metabolomic properties remain unclassified. This study sought to increase knowledge of the metabolic potential and influences of endophytic fungi in M.azedarach. Its leaves were sampled from locations of varied climate and environmental conditions: central Kenya (semi-arid climate) and coastal Kenya (semi-arid/tropical climates). Fungal endophytes were isolated from the leaves. Morphological and molecular characterization of the fungal colonies were performed. The results reflected overlapping endophytic communities between the regions. In both central and coastal Kenya, M. Azedarach

leaves contained Colletotrichum gloeosporioides, a well-known beneficial endophyte that can become pathogenic in fruit crops. In contrast, Preussia minima was observed only in coastal Kenya. Aspergillus and Penicillium were among the remaining fungi identified. In conclusion, C. gleosporioides can survive across environmental gradients while P. minimaprefers a tropical climate. The bioactive secretions of the endophytic samples will be identified using High-Performance Thin Layer Chromatography (HPTLC).

Abstract Name: The Impact of Non-Native Red-eared Sliders on Native Freshwater Turtles in Maryland Wetlands

Non-native species are one of the leading causes of extinction, worldwide, and are particularly problematic in freshwater ecosystems. However, not all non-native species have significant ecological impacts or warrant control. Here, we critically examine the influence of the non-native red-eared slider (Trachemys scripta elegans) – a commonly released pet – on native freshwater turtles in Prince George's County, Maryland. Specifically, we focus on potential impacts to the abundant eastern painted turtle (Chrysemmys picta picta) in the Patuxent Research Refuge and nearby Bowie State University campus. We quantified eastern painted turtle abundance, body condition, and diet in wetlands where they coexist with red-eared sliders and at similar wetlands extending up to 2.4 km away from known red-eared slider capture locations. Catch per unit effort (number of turtles per trap-day) and body condition of eastern painted turtles did not vary significantly based on proximity to red-eared sliders over the two years of our study. However, we found a cline in diet (quantified as by stable carbon and nitrogen isotope ratios in turtle claws) moving away from red-eared slider capture sites in both Patuxent Research Refuge and Bowie State campus. Our stable isotope data suggest that eastern painted turtles shift to a lower trophic level and more benthic diet when they must compete with red-eared sliders. Overall, our data strongly suggest that red-eared sliders compete with the native eastern painted turtles for food, effectively shifting their dietary niche. However, we do not have sufficient evidence to conclude that the local painted turtles suffer in their abundance or fitness, potentially because of the relatively low abundance of red-eared sliders in our study sites.

Abstract Name: The Politics of Reproductive Health: Understanding The Impact of the Global Gag Rule on International NGOs

Our central research question was: how have non-governmental organizations (NGOs) adjusted their practices and policies in reaction to the partisan flip-flopping of the Global Gag Rule (GGR) since the Obama administration? The Mexico City Policy, or Global Gag Rule (GGR), is a policy that prevents international organizations that receive USAID funding from referring, providing, or advocating for abortion services. Since its first enactment, the GGR has been rescinded and reinstituted multiple times, depending on which party is in the executive branch. This political flip-flopping has led to a need for constant adjustment by NGOs and has impacted health care provisions in vulnerable countries. During the Trump administration, the GGR was expanded to include nearly all global healthcare providers, but it was later rescinded by President Joe Biden. While the literature assumes that these NGOs would struggle uniformly, we investigated how different people viewed the policy changes and reacted creatively. Our methods were primarily a series of semi-structured interviews of employees at different NGOs and US experts. Using the responses from these interviews, we were able to draw conclusions about how NGOs have perceived and responded to GGR changes. Our project analyzes the GGR policy and uses Marie Stopes Nepal as a case study to illustrate how NGOs have been affected, and what their current action plans are for when this flip-flopping occurs. We learned that NGOs need to rely on a heightened level of self-reliance, diversify their funds, and pay close attention to the political climate in the United States so that they can continue to provide essential health services. Our goal is to create a documentary that aims to provide a toolkit offering information to policymakers, NGOs, and the public, highlighting the different ways the GGR affects people around the world.

Abstract Name: Global Network Learning Project: Investigating and Comparing Sustainable Development Goal #4 Quality Education

The purpose of our research is to investigate and compare aspects of the Sustainable Development Goal (SDG) #4: Quality Education. The main research questions for our international comparative study are: What are the similarities among Germany and the United States related to target goals for Sustainable Development Goal #4 Quality Education, guarantee quality and equitable education while creating educational opportunities for all? What are the differences? Are the countries on track to make progress on SDG #4 Quality Education by the 2030 goal year? To conduct this research, we wrote an annotated references document and used a literature review research design to develop an Executive Summary of our findings. The literature review included international reports and the method was framed by Bereday's (1964) Comparative Model. The research was part of a semester-long Global Networked Learning (GNL) research collaboration among students at UNC Charlotte with and students at the PH Ludwigsburg in Germany. A GNL project is a collaborative approach to learning that enables students and instructors from different locations around the world to participate in learning and creation of knowledge together. GNL allows for access to international experiences for all students. In our research, we report the comparative findings of our GNL project. The

research includes an examination and discussion of the challenges and possibilities in meeting selected target goals of SDG 4 Quality Education, guarantee quality and equitable education while creating educational opportunities for all by the 2030 goal year.

Abstract Name: Support for Constitutional Change as a Measuring Tool for the Necessity of Truth and Reconciliation Committees

Establishing common ground among separatist groups cohabiting within a state is imperative for fostering peace and security for both the state and its inhabitants. In regions marred by intense conflict, divergent narratives emerge, creating a complex set of conflicting "truths." This historical ambiguity often persists and is passed down through generations, as the youth grapple with competing interpretations of the past. To address these divergent “truths”, Truth and Reconciliation Committees (TRCs) have proven to be instrumental. These committees aim to uncover the most accurate account of violent events and promote reconciliation among communities. Why then, do some post-conflict resolutions need to create formal Truth and Reconciliation Committees, while others do not? I propose that a critical factor lies in the degree of widespread support for constitutional changes in the post-conflict state. The unification of people in the aftermath of conflict is intricately tied to the endorsement of constitutional reforms. When there is widespread support for such changes, the need for implementing Truth and Reconciliation Committees diminishes, as the constitutional framework itself becomes a catalyst for reconciliation among previously divided communities. To illustrate this, I compare the conflicts in Northern Ireland druing The Troubles and in Bosnia and Herzegovina during the Bosnian War. With similar social cleavages, paramilitary actors, and international military intervention, we find only one signifigant divergence between these two case studies; the level of support for the constitutional changes outlined in their peace agrrements. A widely accepted constitutional framework can remove the need for formal TRCs, offering a pathway for reconciliation that is rooted in shared values and a collective commitment to a peaceful future. But, if widespread consensus cannot be made, a formal TRC is imperative to sort out the most accurate account of the “truth” so that the people of that state can move forward, together.

Abstract Name: Examining the Five-Factor Personality Model: A Latent Profile Analysis in Individuals with Above Threshold PTSD Symptomology

Latent Profile Analysis (LPA) has been extensively used in psychological research to uncover distinct subgroups within heterogeneous populations. Historically, these subgroups have been pivotal for

understanding the nuanced differences in symptom presentations, especially in conditions like PTSD. In this context, individuals with PTSD can vary in their expressed personality traits, which can impact treatment outcomes. This study aimed to understand these variations within a population exhibiting above-threshold PTSD symptomology. Similar to previous literature, LPA revealed three distinct profiles: 'Adaptive', 'Highly Adaptive', and 'Maladaptive'. These profiles were derived from the five-factor personality dimensions: openness, conscientiousness, extraversion, agreeableness, and emotional instability. Follow-up ANOVA outcomes showed significant differences across these profiles in multiple variables, including PTSD severity, resilience, and quality of life measures. Notably, the 'Maladaptive' group showed heightened PTSD symptomology and reduced quality of life, highlighting the importance of personalized therapeutic strategies. Building on previous literature, these findings underscore the necessity of tailoring treatments based on personality profiles, which may lead to improved therapeutic outcomes for individuals who struggle with PTSD.

Abstract Name: Post Processing Error Correction for Quantum Algorithms

In the era of the noisy intermediate-scale quantum computers (NISQ), the ability to control error rates is a key factor in our ability to achieve quantum supremacy. Current methods to reduce error rate include both using additional qubits and gates in quantum circuit design and post-processing techniques. Our method is a post-processing technique applicable to any circuit with a single desired output and less than 50% error rate. It operates by analyzing the occurances of 1s or 0s in each bit's place value and reconstructing a string by using the most occurring number for each place value. We predict that implementation of this method can help reduce error at a set number of shots and reduce the number of shots required to reach a reliable answer. Benefits of this technique include (1) reduced need for in-circuit error correction, which can lead to a higher likelihood of decoherence if too many operations must be done and (2) more real-estate on open source quantum computers due to a reduction in the optimal run time for a conclusive answer. Our method was built from analyzing uniform bit-flip error models and was tested on the Bernstein-Vazirani (B-V) algorithm. We also look forward to how the information gained from this processing technique can facilitate educated guesses to find the intended output for cases with bits at and near 50%.

Abstract Name: Quantification of Uncertainties in Operating Conditions on the Features of High-Pressure Turbulent Premixed Flames Using Surrogate Modeling Techniques

Turbulent premixed flames observed in energy conversion and propulsion devices encounter uncertainties that arise from various factors such as operating conditions, chemistry, turbulence, and turbulence-chemistry interactions. Such uncertainties pose challenges to the numerical investigation of such flames in terms of reliable predictive capabilities. Uncertainty quantification (UQ) is an effective computational strategy to quantify such uncertainties. UQ studies can be performed either using direct or surrogate modeling techniques. While the direct Monte Carlo (MC) sampling technique is popular and accurate, it tends to be computationally prohibitive for the investigation of practically relevant configurations. To this end, surrogate modeling techniques offer a computationally tractable approach. In this study, three popular surrogate modeling techniques, namely, polynomial chaos expansion (PCE), stochastic collocation (SC), and Gaussian process (GP) are assessed for their capabilities for the investigation of freely propagating laminar premixed flame. In this study, a non-intrusive forward UQ strategy is considered to examine the effect of the uncertainties in the operating conditions on the features of premixed flames. First, we consider freely propagating laminar premixed flame to assess the accuracy and efficiency of PCE, SC, and GP techniques in comparison to the MC approach, where the operating pressure is considered as the uncertain parameter. Afterward, the optimally performing surrogate technique is used to examine the uncertainty of pressure on the features of high-pressure turbulent premixed flame.

Abstract Name: Will University Students Agree With Political Opinions Along Party Lines?

One of the hallmarks of modern American politics is growing political partisanship. This gap between ideological liberals and conservatives is observed in descriptive and statistical data for measures of both the American public and with national politicians. Another hallmark of the current system is the relatively low levels of trust that the American people have in their elected officials and in the political institutions as a whole, though the public tends to be more trusting of officials from the party they align with. What we know less about is how far this trust in a partisan figure can be pushed. Could it be that someone with high trust in their party would be more likely to accept incongruous information? Will people agree with a statement that goes against their political beliefs simply because the statement is attributed to a candidate that they like? Leveraging a unique survey, data from a sample of college students at the University of Wisconsin-Stout was collected and analyzed. The results suggest that, overall, both young Democrats and Republicans do often stick with their perceived favored political ideas. This is opposed to leaning toward supporting an individual candidate they may like and, more importantly, trust. However, the research also suggests that at least a small level of polarization and partisanship are alive in the college age group.

Abstract Name: Learning strategies that advance acceptance and adaptation among descendants of Dakota

and European in Minnesota

The US-Dakota War of 1862 in Minnesota influenced President Abraham Lincoln to order the execution of 38 Dakota men. The entire oppressive and genocidal context created generational trauma for the Dakota community in southern Minnesota. For years after the war, many Dakota people were targeted and persecuted. Even today, many European descendants living in Minnesota are unaware of Dakota culture even while living together. The broader community has not been able to conclude what reconciliation would look like in southern Minnesota. Many community organizers have attempted to implement learning strategies in action to bridge the knowledge gap and bring reconciliation between Dakota and European descendants, such as the Mahkato Wacipi (Mankato Powwow), the annual Dakota 38+2 Ride, service learning by university students, and more. This study examined how previous service-learning experiences fostered a better understanding of Dakota culture among European descendants. Researchers predicted that students who completed service-learning hours had a better understanding of Dakota culture and the history of the US-Dakota War. Investigators also expected that students would develop a commitment to reconciliation and restoration of understanding and relationships.

Abstract Name: “Myself should send their hateful souls to hell:” Constancy and Passion in Early Modern Drama

This study focuses on the tension between feminine constancy and the intense passion concomitant to vengeance in early modern revenge tragedies. In much early modern literature, enduring faithfulness and a commitment to invariability were hallmarks of admirable feminine character; remarkably, these traits are still present in women whose actions are anathema to admirability: female revengers. While revenge was considered fundamentally effeminate by Stoic philosophers because of the passionate sensitivity necessary for its action, the act of avoiding vengeance was characterized as equally effeminate by several early modern plays, including Shakespeare’s Hamlet. In plays like Thomas Kyd’s The Spanish Tragedy and John Marston’s Antonio’s Revenge, female conspirators embody exceptional constancy crucial for offsetting the intense mercuriality and emotional vigor displayed by their male counterparts. Ultimately, the most constant of female revengers, like The Spanish Tragedy’s Bel-imperia, quell the vulnerability sown by grief-born sensitivity in male conspirators, allowing them to realize their abstract machinations by stabilizing them with practicality and concrete thought. Femininity in revenge tragedies, then, much like modern and historical understandings of the concept, is fraught with contradiction: it is at once celebrated and condemned, virtuous and cowardly.

Abstract Name: The Effect of Propylparaben on the Reproductive Anatomy of the Fathead Minnow (Pimephales promelas)

The fathead minnow is a commonly found species that is an excellent model organism for reproductive system studies. Propylparaben is an antimicrobial agent found in many personal products such as deodorant, soaps, shampoos, cosmetics, and many others. Estrogen agonists, such as 17β-estradiol, are chemicals which affect the body's physiological responses by imitating the effects of estrogen. This disrupts various pathways such as the Hypothalamus-Pituitary-Gonad axis, which controls the development of the gonads and secondary sexual characteristics. There has been some evidence suggesting that parabens may have estrogen agonists effects in animal model systems. When exposed to estrogen agonists male fathead minnows can fail to develop secondary sexual characteristics such as tubercules and fleshy dorsal pads, and both sexes can experience delayed growth and deformities within the cellular structure of the gonads. This study aimed to determine whether these effects are significant at ecologically relevant concentrations in fishes such as the fathead minnow. To determine if the paraben had any effect, fishes were weighed, photographed, and dissected under a microscope. The reproductive organs were harvested, weighed, placed into fixative, and sent out for histological examination. It is hypothesized that propylparaben will have a moderate estrogen agonist effect on fathead minnows.

Abstract Name: Variations in System Parameters on Thermosiphon Collector Efficiency

A passive thermosiphon is a water heating device without any mechanical or electrical inputs. In a thermosiphon, the working fluid is heated in a collector and rises into the top of a reservoir through hot leg tubing. The fluid cools, increasing the density, and it returns to the collector through cold leg tubing to complete the cycle. Prior research at the University of Evansville has shown the need to carefully control the test conditions. This has resulted in the use of an insulating enclosure around the thermosiphon to control the ambient temperature. Heat tapes, as opposed to solar input, provide and maintain consistent power to the device. The system has thermistors located at critical points throughout the system to record temperature. An open-bore flow meter is located along the cold leg tubing. The data from these collection systems are monitored and recorded with LabView software. The aim of this research is to investigate trends in efficiency by varying parameters on the system with a more specific goal of understanding any efficiency enhancing mechanisms. Before any parameter-varying tests are performed, baseline tests are conducted to establish an efficiency to compare to previous years and compare between series. The main parameters that drive flow through the thermosiphon are the heights of the hot leg (which includes the collector height) and cold leg and the temperature, or density, difference of the working fluid between the two legs. When performing a test series, one parameter is varied while all others remain constant to determine its effect on the thermosiphon efficiency. The parameters that are varied include the cold leg height, hot leg height, and the input power to the collector to vary the hot leg temperature.

Abstract Name: Healthcare Attitudes of Former Soviet Union Immigrants in the U.S

The Soviet model of healthcare was built on a centralized, paternalistic standard of care. Many citizens of the USSR held negative perceptions of this style of care and its outcomes, and they came to distrust the government's healthcare programs and mandates. But do residents of the United States who grew up in the USSR hold similar attitudes towards the U.S. healthcare system? Though there is some existing research on the current general sentiments of Russians in the former USSR towards health decisions, their fear of their government, and the impact of these sentiments on their healthcare, there has been little research on immigrants living in the United States. Research has also provided data on Soviet immigrants in the U.S. and it has been observed that many of them suffer from poor health. However, these studies fail to consider whether mistrust in the system explains these poor outcomes. This study will employ a survey of immigrants from the USSR to determine (1) whether they hold negative attitudes towards U.S. healthcare and (2) whether these attitudes can be explained by their previous experiences in the USSR. Specifically, the survey will explore attitudes of distrust towards school-mandated vaccines as well as more recent COVID-19 vaccine mandates that have impacted many more individuals, such as those who work in federally funded healthcare facilities. I hypothesize that the participants will exhibit higher rates of distrust towards U.S healthcare when compared to the average American as a result of their former experiences in the USSR. This data will be especially useful for public health and healthcare professionals, as it will explore whether certain immigrant populations express mistrust of medical procedures, policies, and institutions, and it will inform them as they attempt to improve the health outcomes of these populations.

Abstract Name: Exploring a Montessori-Based Activity with Progressive Complexity for Individuals with Dementia: Student Learning Experiences

The purpose of the study was to explore how implementation of a Montessori-based group activity promotes more active engagement for individuals with dementia. The study explored activity implementation with a progressive complexity influencing engagement amongst individuals with dementia. Activity modification includes simplifying task demands (downward) and challenging cognitive and motor skills (upward) (Jarrott, Gozali, & Gigliotti., 2008). This treasure hunt activity required an individual with dementia to use a magnetic fishing pole to fish small magnetic-themed-based objects from a bin. Individuals with dementia were invited to participate, prompted to engage, identify different objects in the bin, and share their thoughts. Pre-set questions were developed to support conversation based on the individuals' abilities and their intact senses. For example, "this looks like a spoon to me. Let's look at this together" for the downward version.

“What would you like to say about this? What does this remind you of?” for the upward version. The research participants were eight college students who completed dementia-friends training and were mentored by a faculty member who specialized in dementia. Research participants conducted the activity with a small group of residents with dementia twice a week for ten weeks. Each participant interacted one-on-one with an individual with dementia during the activity and engaged in a personal conversation. Research participants followed a protocol to identify the preferred complexity version (upward/downward) based on engagement level and conduct the activity with modifications as needed for individuals with dementia. Student learning outcomes will be obtained through qualitative and quantitative measures before and after completing the program. Specific measures will be used to document their perception of ageism, dementia, and engagement of individuals with dementia. The expected outcome is for college students to create appropriate meaningful engagement activities by capitalizing on the abilities of individuals with dementia.

Abstract Name: Structural Analysis of Biominerals with X-ray Microscopy: Development of Phase Reconstruction Techniques

Biominerals are a widespread phenomenon where living organisms produce minerals to strengthen existing tissue [1]. Two essential parts of a biomineral’s tissue are the organic and inorganic mineral part [1]. Biocrystallization involves complex and regular biochemical processes where living organisms control the crystalline form and texture of their organo-mineral components. When concentrating on the nanoscale granular structure of a biomineral, almost all calcareous crystallizing organisms contain a generic biomineralization and assembly process [2]. This truth will provide a key to building realistic scenarios of biomineralization and reveal the crystalline architecture at the mesoscale, which none of the existing nano-characterization tools is able to provide [2]. The focus of this study will be the exploitation of the synchrotron coherent x-ray diffraction imaging technique that will provide access to a 3D mesoscale image of crystalline properties, with required flexibility, nanoscale resolution, and non-invasiveness [2]. In result, revealing the generics of the mesoscale crystalline structure of CaCO3 biominerals through crystalline biominerals produced by marine calcifies like sea urchins [2].References[1] Gurvinder Singh Chana, ‘Biomineralisation: Calcite Structures in Sea Urchin Tests using X-ray Ptychography’, Thesis 2012[2] Virginie Chamard. ‘A New Look on Biomineralization with X-ray Crystalline 3D Microscopy’, Microscopy and Microanalysis 2018, 24 (supp 2), 2-5

Abstract Name: Microwave Assisted Optimization of bisguaiacol F Synthesis

Bisphenol A (BPA, 4-[1-(4-hydroxyphenyl)-1-methylethyl]phenol), a monomer used to produce epoxy resins and in thermal printing processes, is problematic from environmental and toxicological perspectives as it is synthesized from non-renewable sources and is estrogenic. One BPA mimic with the advantage of renewable feedstock and non-estrogenic toxicology is bisguaiacol F (BGF, 4-[(4-Hydroxy-3-methoxyphenyl)methyl]-2-methoxyphenol). The typical BGF synthesis via electrophilic coupling of vanillyl alcohol and guaiacol results in a mixture of p,p' and o,p' isomers in moderate yield (40-60%) following laborious workup and purification. This research project aims to optimize the synthesis and purification of p,p' BGF. Optimized conditions with water and acidic amberlyst resin were used as a baseline for microwave assisted synthesis. The effects of solvent (i. e. DMF, ethanol, DME), acidic catalyst (i. e. Amberlyst resin, sulfuric acid, functionalized silica gel), temperature/pressure, reaction time, and workup/reaction conditions on yield of p,p' BGF to o,p' BGF ratio will be reported. Efforts towards scale up and preliminary reaction work-up/purification efforts will be reported.

Abstract Name: Texas Gambling Law: A Hegelian Dialectical Approach to Addressing Problem Gambling

With the aim to determine the most effective method to address problem gambling, Hegelian dialectic was used to compare expanding versus reducing Texas gambling restrictions. Problem gambling is a psychological diagnosis of gambling behavior that disrupts major life events, with an estimated 6.2 million U.S. adults afflicted. The Hegelian Dialectic is utilized to provide a synthetic argument between outlawing gambling and liberalizing gambling to address problem gambling comprehensively. A synthetic argument is built by utilizing the potential treatment methods from "Problem Gambling in the 21st Century Healthcare System," by Kagan et al. and comparing them to Texas gambling law's historical context provided by Scott Sloan's "Putting Texas back in Texas Hold 'Em." This approach concludes that liberalizing gambling restrictions on the Texas state level is the most effective way to address problem gambling, as the revenue generated for the state can be used to fund social programs that treat it while also promoting treatment at physical or digital gambling locations. While this may be true within the Texas government, further research is needed on how the federal government could intervene on the proliferation of problem gambling and if there are nations that could be modeled in order to address it.

Abstract Name: Perceived Discrimination, Test Anxiety, and Intelligence Mindsets

Among college students, perceived discrimination is associated with lower levels of well-being and impacts educational outcomes (Schmitt et al., 2014). However, there is little understanding regarding the process of how perceived discrimination impacts performance amongst diverse college students. Furthermore, previous studies have shown that an individual's intelligence mindsets (e.g., whether one believes intelligence is a fixed trait or is malleable) is predictive of their academic outcomes (Haimovitz & Dweck, 2017). This research project will assess the impact of perceived discrimination on test anxiety and if intelligence mindsets serve as a mediator of this impact. This study seeks to answer two research questions: (1) What is the relationship between perceived discrimination and level of test anxiety? and (2) How does mindset (growth vs fixed) impact this relationship? It is hypothesized that perceived discrimination and test anxiety will be positively related and that intelligence mindsets (e.g. growth mindsets and fixed mindsets) will partially mediate the relationship between perceived discrimination and test anxiety. Participants for this study are adult college students at a small liberal arts college in Florida. Study data was collected via an online survey that consisted of the following instruments: (A) Demographic Questionnaire; (B) The Everyday Discrimination Scale; (C) Cognitive Test Anxiety Scale; and (D) the Intelligence Mindsets Questionnaire. Regression analyses will be used to address the research questions and hypotheses. A multiple regression analysis will test the relationship between perceived discrimination, intelligence mindset, and test anxiety. A mediated regression analysis will be used to determine if intelligence mindset mediates the relationship between perceived discrimination and test anxiety. The results of this study will inform future interventions for students who are more susceptible to experiences of discrimination in an academic setting. These results will help identify how intelligence mindsets and test anxiety interventions can provide support to diverse student groups.

Abstract Name: Monitoring Selenium Bioaccumulation and its Potential Effects in False Map Turtles (Graptemys pseudogeographica)

Selenium is an element that becomes bioactivated in aquatic environments. Selenium bioaccumulation may threaten a South Dakota state threatened species, the False Map Turtle (Graptemys pseudogeographica). Invertebrate filter feeder species like zebra mussels (Dreissena polymorpha) are known to uptake selenium via their exposure. Previous laboratory work has found that False Map Turtles consume large amounts of zebra mussels throughout the summer months leading to selenium bioaccumulation from selenium transfer. A myriad of negative effects like selenosis, reproductive infertility, and death are associated with high selenium concentrations. Sampling was done on the False Map Turtles in the summer of 2022. Samples were taken once a month from July to September. A blood sample and several morphometric measurements were collected from each turtle. Data were collected from 15 male and 38 female False Map Turtles. The average selenium concentration present during each month appeared to peak in July with an average concentration of 0.941 ug/g and a maximum concentration of 6.24 ug/g. The relationship between sex and the average selenium concentration per month showed relatively equal concentrations among males and females with similar concentrations during August and September. Yet, during the peak month of July, male turtles had a much higher selenium concentration (1.37 ug/g) than their female counterparts (0.732 ug/g). When accounting for turtle body mass in relation to sex, males appeared to have over 600% more selenium present per gram of body weight. Further work needs to be done to determine why this difference exists. Differences

in overall size might alter prey selection where males are more likely to consume the smaller zebra mussels. Additionally, detoxification systems in the turtles themselves might differ between the sexes. Regardless, these findings highlight the importance of understanding the role of invasive zebra mussels in contaminant distribution in aquatic ecosystems.

Abstract Name: The Impact of Media Sources on Political Behavior

With the dawn of the internet, our communication fundamentally changed. Conversations shifted online, workflows became digital, and social media emerged connecting individuals in a new and constant manner. The political world too felt this massive movement. I seek to discover if the tactile media, that is the physical attributes of the media (i.e., online, visual, verbal, etc.), with which we consume political information influences our subsequent behavior. To investigate this, I will look at the influence of online/internet media on the actions of voters in comparison with already established media, (i.e., newspaper, radio, TV news). I begin by examining the distinction between online media and traditional media; from there, I look deeper into the types of internet media and their impact on political behavior. Finally, I investigate potential mechanisms behind the shift by examining the impact of visuals and the availability of new information online compared to the limited nature of news released on a predetermined schedule. Previous research establishes connections between online/traditional media and several voter beliefs, i.e. perception of candidates (Garzia, da Silva, and De Angelis 2020 and Maj and Lewandowsky 2020). Additionally, previous scholarship emphasizes the importance of including multi-media users (Stromback, Falasca, and Kruikemeier 2018). However, there is less research focused on understanding the connection between media characteristics i.e., visuals, writing, timing, across platforms, and engagement. I use the 2020 American National Election Survey (ANES) data to test several hypotheses. My dependent variables are additive scales that measure electoral and non-electoral political engagement. For the independent variables, I categorize respondents as being pure traditional media users, multi-media users, or only digital media consumers. Regression analyses with controls suggest an association between social media usage and political engagement. I find support for my hypothesis that the 24-hour media cycle has increased political engagement.

Abstract Name: Applying a First Amendment Values-Based Analysis to Conversion Therapy-Banning Legislation

The purpose of this research was to construct a legal argument that allows states to ban the harmful practice of conversion therapy on minors. This issue has been considered in federal courts and discussed in detail by lawyers and law students in various legal publications, but there has been no general consensus thus far.

Conversion therapy is a discredited therapeutic practice that attempts to change the client's sexual orientation from gay to straight. This therapy exists in the form of nonaversive (talk) and aversive (physical) therapy. The prevalent legal argument against banning nonaversive conversion therapy on minors is that such laws violate therapists' First Amendment freedom of speech. To create my legal argument, I researched the law and binding precedent set by federal courts and consulted law review articles to further my knowledge of the current understanding of the issue. Avoiding bias and assumptions, I analyzed these sources to construct my own legal theory. I found that the speech aspect of nonaversive conversion therapy can be categorized as non-expressive speech, because it is not primarily meant to express an idea or message. The intent of nonaversive conversion therapy is to change an aspect of their client using words as a tool. Non-expressive speech as a category does not directly represent the primary values the Free Speech Clause protects, which are the free marketplace of ideas and U.S. people engaging in democratic self-governance. Banning conversion therapy does not restrict therapists' ability to add to the free marketplace of ideas by spreading their opinions and research or petitioning for conversion therapy to be legalized. It simply restricts a less-valuable category of speech, which should be subject to a lesser form of legal scrutiny. Due to the harmful nature of conversion therapy, conversion therapy bans for minors pass lower constitutional review.

Abstract Name: Assessing the Noun Bias in Vietnamese Monolingual and Vietnamese-English Bilingual Children

The natural partition hypothesis suggests that children universally display a noun bias, learning nouns more readily than verbs due to the concreteness and ease of encoding associated with nouns. Verbs are more abstract and often require a child to have a relational understanding between two agents. While studies on English-learning children support this idea, cross-linguistic research challenges the existence of a universal noun bias. The current study further tests this hypothesis by studying Vietnamese-learning children. Vietnamese, with its structural similarities to Mandarin and Cantonese—both considered verb-friendly languages—provides grounds for anticipating a verb bias. Additionally, we explore whether bilingual exposure modulates the noun bias by comparing Vietnamese monolingual and Vietnamese-English bilingual children. We plan to collect data from a convenient sample of parents of 16- to 34- month-old children. Participants are divided into two groups: parents of Vietnamese monolinguals and parents of Vietnamese-English bilingual children. Parents are asked to fill out the Vietnamese adaption of the Communicative Development Inventory (CDI). Parents in the bilingual group are asked to fill out the English CDI additionally. Data for English-learning children will be pulled from the Wordbank data repository. Consistent with previous studies, we will compute the proportion of reported verbs and nouns to the total verbs and nouns in the CDI in each language. We will, then, make group comparisons using these proportions. The study also evaluates the Vietnamese CDI's validity and reliability level for measuring vocabulary in monolingual children. The findings reveal potential differences in noun vs. verb acquisition between English- and Vietnamese-learning children, as well as between monolingual and bilingual children.

Abstract Name: Solicitation of viral evolution: analysis of diversification of deformed wing virus (DWV) in the western European honey bee (Aphis melifera), by observing DWV mutations over several generations

Responsible for 80% of global agricultural crop pollination, bees are essential to food production efforts. Deformed wing virus (DWV) is the leading cause of death, disability, and colony collapse disorder in honeybees (Apis mellifera). DWV does not only jeopardize the health of bees but global food security as well, inhibiting goods production. This study investigates the viral diversity of DWV and how viral mutations influence strain virulence across multiple honeybee generations, allowing researchers to accurately predict future DWV polymorphisms/prevalence aimed toward cross-reference in "vaccine" development. Honeybee pupae were sampled (n=64) from three randomized source colonies (#57, #75, and #78). They were then

inoculated with a tagged nano-luminescent DWV strain (10^6 viral particles) via injection. After 72 hours of growth at 35°C, viral mRNA was extracted using the QIAGEN Viral RNA Extraction Kit and isolated by creating cDNA, which was used to perform qPCR to quantify viral loads and then deep sequenced. Procedures were replicated thrice with two parent-to-child colony injections and a final three-way cross. The susceptibility of recipient colonies influences the virulence strength of DWV strains rather than the donor strain, as colony #75 experienced elevated DWV levels in reaction to all donor pools. Experimentation found seemingly no interaction link between source colony and viral levels indicative of virulence patterns consistent with the laws of natural selection, suggesting an increase in the prevalence of inheritable traits promotes DWV growth in isolated to exposed populations over time. Honeybees insect-like innate immunity poses a unique barrier to vaccine-centric immune treatment, as bees lack the memory-based immunity (Larsen, José Reynaldi, & Guzmán-Novoa, 2019) essential for vaccine expression. Findings are aimed to expand scientific knowledge on mutative patterns in the DWV genome by providing an evolutionary template of DWV to potentially improve the efficiency of epidemiology models/further treatment development.

Abstract Name: Screening stabilizing additives for the solubilization of Cytochrome P450 (CYP) and Cytochrome P450 Reductase (CPR) enzymes expressed in Escherichia coli

Recombinant proteins are proteins expressed inside a host through the combination of DNA from another organism with its own. One such host is Escherichia coli, and its cells must be lysed to extract the protein from solution. During this step, however, the protein yield is often hindered by the formation of inclusion bodies (unfolded protein) since only fully folded protein in solution can be purified and potentially crystallized for further analysis. Inclusion body formation is likely partly a consequence of the proteins of interest not usually being native to E. coli. The production of soluble protein is therefore a major bottleneck in enzymology and structural genomics. Some theories assert that inclusion bodies form as proteins denature and aggregate when they are exposed to the buffer solution during lysis. Nevertheless, there is evidence that protein can be made soluble through the introduction of certain stabilizing additives during this lysis step. Osmolytes have been the most successful additives which protect proteins from denaturing in vivo, but other additives have been shown to work. I intend to screen various additives under the lysis conditions for Cytochrome P450 71AV1 (CYP71AV1) and Cytochrome Reductase 1 (CPR1). These enzymes are membrane bound in the cells of the plant Artemisia annua, and are involved in the synthesis of the antimalarial drug artemisinin. The membrane-bound nature of these enzymes make them good targets for employing osmolytic stabilizers since membrane enzymes are notoriously difficult to express and purify from E. coli under natural conditions. The additives I will use for the screen are trehalose, octyl-d-glucopyranoside, glycine-betaine, proline, arginine, mannitol, and xylitol. Determination of which additives contribute to solubility will provide insight into the underlying mechanisms driving protein solubility and help optimize recombinant protein lysis protocols.

Abstract Name: Rapid Bioassement of Messer Brook, New Hampshire: Benthic Macroinvertebrate and Fish-assemblage as Bioindicators

Aquatic bioindicator species are essential in determining the health and integrity of streams throughout the world and are regarded as a better means of measuring water quality in a system compared to instrumental methods (EPA,2023). Rapid bioassessment utilizing bioindicators allows for a cost-effective and quick measurement of the stream's health. Bioindicators themselves allow researchers to quickly determine the health of an ecosystem due to their increased sensitivity to their environment (Kenney et al, 2009). Utilizing the bioindicator's hypersensitivity to their environment allows for a rapid characterization and the existence of an impairment, the severity of an impairment, and the evaluation to control action causing the impairment as well as possible restoration efforts (EPA, 2023). The study conducted uses benthic macroinvertebrates as well as fish assemblage data as bioindicators to assess the water quality in Messer Brook, New Hampshire. It utilizes the Hilsenhoff Biotic Index (HBI), which is a quantitative method of evaluating the amount of Arthropoda within a system, as well as the New Hampshire Benthic Index of Biotic Integrity model (NH B-IBI) to grade the health of the stream. By following the EPA's Rapid Bioassessment protocol and the New Hampshire Department of Environmental Services protocol for macroinvertebrate and fish collection, three rock basket macroinvertebrate habitats were deployed in Messer Brook for a period of 90 days. After 90 days the macroinvertebrate habitats were removed and sent to Lotic Incorporated for macroinvertebrate sample processing for identification. Electrofishing within a 150-meter reach was conducted to determine the fish assemblage with a total of 222 individuals and 7 different species. This bioassembelage data was put into the HBI and NH B-IBI where it showed moderate impairment. With the knowledge of an impairment and what is causing the impairment, the next course of action is to construct a method for restoration efforts.

Abstract Name: Screening marine compounds for antimicrobial activity against Mycobacterium abscessus

Mycobacterium abscessus (Mabs) is a nontuberculous mycobacterium (NTM) that causes severe disease in patients with cystic fibrosis (CF) and other underlying lung diseases. Mabs is ubiquitously present in tap water, can infect immunodeficient patients, and cause nosocomial outbreaks. Chronic Mabs infection in CF patients is associated with declining lung function, adds challenges to lung transplantation, and contributes to fatal airway damage with mortality rates up to 60%. Mabs is the most pathogenic and chemotherapy-resistant rapid-growing mycobacterium and is resistant to most common antibiotics. As a result, there is an urgent need for new antibiotics against Mabs. Classically, screening compounds and extracts is the preferred way to identify new antibiotics. We used automated microscopy and high content screening (HCS) for rapid screening of drug candidates against Mabs. 251 marine compounds, originally isolated from deep sea ocean invertebrates, were screened at a concentration of 20 ug/mL against Mabs growing in broth. Compounds with >90% inhibition were followed up with dose-dependency assays to determine minimum inhibitory

concentrations (MIC). Compounds were then tested in a THP-1 macrophage infection model to assess the intracellular antimicrobial activity of the compounds together with their associated toxicity to the host cells. Of the 251 compounds, 7 were found to have significant antimicrobial activity against Mabs when tested in broth. When tested in a macrophage infection model, 6 compounds were found to inhibit Mabs growth intracellularly with low cell cytotoxicity. The mechanisms of action of these compounds will be further investigated. The findings of this study may potentially identify a compound for further development into a novel treatment for Mabs infection.

Abstract Name: Teaching At Risk 6th Graders Operations with Decimals

My study consists of two sixth grade students who demonstrate similar needs in the area of decimal operations. To help students gain proficiency with decimal subtraction, multiplication, and division, I have chosen to design a series of nine interventions two for subtraction, two multiplication, one for review of multiplication, addition, and subtraction. The fifth intervention serves as a review as well as a form of progress monitoring to determine if students are ready for decimal division, the most complex of the four operations for sixth grade students.

Abstract Name: Designed for Inclusion: Innovation in An Undergraduate Robotics & AI Research Program

Science and technology drive innovation, create economic opportunity, and are critical to national security. With increased competition for a skilled STEM workforce, high barriers to participation in STEM, the missing millions (Gershenfeld et al., 2021), and the longstanding underrepresentation of minoritized US communities, collective action is urgently needed to expand STEM education and training. Strengthening and expanding STEM education is necessary to meet critical workforce demands and to fortify the national research pipeline. Undergraduate research experiences, long recognized as a high-impact education practice (Kuh & Schneider, 2008), are critical to growing the nation's research and science communities. In 2006, Carnegie Mellon University's Robotics Institute launched a summer undergraduate research program, the CMU Robotics Institute Summer Scholars (RISS), to provide early robotics research exposure. Initially, RISS followed the traditional undergraduate research experience (REU) site model, coupling experts (science faculty) with undergraduate students to enable involvement in a research project, providing communications and graduate school preparation workshops, hosting social activities, and an end-of-program poster session. Over time, RISS became a living lab to design, implement, and evaluate educational interventions to increase domestic student participation in STEM graduate programs. This poster will discuss CMU's RISS program's

evolution and current framework guided by 1) David Kolb's Experiential Learning Theory (ELT) and 2) Wenger's Community of Practice Model.The reimagined, four-phase CMU Robotics Institute Summer Scholars (RISS) program provides immersive undergraduate research experiences, professional development, mentorship, and service learning to nurture future roboticists. The 100-plus RISS mentors include faculty from the Robotics Institute, Mechanical Engineering, and Electrical Engineering Department, current graduate students, alums, and leaders from the community. An analysis of RISS student outcomes showed that more than seventy-five percent of RISS alums from 2012 to 2018 pursued graduate studies in STEM.

Abstract Name: Imagining and Engaging Futures Through Rural-R1 Collaboration in STEM Education

Rural students are underrepresented in STEM fields and less likely to attend R1 schools (Carnegie Classification for High Research Activity), especially for computing-related majors (Postsecondary National Policy Institute, 2023). Rural spaces remain understudied and underserved and are at high risk for further exclusion from participating in the innovation economy and imagining and creating their own pathways and engagement. In response to this overwhelming need, we, Carnegie Mellon Robotics Institute Summer Scholars (RISS) and local rural partners, developed a pilot project that coupled robotics undergraduate researchers with rural communities, educators, and political leaders. Establishing trust and beginning to see each other as individuals were the first steps towards collectively trying to understand the opportunities, perspectives, and possibilities for R1-rural shared futures. Carnegie Mellon University’s RISS uses evidence-based approaches and engages an extensive network of mentors to extend the traditional 10-week summer research experience into a multiple-stage scholar development community. Undergraduate research & service learning are well-documented high-impact practices (Kuh, 2009) that have a measurable impact on scholar development and future civic engagement (Chittum et al., 2022). During our initial engagement, the project shifted from a one-direction service-learning pilot to an ongoing rural-R1 collaboration focused on mutuality and reciprocity by embedding collective impact and appreciative inquiry practices. By doing so, space was created for the community and undergraduate robotics researchers to imagine futures connected to and impacted by STEM that were empowering and supportive rather than solely connected to careers, economic survival or development.In this Narratives and Storytelling presentation, presenters will share observations, promising practices, and experiences within rural spaces to break down barriers of exclusion and discuss the potential impact and long-term engagements emerging from the project.

Abstract Name: Distribution of Neurotransmitters in the Parabrachial Subnuclei of Primates: A Cross-Species Comparison of the Human and Cebus Monkey

The parabrachial nucleus (PBN) is located in the pons, surrounding the superior cerebellar peduncle. Data collected from rodent models have shown that it plays an integral role in various physiological functions, including sleep and wakefulness, taste, appetite, visceral sensation, nociception, temperature regulation, itch, and chemosensation. The present work aims to identify whether the primate PBN contains the diversity of neuropeptides that have been described in rodents.We performed a detailed literature review on this region and also mapped the distribution of calbindin (CAL), cholecystokinin (CCK), dynorphin (DYN), galanin (GAL), neurotensin (NT), somatostatin (SOM), and substance P (SP) applying immunohistochemical techniques on horizontal brainstem cross-sections obtained from four neurologically normal human subjects and five male Cebus monkeys. Overall, cell body morphology and fiber distribution in the external lateral and external medial subnuclei were similar in both primate species, but there were clear differences in peptide distribution. Both the external lateral and external medial subnuclei contained CAL, CCK, NT, SOM, and SP immunoreactivity. DYN was observed in the external lateral PBN, and GAL was present in the central lateral and dorsal medial PBN. The external lateral subnucleus exhibited a distinct topographical distribution of GAL, CAL, CCK, DYN, and SOM, with DYN and SOM overlapping in the ventral corner of the subnucleus.The results of our literature review and histological analysis suggest that the neuropeptide distribution in the primate Lateral PBN is similar to the one described in rodents. This allows for inferences into possible physiological parallels.

Abstract Name: DESKTOP APPLICATION TO MANAGE AND STORE DETRITAL ZIRCON GEOCHRONOLOGICAL DATA IN A SQL DATABASE

Detrital zircon datasets contain vast amounts of geochronological data, and different labs, researchers, and institutions all have their own formatting standards. Detrital zircon data are also becoming cheaper and easier to produce, increasing the quantity of datasets available to researchers. This data increase only makes the problem of organizing, sorting, and filtering the data that much more difficult. This application aims to fix this problem of organizing and managing data by importing and storing it in a personal local SQL database, similar to a reference manager for publications. When the application is unsure how to import the data, it prompts the user with a step-by-step wizard to confirm or modify the assumed data values, which are then remembered for future imports. Users can create custom tags to classify the data. The data inside the local SQL database can then be used by the built-in filtering and basic plotting to allow users to visualize the data quickly based on current filtering options. Once the user is satisfied with the selected data, it can be output in varying formats for Excel, IsoplotR, DZstats, detritalPy, etc. Users can also split, merge, and share the SQL database for other researchers to merge into their own databases with little user input unless there are conflicting entries. New AI tools such as Chat GPT are intriguing, but we find them insufficient for our needs as they are still unreliable, and the results cannot be shared, merged, or stored. The application will use open-source version control methods so that users can submit their own feedback or help contribute to the application through GitHub. Once closed alpha development is completed and the application is published, it will help all geochronologists optimize their own research methods while seamlessly integrating with existing tools.

Abstract Name: The Origins of the Comanche Nation in North America

Purpose: My research showcases the transformation of the Comanche Nation from their origins as Western Shoshone to their dominance of the American Plains. The origin of the Comanches is explored through the development of an exhibit that tells this story through primary sources, artifacts, and art. The purpose of this exhibit is to highlight Native American culture of the Comanche Nation and allow viewers to rediscover the importance of Native American History.Research: This exhibit uses primary sources in forms of artifacts and artwork in order to portray the history of the Comanche Nation. These sources will tell the story of the beginnings of the tribe, what makes them different from other nations, and how they adapted to the rapidly changing country. One of these primary sources includes a Comanche Horse Mask. This artifact is crucial to the history of the Comanche nation, for it showcases the importance of the acquisition of horses in their culture. Another primary source includes the art piece, “Comanche Motion,” by Eric Tippeconnic. This work of art showcases who the Comanches were and how they continued to persevere as a nation during the foundation of America.Methodology: The research conducted in this exhibit was gathered through reviewing primary sources, museum artifacts, journals, and scholarly articles. A presentation was created to display artifacts that were distinctive to the Comanche Nation.Conclusions: This presentation is important because it places a new perspective on Native American history by telling a story through the eyes of the Comanche Nation. This presentation will focus on one of the many Indigenous groups who played a significant role in how our country was created and will bring to light the forgotten stories of one of the most powerful Native American tribes in history.

Abstract Name: Inter-rater Reliability Between an Emerging Professional and Professional Using Skinfolds to Measure Body Fat Percentage

Introduction: Assessing body composition is a common practice for Exercise Science professionals. It provides a baseline assessment of the individual who is starting an exercise program. Therefore, it is also an important skill to master in undergraduate Kinesiology as future professionals. One way of assessing body composition is by Skinfold (SKF) measurements. SKF is one of the most accurate and common field methods for assessing Percent Body Fat (%BF). Purpose: The purpose of this study was to create Inter-Rater Reliability (IRR) between an emerging professional and professional through SKF in order to assess %BF. Methods: Students were recruited from the Department of Kinesiology and Health Studies (KHS) at a regional university. At the university, the KHS students (N=11) consented and responded to a series of demographic questions. The professional and emerging professional then conducted two trials of a 7-site SKF assessment for a minimum of four trials each. The data collection process consisted of two rounds to

determine IRR. The IRR between the emerging professional and professional was investigated through Intraclass Correlations (ICC). Results: ICC estimates for two-way mixed-effects (absolute agreement, single measures) showed moderate to excellent IRR for point estimates in both rounds of SKF. Excellent IRR was established for %BF (> .980) while 95% Confidence Intervals (CI) indicated more variability for specific sites. Conclusion: The results indicate the emerging professional and professional are equal to excellent when it comes to assessing %BF using SKF. The CI for the various sites provides useful information about where the assessors have more variability for the two rounds of testing and where more training between the assessors may be needed. IRR was established between two assessors which indicated the emerging professional obtained the skills to assess %BF using the field method of SKF.

Abstract Name: Creation and Curation: The Narratives of Festival Culture in the Religious Imagination

A sensory overload of blaring/loud music that can be heard long before you arrive at the entrance, a kaleidoscope of colors that blur into art, and pungent smells that leave you questioning their source, festivals like Coachella and Bonnaroo might easily be seen as mere recreation. But as Gilmore (2010), Lucia (2020), and others have argued, festival culture exists at the intersection of relational community and recreational fun. In my work, I examine religious practices found at seemingly secular festivals, including various ritualized processes, such as the ubiquitous presence of altars and the creation of shared communal experiences, in order to unpack how the construction of secular festivals parallels religious practices. This project looks at two festival sites, Coachella 2023 and Bonnaroo 2023, where I conducted ethnographic research to study approximately 100 participants and their experiences. Methodologically, I employed a three-step cross-sectional approach that examined the creation of festival culture and how, in return, it is presented and performed within and outside the festival site. My analysis centers youth culture, narrative theory, and digital culture and argues that participants create and curate their experiences, both orally and digitally, in a way that contributes to the authenticity of a festival space as religious worldmaking.

Abstract Name: Advanced Simulation of Thermal Striping in HTGR Plena Using the STRUCT Turbulence Model

Advancements in understanding and predicitng thermal striping are crucial for the development and safety of future nuclear systems. This research focuses on developing a reliable and computationally efficient method for predicting thermal striping in the upper plenum of High Temperature Gas Reactors (HTGR). The higher

energy efficiency offered by elevated coolant temperatures in gas-cooled fast reactors marks a significant departure from traditional light water reactor technologies, bringing unique challenges in simulating thermal fluctuations and the resulting stresses on reactor components. We propose the STRUCT hybrid URANS/LES turbulence model as a candidate, capable of generating high-resolution thermal fluctuation data akin to Large Eddy Simulation (LES) but at computational costs comparable to Unsteady Reynolds Averaged Navier-Stokes (URANS) methods. The aim of this research is to assess the STRUCT hybrid model's performance by benchmarking it against results obtained from the NekRs GPU-accelerated spectral element Navier-Stokes solver. This study not only evaluates the STRUCT model but also aims to deepen the understanding of thermal striping mechanisms, contributing to the development of safer and more reliable HTGR systems.

Abstract Name: Milton Glaser An In Depth Analysis On A Design Hero

This abstract is an homage to the design hero Milton Glaser, and the wonderful life that he led and the impact that he had on not only design but art as a whole. This paper talks not only about the beginning of his journey in design, but also the end of his story, and the things that happened in between. This paper is meant to show the reader that not only was Milton Glaser a wonderful man, but a truly brilliant designer, and not one that will soon be forgotten.

Abstract Name: Patriotism and Persecution: The Experiences of Queer Communities in the Wake of World War II

On June 27, 1969, a routine police raid was conducted on the Stonewall Inn, a gay bar in New York City. Police frequently conducted these raids, but that night was an exception as the queer bargoers stood their ground. They would perform what would come to be known as the Stonewall Riots for the following three days. However, these three days did not come about suddenly. This was the culmination of over two decades of oppression at the hands of the United States government, which arose at the start of the Second World War. Although the military and federal government had previously kept lesbian women, gay men, and transgender people out of the armed forces, the need for troops required these restrictions to be set aside. This provided an opportunity for relationships to form like never before. The war empowered some queer people to become visible in the United States, forming safe spaces to embrace their identities and fighting for their right to exist. However, Cold War paranoia was a setback to the advancement of the queer community in the United States. Drastic changes in American society as a byproduct of World War Two led the government to enforce sweeping policies to root out any suspected communist infiltrators or gay employees, as they were both deemed too immoral to be employed. Unfortunately, this homophobic attitude extended to local law

enforcement agencies and the public as well. But this did not deter queer communities from resisting oppression. Gay men and women, both veterans and non-veterans alike, founded activist organizations, built clandestine support networks, and performed early protests. Their struggle for equality and gay rights laid the groundwork for Stonewall and for the flourishing of LGBTQ+ identities that has occurred in the years since then.

Ashlynn Burrows

Abstract Name: Social Media, Safety, and School Shootings

I will never forget the day I was strolling down the school supplies aisle of Target and I overheard a young boy, who was back-to-school shopping with his grandmother, ask for a bulletproof backpack. School shootings are an epidemic in our country and it is not going unnoticed by the youth. The purpose of this mixed-methods study is to explore the level of safety students feel in their respective schools and explain whether their perceived level of safety is based more on social media or their school's safety procedures. The study aims to understand the phenomenon of social media's influence on public school students' perceived levels of safety at the elementary, middle, and high school levels in Wicomico County, MD. Previous studies have attempted to identify why school shooters become school shooters, the motivating factors behind school shootings, precursors to violent behavior, and the efficiency of current school intruder policies. However, previous studies lack focus on the general population of students that are in attendance at schools. To understand the way in which to move forward and improve school safety systems, we need to first understand the actual people that the safety precautions are designed for, which is students.

Abstract Name: Analysis of the Efficacy of Magnetic Coils for Neutron Electric Dipole Moment Experiment

Measurement of the Neutron Electric Dipole Moment (nEDM) is one of the top priorities in nuclear and particle physics because of its discovery potential for physics beyond the currently accepted standard model. The neutron EDM would, if non-zero, violate Charge-Parity (CP) symmetry and is therefore associated with time-reversal asymmetry. Some amount of CP/T violation is predicted by the standard model, but a significantly higher amount would fulfill one of the three conditions required for baryogenesis, the hypothesized method of conversion of antimatter into matter in the very early universe. This is not predicted by the standard model. If a non-zero nEDM is measured by the high sensitivity apparatus at Paul-Scherrer Institute in Switzerland, it would provide evidence for baryogenesis. In order to measure the nEDM at such high precision, magnetic coils were fabricated and installed to preserve the identical precession of the

neutrons through the measurement cell. The efficacy of the coils' ability to generate this uniform field will be assessed by mathematically fitting laplace solutions to the data collected by Paul-Scherrer Institute.

Abstract Name: The Mind of Thomas Henshaw: The Scientific Method Through the Ages

Today’s scientific method, which is used in most modern experimental disciplines, has been refined over hundreds of years to best describe how an experimentalist should approach research. Its use dates back to the 11th century but was refined and propagated in the 17th century by European scientists. The research of this era is notable for alchemy, an early form of religiously motivated science which later evolved into chemistry and physics. The European alchemical work of this period emerges as one of the most intriguing, marked by transformative shifts in response to technological advancements coupled with the sociopolitical power of the church. Enter Thomas Henshaw (b. 1618): while much of his written work is lost to time, it is known that he published several papers on saltpeter and gunpowder, as well as a few historical and political discussions. This work led Henshaw to assist in the founding of the Royal Society of London for the Improvement of Natural Knowledge, which is known to this day as the Royal Society. The University of Kentucky’s Special Collections Library has recently acquired an original copy of La Vie Devote (or The Devout Life), a religious text written by Saint Francis de Sales in 1644. The text was Henshaw’s personal copy and contains his own thoughts and annotations. Analysis of Henshaw’s markings in his copy of La Vie Devote paired with his known works is likely to reveal crucial connections between Henshaw’s use of the early scientific method and the one that science widely accepts today.

Abstract Name: Understanding the Value of Function Following Form

Which approach creates more interesting and beautiful buildings: Those who utilize ‘form following function’, or ‘function following form’? When an architect designs only using form following function, the building can have an excess of the utilitarian, resulting in a building that is very useful but can suffer in its overall design aesthetic, lacking attention to beauty. When the opposite occurs, the building can be an incredible work of art, but perhaps suffer in its usage. For an architect to be successful, there needs to be a balance of both methods. In the field of architecture, many architects and designers follow the adage ‘form ever follows function’. While the purpose of this research project is not to discredit this philosophy, the goal is to prove that the other side of the architectural coin, so to speak, has value and that there are multiple philosophies to consider. The research methodology for this project was comparing the buildings of architects that utilize differing philosophies with various building types, and utilizing eye tracking software to help

determine which philosophy is more engaging, and beautiful to the average person. The results show that function following form typically produces buildings that are considered more pleasing to the eye, when it comes to the building facades that are evaluated. Building with form in mind first will allow for the designs to better fit their perceived building typology. There is worth at looking into different perspectives. When one is approaching design, they should be willing to implement multiple methods to achieve the best version of their building. Function following form is one method that can help us attain a more beautiful building experience that will impact the world for generations to come.

Abstract Name: Analyzing Perceptions of Mental Health among Individuals with Polycystic Ovary Syndrome

Introduction: Individuals of reproductive years with polycystic ovary syndrome (PCOS) are up to three times more likely to have mental health issues such as depression, and seven times more likely to attempt suicide. However, mental health issues associated with PCOS often go unrecognized. Without proper treatment, mental health conditions can worsen over time. The purpose of this study was to explore how physical, mental, and social experiences and perspectives impact the mental health of individuals with PCOS aged 18-26 years. Methods: Participants were recruited using flyers, social media, the snowball method, and ResearchMatch (NIH digital recruiting technology). Using a semi-structured interview guide created through the lens of the biopsychosocial theory, interviews were conducted and audio recorded using Zoom and surveys were sent to be returned after the interview. All data were de-identified. Interview data were transcribed and analyzed using thematic analysis. Survey data were entered in SPSS and analyzed. Results: Participants (n=24) were aged 22.2 (+/- 2.3) years, single (75%), and resided in different regions of the United States. Mean depressive symptom scores (PHQ-8) were 10.9 (+/- 7.3), indicating moderate depression. Preliminary interview themes were: 1) feeling initially dismissed by healthcare providers when discussing PCOS and pharmacological interventions; but validated after receiving a PCOS diagnosis; 2) perceiving that mental health was affected by physical symptoms, such as weight gain, hirsutism, and fatigue; and 3) expressing concerns about the future given recent changes concerning reproductive rights. Conclusion: HCPs should consider biopsychosocial aspects of PCOS to better provide patient-centered care and earlier recognize signs of mental health distress. A holistic medical assessment could improve patient-provider communication, inform individualized treatment plans, and ultimately lead to better mental health outcomes for individuals with PCOS. Further research could help develop PCOS-specific evidence-based biopsychosocial screenings, consider their point of integration, and create decision-trees based on results.

Abstract Name: Use of X-Ray Fluorescence to Map Colorant Localization in Crystalline Glazes

Crystalline glazes are ceramic glazes formulated to favor the growth of macroscopic crystals that can reach several centimeters in diameter. The glaze base is primarily colorless zinc silicate. Copper, nickel and cobalt compounds are added at single percent-by-mass levels to generate colored macrocrystals. These crystals often imply localization of the colorants, despite being applied uniformly. The application of X-Ray Fluorescence (XRF) spectrophotometry to analyze colorant localization, crystal thickness, glaze flow and glaze depth are discussed.

Abstract Name: How Mathematics Faculty Strive to Create a Classroom Environment Where Students Feel Comfortable Contributing

Our research team developed the Teaching Equity-minded and Active Mathematics (TEAM) Tool, a tool for professional development and reflection, to help faculty transition their instructional practices to be more equity-minded and active. As active learning and equity-minded instruction are becoming more commonplace in mathematics education, we invited various mathematics faculty to engage in reflection cycles using the TEAM tool. Reflection cycles consist of three phases: planning, implementation, and reflection. Reflection cycles provide professors the opportunity to collaborate with undergraduate mathematics researchers to discuss teaching practices and strategies that can be implemented in the classroom to encourage equity-minded active mathematics. We investigated what teaching practices faculty selected from the TEAM Tool, their rationale for their selected teaching practices, and their reflection after implementation. We share the data gathered from 10 reflection cycles from Fall 2022 to Spring 2023 from participating CSUF math faculty. We found that Teaching Practice 5, Creates a classroom environment where students feel comfortable contributing, was chosen most frequently among the faculty members. After analyzing their rationale and reflection we concluded that faculty see great value in fostering a positive classroom climate. The TEAM Tool helps to increase faculty awareness of how to be more inclusive within the classroom, consistently building toward a climate that encourages and reassures students to actively participate in learning. Further, our findings indicate that leveraging the TEAM Tool in professional development can help faculty and/or faculty learning communities in greater self-reflection towards continuous instructional improvement.

Abstract Name: Bears, Cow, Crows, and Humans: A Historical Study of Animal Influence on Societies and Cultures

Human fascination and interaction with animals is innate and apparent across time and cultures. Throughout

history humans have observed, revered, and hunted animals, and in some cases domesticated them for their own benefit. Human usage of animals had a massive impact on the development of human civilizations. For example, the domestication of the horse enabled mass conquest of cultures who had not yet developed horseback riding. Also, many zoonotic diseases, such as smallpox, have been connected to domesticated animals, with many of these disease devastating cultures who lacked prior exposure. Finally, domesticated animals played an extensive role in human agriculture and economics as demonstrated in Sumerian cattle rearing. Bears, Cattle and crows capture unique attention from cultures across the world. While numerous animals receive human consideration, these three are particularly ubiquitous and important. Some significance to these animals exist almost everywhere amongst the cultures that live with them. Examining how societies view these animals tells us a lot about both human cultures and the animals themselves. It provides unique insights on human relationships with these animals and sometimes even reveals something about animal behavior. This essay draws on extensive, interdisciplinary academicresearch in the fields of anthropology, psychology, and history. It was initially developed as part of a cart presentation for the author's internship project at the North Carolina of Natural Science in Raleigh, North Carolina.

Abstract Name: Positive Effects of Social Support on Stress Levels in College Students

Previous research shows that stress is a massive problem in the college-aged community. Social support has been understood as a helpful combat to stress. The present study explores the effect of perceived social support on stress levels in college students. The researcher hypothesized that perceived social support would positively influence reducing stress levels among college students. In this study, stress level was measured with the College Student Stress Scale (Feldt, 2008). Social support was measured with the Multidimensional Scale of Perceived Social Support (Porter et al., 2019). The sample included 59 full-time college students from a Christian university. A t-test and a simple regression analysis were conducted to analyze the data. The findings in this research revealed that perceived social support significantly predicted stress levels ($b1 = -202$, $p = .013$). The more social support perceived was associated with lower stress levels in college students. In addition, there was a statistically significant difference in stress levels between males and females ($t = -2.001$, $p = .05$). Female students ($M = 36.30$, $SD = 7.7$) reported higher levels of stress than male students ($M = 30.40$, $SD = 11.7$). In accordance with the hypothesis, perceived social support has a positive influence on stress levels among college students. The findings emphasize the need for society and university institutions to recognize that stress levels in college students are impacted by social support. Furthermore, future implications address the need to understand how perceived social support can be increased among college students.

Abstract Name: Asteroid Disruptions of the Datura Family

To research the Datura Family of asteroids, a prewritten dynamical IDL code was run to track the orbital decay of asteroid fragments released in an asteroid disruption. Different particle sizes were used to analyze the outputs of each size, including the semi-major axis, eccentricity, and inclination, to observe how certain particle sizes' orbital elements evolve. Using a young asteroid family like the Datura family gives more insight into their original structure and formation because the time is closer to before the asteroid's breakup. We use these models to constrain the dust parameters by comparing the conditions to infrared satellite data sets. The semi-major axis utilizes Poynting-Robertson drag, while the eccentricity and inclination are related to the effects of Jupiter. But all of these orbital elements relate to the role of the radiative forces. This research is important to understand potential Earth hazards from space.

Abstract Name: Electrochromic Device: Tungsten Oxide

In today's world, the increase in energy consumption has significant implications for our environment, economy and our overall quality of life. Research has shown that buildings contribute to one third of the energy sector; and a total of fifty- percent of energy being used comes from heating, ventilation, and air conditioning (HVAC) usage; this number is only projected to grow in the future. Our research aims to contribute to the reduction of total energy consumption by increasing the usage of renewable sources through the development of energy-efficient glazing solutions, i.e., the smart window. The process of creating the energy glazing (e g)smart window involves the development of an electrochromic Device. This device is comprised of an electrolyte sandwiched between two electrodes. The electrodes are thin films that are spin coated. Spin coating is a simple and cheap method to create conformal and low-surface roughness films. The films that are spin coated are able to change color or transparency in response to an electrical stimulus. We report on the use of transition metal oxide (tungsten oxide) to fabricate electrochromic devices. The fabricated device showed promising electrochromic properties; for instance, it holds the ability to generate a fast switching time and exhibited great chemical stability.

Abstract Name: Home Runs and Racial Bias: The Unjust Treatment of Minority Baseball Players in Steroid Era Media Coverage

One of the most controversial time periods of baseball occurred in the 1990s and early 2000s. While the period is known for record-breaking homerun hitters (notably, Mark McGwire, Barry Bonds, and Sammy Sosa), it is also known as the Steroid Era. Many players from this time were accused or proven to have used illegal performance enhancing drugs, including McGwire, Bonds, and Sosa. My research looked to determine, "What role did the race of these players have in the way they were covered and depicted in the media following these accusations of steroid usage?" Many previous historians have looked at race and baseball regarding the league's integration, but there is little research that deals with MLB media coverage during the Steroid Era and issues of race. This research contributes to the field by comparing the media coverage of McGwire, Bonds, and Sosa, each a player of a different race. After examining articles published by ESPN, Bleacher Report, and Sports Illustrated, this paper argues that the media vilified and condemned minority players accused of steroid usage and showed greater forgiveness to accused white players. The media repeatedly judged minority players more harshly, showing that the long-standing racial discrimination towards minority baseball players, still existed at the beginning of the 21st century. It is essential to understand that the campaign for equality in sports and media coverage continues today, and we can only hope to achieve this inclusivity if we first confront and recognize the history of racial bias that has existed in baseball's past.

Abstract Name: Mixed Methods Study of Diversification Factors Affecting Meal Service Recruitment

Meals on Wheels strives to increase services to community residents of color. This exploratory study focuses on the impact of diversity at Meals on Wheels and the factors involved in the limited number of participants of color. There are clients who are unable to communicate with the agency because of language barriers. The student researchers reviewed a total of 16 journal articles relating to how the diversification of staff at Meals on Wheels affects vulnerable populations. Researchers created a 17-question survey that included open ended and closed ended questions to ask 100 community residents of color. Researchers collect data to assess the interest of having a diversified staff at Meals on Wheels. This research aims to understand what accommodation is necessary to have within the Meals on Wheels agency in order to reach more potential clients. The student researchers use the Statistical Package for Social Sciences (SPSS) to perform parametric and nonparametric tests. The researchers ran a measure of central tendency focusing on mean of age and mode of preferred language and gender. The student researchers ran a measure of variability focusing on the range of living arrangements and employment statuses. The student researcher ran correlation between the comfort levels of participants with people of their own race and people from different races. The overall results inform possible accommodations to be implemented within the agency to increase clientele. This study provides knowledge to the Meals on Wheels agency in Erath and many other Meals on Wheels agencies about the effects that diversification of the staff at MOW has on underserved populations. These findings contribute to the importance of having a diverse staff and supports advocacy for a vulnerable population.

Abstract Name: Investigating Multiple Sclerosis Incidence by Proximity to the Equator

Multiple sclerosis is an autoimmune disease wherein the immune system attacks the myelin sheath causing communication issues between the brain and body. Symptoms vary depending on the patient's severity, some obtain numbness or weakness in limbs, tingling, lack of coordination, vision issues, slurred speech, and even cognitive disabilities. There is currently no cure for the disease, but there are several ways to help reduce the severity and the rate of occurrence of flare ups using different prescribed medications, with research, further medicinal solutions may be found after considering geographical location. It has been found that MS patients living closer to the equator had a higher severity. It was also found that those with darker skin tones were less likely to develop MS due to some UV radiation protection. The research investigates the interplay between temperature at location of residence and genetics on the incidence of MS. Zip code, demographics, and genomic data were obtained from the All of Us Research Program. Data was analyzed using R in Jupyter

Notebook. Hail was used to run a GWAS with MS as an outcome and temperature-by-location as a covariate. A t test was administered between age and MS diagnosis with a p-value of 0.01927. A chi-squared test analyzing race and MS diagnosis resulting in a p-value of 2.2*10^-16. Although the data suggests that the data is statistically insignificant, the analysis is somewhat accurate considering the representation for this disease in the All of Us Research Program database. GWAS showed GPC6, TMC1, CDH23, and SYNGAP1 as genes of interest. These genes function in physiological and pathological conditions, CDH23 and TMC1 function in sensory perception, while GPC6 and SYNGAP1 function in cell signaling and other neurological functions. While the genes have different focuses, all have some relation to MS.

Abstract Name: Vitamin C Content of a Bell Pepper in Different Environments

This study investigated the impact of different storage environments on the Vitamin C content of bell peppers. Four distinct environments were examined: a frozen environment, a refrigerated environment, an open environment, and a closed capsule. Each bell pepper was stored in a bottle within these environments. The mass of the bell peppers was recorded both before and after the experiment to account for any changes. The results of this study could provide valuable insights into the optimal storage conditions for preserving the nutritional value of bell peppers, particularly their Vitamin C content. Further research is needed to confirm these findings and explore their implications for food storage practice.

Abstract Name: The Evolution of U.S. Presidential Executive Orders 1936 to 2022: Historical Trends and New Modern Changes

Executive orders are an important tool for the U.S. president to implement policy goals and execute laws. Scholars, such as Mayer (1999), have spent considerable time studying the use of executive orders; however, research on this topic has largely been limited to before Clinton's presidency. Examining executive orders in the 21st century is crucial for a complete understanding of the topic, especially given recent changes in American democratic processes. This paper analyzes historical trends in executive orders since 2000 with research questions and hypotheses based on replication of Mayer (1999): There would be more executive orders during a united than divided Congress; Democratic presidents would issue more executive orders; a negative correlation exists between approval rating and executive order issuance; and there would be no noticeable change in executive order issuance at the beginning or end of presidential terms. I gathered information from publicly available data and conducted t-tests and multiple regression analyses for relevant

yearly data during the presidencies of W. Bush to Biden. I conclude that the majority of trends observed by Mayer (1999) are not applicable today. I found no significant difference (t= -.65, p = .53) in the number of executive orders issued during a united or divided Congress. There was no significant difference (t = .56, p = .29) between the number of executive orders issued by Democratic or Republican presidents, although, Democrats issued slightly more orders (41 to 37). Finally, there was no significant association between presidential monthly approval ratings and executive order issuance (r2=.03). The number of executive orders issued by presidents was significantly higher during the first and last month in office compared to overall averages. Variables related to when a president uses executive orders appear to have changed since 2000.

Abstract Name: MRSA Antibiotic Potential of PEGA-Nucleoside Compounds: In Silico Results and Next-Phase Design

MRSA has quickly arisen as a deadly hospital superbug, due to causes such as overuse of antibiotics on livestock, tendency of patients to stop treatment regimens early, and horizontal gene transfer during comorbidity. In MRSA and other resistant bacteria, this largely results from the ability to produce beta-lactamases inactivating penicillins, as well as the presence of the modified peptidoglycan synthesis protein PBP2a, which penicillins have reduced binding affinity for. Mendoza et al. (2021) proposed PEGA-nucleosides as theoretical drug candidates targeting the class B1 metallo-beta-lactamases NDM-1, IMP-1, and VIM-2; however, their study only considered uridine and adenosine analogues. This study built upon Mendoza et al.'s research by performing computational analysis for L- and D- isomers of ten different PEGA-nucleosides in order to see if uridine remained the superior analogue; currently, 5-azadihydrouracil analogues perform best for all targets tested. To determine this, the twenty analogues were run through icmMolsoft to calculate binding energies and protein residue interactions against both PBP2a and the metallo-beta-lactamases. SwissADME, admetSAR2.0, and PASS prediction programs were also used to determine properties and safety profiles; however, as currently administered antibiotics have harmful effects, toxicity was not considered immediately disqualifying. Poor candidates, such as cytidine analogues, have been removed from further study, and the most promising analogues will be synthesized for in vitro and in vivo testing with proteins. Plans for in vitro and in vivo testing for metallo-beta-lactamase and PBP2a inhibition using MRSA are also discussed, with Kirby-Bauer diffusion and nitrocefin assays among proposed diagnostics.

Abstract Name: Lafayette at Yorktown (1782): An Art Historical Case Study of African-Americans in the American Revolution

This research uses Jean-Baptiste Le Paon's painting, Lafayette at Yorktown (1782) as a case study to illuminate one of the marginalized communities of history: African-Americans. The painting depicts the Marquis de Lafayette in uniform pointing to a battle scene—Battle of Yorktown (1781)—unfolding in the distance. Next to the Marquis, stands a restless horse and a mysterious unknown African-American man, also dressed in an extravagant uniform, perhaps, even grander than Lafayette's. The latter prompts the question, who is he? Only a singular chapter serves as the most comprehensive piece of scholarship on the painting. The most accepted interpretation posits the figure is James Armistead Lafayette, a double agent black spy at Yorktown. This research, however, presents alternative theories that have not previously been considered. A mixed-method approach was employed, mainly consisting of a content analysis of Marquis de Lafayette letters from repositories around the globe, artwork from Le Paon contemporaries, and a site-visit to Yorktown. Other means included oral history interviews and the current scholarship. Ultimately, no direct evidence surfaced that James is the figure. The research presents a new alternative theory—albeit rooted only in circumstantial evidence like the James theory—that the figure is a composite character for African-Americans from the First Rhode Island Regiment at Redoubt 10 at Yorktown. Despite inconclusive results on the whole, the research is a testament to the resurgence of African-American history that has long been under-recorded and is also commentary and a critique of historian's story-telling. It is an early attempt to create a more complete picture with Lafayette at Yorktown being one of the only sources of African-American espionage. More practically, it is a guide of how to rethink current notions of the American Revolution with its semiquincentennial quickly approaching in 2026 for audiences both domestically (America250) but also internationally (France's America2026 movement).

Abstract Name: Leadership Initiatives Public Health Campaign

Leadership Initiatives is an international non-profit organization focused on youth development, specifically through their International Public Health Internship Program. This nine-month program is designed to address key health issues affecting populations in sub-Saharan Africa. The program empowers interns to collaborate and create public health campaigns targeting prevalent concerns like water safety, hunger, and tropical diseases. One particular campaign undertaken by Leadership Initiatives was centered around menstrual hygiene in Bauchi State, Nigeria. The goal was to establish an educational campaign that would explain and dispel misconceptions in the community. Menstruation is a natural phenomenon experienced by approximately 1.9 billion people worldwide, yet stigma and neglect persist. Through promoting proper healthcare practices, the organization aimed to create a ripple effect in the region, making the dangers of menstrual hygiene more familiar and less stigmatized. The campaign sought to reach not only the participating group but also their families and friends, further extending its influence and potentially spreading throughout Nigeria for generations.

Abstract Name: Exercise Attenuates Methamphetamine-Induced Neurotoxicity in Male Rats

Methamphetamine is a highly addictive drug. Recreational use of methamphetamine induces neurotoxicity that leaves users with cognitive deficits, such as impairment in memory, which is often irreversible. This occurs due to cell death of neurons, specifically in the caudate-putamen. In methamphetamine induced neurotoxicity, the terminals of the dopaminergic neurons degenerate, resulting in memory impairment. An action potential in the caudate-putamen region results in the release of dopamine. DAT protein aids in the overflow of dopamine by transporting dopamine from the post-synaptic terminal to the presynaptic terminal. Methamphetamine also acts as a substrate as a monoamine transporter, resulting in even more dopamine release. Several studies have found that chronic exercise can have beneficial effects on memory, specifically short term. Our project aimed to analyze whether exercise improved a rat's ability to perform better in cognitive tasks that assessed memory after experiencing methamphetamine-induced neurotoxicity. A female and male cohort were used in this study to assess whether gender differences existed in methamphetamine use and the impact of exercise. Both sex cohorts of rats were either dosed with saline or methamphetamine and randomly chosen to receive a sedentary or active lifestyle, via a wheel in their cage. The rats with access to wheels were allowed 7 days to rest without a wheel in their cage post-dosing. To assess memory, two cognitive tests, object in place test and odor recognition, were tested on the rats. Post-euthanasia, immunohistochemistry was used to analyze neurotoxicity in the brains. The study revealed that female rats, saline or methamphetamine dosed, ran further distances than male rats. Methamphetamine had significant neurotoxic effects in both sex cohorts but exercise significantly attenuated the neurotoxic effects of methamphetamine in males. As the data displays, in male rats only, exercise helps attenuate the methamphetamine-induced neurotoxicity displaying that there are gender differences.

Abstract Name: Statistical Modelling of Alaskan Coral Biodiversity

Cold-water corals are incredibly diverse marine organisms, ranging from deep water habitats in the tropics to shallow depths at the poles. They have an enormous range of structures, provide food and shelter for many organisms, and are the foundation upon which oceanic health rests. Warm-water corals have experienced a

decline over the past few decades, but less is known about cold-water corals. Current research points to shifting environmental conditions (e.g., climate change) and fishing practices leading to decreased coral biodiversity. My research seeks to better understand how environmental trends affect coral biodiversity around the Gulf of Alaska, the Aleutian Islands, and the Chukchi Sea. I used the National Oceanic and Atmospheric Administration's Deep-Sea Coral Database, one of the largest spatial and temporal data sets available. There are nearly 30,000 coral records in the database for these regions. Using these records, I analyzed the biodiversity of cold-water corals to show how this diversity is distributed around Alaska. I discuss the potential effects of these results, as understanding biodiversity trends is vital in predicting how coral reefs may change in the future and in protecting this ecologically crucial region.

Abstract Name: NP Length Matters: An Analysis of Relative Clauses in Min Nan

Min Nan is a Sinitic language spoken in the southern coast of China and in Taiwan. It belongs to a larger family the Min languages, which are a group of related languages but not mutually intelligible (Chappell, 2019). The current paper examines the usage of the structural particle e and the preposition/light verb ga in Min Nan in relation to relative clauses. The particle e in Min Nan is used in various constructions and plays a significant role in forming relative clauses. On the other hand, ga functions as a constituent allowing the object to be moved to a sentence-initial position. We conducted 6 elicitation sessions with a native Min Nan speaker, asking them to translate 108 English sentences. Our findings suggest that Min Nan exhibits a preference for ga-fronting in relative clauses, while e is primarily used for shorter sentences. This preference can be attributed to the fact that e has multiple functions and can be used in different constructions, which may lead to ambiguity in surface structures. In addition, when the objects were heavy, we observed two different patterns: 1) objects were fronted with the shi copula, with the e particle following the head noun, and 2) the object was fronted, but the ga marker remained in the object position without being fronted. The shi-e copular pattern was more commonly found in our data, supporting the argument by Yang (2016) that ga-fronting is unacceptable when used with a heavy noun phrase. This paper contributes to the ongoing discussion on relative clauses in Sinitic languages, particularly in determining whether they constitute a distinct category or a subtype of noun-noun clauses. Furthermore, the analysis of weight distribution in relative clause fronting adds to the existing literature on the cross-linguistic preference for end-weight structures.

Abstract Name: Develop a portable mentorship training program for a summer undergraduate research experience program

High quality mentoring is essential for the success of undergraduate research, as it’s known to be associated with positive student outcomes in research skills, professional identity and self-efficacy, as well as persistence in STEM. In certain disciplines, like life sciences, graduate students and postdoctoral researchers are usually the ones who work with undergraduate researchers on a daily basis, where the majority of the mentoring activities take place. However, rarely there is mentorship training opportunities or programs developed specifically for these early-career scientists. Here, we report the development of a mentorship training program targeting graduate and postdoc mentors for a summer undergraduate research experience program in the discipline of plant biology. In addition to common skills and competencies for effective mentoring, including maintaining communication and establishing expectations, our mentorship program emphasized the unique role that graduate/postdoc mentors may serve as the communication bridge between undergraduate researchers and their faculty mentors. Moreover, our training program emphasized how to engage and successfully mentor underrepresented trainees. Additionally, summer undergraduate research experience programs tend to have shorter turnover for recruiting, shorter program length, and more intense working schedules. Thus, we designed our mentorship training program into a portable asynchronous online format that requires about 1 hour of participants’ time for the training and assessment. Participants of the training program also have access to all the learning materials over the course of the summer program. Our mentorship training program fills the gap of lack of official mentorship training targeting graduate/postdoc mentors for undergraduate researchers. Even though the program was developed for a specific summer undergraduate research experience program, the training material can be easily adapted to be reused in other similar summer undergraduate research experience settings.

Abstract Name: Healing Spaces Through Time: An In-Depth Analysis of the Evolution of Children’s Hospital Healthcare Interiors During and Directly After WWII

BACKGROUND: Historically, children's hospitals have undergone ideological transformations, with recent research promoting increased interaction between young patients and their families within these medical settings. Consequently, there has been a notable shift in children's hospitals towards embracing family-centered care. Children’s hospitals serve as the cornerstone for promoting health equity, conducting research, and advancing pediatric medicine, playing a crucial role in the holistic well-being of disadvantaged children. Established in 1924, Riley Children’s Hospital has experienced substantial transformation and expansion, prompting an examination of its interior design evolution, especially during and post-WWII. RESEARCH QUESTION: How do hospital patient room interiors serve as artifacts of material culture, record the narrative told in the interior design, and observe the reflection of cultural values? Specifically examining Riley Children's Hospital as a case study and delving into the evolution of its healing spaces during and after WWII. METHODOLOGY: A team of undergraduate students collected data from databases and university archives, which were then analyzed through qualitative template analysis. Analysis areas included privacy, materiality, equipment, and design. PRELIMINARY FINDINGS: During and directly after WWII, patient

rooms were commonly open wards separated by adjustable partitions. However, these did not extend to the floor and ceiling, raising concerns about privacy. The materiality of partitions and medical equipment was commonly metal, indicating sanitation considerations. The layout of patient beds allowed for efficient patient surveillance. In later decades, around the 1940s, personal touches like flowers and balloons near beds, artwork on walls, and a greater variety of furniture signaled a shift towards more personalized and domestic interiors. FUTURE CONSIDERATIONS: In the interwar era, Riley Children's Hospital emphasized safety, sanitation, and efficiency, subtly transitioning towards family-centered care, signifying an ideological shift. With children's hospitals being integral spaces for underserved populations, these ideological shifts represent designed health equity.

Abstract Name: The Impact of Social Media on the Travel Industry

This thesis paper focuses on the impact that social media has on the travel industry now and over the last ten years. With an increased use of social media and user-generated contact, this new way of gathering trusted information has also led to changes within the travel industry. The use of social media has both clear positive and negative impacts. This research focuses on both those aspects of impact. Along with looking at how social media has impacted the travel industry, the researcher will look at how it has impacted the tourism industry as well. With user-generated contact helping target individual's feeds with content related to travel destinations, this is now encouraging inexperienced travelers to plan those dream trips finally. This can lead to issues in areas with already high tourism rates, now increasing and affecting the lives of locals in these areas. The researcher looks at primarily secondary research information,and, with outlining all the benefits and setbacks of social media on the travel industry, the researcher explains why this is occurring. The research is applied through the psychological theory of social proof, through a public relations viewpoint. This is an important topic because the travel industry is one of the biggest industries globally, and the use of social media has helped it to continue to grow.

Abstract Name: The Face of Fear: How Fear Learning Influences Face Representations

The capacity to discriminate between threatening stimuli and non-threatening stimuli is an important survival strategy. A leading model for studying fear and anxiety in the brain is Pavlovian fear conditioning, a procedure in which an emotionally neutral conditioned stimulus (CS), such as a face, is paired with an aversive unconditioned stimulus (US), such as a gunshot sound. Previous research has found that the perceptual representation of a CS changes following fear conditioning, changing how well the CS can be

discriminated or support generalization. However, the mechanisms behind these perceptual changes are poorly understood. Moreover, little is known about how fear learning might modify the information extracted from a complex CS, such as a face. Here, we aim to characterize the effect of fear conditioning on face perception by recovering the information used for face identification with and without fear conditioning. To test this, two groups of participants are first trained to learn to discriminate two face stimuli of different identities, one paired with an aversive sound (CS+) and the other paired with a neutral sound (CS-) and are then asked to rate their expectation of the US, while recording their Skin Conductance Response (SCR) to measure their autonomic fear response. Using reverse correlation, a psychophysical technique that estimates visual proxies of mental representations based on participants' judgements of randomly varying noise added to the stimuli, we aim to identify what face features are represented more or less strongly after fear conditioning, as well as whether this effect depends on face identity. These findings could help understand the mechanisms that contribute to abnormal responses that underlie psychopathological disorders.

Abstract Name: Changes in Cultural Learning Strategies in U.S. Youth Education K-8.

Historically, monolingual America was the socially acceptable norm for school children in America. Multilingual education was frowned upon. As early as the 1900s, assimilation to the English language and American culture has been ingrained in the U.S. education system. Non-English-speaking students were most likely to be channeled into speech therapy and English as a Second Language (ESL). "This is America, we speak English here" was the welcoming slogan to newcomers. Since 2000, there has been a shift from monolingual conformity to multilingual celebration in educational programs. Dual-language programs, such as the Mandarin-English or Spanish-English, show advancement in cognitive skills for their students. This research project examined changes in cultural learning strategies in the U.S. education system K-8 grade. The investigator found common themes among LifeStories Matter podcasts that had been collected as part of a course at a mid-sized midwestern university. Results suggested a significant connection between the newer cultural learning strategies and growing diversity in American demographics. For example, education programs such as ESL were rebranded as English Language Learners (ELL). The results shed light on a centuries-long, derogatory system. Investigators comment on improvements to better diversity, equity, inclusion, intercultural competence, and multicultural awareness.

Abstract Name: Social Anxiety Across Genders and Sexualities

Transgender and nonbinary people have rates of anxiety that are almost three times as high as cisgender

people. This study compares level of social anxiety between transgender and nonbinary, cisgender LGBQ+, and cisgender heterosexual individuals and looks for correlations between social anxiety, dysphoria, and body image. Data were collected through an anonymous survey that included the Social Interactions Anxiety Scale (SIA), Centre for Appearance Research Salience Scale and the Centre for Appearance Research Valence Scale (CARSAL/CARVAL), and questions about sexual orientation and gender identity. Participants who identified as transgender or nonbinary also scored their social and physical dysphoria. A one-way ANOVA found that transgender or nonbinary participants had significantly higher SIA scores than cisgender LGBQ+ or cisgender heterosexual participants. Pearson's r tests showed that there was a correlation between physical dysphoria and CARSAL/CARVAL score and between CARSAL/CARVAL score and SIA score, but there was not a correlation between physical or social dysphoria and SIA score. This indicates that increased rates of social anxiety among transgender or nonbinary individuals may not be explained by their experiences with dysphoria.

Abstract Name: Pregnancy Behind Bars: Exploring the Impact of Incarceration on Prenatal and Postnatal Care for Female Inmates

Incarcerated women have a constitutionally protected right to obtain appropriate medical care. Past research has found that "38 states had inadequate or no prenatal care in their prisons" (NWsLC, 2010). A report from The US Department of Justice states that "46% of pregnant imprisoned women reported they received no pregnancy care" (Maruschak, 2008). There is a gap in the literature of analyzing primary accounts of pregnant inmates. The current study is investigating the interaction of incarceration and the available care and quality of care given to female inmates in American correctional institutions. This study is comprised of a qualitative video analysis using a convenience sample. We selected 10 videos of incarcerated women and 10 of non incarcerated women speaking about their pregnancy experience in America. Inclusion criteria includes the videos being made within the past five years, being at least ten minutes long, and showing their face. The software system "ATLAS.ti" will be used to analyze the transcripts and visual notes of the video testimonies. The analysis will focus on the spoken experiences and the visual social cues that are present. Considering these variables, we will be able to account for the similarity and differences of provided care to inmates. The visual cues will provide information about how the subject feels recounting their experience, which can give another element to the analysis as some mental health conditions, such as PTSD, has visual cues. As a control, video testimonies from non-incarcerated women sharing their pregnancy experience will also be analyzed. We hypothesize that prenatal and postnatal care being given to inmates will vary greatly since there is very little legislation protecting pregnant inmates' access to honorable prenatal and postnatal care. We also hypothesize that women that were incarcerated while pregnant will show more visual signals of mental distress.

Abstract Name: On the Brink of Adulthood: The Growing Young Adult Mental Health Crisis

Mental health is a growing problem in the United States, especially for the young adult population. Before the pandemic 19% of high school students had seriously considered suicide and 16% of those had made a plan; these numbers have increased significantly since COVID-19. Through an extensive literature review, this research evaluates the existing solution to this crisis, integrated mental health care, and acknowledges its potentially beneficial impact on young adult mental health. However, this solution falls short of solving the problem due to its inability to address the social and cultural barriers that dissuade young adults from seeking care for their mental health, the high costs of implementation, and the failure to address basic accessibility barriers for these programs. This paper proposes a four-step plan for integrating mental health treatment and education into the school system. These four steps are integrating mental health lessons organically into the established curriculum to teach emotional intelligence at all ages, increasing teacher and administrator training in mental health affairs, decreasing teacher stress, and increasing the number of school counselors. The paper acknowledges that increasing the number of school counselors in schools would cost a significant amount of money, but the low cost of implementing the other three steps renders this solution the more sustainable option.

Abstract Name: Applying Empathy-Based Childcare Methods to the Care of our Peers

My project considers how we foster growth and development in children, specifically the methods by which we apply empathy to meet their wants and needs-and how we might apply these methods to our care of adults, including how doing so would alter our “kindness” to one another. The project seeks to propose a lens through which we can view our peers, not necessarily as adults but as the child we carry with us, to foster greater empathy as if we were interacting with a child unaware, or by nature, non responsible for their (or our own) actions. The project combines elements of psychology with an analysis of literature, examining previous research on what exactly a child is, why we respond with empathy to children, why we may respond differently to adults who have developed autonomy and a sense of responsibility, and what it would take to bridge the gap in our perceptions in order to develop a greater sense of empathy to our peers and ourselves in a healthy and forgiving way. I will also consider contemporary literature that centers around the Bildungsroman, the coming-of-age story, to discover our perceived difference between childhood and adulthood. Research will consist of interviews with various health professionals, educators, students, and parents, to discover the capacity for empathy, and how altering the perception of another individual may alter the capacity for empathy likewise. I will employ a survey to ascertain the limits and reaches of one’s personal empathy in an attempt to understand the philosophical differences and hopefully bridge the gap to foster more empathetic, understanding, kind, and thoughtful interactions with others.

Abstract Name: Revealing structural dynamics of transcription factor by changes in cell volume

C/EBP**β** is a transcription factor that regulates a variety of cellular functions including cell proliferation and differentiation. It consists of a folded DNA binding domain and an intrinsically disordered N-terminal transactivation domain. Unlike folded domains, intrinsically disordered regions (IDRs) lack a stable tertiary structure and exist in an ensemble of fluctuating conformations. Structural preferences within these dynamic ensembles have been linked directly to IDR function. At the same time, due to their extended conformations and low number of intramolecular bonds, IDR ensembles are sensitive to physical-chemical changes in their surroundings. We hypothesize that the sensitivity of the C/EBP**β** N-terminal IDR can cause its ensemble to change as a result of abiotic perturbations to the intracellular environment, possibly leading to changes in function. To test this, we measured the ensemble dimensions of IDRs derived from C/EBP**β** using live-cell FRET microscopy in cells before and after subjecting them to an osmotic challenge. Our results showed that specific regions of C/EBP**β** displayed elevated sensitivity compared to other regions. This suggests that these regions may influence C/EBP**β**'s transcriptional response to changes in cell volume induced by osmotic stress. We propose that this is a general mechanism for how transcriptional activation IDRs tune regulation in response to physical-chemical changes inside the cell.

Abstract Name: Mental Health Disparities among College Students: An Intersectional Analysis of Racial Backgrounds

College is an inherently stressful environment for students, and mental health problems can intensify stress, impacting various areas of student lives, including quality of life, academic success, physical health, and relationships. This research aims to analyze mental health outcomes among students across diverse racial backgrounds. Acknowledging the profound impact of mental health diagnoses, treatment-seeking behaviors, and overall well-being among students from different racial backgrounds, this study will examine existing research on mental health in college students, emphasizing the intersectionality of race and mental health. Recognizing gaps in current knowledge, the study takes on a mixed-method approach incorporating surveys, interviews, and potential voluntary focus groups with undergraduate students who attend a large land-grant institution. Participants will encompass a diverse range of racialized backgrounds, considering factors such as ethnicity, nationality and cultural identity. Statistical methods will be employed to compare aggregate quantified survey data pertaining to mental health outcomes and treatment-seeking behaviors across racialized groups. Simultaneously, qualitative data will undergo thematic analysis, offering a refined exploration of participants' experiences. Results will be presented highlighting any statistically significant differences in mental health outcomes and treatment-seeking outcomes will offer qualitative analysis providing depth and context to quantified findings. The discussion will interpret implications within the existing literature, exploring potential cultural, systemic, and individual factors contributing to the observed disparities.Overall, this research will summarize key findings, emphasizing the importance of recognizing

and addressing mental health disparities on college campuses. Furthermore, these findings have the potential to contribute valuable insights that can inform mental health support services and policies on college campuses, fostering a more inclusive and equitable environment for students of all racialized backgrounds.

Abstract Name: Utilizing Detrital Zircons for U-Pb Age Analysis and Investigating the Similarities Between the Eastern Hayfork and North Fork Terrane, and their Association with the Western Margin of North America

The Klamath Mountains are located on the west side of the United States on the border of Oregon and California. The region is made of oceanic rocks that have accreted to North America and is divided into four different belts: the Eastern Paleozoic, Central Metamorphic, Western Paleozoic and Triassic, and the Western Jurassic. The oldest rocks in each belt become younger from east towards the Pacific Ocean. Within the Western Paleozoic and Triassic belt, the Eastern Hayfork terrane is a mixture of rock that formed in a subduction zone complex with the folded North Fork terrane. There are questions about how and when these terranes formed as well as the relationship between them. The Eastern Hayfork terrane consists of metamorphosed sedimentary blocks. Mixing may have begun as early as Permian time, and the terrane may have become part of North during the Late Triassic. Some sedimentary blocks are very old but do not tell us when mixing occurred. The sedimentary matrix surrounding them likely formed during mixing, but it is not well studied and so far, shows a large range in ages. The North Fork terrane consists of folded volcanic and sedimentary rocks with oceanic characteristics. Although the rocks are not mixed, the North Fork terrane has been compared to the Eastern Hayfork terrane due to its similarities of rock samples. However, there is little age data to support this. Metamorphosed sandstones have been collected from both terranes to find detrital zircons and obtain U-Pb ages to identify similarities between the Eastern Hayfork and North Fork terranes. The goal is to find an age and compositional relationship between both terranes to be able to understand how both terranes are related with each other and how the western margin of North America developed over time.

Abstract Name: Native Americans in the University of California System

Do Native American students, faculty, and staff at select University of California (UC) campuses feel that their interests are recognized and represented within the UC system? This research analyzes the opportunities and barriers Native Americans face in higher education in the United States and Canada. In the United States, Native Americans have the lowest enrollment and graduation rates of all racial and ethnic minority groups that seek out higher education and are the only group to have not experienced a consistent rise in attendance.

If the University of California system wants to improve the experience of the Native American demographic at UC campuses, then understanding their experiences is critical. The research methodology included an annotated bibliography, interviews and ethnographic participant-observation amongst Native American students, faculty, and staff members at select UC campuses. Phase 1 of the research project analyzed data and scholarly literature about the problem, including potential solutions. This resulted in an annotated bibliography. Phase 2 of this research project involved interviews and participant-observation fieldwork with Native American students, faculty, and staff members at select UC campuses. In addition, Native American community events were attended for a first-hand experience of the festivities and people attending the event. Statistical and secondary data provided by the UC websites and other information sources were also utilized. The results of the research provide information about what is working, what can be improved, and potential solutions to enhance the academic experience of Native Americans in higher education.

Abstract Name: Fatty Acid Composition of Peanuts With Different Solvents and Methods Of Extraction

Peanuts, Arachis hypogaea, are an important food source and crop across the world. One of the ways researchers study peanuts is by analyzing the fatty acid content (FAC) present. Knowing the FAC is beneficial because around 50% of the fat in peanuts is monounsaturated fat, the “good fat” that lowers blood cholesterol and provides health benefits to consumers. One way to extract peanut oil is by using solvents. Since multiple methods of extraction and solvents could be used, this project aims to answer the question, “Is the fatty acid composition in peanut oil affected by the solvent and method of extraction?” We will compare FAC determined by gas chromatography (GC) from samples extracted with two different solvents, hexane and dichloromethane (DCM), and two different methods, vacuum filtration and Soxhlet extraction. The current hypothesis is that different solvents and extraction methods will produce variable amounts of total oil and FAC. This project will follow the Biochemical Research Lab (BRL) “Oil Content- Raw Nut Procedure” protocol with triplicate peanut samples as written and repeat the procedure with triplicate samples, replacing the DCM with hexane. Once the oil has been extracted, the BRL “Sample Methylation for Fatty Acid Content (FAC) or Oleic:Linoleic (O:L) Ratio Analysis Protocol” will be applied to all samples to prepare them for GC analysis. In addition, previously collected samples run with DCM or hexane and varied run times following the BRL “Oil Content by Soxhlet- Peanut Procedure” will also be methylated and analyzed using GC. The collected data will include the percent oil content and the samples' FAC and O:L ratios. This data will be used to determine if the method of extraction and solvent used affect the total oil and FAC.

Abstract Name: Evaluation of the Efficacy of At-Home Genetic Testing Kits Between Identical Twins

Direct-to-consumer (DTC) genetic testing kits, also known as at-home kits, have gained immense popularity since their introduction in the early 2000s. However, concerns have emerged regarding the accuracy and reliability of the ancestry reports provided by these kits. Previous research conducted in this laboratory has revealed significant discrepancies in the results provided by different companies, despite their claims of over 99% accuracy. Out of 42 individuals previously tested, 39 exhibited major variations in their genetic ancestry categories across different companies, with differences of up to 40% in some cases. The current study aims to investigate whether these testing discrepancies exist within companies or only between them, focusing on identical twins because they share the same DNA. The study involved the same three genetic testing companies previously examined: Ancestry, 23&Me, and MyHeritage. So far, complete results have been obtained for six sets of identical twins, with additional sets currently being processed. The findings have remained consistent with the previous study, as each company reported discrepancies in ancestry categories. Surprisingly, in addition to the variations between companies, differences were also observed between twins in the data reported by the same company. None of the sets of twins had completely matching results, and in some cases, one twin had an ancestry category that the other did not have at all. These inconsistencies raise significant ethical concerns, particularly considering the companies' claims of near-perfect accuracy and their marketing of genetic health screenings for specific diseases and health conditions. It emphasizes the need to address how these companies market and report data to consumers who may not possess sufficient knowledge in this field.

Abstract Name: The CONNECT Network: Mentoring Undergraduate BIPOC Women as Biosciences Entrepreneurs

Currently, undergraduate biology education lacks bioscience-focused entrepreneurial training. While students may be aware of entrepreneurship as a career, they may fail to see themselves as innovators, find the pathway daunting, or not consider entrepreneurship as a way of solving real-world challenges. The Community of Neighboring and National Entrepreneurial Centers and Trainees (CONNECT) network is an NSF-funded initiative empowering undergraduate biology educators to increase entrepreneurial opportunities and training for BIPOC women. Within the first year of funding, CONNECT has grown to include 17 undergraduate biology educators from 14 institutions across 10 states, developed a SWOT analysis for implementation of entrepreneurial training into undergraduate biology curricula, and surveyed nearly 250 biology undergrad students regarding their current experiences and future needs around biosciences entrepreneurship. To better understand how the intersection of gender identity, race, and ethnicity may impact students' perceptions of entrepreneurship, we identified ID groups within our dataset: BIPOC Female+ (N=85), White Female+ (N=73), BIPOC Male (N=25), White Male (N=25). Notably, BIPOC Female+ respondents rank higher than all other identity groups for seeing entrepreneurship as an investment and being 'very interested' in learning more about biosciences entrepreneurship as a career path. BIPOC Female+ respondents were second only to White Male respondents in percentage of respondents who have 'very seriously' considered a biosciences entrepreneurial career path for themselves. However, BIPOC Female+ respondents were the lowest among identity groups in affirming that they had the support they needed at their college or university to consider entrepreneurship in the future. This preliminary data and the faculty-led SWOT analysis will inform the mentor-led presentation and encourage discussion among attendees about future implementation of inclusive curricula and research opportunities within undergraduate biosciences entrepreneurship. We strongly encourage faculty and students to join the CONNECT network and start mentor-student hubs at their universities.

Abstract Name: Exploring Affect and Cognition during Human-Robot Collaboration

Integrating robots into workplaces promises to revolutionize manufacturing and production processes, optimizing quality and cost-effectiveness. Effective collaboration between humans and robots is paramount for achieving productivity, safety, and efficiency enhancements.However, the challenge lies in addressing the inherent variability in human cognitive and affective states to enable robots to provide optimal support to human operators. Human decision-making abilities are significantly influenced by affective and cognitive states—areas where robots traditionally lack understanding.This project, situated in the domains of Human-Robot Interaction (HRI) and Brain-Computer Interfaces (BCI), seeks to investigate the potential of leveraging information about the emotional and cognitive states of human operators to robotic systems looking to enhance collaboration outcomes and operator experiences while realizing manufacturing tasks. Specifically, we developed a distributed system where (1) brain signals from human operators were gathered by a consumer-grade EEG device; (2) affective and cognitive states were inferred using a machine learning commercial software; (3) affective and cognitive data were transmitted to a robotic unit powered by a Raspberry Pi; (4) implement an adaptive algorithm in the robot to make it responded in real-time to stress and concentration levels in the operator.The results obtained from stress and concentration measurements demonstrated the applicability of this real-time cognitive state feedback in improving collaboration. The robot's adaptive responses contributed to smother interaction by (1) actively adjusting its motor speed in

response to high or low levels of concentration and stress (2) activating RGB lighting to alert the operator when stress levels exceed a predetermined threshold – prompting them to take a break for optimal well-being. These results serve as a foundational step for our next endeavor, involving multiple users and multiple robots collaborating simultaneously.

Abstract Name: The Impact Social Capital has on Microfinance Success

This paper examines the evolution, challenges, and impact of microfinance, focusing on its development in Bangladesh and replication in India. The study emphasizes the role of social capital in microfinance, particularly through group lending, and explores its positive intricacies and limitations. The objective is to analyze the historical evolution of microfinance, with a focus on the role social capital plays in the success. The study aims to understand the challenges faced during its third generation, marked by controversies and a crisis in the replication in the Indian microfinance industry. The paper utilizes historical analysis, drawing from the inception of microfinance in the mid-1970s to the crisis in the 2010s. Additionally, it incorporates a quasi-study on social connections and banking, using regression analysis to explore the relationship between loan default, savings behavior, attrition, and social connections. The analysis reveals the positive impact of microfinance in its early stages, emphasizing the success of joint liability and social capital. However, it uncovers the challenges triggered by the rapid expansion of microfinance institutions which resulted in the "overlapping" of loans and debt traps. The study provides insights into the advantages of social connections, showcasing improved group lending outcomes and a strong link to forgiveness in cases of sincere misfortune as a result of the interconnectedness. The findings underscore the importance of social embeddedness for the success of microfinance programs. While social connections contribute positively to monitoring and enforcement activities, the study acknowledges that the same social connections relied on, could also negatively impact relations especially post-default. The research contributes to ongoing discussions on the role of social capital in microfinance and its broader implications for development.

Abstract Name: You Can’t Park There!: Urban Revitalization and the Regulation of Public Space

The consequences of gentrification include conflicts over the appropriate uses of public space. One way that this occurs is through the regulation of on street parking. Changing development patterns may motivate changes in parking regulations and enforcement across neighborhoods, which can lead to financial consequences for motorists who violate new regulations. Considering this, two research questions frame this study. First, what is the geographic patterning of traffic citations in Washington, DC? And second, what is the effect of neighborhood gentrification on the issuance of parking violations? Using citation data from Open Data DC, we constructed an average count variable of citations issued between 2017 and 2019. The gentrification measure was constructed using census data downloaded from the National Historical Geographic Information System. This included six variables that indicate gentrification, including the proportion of white residents, educational attainment, post-industrial employment, income, rent, and home values. We included a number of controls, including 311 calls for parking related issues, the proportion of Black residents, and the part one crime rate. Geospatial mapping technology was used to create maps of the distribution of parking citations and the distribution of gentrification based changes. In addition, regression models were used to estimate the statistical effect gentrification had on citations. We found that parking citations are not equally distributed across space. In addition, the regression model suggests that as gentrification progresses, the effect 311 calls for service has on the rate of citations weakens. Post-Industrial policing literature states that order maintenance policing tends to be strongest when gentrification is just beginning, but decreases as the community turns over and the conflict over public space balances. These findings support that theory. This research expands our understanding of the social control mechanisms city governments have available to affect gentrification.

Abstract Name: An Adamless Eden? Lila Clay’s Ladies’ Orchestra in Late Nineteenth-Century London

In September of 1879, nineteen-year-old Lila Clay signed a Memorandum of Association for a new organization titled “Miss Lila Clay’s Company of Lady Minstrels,” confidently listing herself as “spinster” and solidifying her role as sole Conductress and leader of this all-female ensemble. While originating from humble beginnings, Clay’s orchestra initiated their career with a bold statement: one of their earliest productions, a comic operetta titled “An Adamless Eden,” told the story of an island devoid of any men. Their performance was quite striking, and reviews of the performance reflected the audience’s amazement and intrigue. This production also acted as the catalyst for the ensemble’s international tour, which traveled across Europe and North America and featured operas, symphony orchestra concerts, and gala performances complete with new original works by Lila Clay herself. Using a survey of archival material, contemporary newspapers, and recently rediscovered scores, this paper will highlight the remarkable successes of the Lila Clay Ladies’ Orchestra, both in their musical achievement and in their establishment as a professional ensemble in a time where a career as a female instrumentalist was atypical. The Lila Clay Ladies’ Orchestra

expanded the ways in which women were viewed in musical society as well as provided other women of their time a voice of advocacy and publicity uncommon for their era. Their work, while unusual in its age, thus reveals that female musicians asserted themselves in the public realm in the late-nineteenth century, and even accrued esteem and appreciation in the process.

Abstract Name: Immersive Experiences Through Hotel Design

Travelers today aren’t looking for the same accommodations they were looking for ten years ago. In 2023, millennials make up the highest percentage of travelers when divided by age groups. The main problem hotels face today when attracting this demographic is the lack of providing experiences. Whether that be through style, technology, or both. Hotels providing immersive experiences post pandemic have proven to be the most successful. So I came up with Kingsley On Fifth, a boutique hotel located on Fifth Avenue in New York City, NY. Every room in the hotel provides a different immersive style based on famous US fashion designers. The first level features the aesthetics of Anna Sui and Henri Bendel. The second level features Rick Owens, Ralph Lauren, and Tom Ford. The third level includes Kate Spade and finally the rooms and suites feature the styles of Dapper Dan and The Row. Along with this, the hotel will support new and upcoming US designers by providing a gallery for them to showcase their new collections, as well as by selling their pieces in the hotel boutique. With fashion tourism being one of the main draws in New York City there’s absolutely no doubt that this is bound to be the go-to spot for any fashion junky and as well for the fashion industry.

Abstract Name: The Effect of Emotion Brokering Frequency and Gender on Maternal Relationship Quality Among Latinx College Students

Existing research on language brokering (i.e., interpreting language for others) has investigated the relationship between language brokering frequency and familial relationships (Shen et al., 2022). For example, there is evidence that language brokering is often associated with more parent-child conflict, but not parent-child bonds (Hua & Costigan, 2012). Prior research has not investigated how this applies to the relationship between emotion brokering, a process that involves helping others navigate interactions between social partners who hold different norms in the expression and experience of emotions (Subramoney et al., 2013) and relationship quality. This study examined the association between emotion brokering frequency and maternal relationship quality among a Latinx college student sample (n = 118). In addition, we explored

whether these associations would differ by gender. We hypothesized that similarly to language brokering, emotion brokering frequency would predict relationship conflict but not relationship support. Participants reported their emotion brokering frequency for their mother, levels of conflict, and levels of support in their relationship with their mother. As expected, analyses revealed that emotion brokering frequency was associated with relationship conflict, but not relationship support. However, analyses also revealed that the association between emotion brokering frequency and relationship conflict varied by gender. Specifically, emotion brokering frequency was only positively associated with relationship conflict among men in the sample (p =.005). Like language brokering, emotion brokering frequency also predicts parent-child conflict but not support. Our study extends prior brokering research by highlighting how these associations only occur for men. Investigating these associations is important as it allows us to understand the various, complex characteristics of Latinx parent-child relationship dynamics as well as assess the cultural gendered difference that can exist in such relationships.

Abstract Name: Mrs. Packard: How Misogyny and Ableism Intersect, Historically and in the Present

Mrs. Packard (2009) by Emily Mann is a play inspired by the true story of Elizabeth Packard, a woman who was committed to an insane asylum by her husband in 1860. Elizabeth Packard's story exists at the intersection of misogyny and ableism, whose combined effects left her nearly helpless and at the mercies of neurotypical men. Intersectionality is a key concept in understanding the play; Packard's struggles were not the result of her being merely a woman, or married, or possibly mentally ill. Rather, the disenfranchisement she experienced was a result of the converging of all of these issues into one situation.Elizabeth Packard was committed in 1860, at which time it was legal for a man to have his wife committed with no proof of her insanity. Packard protested her confinement for 3 years. When she was finally released, she fought in court to be declared sane, and went on to campaign for the rights of married women and the mentally ill.This dramaturgical project examines the play and its historical context in view of intersectionality. Research topics include the life of Elizabeth Packard, the rights of women and the mentally ill in the nineteenth-century United States, and the effects of misogyny and ableism in the present day. Women still struggle to be taken seriously by doctors, as do mentally ill and neurodivergent people. While the biases present in the medical field today may not seem as egregious as those displayed in Mrs. Packard, they can and do cost people their lives. All of this information is used to argue that the play is a valuable part of the conversation surrounding the intersection of misogyny and ableism as they exist today.

Abstract Name: Factors Influencing High School-Aged Student Success: Exploring Familia in a Rural South Texas School District

Minimal research has been conducted regarding the success factors associated with high school students in rural school districts, leaving a gap in our understanding of the elements that influence students' academic, technical, and life success. This study's purpose was to identify factors that contribute to the success of juniors and seniors enrolled at one rural public high school in South Texas. This study utilized a mixed methods design, which involved the collection of qualitative data first and then quantitative data. Researchers accessed public records of the Texas Education Agency (TEA) to examine the relationships between juniors and seniors at the subject school compared to other junior and senior students in the same Education Service Center (Region One). A holistic approach was implemented during observation and semi-structured interviews to assess students' perceptions of support systems and the campus environment. The results of this study could inform the faculty, staff, and students by identifying potential factors contributing to student success. The findings may also be transferred to districts of comparable size, composition, and TEA classification to achieve higher levels of student success and accomplishment in their own communities.

Abstract Name: RASTER ANGLE AND INFILL PERCENTAGE INFLUENCE ON SELECTED MECHANICAL PROPERTIES OF 3D PRINTED POLYETHYLENE TEREPHTHALATE GLYCOL (PETG) AND HIGH IMPACT POLYSTYRENE (HIPS)

This work investigated the influence of raster angle and infill percentage on selected mechanical properties of two commonly used 3D Printed materials: Polyethylene Terephthalate Glycol (PETG) and High Impact Polystyrene (HIPS) at room temperature. Their Elastic Modulus, Yield Strength, and Toughness were experimentally determined and compared for infill densities of 5%, 25%, 50%, 75%, and 100%, and raster angles of 0/90, 45/45, and 30/60. The materials were printed using Fused Deposition Modeling per ASTM D638-22 standards, with a layer thickness of 0.3 mm, an initial layer speed of 35 mm/s, and an infill speed of 50 mm/s. The initial layer and infill speeds were 35 mm/s and 50 mm/s, respectively. The team concluded that PETG material, on average, outperformed HIPS when looking at Young's Modulus of the printed samples. There are few instances where HIPS has a higher Young's Modulus, i.e., 45-45 at infill 100%, 45-45 at infill 50%, and 30-60 at infill 100%. The PETG samples often exceeded the toughness of HIPS as well. As seen in the tables, there are a few cases in which HIPS has much higher toughness than the same raster and infill percentage as PETG. For instance, HIPS samples at 0-90 angles and infill percentages of 50% and 75%. Overall, the team concluded that PETG, on average, outperforms HIPS in both Young's Modulus and toughness during the testing. PETG would be suitable for most situations, whereas HIPS would fail more often if substituted for PETG.

Abstract Name: Philosophy of Ornament in Design

Design is defined by its utilitarian foundation in practicality. This emphasis on practicality is especially evident in the case of graphic design, as its primary purpose is to disseminate objective information. Still, the graphic designer has the creative license to decide how to translate this information into their design through various styles and ornamentation. However, in a 1908 essay titled “Ornament and Crime,” Adolf Loos argued that ornament no longer served a utilitarian purpose for design in his day. Thus, the age of Modernism came - an age without ornament in design. Even though Adolf Loos was an architect himself, his views were likely known more in the world of philosophers than that of designers. Yet, the prevalence of Modernism in 20th century design demonstrates the applicability of Adolf Loos’ pervasive thoughts nonetheless as his work seemingly marks the Modernist perspective of his time. Though, this pervasive thought did not begin in 1908, and is instead a result of centuries of precedent in philosophy. This paper explores the origin and development of these pervasive thoughts within Adolf Loos’ Ornament and Crime, beginning in ancient Greece and continuing to the present-day. In this way, ornamentation is examined through its philosophical foundations and real-world applications to design. This examination not only includes the relationship between ornament and crime but that of design and art as well — all within the context of Adolf Loos’ 1908 essay and graphic design, ultimately showcasing the historically negative view of ornamentation in design with contrast to the newfound growth of design as an art today.

Abstract Name: Game Theory and Hotel Pricing Strategy Concerning Perceived Value

Game theory displays a situation where one player's strategy depends on another's actions, and the payoffs hinge on the strategies employed. Hotel managers can implement their KPIs to compare against reports from other businesses. The core of this research revolves around the transposition of KPI values set into matrices. Game theory matrices show that acquiring the best room standard among resort and suburban hotels is pivotal in ADR analysis. Research combining ADR data and TripAdvisor reviews shows that guests are willing to pay higher prices when expecting higher room standards. Hotel criteria that establish the guest’s evaluation of a hotel’s standard include cleanliness, location, room quality, sleep quality, service, and value. Linked with the associated qualities, mathematical models can determine how guests perceive the standard and their willingness to pay the current price (ADR) given the previous criteria. Since hotels increasingly serve as both workplaces and family connections, travelers are spending more time inside the rooms, thus becoming more subject to evaluation. Regarding operations, managers can utilize these values to form their strategy for maximizing the guest’s perception of benefiting from a higher standard, resulting in appropriate pricing for the rooms. Although the major hotel properties of Pensacola are critical in understanding revenue performance, they have not yet been combined with Game theory practices. This method has provided

powerful insight into operational changes that can lead to more satisfied guests. We suggest that the resort hotels (Hilton, Hampton Inn, Holiday Inn Resort, and the Surf and Sand) need to increase the price during the peak season, while Hyatt Place (suburban hotel) needs to decrease the price during the peak season so that both areas can increase room standards and guest satisfaction.

Abstract Name: The Protective Effects of Exercise on Binge Alcohol Use-induced Neuron Injuries

Alcohol use disorder (AUD) is a very prevalent issue in today's society. Consistent binge drinking has been shown to decrease brain matter within the hippocampus and piriform complex, which regulate learning, memory, and olfactory processes. Moderate alcohol use and exercise stimulate similar areas of the brain, specifically the mesocorticolimbic pathway, which is involved in our body's natural reward system. Because exercise has been shown to have protective effects on the body, it was hypothesized that exercise might protect brain cells against the harmful effects of binge drinking. To test this hypothesis, human brain cells were cultured, subjected to excessive ethanol consumption, and then exposed to the exercise mimetic AICAR. Cellular death and regeneration were observed via fluorescent markers and compared among the groups. Western blots were then completed to analyze and compare concentrations of specific cellular proteins. It was found that the samples containing AICAR had fewer cellular death markers under fluorescent microscopy compared to their ethanol-only counterparts. Samples treated with ethanol only were found to have higher concentrations of proteins that induce apoptosis, whereas ethanol/AICAR groups had lower concentrations of proteins that respond to oxidative stress. In conclusion, treating human SHY5Y brain cells with AICAR may protect them against the harmful effects of binge drinking. Future research will be completed through further analysis of antioxidant proteins and western blots related to autophagy, as well as mitochondrial biogenesis and how it is affected by binge drinking.

Abstract Name: Examining the role of heparan sulfate modifying enzymes in hepatocellular carcinoma

Hepatocellular carcinoma (HCC) obtains the third highest cancer-related mortality rate in the world particularly due its high level of metastasis. HCC accounts for 80 percent of all liver cancer cases and is difficult to treat as it does not respond to chemotherapy drugs. A recent discovery in HCC structure is the overabundance of glypican-3 (GPC3) on the surface of the cell compared to that of healthy liver cells. GPC3 belongs to the heparan sulfate proteoglycan family as it consists of heparan sulfate chains that come off the core protein. The heparan sulfate chains can be cleaved by an enzyme, heparanase (HPSE) that is known to promote the progression of several cancer types. This cleavage degrades the heparan sulfate chains which causes the release of growth factors that can induce proliferation, angiogenesis, and invasion. Here, we utilized CRISPR technology to create a functional HPSE knock out HCC cell line for comparison to the wild-type cell line. We measured the effects of HPSE cleavage of heparan sulfate chains using an ELISA assay. This comparison data allows us to better understand the role heparan sulfate modifying enzymes perform in HCC progression.

Abstract Name: Functional consequence of sequence variation in the C-terminus of RsmE in Pseudomonas fluorescens

The posttranscriptional regulator RsmE inhibits extracellular secretions across diverse bacterial species. RsmE homologs are highly conserved in sequence with the exception of their C-terminus tail. The tail region is generalized to be functionally insignificant since it has neither predicted nor resolvable structure. However, mutations in the tail region appear to manifest as a spatially dominant phenotype within a crowded colony. We assessed twelve naturally emergent rsmE isolates with mutations in the tail region and classified them into four groups using several phenotypic screens and bioinformatics analysis. Under the hypothesis that these four groups should exhibit distinct levels of competitive advantage, each of the twelve mutants were competed against the wild type to compare their relative fitness. We found that variations in the tail sequence correlate with variations in extracellular secretions and relative fitness. Although additional experiments are necessary to define the underlying molecular mechanism, our study presents the first evidence that the C-terminus region of RsmE is functionally significant.

Abstract Name: Effect of pH on Mung Bean (vigna radiata) Germination and Shoot Development

Mung beans (vigna radiata) are rich in vitamins, minerals, and proteins and are important to maintaining many diets across the world. As such, it is important to understand the factors which allow them to grow and thrive. Previous research has determined that mung beans prefer acidic soil and suffer in basic soil due to how it limits nutrient uptake and metabolic function. From here, this study was conducted to determine what effect a basic pH will have on the germination and shoot development of mung beans. Two groups of mung beans (n=10) were prepared and placed in either a control solution of water (10 mL H_2O, pH 7) or the experimental solution of baking soda (10 mL 1% $NaHCO_3$, pH 9). For one week, the amount of seeds which had germinated was noted, and the length of the seed shoots was measured. After analyzing the data in Microsoft Excel, it was found that as pH increased, germination and growth were both inhibited severely, as none of the beans in the experimental group produced shoots and all of the beans in the control group did. This pattern of inhibition further solidifies previous research into the subject and confirms that mung bean growth suffers when grown in a high pH environment.

Abstract Name: Continuous Measurement of CSF Flow in Drainage Shunts for Hydrocephalus using Conductance Measurements

Hydrocephalus is a chronic condition caused by an accumulation of cerebrospinal fluid (CSF) in the ventricles of the brain and requires the surgical implantation of a life-long drainage shunt to manage intracranial pressure. If a shunt blockage occurs, emergency shunt replacement surgery is required. Yet, the symptoms due to shunt blockage and other unrelated diseases are often non-differentiating. Thus, there is a pronounced need for a reliable CSF flow monitoring system for shunts. Such a technology can significantly reduce unnecessary shunt replacement surgeries, suffering of patients, and healthcare costs associated with the treatment of hydrocephalus. We aim to develop a novel, wearable continuous flow monitoring technology that relates conductance measurements of the CSF to the flow rate through the shunt. Vitamin C (ascorbic acid) ingested by the patient appears in CSF, resulting in a measurable change in CSF conductance. By continuously monitoring the conductance of the fluid through a shunt with an embedded electrode, changes in conductance are correlated with the flow rate. A prototype shunt has been made and a bench-top model designed to replicate common scenarios for CSF shunts including blockages, kinks, and varying head positions. The prototype was tested by alternating ascorbic acid solution of varying concentrations through the tubing at known flow rates. Results show that the prototype accurately determines flow rates and detects shunt malfunctions. This technology has the potential to help physicians and researchers fully understand the behavior of fluid within CSF shunts and to reduce unnecessary testing and treatment.

Abstract Name: Sustainable and Inclusive Aquarium Designs: Focusing on Immersive Experiences.

Aquariums are gargantuan projects that can provide visitors with unforgettable experiences while educating them about marine life and promoting the conservation of aquatic biodiversity. However, depending on the scale of the exhibition, the aquarium design process can take time and effort as well as require a high budget.Data collection methods include case studies of existing facilities, interviews, surveys, and reviews of articles relating to design solutions and trends of an aquarium facility. An Interview was conducted with a local aquarium employee to get insight on what goes on behind the scenes as well as a survey questionnaire regarding what kind of features and exhibits the general public would want implemented in an aquarium. The research results indicated that improving the immersive environment can enhance the users' experiences with aquariums. Therefore, this project aims to design an aquarium that promotes marine life conservation, sustainability, and education through smaller and easily interchangeable exhibitions that utilize new augmented reality and projection technologies.The specific design solution for interchangeable exhibition spaces is incorporating AR and projection technologies, such as apps, touch screens, and video displays. These tools help create an interactive and immersive visitor experience using a small exhibit space. Various exhibits can be efficiently planned and programmed with these new technology features without the high budget needed to make a physical exhibition. Projection technology can be used to program certain kinds of exhibitions, which react when specific sensors are triggered and are projected on floors, walls, and ceilings. These new technologies allow for endless possibilities in exhibition design.

Abstract Name: The Relationship Between Perceptions of Motherhood, Religiosity, and Attitudes Toward Voluntary Childlessness

Procreation attitudes are impacted by cultural expectations and ideological beliefs. Aspects of culture, such as religion, have been shown in previous research, to influence individual’s perceptions of having children, voluntary childlessness, and motherhood. The present study explores the effects of religiosity on procreation attitudes as well as differences in gender in procreation attitudes. The researcher hypothesized that religiosity would correlate with higher levels of positive procreation attitudes. The scales utilized in this study include the Procreation Attitudes Scale (PrAttS) (Marhenke & Imhoff, 2020) and the Religiosity Measure (Aalsma et al., 2013). The sample was comprised of 114 college students from a Christian university. A t-test and a simple linear regression analysis were conducted to analyze the data. The findings revealed that religiosity did not significantly predict procreation attitudes (b1 = -.105, p = .177). There was a statistically significant difference in procreation attitudes between male college students and female college students (t = -2.001, p = .05). Male students (M = 3.37, SD = .263) showed higher levels of positive procreation attitudes than female students (M = 3.067, SD = .526). These findings were not in accordance with the hypothesis, however, they point to the importance of further research on procreation attitudes, specifically to better understand what factors are part of the effect for the male participants having more positive procreation attitudes than female students.

Abstract Name: Uneasy Peace: Imperial Japan at Versailles

The Paris Peace Conference of 1919 was a storm of nations, all pursuing their own agendas with respect to the coming peace. Most notable were the Big Four: Great Britain, the United States, France, and Italy. Close behind them, however, was Japan, the Allied power largely responsible for the capture of German colonies in East Asia. Though it acted under the approval of a treaty with Great Britain, Japan's true aim was to utilize the chaos embroiling Europe to solidify their influence and territorial gains in Asia. Their territorial ambitions sated for the moment, Japan largely ignored the Western theater of the war, and their peace plans assumed that each nation would tend to its own affairs. However, after the Western powers announced an armistice and declared that the following peace would be determined by President Woodrow Wilson's Fourteen Points, Japan set out once more to establish its place in the post-war order. Its requests of the Conference were twofold: Japan would retain control of all territories captured from Germany during the war, and the soon-to-be League of Nations would guarantee racial equality among its member states. Seeking to protect its own colonial territories, yet not wanting the League to fall before it started, Great Britain assented on the former point but refused to vote on the latter. The United States followed suit and dismissed the proposal for racial equality, stating that such a matter must be agreed upon unanimously. Japan never forgot this perceived insult, and resentment festered until it finally withdrew from the League in February 1933. Japan's behavior during World War I and the ensuing peace talks proves that its territorial ambitions were nowhere near sated by its wartime acquisitions.

Abstract Name: The Sleep of University Student-Athletes

University students' sleep has been found to be consistently inadequate. Within the undergraduate population, student-athletes are among those who have reported the worst sleep outcomes. This study presents data on undergraduate's sleep at a university in Honolulu, Hawai'i contrasting the experience of athletes versus non-athletes. A survey was administered to a convenience sample of undergraduates in the Spring of 2023. The survey included questions of demographic characteristics and the Pittsburgh Sleep Quality Index. A total of 458 students representing 48% of the total student population completed the survey. A total of 59 participants identified as student-athletes representing approximately 40% of those participating in university sports. Data analysis included descriptive statistics and t-tests. Student-athletes reported earlier bedtimes and awakening times compared to non-athletes. The mean total sleep time of non-athletes was 6 hours and 18 minutes compared to athletes was 6 hours and 36 minutes. This difference was not statistically significant. The

amount of sleep for both groups is below the recommended minimum of 7 hours. The quality of sleep appears below levels considered adequate for good health. The average PSQI score reported for athletes was 7.9, and for non-athletes was 7.16, which was also not statistically significant. Among varsity sports, soccer players reported the poorest quality sleep with a PSQI score of 8.8. Soccer players reported the earliest awakening time and the most daytime sleepiness. Most student-athletes reported practice times interfered with their sleep. Limitations of this study include a reliance on self-report, limits to significant testing due to small sample sizes of student-athletes, lack of prospective monitoring of sleep, and no attempt to measure physiological sleep parameters. Athletes and non-athletes appeared to be poor sleepers. Interventions seem warranted to improve sleep of all students, and may be particularly needed for varsity soccer players.

Abstract Name: Broadening Participation in STEM for Underrepresented Minorities - Application of the Bowman Strengths-Based Model to DEI Interventions: Investigating peer mentoring as a program-level strength

In higher education, some racial minorities such as African Americans, Latinxs, American Indians, and Native Hawaiians/Pacific Islanders remain underrepresented in academia, particularly in STEM majors (NCSES, 2023). In addition, some STEM fields continue to exhibit gender disparities. The National Science Foundation implemented the Louis Stokes Alliances for Minority Participation (LSAMP) as one initiative to address this issue. The Michigan LSAMP (MI-LSAMP) seeks to mitigate this discrepancy by providing support to students such as tutoring, career exploration activities, faculty-sponsored research opportunities, and peer mentoring. Guided by the Bowman Strengths-based Model (2011), the overall MI-LSAMP research program bestows insights into the multilevel strengths (i.e., personal, program, campus) that can clear the way for underrepresented students' success in college. From one point of view, peer mentoring can be viewed as a program-level strength. Previous research (e.g., Reio 2013) suggests that peer mentoring facilitates positive outcomes for mentees. Using a subset of questions in baseline surveys administered to the 2022-2023 cohort of the MI-LSAMP participants, I conducted t-test and chi-square tests to examine baseline gender differences in students' experiences and perceptions of peer mentoring. T-tests revealed that, compared to males, females discussed more topics with their peer mentors and engaged in discussion more frequently than males. Interestingly, I found that both genders infrequently discussed family support with their mentors as well. The findings will be discussed in terms of the limitations of the study, the implications for educational practice or policy, and my future research plans.

Abstract Name: Hablando Sobre Inmigracion: How Members of the House of Representatives in 118th

Congress Frame the Issue of Immigration

Historically, Immigration has played a critical role in forming the nation's identity, economic prosperity, and promoting cultural diversity. Considering that the issue of Immigration has been in the news and is considered by many to be important and in need of policy solutions, little progress has been made on passing comprehensive immigration reform since the 113th Congress in 2013. How members of Congress talk about Immigration is important because framing can influence public opinion, shaping perceptions of the issue and affecting policy decisions. Members may use their platform to communicate how they think about policy issues. Research has been done about Senators' communication about the issue of immigration on their websites and have found that immigration is often framed as a security threat and the economic aspects related to immigration. This thesis asks how members of the House of Representatives in the 118th Congress frame the issue of immigration. Using content analysis this thesis will examine members' websites, floor speeches, and press releases to evaluate how they frame the issue of Immigration. Immigration is an issue that affects everyone and Congress is responsible for passing laws about immigration. Laws tend to have the best chance of getting passed when issues are salient, the agenda has been set, and people understand what a policy aims to achieve. This thesis will shed light on how comprehensive immigration reform is discussed by members of the House of Representatives in the 118th Congress.

Abstract Name: Integrating Inexpensive GPS Module with Robot Quadruped for Active Precision Tracking & Mapping

Various sectors and industries significantly expand the development and integration of robotic systems. These systems need to have the ability to perceive their surroundings, this is typically achieved by cameras and sensors. However, each type of camera or sensor has limitations in real-time adaptability and mobility on complex terrains. This research study focuses on integrating GPS modules with Robot Quadrupeds to achieve precise tracking and accurate mapping. It aims to overcome potential sensory limitations in dynamic and challenging environments while remaining economically reasonable. A critical aspect of this investigation involves obtaining Cartesian coordinates through a defined system to establish successful localization and communication. We strategically placed a GPS module to the quadruped, facilitating real-time data collection and active-feed communication. Integration with Arduino and Raspberry Pi allows a low-cost solution for a continuous GPS feed transferred to the Robot Quadruped via Transmission Control Protocols (TCP) and Python Socket Programming. The mobility of Robot Quadruped plays a pivotal role in enabling a comprehensive analysis of accurate GPS coordinates and global mapping. Furthermore, integrating publicly available positioning platforms allows for real-time tracking of the robot quadruped's precise position in various environments. This research observes and factors in the inherent capabilities of the Robot Quadruped within its various data points. Each data set is carefully analyzed to pinpoint changes corresponding to operations and movements within indoor or outdoor environments. The results of this study successfully demonstrate the addition of geolocation capabilities to a quadrupedal robotic system to be feasible, accurate, and affordable. In conclusion, this research represents a significant advancement in the utilization of GPS and robotic systems, paving the way for a wide range of potential applications where precise tracking and coordination are indispensable.

Abstract Name: The Red Thread of Influences: Communist Propaganda and Western Culture

This paper will explore the profound influence of Western design, advertising, and art due to communist propaganda, by revealing a captivating interplay between one's political ideology and their creative expression. With the emergence of revolutionary movements throughout the world in the early 20th century, communist propaganda has left an indelible mark on the visual language of the western world. The impact of communist propaganda may be seen in Western art through the use of strong visual symbols, striking imagery, and a focus on the collective identity. Western artists have quietly communicated themes of resistance and unification via the use of color, such as red, and the universally recognized communist symbols such as the sickle and hammer. The power of communist propaganda to captivate and influence audiences has been echoed by artists like Barbara Kruger, Keith Haring, and Shepard Fairey through the use of stunning images and easily understood symbols. The study examines how communist propaganda tactics have been used in Western advertising to further the interest of capitalist. Advertising and propaganda share a common ground by using persuasive communication, visual storytelling, and the use of compelling narratives to sway the public opinion. Commercials such as Apple's "1984" and Coca-Cola's "Hilltop" use aspects of political propaganda to give their consumers a subversive and a captivating message. In conclusion, this essay will be exploring the complex interrelationships among art, design, and advertising as well as the ways in which political ideas influence and permeate Western society. It highlights how communist propaganda's visual language continues to influence many creative fields and sheds light on how the cultural environment is changing.

Abstract Name: Stress, Misinformation, and the Impacts on Athletes' Cohesion and Performance

In an era of high political polarization and proliferation of online misinformation, little is known about how such phenomena affect athletes' team cohesion and performance — nor whether the stress of competition exacerbates such issues. The objective of this study is to determine whether stress, in the context of competition, contributes to negative interactions with online misinformation among collegiate student-athletes, and specifically whether it increases susceptibility to the consumption of misinformation. Using a randomized stress/relaxation exercise during team training time, I test whether stress conditions increase vulnerability to online misinformation, and whether higher engagement with misinformation mediates negative effects on team trust, cohesion, and performance. The study is currently under IRB review, with data collection in early 2024. The experiment will take place within the Recreation and Athletics Department at the University of California, Merced. Collegiate student-athletes will be recruited to participate in the experimental study that randomizes them into two groups. Group 1 participates in competitive exercises that increase psychological and physiological stress, while Group 2 participates in a relaxation exercise that decreases stress. Afterwards, individuals in both groups will come together and take a survey. The survey

includes a simulated social media feed, which presents a combination of true and mixed-truth stories and tracks fact-checking via JavaScript. The survey also measures perceptions of story reliability, plus a set of vignettes and direct questions assessing impact of teammates' engagement with misinformation on team trust and performance. I hypothesize that collegiate student-athletes enduring more sports-related stress will have more negative interactions with online misinformation, and that misinformation will have adverse impacts on team cohesion, trust, and performance. I expect to present my experimental research design, methods, and preliminary results.

Abstract Name: Runx2's Correlation with Breast Cancer Metastasis to the Bone

Breast cancer is widely known as one of the most prevalent cancers in women. It is caused by multiple factors that affect the expression of genes that are involved with cell signaling, proliferation, and apoptosis. Breast cancer can also metastasize into other parts of the body. Once breast cancer has metastasized to the bone, the bones become weak and have an increased risk of fracture. Bone metastasis from breast cancer tumors can significantly decrease quality of life and lower survival rates. A gene that has been identified as a possible mechanism of bone metastasis is Runx2, or runt-related transcription factor 2. Runx2 is primarily involved in bone formation but can also be found in the estrogen signaling pathway within mammalian breast cells. We examined publicly available gene expression data of breast cancer patients to determine if a change in Runx2 expression plays a critical role in bone metastasis. The correlation between Runx2 expression and menopausal and estrogen receptor statuses were also examined. We hypothesized that an increased expression of Runx2 will have a positive correlation with bone metastasis from breast cancer patient gene expression data. It was also hypothesized that there would be an increased expression in postmenopause and estrogen receptor positive samples. It was found that there is increased expression of Runx2 in breast cancer tumor tissue compared to normal tissue. However, there was no significant difference between expression in bone metastasized samples and primary breast cancer tumor samples. In postmenopausal patients there was significantly increased expression compared to premenopausal patients. It was also found that there is a significant increase in expression in estrogen receptor positive patients compared to estrogen receptor negative patients.

Abstract Name: Oakland Cemetery as a Reflection of Atlanta's Urban Fabric

A cemetery reflects the urban fabric of a city within its confines, and the historic Oakland Cemetery of Atlanta is no exception. This research will explore Oakland Cemetery as a case study to show how it reflects Atlanta's history and unique culture. Site visits, historical research in archives, interviews with a former

employee, and architecture analysis will come together to inform why Oakland Cemetery is laid out in a manner that reflects Atlanta's historical (and current) urban layout. This paper will help deepen the knowledge and appreciation of the context surrounding the cemetery's distinct layout.

Abstract Name: Decoding Toxic Boards: The Dynamics and Consequences of Toxicity and Inequality in Colorado School Board Meetings

Primary education is a unique social institution within the United States because of local school board governance. However, school board governance processes have been overlooked as an explanation for performance differences. Against the backdrop of pandemic adaptations like remote learning and masking as well as debates about parental rights and inclusive pedagogies, school board meetings have become sites of profound political and cultural conflict. This project extends qualitative analyses of Board of Education meeting transcripts by using AI tools to transcribe and analyze the YouTube videos from school board meetings for all public K-12 schools in Colorado from 2019. Using natural language processing methods on this large corpus, this project will measure linguistic patterns related to sentiment and toxicity at multiple levels to track patterns within and across school boards over time. My research will create an accessible database for educators and parents to search Board of Education meetings and provide data analysis resources for analyzing this corpus. Methodology: This study will use the Council Data Project framework for automated meeting collection, and a host for the school district websites. A Python script will collect these meetings from their YouTube videos and use Google Cloud's transcription service to convert them into text documents. I will then use NLP methods to analyze this data to measure constructs like inequality and toxicity using sentiment analysis and text classification tools. I will use statistical analyses to identify the impact of inequality and toxicity over time and its effects on school and student performance data. Results: This study will establish the relationships between board governance processes and district performance. The project will provide data tools and resources for researchers and community members to track behaviors in school board meetings through linguistic trends and patterns.

Abstract Name: Navigating Temporary Protection While Building Community: The Crucial Role of a Volunteer-Run Refugee Aid Organization in Vienna, Austria

As the number of displaced people across the world surpasses 100 million and continuously breaks records for the highest number ever recorded, conflict-induced displacement shows itself to be an especially pressing global issue. People flee their homes because of persecution or nearby fighting, and are escaping violence, dislodgement, and human rights abuses, resulting in displacement crises that leave civilians to bear the brunt

of war and conflict. Following the full-scale Russian invasion of Ukraine in 2022, thousands of Ukrainians fled into nearby European countries, including Austria. Although Austria is involved in the European Union's current Temporary Protection Directive, it positions itself as a transit country and enforces restrictive asylum policies, with the state currently contracting out all care to non-governmental organizations (NGOs). There are few long-term resettlement solutions, and refugees face bad housing conditions, insufficient social benefits, language barriers, and isolation (Koziienko, 2023). This transdisciplinary qualitative case study explores the role of a small-scale volunteer-run refugee aid organization in Vienna, Austria, and the ways in which they employ a community building framework as a tool to provide long-term aid, and increase senses of well-being and belonging amongst Ukrainian refugees. Research for this study was conducted in Vienna over a three-month period from September-November 2023, with a methodology consisting of participant observation, archival research, and semi-structured interviews. The findings of this study demonstrate the Austrian government's extraordinary reliance on civil society for the care of refugees, the protracted nature of uncertainty and disconnection experienced by individuals following displacement, and the importance and necessity of an aid organization focused specifically on establishing a long-term community support space. By highlighting a small-scale NGOs aid provision and community-building methods at the local level, these findings offer a crucial and transferable perspective on the role of community-based initiatives in alleviating the adverse effects of displacement.

Abstract Name: Acceptable Business Practices In The Video Game Community

Throughout a video game's development and post-release lifespan, the relationship between the developers and the community of people that play those games is undeniable. In most cases of AAA titles, developer teams for a given game could include hundreds of people and can either publish their games on their own as an "independent" game studio or through a video game publishing firm. Video game development is thus a complex task whose form can vary greatly in size and scale for the project, but how a community responds to these games can be hard to decipher. Critical analysis of video games through an academic lens has not been done until recently. Thus, although the fandom related to interactive media is relatively unknown territory, what little research has been conducted suggests that the reasons for a community to respond well to a video game can be multifaceted – related to narratives, mechanics, or the quality of interactions. This project seeks to expand on this work, and I show that the community response to a video game and its developers largely depends on the developers' philosophy of play, as well as upper management/executive decisions that have to do with the money-making aspects of a video game. In particular, money-making aspects such as the introduction of microtransactions and other paid content can put a stain on the otherwise positive relationship a developer team can have with the community. This phenomenon is largely due to publishers or upper management who do not directly have a hand in a game's development. Although there is a growing awareness of upper management's actions in this regard, I find that many still believe that it is the developer's fault. After discussing these findings, I share the implications they have for the future functioning of this growing industry.

Abstract Name: The Man Behind CBS

Abstract Lou Dorfsman was a graphic designer that worked for CBS. During his time there, he changed the design department for the better. Before working for CBS, Dorfsman originally was going to study bacteriology at New York University but with the tuition being so high he could not attend. Dorfsman instead went to The Cooper Union for the Advancement of Science and Art for graphic design on a full ride scholarship. Dorfsman met his future wife, and his lifelong friend while attending Cooper Union. While there, Dorfsman held 11 design jobs, including making displays for the New York World's Fair in 1939. After graduating Dorfsman joined the Army from 1943 to 1946 during World War II and won first and second in the National Army Art Contest. After leaving the army in 1946, Dorfsman joined CBS. He worked under Bill Golden as his assistant and learned more about advertising. He would also have lunch with people from the Programming and Research department and would ask them questions to help with advertisement. Dorfsman designed Of Black America which was a full-page newspaper ad that was the first network series on black history. The design was of a man with a white American flag painted on his face looking at the viewer. Dorfsman's most well-known piece was the Gastrotypographicalassemblage that was 35 by 8.5 feet and was made of hand-milled wood and the word type. Dorfsman became Senior Vice President and Creative Director for Marketing Communications and Design for the CBS Broadcast Group in 1978. A book called Dorfsman & CBS was published in 1987 and he helped design the cover. Dorfsman was put in the Art Director Hall of Fame in 1978, retired in 1991, and died in 2008.

Abstract Name: Influence of Biomolecules on ZIF-67 Metal-Organic Framework Nucleation and Growth

The grand challenge in immobilization strategies for enzymes is the development of methods that result in high enzyme loading withoutloss of catalytic activity. The encapsulation of enzymes within metal-organic frameworks (MOFs) to form crystalline materials known asE@MOFs is an emerging technology in bio-catalysis, bio-sensing, and biopharmaceuticals. A key advantage of E@MOF composites is that they can be synthesized by simply mixing the metal, ligand, and enzyme at room temperature in aqueous solutions. However, controlling E@MOF formation is yet to be fully realized, as there is a major knowledge gap in understanding how the enzymes influence the crystal size and structure of the MOF. The objective of this project is to obtain a fundamental understanding of the structure-function relationship in the biocomposite materials to enable prediction of encapsulation efficiency, enzymatic activity, stability, and recyclability based on the interfacial structure of the enzyme. Our preliminary data demonstrate that variation in synthetic parameters (ligand:metal ratio, enzyme concentration, solution pH) provide access to different non-classical crystallization nucleation pathways which result in E@MOFs with different structural features and properties (encapsulation efficiency, catalytic activity, stability). These preliminary results show that size, morphology, composition, and surface charge of the amorphous precursor play a role in determining these parameters. This fundamental understanding enables the design of new nanostructured E@MOFs with enhanced catalytic properties using cost-effective synthetic methods.

Abstract Name: Role of newly identified gene in the lanthanide response and biofilm formation

The human release of greenhouse gases, including methane, poses an ongoing threat to our environment. Methanotrophic bacteria can aid in the decrease of greenhouse gases by converting methane into less potent gases such as carbon dioxide (CO2). Though previously thought to be biologically inert metals, lanthanides are involved in certain biological processes in many bacteria, including methanotrophs. Specifically, an enzyme called XoxF methanol dehydrogenase utilizes lanthanides in the second step of methane metabolism – the conversion of methanol to formaldehyde. Thus, these methanotrophic bacteria could also assist in harnessing lanthanide metals from batteries or hard-drives – in other words, we may be able to recycle lanthanide metals from old technological devices. A mutant methanotroph revealed a new gene which encodes an important hybrid histidine kinase protein involved in the lanthanide response. Moreover, it is suspected that this gene may also be involved in biofilm formation because it displays severe growth defects when grown on nitrate as its nitrogen source. Utilizing gene deletion methods, site specific mutagenesis and gene expression analysis, we will determine the roles of this histidine kinase gene, as well as an associated TonB dependent transporter (TBDT) and transmembrane (TM) protein. Preliminary results demonstrate the successful creation of a linear construct, cPAC1, designed to knock out the histidine kinase gene. Future steps involve electroporation to introduce our deletion construct. The resultant mutant strain will be used to reveal the role of the histidine kinase gene in the lanthanide response and its implications for methane conversion.

Abstract Name: "Contraceptive Testing, Sterilization, and Puerto Rican Women: Unveiling the Impact, Spirituality, and Contemporary Perspectives"

This research delves into the historical and contemporary implications of contraceptive testing on Puerto Rican women, specifically the birth control pill. Focusing on the complex interplay of factors such as religion, spirituality, and intergenerational experiences, this study explores how the experiences of Puerto Rican women during the 20th century continue to shape the reproductive decisions of young Puerto Rican women today. By examining the limited documentation of unethical contraceptive research and the legacy of mass sterilization, this research aims to challenge prevailing narratives of reproductive choice and offer a more nuanced understanding of family planning in Puerto Rican communities. Utilizing an intersection of Africana Studies and Sociological Research methods, I plan on conducting interviews to investigate my thesis.

Abstract Name: Behavioral Analysis of Simultaneous Inhibition of Fatty Acid Amide Hydrolase and Soluble Epoxide Hydrolase on Migraine-related Behavior in Rats

Migraine is the most common neurological disorder, and is characterized by severe headaches, nausea, and light sensitivity. Current treatments, including opioids and triptans, produce dangerous side effects. Moreover, modern anti-migraine drugs lack novel mechanisms of action. Our aim is to revolutionize migraine pain management by finding new medications with novel mechanisms that can provide relief from migraine without causing any negative side effects. Fatty acid amide hydrolase (FAAH) and soluble epoxide hydrolase (sEH) are two pain-related enzymes. The benefits of dual-enzyme inhibitors include fewer drug-drug interactions and improved drug synergism compared to one enzyme inhibitor. These dual inhibitors may require lower doses than traditional anti-migraine agents. We synthesized 19 analogs of our dual sEH/FAAH inhibitor and evaluated their potencies at inhibiting human, mouse, and rat enzymes. We hypothesized that simultaneous inhibition of FAAH and sEH using SW-17, the most potent inhibitor, will alleviate migraine-related pain in rats. In migraineurs, an injection of nitroglycerin triggers a migraine attack and generates headache-like pain in animals. An injection of nitroglycerin produces hypersensitivity and alters locomotion. Thus, we investigated the effects of various doses of dual inhibitors of sEH and FAAH in a rat model of nitroglycerin-induced migraine to assess its efficacy. We injected nitroglycerin, a vasodilator that induces migraine-like pain. We treated rats with a dose of SW-17, the sEH/FAAH dual inhibitor, in varying doses (0.1-3 mg/kg) or sumatriptan. Mechanical thresholds and locomotor behavior was assessed after nitroglycerin injection in rats. Both nitroglycerin and SW-17 change measures of hypersensitivity and locomotor in this animal model. The wheel running test indicated that dual inhibition of sEH and FAAH does not decrease activity in rats indicating that this drug may not produce sedation. Future studies will determine the full efficacy of FAAH and sEH inhibition in alleviating migraine-like pain in rats.

Abstract Name: Finding Broken United States Government Treaties within the Osage Nation, Cherokee Nation and Oglala Sioux Tribe constitutions with a hint of colonization hidden.

The United States created treaties between Native American Tribes is much hidden within the United States' "American" history. The treaties are "contacts" that were created and fulfill promises between the United States government and Native American tribes. The treaties were seen as broken promises that the

government never fulfilled. Many Native American tribes in modern times are continuing this fight to have the United States government follow each signed treaty as they have agreed beforehand. When looking at the Osage Nation, Cherokee Nation, and Oglala Sioux Tribe do have such a complex relationship with the US government seen through various timelines. Finding the theme of the government was seen in the three tribal constitutions highlighting broken treaties within these documents. These documents seem to push focus around these treaties in various aspects such as acknowledging their right to government and their rights for their land and other minerals. Each constitution does reflect the theme of colonization within their current government structures through leadership roles for a prime example. The theme of colonization has developed over the years as each of these tribal nations' constitutions is shown within their government aspects such as the hierarchy of governmental power. They have used this form of colonization within the governing aspect to keep their tribal sovereignty successfully functioning to survive in modern society. This matches the reflection of the United State own government structures that we as a whole general public see in everyday life. These three tribes which are the Osage Nation, Cherokee Nation, and Oglala Sioux Tribe are continuing to battle for these treaties to be acknowledged in various aspects as well and they are continuing the fight against colonization.

Abstract Name: The Use of Pectin Based Microsphere for Pharmaceutical Applications

Pulmonary drug delivery via microspheres has gained growing interest as a noninvasive method for therapy. However, drug delivery through the lungs via inhalation faces great challenges due to the natural defense mechanisms (physiology) of the respiratory tract, such as the removal or deactivation of drugs. Pectin, a polysaccharide mostly derived from citrus and apple peels, was chosen as the foundational material due to its biocompatibility and degradability in physiological environments. This study aims to develop a biocompatible microsphere system with a diameter of around 3 μm for encapsulating pulmonary drugs and facilitating their delivery to the deeper lungs. Electrospray was used to produce the pectin microspheres. Parameters, pectin:PEO ratio, voltage, feed rate, and distance between the syringe tip and collection sheet, were determined to be the dominant factors impacting particle size and morphology (including uniformity). The Design-Expert software was used to optimize the process with the microsphere size and morphology. The optimized condition is pectin:PEO of 3:1, a voltage of 14.4 kV, 18.2 cm distance, and 0.946 mL/hr flow rate. The rate of pectin microsphere degradation can be altered through coating with polymers such as gelatin. Furthermore, the study emphasizes the responsiveness of the microspheres with and without gelatin coating in the simulated lung fluid (Gamble's). The results indicate the responsiveness of the microspheres- reaching the deeper lung and rapid release of the drug. The findings of this study contribute to the understanding of pulmonary drug delivery and provide insights into novel approaches for particulate drug delivery systems.

Abstract Name: Enhanced Pyruvate Uptake by Naive Embryonic Stem Cells

During early embryonic development both rapid cellular proliferation and the maintenance of pluripotency are tightly regulated to control proper cell fate specification. However, little is known about the metabolic requirements that allow the dramatic cellular changes and unique demands of this critical period. We previously found that mouse embryonic stem cells (ESCs) cultured in the naive 'ground state' of pluripotency have unique amino acid intake strategies, but how naive ESCs obtain other nutrients to sustain their growth remains unknown. To study these nutrient acquisition strategies, we utilize pluripotent ESCs cultured in different media conditions that allow us to effectively model the different stages in embryonic development. ESCs cultured with serum and leukemia inhibitory factor (S/L) represent a metastable population while addition of MEK and GSK3β inhibitors (S/L+2i) represent the naïve or 'ground state' of pluripotency. Nutrient consumption by S/L or S/L+2i-cultured cells was measured by gas chromatography-mass spectrometry of conditioned media collected over 24 hours from each respective cell state. MCT1-deficient cell lines were generated through CRISPR-Cas9 genome editing and the gene knockout was confirmed by Western blot. Expression of MCT1 was exogenously restored in MCT1-deficient cell lines with the addition of MCT1 cDNA using the piggyBac transposase system. Clonogenic capacity of ESCs was measured using colony formation assays. Here, we profile the nutrient consumption of naive and differentiated ESCs and found that naive ESCs preferentially consume pyruvate relative to their more differentiated counterparts. Mechanistically, pyruvate uptake was dependent upon the monocarboxylate transporter MCT1, as MCT1-deficient ESCs were unable to increase pyruvate uptake in the naive state. Restoration of MCT1 in MCT1-deficient cell lines was sufficient to rescue pyruvate consumption. Notably, MCT1-deficient ESCs display decreased proliferation and naive colony-forming ability. Collectively, these results suggest that enhanced pyruvate uptake enables naive ESCs to sustain their cellular fitness and the pluripotent state.

Abstract Name: Impact of α-Synuclein Pathology on Corticostriatal Synapses in Parkinson's Disease

Parkinson's disease (PD) is the most common neurodegenerative motor disorder, pathologically characterized by proteinaceous α-synuclein aggregation. Termed Lewy pathology, these aggregates are found in a subset of cortical layer 5 neurons projecting to the striatum. However, little is known about how Lewy pathology affects corticostriatal excitatory synapses. Our research aims to induce α-synuclein pathology in the secondary motor (M2) cortex to decipher the impact of aggregated α-synuclein on the morphology of M2-corticostriatal synapses. To recapitulate α-synuclein aggregation in rodent models, we utilize the preformed fibril (PFF) model for template corruption of endogenously expressed α-synuclein. PFFs or control α-synuclein monomers were injected into the M2 cortex to study M2-specific inputs in the striatum. To study corticostriatal synapses, we combined the high-resolution imaging technique Expansion Microscopy (ExM) with IMARIS software for synapse morphology analysis. M2-cortical PFF injections caused robust somal and neuritic pathology in layer 5 neurons of the M2 cortex, neighboring cortical areas, and brain areas projecting to M2, including the amygdala and orbital area. We also observed neuritic pathology in the striatum, which predominantly overlapped with the cortical, presynaptic terminal marker vGlut1. Using our combined analysis approach, we found a significant reduction in corticostriatal synaptic loci in the dorsal striatum of M2-PFF injected animals. Additional data indicate morphological changes to the volumes of cortical

presynaptic terminals upon aggregate formation. Our results suggest that cortical α-synuclein aggregation affects the density and morphology of excitatory synapses in the striatum. These findings are consistent with human and non-human primate PD models showing striatal excitatory synapse loss. Furthermore, our data points to an important role of cortical Lewy Pathology on the functionality of corticostriatal synapses, elucidating the mechanisms of Lewy pathology disruption of corticostriatal synapses to symptoms of PD.

Abstract Name: Trichloroethylene exposure influences brain lipid dysregulation as a putative mechanism in Parkinson’s neurodegeneration

Parkinson’s disease (PD) is a neurodegenerative disease that is marked by dopaminergic neuronal loss in the substantia nigra pars compacta and the accumulation of the protein alpha-synuclein, which comprise Lewy Bodies. Most (~85%) of PD is idiopathic, and environmental triggers of neurodegeneration are prevalent risk factors in PD etiology. Our lab has demonstrated that trichloroethylene (TCE) exposure in rats resulted in the death of nigrostriatal dopaminergic neurons as well as the accumulation of alpha-synuclein, indicating that TCE may influence multiple pathogenic disease pathways involved in PD. As TCE is reported to integrate into phospholipid bilayers, we hypothesized that the halogenated solvent may disrupt lipid membranes within the brain, resulting in increased risk for alpha-synuclein misfolding and aggregation.Whole brain tissue was collected from aged adult male Lewis rats that either received a dose of 800 mg/kg of TCE or olive oil via oral gavage daily for 3 weeks. The tissue was assessed for lipidomic analysis using mass spectrometry (MS). The MS data was analyzed via Metaboanalyst, using peak intensities of the 10 most abundant lipids in each lipid category: phospholipids (positive and negative), sphingomyelins, and triacylglycerols. Metaboanalyst revealed differences in lipid composition between vehicle and TCE treated rat brains, with direct comparisons of the top 10 lipids in each group revealing an overall trend of reduced lipid peak intensities. It was found that a single triacylglycerol (TAG) 54:3+NH4(-FA 18:2 (NH4)), had the greatest variation in vehicle and TCE exposed rats (t-test, p<0.001). This lipid contains fatty acid (FA 18:2), which corresponds with linoleic acid, a triglyceride that is reduced in PD patient plasma and brain tissue. This data suggests that TCE-induced alterations in lipid composition in the brain may be a novel mechanism that may possibly drive synucleinopathy and PD risk from exposure to TCE.

Abstract Name: Function and Clinical Relevance of RHAMM Isoform B in Pancreatic Cancer Initiation and Progression

Approximately 90% of cancer-related deaths are due to metastatic spread. Pancreatic cancer patients are often asymptomatic until the disease advances to later stages, at which point the tumor has already metastasized to distant organs. Pancreatic ductal adenocarcinoma (PDAC) comprises over 90% of pancreatic malignancies, is highly aggressive, and is characterized by rapid and infiltrative growth. We identified that the receptor for hyaluronan-mediated motility (RHAMM; gene name: HMMR) is overexpressed in pancreatic cancer, while undetectable in the normal adult pancreas. Different RHAMM isoforms exist as products of alternative splicing. We found that RHAMM isoform B (RHAMMB), which lacks exon 4, is the predominant isoform in pancreatic cancer, and its overexpression is associated with the poor survival of PDAC patients. The role of RHAMMB in PDAC initiation and early-stage progression is still unknown. To address this gap of knowledge and study the impact of RHAMMB isoform in the initiation and progression of PDAC, in the context of an intact immune system, we partially humanized the mouse HMMR in immunocompetent mice by CRISPR knock-in in PDAC mouse models. While human RHAMMB exists, mouse RHAMM retains exon 4. We designed a long single-strand donor DNA (lss DNA) to replace mouse exon 4 and the surrounding intronic sequences with the human exon 4 and partially intronic sequences on both sides. Two LoxP sites were added in the lss DNA to flank the DNA and mediate its excision by a Cre recombinase that was expressed under a pancreatic specific promoter (p48-Cre), yielding RHAMMB expression in the mouse pancreas. We are studying whether mice expressing heterozygous or homozygous RHAMMB will exhibit an earlier onset of invasive PDAC, larger tumor burden, and shorter lifespan compared to the control mice that do not express this RHAMM isoform.

Abstract Name: When Jekylls become Hydes: Unearthing the Alter Egos Masked by Social Media

This study sought to identify correlations between online disinhibition and moral disengagement and their links to empathy, narcissism, and weekly total time spent on Instagram, TikTok, X, Snapchat, and Facebook. Previous literature revealed a significant positive relationship between online disinhibition and moral disengagement. Significant positive relationships between both of these variables and narcissism have also been reported while both variables were shown to have a negative correlation with empathy. There was mixed literature regarding online disinhibition, moral disengagement, and time spent on social media sites. In consideration of existing literature, the following hypotheses were formed. Online disinhibition and moral disengagement would be positively correlated. Online disinhibition would be positively correlated with narcissism and social media time, and online disinhibition would be negatively correlated with empathy. Moral disengagement would be positively correlated with narcissism and social media time, and moral disengagement would be negatively correlated with empathy. To test these hypotheses, the Measure of Online Disinhibition (MOD), the Moral Disengagement Scale, the Five-Factor Narcissism Inventory – Super Short Version, and the General Empathy Scale were administered. Based on data collected from cell phones, participants were asked to add their total weekly screen time for Instagram, TikTok, X, Snapchat, and Facebook. Students were surveyed from psychology, history, mathematics, and art classes. The data was

gathered voluntarily and confidentially. The data was assessed with a Pearson r correlational analysis using SPSS software. The results identified a significant positive correlation between online disinhibition and moral disengagement, online disinhibition and narcissism, and moral disengagement and narcissism. A significant negative correlation was demonstrated between moral disengagement and empathy as well as between moral disengagement and time spent on social media. No other significant correlations were found. Limitations include the homogeneity of the sample. Future researchers were advised to survey students from different types of universities.

Abstract Name: Studies on Folliculogenesis in Polycystic Ovaries in the Domestic Cat

AbstractPolycystic ovary syndrome (PCOS) is the most common cause of anovulatory infertility, but the mechanism of anovulation remains uncertain. The typical gross morphology of anovulatory polycystic ovaries is the presence of multiple antral follicles 2–10 mm in diameter, which signifies the arrest of follicle development prior to the preovulatory phase. PCOS is characterized by arrested growth of antral follicles. Although arrested antral follicle growth probably reflects the abnormal endocrine environment, there is increasing evidence of abnormalities of follicle development from the very earliest, gonadotropin-independent stages. The underlying molecular basis of this fundamental ovarian abnormality remains to be determined.Folliculogenesis is the cycle of maturation of a follicle within the ovary of the adult human female. A follicle is a membranous sac of cells that contains an immature egg cell, called an oocyte. The primary purpose of this research included a study identifying various stages of follicle development with special reference to antral follicle development and their respective sizes during the estrous cycle of domestic cat, felis catus. This understanding will help enhance our ability to assess risk and develop preventative strategies of ovarian dysfunction such as Polycystic Ovarian Syndrome as highlighted. Ovaries from adult female domestic cat were obtained from routine spaying procedures conducted at a local veterinary clinic. The primary methods utilized in the study included histology of the ovarian tissue. Briefly ovaries were surgically removed during spaying procedure at a veterinary clinic, and washed in PBS. Ovarian tissue was then fixed in formalin solution, followed by rinsing in graded series of ethanol. They were then embedded in paraffin, serially sectioned (5 μm), mounted onto microscope slides, and stained with hematoxylin and eosin by a standard histological procedure. Gross follicular morphology was then evaluated. Various stages of follicular development in the sectioned ovary were idenfied.

Abstract Name: A Theoretical Investigation on the Performance of a Bifacial Solar Panel Using ANSYS-Based Thermal Modelling

Bifacial solar panels are a recent technological advancement, distinguishable by their increased power output. This increase is attributed to the absorption of solar radiance from the back layer, relying on scattered light from the ground. Before experimentally characterizing the panel, a foundational theoretical model for the panel's temperature distributions as a function of incident solar flux is necessary to understand the impact of surface heating on the panel’s output. This study utilizes a commercially available JJN Solar 200-W Bifacial PV panel. Thermal modeling was performed using Ansys-Icepak, requiring the input of the solar panel’s surface geometry and the layers within the PV Bifacial Solar Panel, such as AR Coating, emitter layer, N-type wafer, and the aluminum back surface. Data related to these layers served as input values for the modeling, including the dimensions of various layers and corresponding thermal properties like thermal conductivities, density, and specific heat. The boundary conditions employed in stagnant air include: heat flux at the top of the aluminum frame and glass surface, convection on the top (h=5W/m2K), convection on the frame (h=5W/m2K), convection on the back (h=1.5W/m2K), and the emissivity of the glass (ε = 0.85). For bifacial solar panels, it was assumed that the heat flux at the back sheet is one-tenth of the heat flux at the front. The Ansys-Icepak model ran under various conditions, including varying incident solar flux. Results include temperature distributions on the panel. The temperature varied from ambient to 50ºC for the incident flux of 200W/m2K. The corresponding efficiencies were calculated and varied between 10-14% as the surface temperature increased. These results will serve as the base for our experimental work. Complete findings will be presented at the conference.

Abstract Name: Association between Serum Urate, Gout, and Prostatic Cancer in European Male Populations: A Mendelian Randomization Study

Background: Gout and serum urate (SU) have been shown to be associated with cancer risk.Objective: We aim to conduct a two-sample Mendelian Randomization (MR) study to assess causal relationships between SU, gout, and prostate cancer.Methods: We conducted genome-wide association studies (GWAS) for SU and gout using males from UK Biobank and used publicly available meta-analyses GWAS for prostate cancer. Instrumental variables were selected based on single nucleotide polymorphism (SNP) correlation and independence. MR methods included inverse-variance-weighted MR, MR-Egger regression, and weighted median to robustly test for causal relationships and horizontal pleiotropy.Results: Our selected GWAS included 145,625 males for SU, 207,780 males for gout, and 140,000 males for prostate cancer. From these, we selected 142 genetic variants independently associated with SU, 230 associated with prostate cancer, and 409 associated with gout. No causal relationship was found between SU and prostate cancer or between gout and prostate cancer in either direction (p > 0. 07 for all). We found no evidence of horizontal pleiotropy from the MR-Egger test.Conclusion: Our MR analysis in a European male population found no evidence of a causal relationship between SU and prostate cancer and between gout and prostate cancer. This indicates that urate level alterations, resulting from urate-lowering drugs or other non-pharmacological interventions, may not change the risk of prostate cancer in patients with hyperuricemia or gout.

Abstract Name: Exploring Natural Dyeing from Orange Peel, Black Bean Peel, and Avocado Seed for Dyeing Hispanic Textile Fiber Content

This study aims to highlight sustainable practices while preserving the importance of natural dyeing traditions in Hispanic culture specifically Oaxaca in Mexico where natural dyeing is predominantly focused upon. Due to the negative impact of synthetic dyes, the discussion of more sustainable and environmentally friendly practices has become a larger discussion, and this has caused cultures to stray away from the art of traditionally dyeing fabrics.The preliminary findings from previous extraction analysis showcase rich red colors can be extracted from avocado pits and different hues of blue from black beans when applied to cotton textiles. While in Oaxacan culture, vibrant orange hues can be derived from orange peels. We decided to expand upon our preliminary findings and experiment with three variables—orange peel, black bean peels, and avocado pits—to naturally dye cotton, a commonly used textile in Oaxacan culture. The methodology includes extracting the color from the agricultural byproducts that can then be utilized to apply to cotton textiles. With methods of testing and analysis, observations can be made to determine the viability of each dye with the consideration of variables such as time, temperature, and pH condition. Aluminum and iron mordants can also be applied to achieve a vibrant color to effectively dye the cotton textiles. These natural colorants from agricultural byproducts in Hispanic textile dyeing, may demonstrate potential to be sustainable alternatives that showcase the significance of preserving traditional techniques and sustainability.

Abstract Name: Catalyzing Labor Market Participation: A Study of State-Level Earned Income Tax Credit Expansion

The Earned Income Tax Credit (EITC) has garnered extensive attention within the field of labor economics. Nevertheless, there exists a noticeable gap in the literature when it comes to understanding the labor-market impact of the state level EITC, which has seen increased policy activity in recent years. This paper employs a combination of Triple Difference with Inverse Probability Weighting (DDD-IPW), and Multinomial Logistic models, all grounded in the framework of an individual employment outcome model. Our objective is to investigate how state-level EITC expansions, with varying levels of generosity, affect the labor market. Rotating panel data from the 2010-2019 Current Population Survey (CPS) provide estimates of this effect.

The result of our estimations reveals that state-level EITC expansions have yielded positive effects, particularly for single women with children, a group recognized as primary beneficiaries of the EITC. However, it is important to note that the degree of influence and significance levels associated with different expansion levels exhibit variations.

Abstract Name: Dissecting the Distinct but Overlapping Brain Circuits that Control Attraction and Repulsion to Smells to Mammalian-Sensed Odors

Organisms across the phyla are capable of sensing an array of sensory cues to control or shape complex behavioral responses to survive in environments consisting of an array of attractive and repulsive dangerous cues. Mammalian systems extensively use olfactory and gustatory behavior to fine tune these sensory-dependent decision-making behaviors. Despite understanding the importance of behavioral responses to cues in the form of odors in shaping decision-making behavior, the underlying mechanisms that mediate these responses at the level of sensation, processing, integration, and modulation are not fully understood. To understand these mechanisms, we use the invertebrate worm, C. elegans, to characterize attraction to mammalian-sensed odorant cues. We show that hermaphrodite worms are attracted to catnip oil and identify select sensory mechanisms that mediate this attraction, identifying multiple sensory genes (molecular substrates) that are involved in this chemosensory response to a mammalian-sensed cue, which is highly attractive in many cats. We have identified sensory transduction mechanisms, including G-proteins, and cyclic nucleotide-gated ion channels, which regulate odor-dependent attraction to mammalian-sensed catnip oil cues. We therefore provide a platform to use C. elegans as a model for studying olfactory-dependent pathways to mammalian cues. This allows for the characterization of neural mechanisms that shape olfactory behavior and decision-making in higher systems.

Abstract Name: Bereaved Children’s Experiences of Peer Support Groups and Posttraumatic Growth

Although professionals regularly emphasize the diagnosis as well as treatment of psychological disorders

such as posttraumatic stress disorder, fewer focus on the growth that can occur after adverse life events. The literature on how peer support groups may influence this growth, especially in children who have experienced grief, is even more limited. Posttraumatic growth reflects an individual's perceived positive change, such as a greater sense of one's strengths or appreciation for life, after experiencing the impact of a traumatic incident. This growth can be facilitated through personal relationships and via some services such as therapy or clinically-oriented or supportive groups. The present research focuses on children's self-reported experiences within a peer support group and their perceptions of posttraumatic growth after the death of a loved one (e.g., parent or sibling). It grows out of a larger, multi-site project involving pairs of caregivers and young children who were engaged in grief-focused peer support programs in the 2022–2023 academic year. Data were collected from nine grief centers across seven states in the United States at two different time points to assess a variety of child and caregiver resources, the caregiver-child connection, as well as other potentially relevant variable. In the initial survey in the fall, 180 children participated; roughly 100 completed the follow-up data collection in the spring. For this study, analyses will explore the association between children's experiences of the peer support groups and their self-reported growth. Analyses will also examine the relationship between how long a child has participated in the groups and their experience within the groups as well as posttraumatic growth. It is hypothesized that children who report more positive experiences with the group and who have attended the support groups for a longer period will tend to endorse higher levels of posttraumatic growth.

Abstract Name: Acoustically Purified Biodegradable Nanoparticles for Cell-Based Cancer Immunotherapy

Immunotherapy is an expansive and growing field that seeks to harness the body's own immune response, resulting in a therapeutic effect. Our work focuses on using macrophages and their intrinsic ability to treat cancer.Previous work has suggested that nanoparticles can be equipped as "cellular backpacks" to the surfaces of various cell types, including macrophages. Our goal is to attach drug-loaded poly (β-amino ester) (PBAE) nanoparticles to macrophages. This will gradually release a pro-inflammatory molecule that enhances the anti-tumoral capabilities of macrophages while utilizing the tumor-homing capacity of macrophages to deliver the drugs directly to the tumor. Our research is directed toward testing the mechanical properties, biodegradation, and drug-loading ability of various PBAE polymers to better understand their role in immunotherapy.To test the mechanical properties of the nanoparticles, tensile testing will be performed on strips of the PBAE compositions using a Universal Testing Machine. To test the degradation of the PBAE compositions, a bulk and a particle degradation experiment will be conducted so that trends can be identified in the ability to tune biodegradation speeds for the various compositions. To test the viability of cells with PBAE nanoparticles attached, cell viability will be measured across various PBAE compositions applied to Human Endothelial Kidney cells using an MTT assay.Previous research indicates that the PBAEs we will be testing should be readily biodegradable, they can be elastomeric and available for acoustic purification, and they can be nontoxic. Our goal is to learn more about various PBAE compositions, and to find the ideal fit to serve as a cellular backpack and have a delayed drug response until it reaches the tumor to maximize the amount of drug reaching the tumor.

Abstract Name: Determining the Genotype Frequency of SNP rs4988235 That Confers Lactase Persistence in an LMU Population

The enzyme lactase hydrolyzes the milk sugar, lactose, into glucose and galactose. In approximately 65% of humans worldwide, lactase is not expressed after weaning, called lactase nonpersistence (LNP). An LNP individual consuming dairy products can experience mild to severe gastrointestinal symptoms such as bloating, gas, and diarrhea. Single nucleotide polymorphisms (SNPs) in the enhancer region of the LCT gene have been correlated with the trait lactase persistence (LP), the ability to express the enzyme lactase into adulthood. The best-studied SNP is the C/T variant (SNP ID rs4988235) at position -13,910 bp upstream of LCT, where the dominant T allele confers the trait of LP. Frequency data for this SNP has been recorded for some homogenous populations, but an estimate for the heterogenous U.S. population has small sample sizes for minority groups. Our work seeks to fill this gap by genotyping individuals from Loyola Marymount University. DNA was extracted from hair follicles, and PCR-RFLP analysis was used to determine the genotype at rs4988235. We have collected samples from 52 individuals and successfully genotyped 44 of them. From these data we predict that 22 individuals have the LP phenotype and 22 have the LNP phenotype. These results were compared to self-reported dairy consumption and symptoms experienced, as well as demographic data. 70% (31) of successfully genotyped participants reported themselves as lactase persistent, even without the presence of the T allele. We found the T allele was less common amongst Asian, Hispanic/Latino, and Black or African American populations although the sample size is currently small. Continued sample collection and analysis will provide a more reliable estimate of the frequency of LP and LNP in a heterogeneous population. The results may suggest a need to revise U.S. dietary guidelines regarding dairy to reflect the needs of our diverse population.

Abstract Name: A review on the role of online nutrition education material for patients diagnosed with cancer

Introduction: The Internet has become a resource for patients seeking information (van Veen MR, et. al); however, unfiltered content presents the risk of encountering information that could adversely affect their health, such as using potentially harmful supplements (ACS). This review aims to examine online nutritional resources available to cancer patients and assess their impact.Methods: We conducted a review using these MeSH terms in PubMed: “cancer,” “nutrition,” and “education.” Our inclusion criteria of the articles: (1) published between 2008-2022, (2) offered nutritional education via the Internet, and (3) evaluated the impact

of nutritional education on cancer patients. Our data extraction focused on: age, type of cancer, language, level of health literacy, type of online resource, method of content validation, and health outcomes. A secondary reviewer (YW) replicated the process, with any discrepancies resolved.Results: A total of six studies were included. The types of cancers identified include: breast, lung, endometrial, bladder, renal, and gastrointestinal. One study indicated online education material designed for low-literacy immigrants. Four of the studies focused on adults and two of the studies included children. Four of the studies included English as the primary language of materials and two of the studies included Spanish. The types of resources that utilized official websites of the cancer organizations as their main source for education material (n = 2). Two studies electronically sent patients reminders (n = 2). Two studies conducted rounds of interviews (n = 2). The content of five studies were validated by several organizations. Health outcomes included improved patient understanding and changes in diet.Conclusion: We found most studies provided validated nutritional information to cancer patients, which improved outcomes. However, the educational material is predominantly in English. This language barrier presents a challenge in delivering equitable healthcare. Future implications include the need for studies that incorporate feedback from healthcare providers.

Abstract Name: Parakeet Lost: Casting Light on North America’s Forgotten Native Parrot

For centuries, the abundance of America’s avifauna was one of its most storied treasures. Early accounts spoke of flocks a mile wide, and forests and shorelines that bristled with feathers. Many of these birds are now gone, driven to extinction through human action and inaction, leaving only fading shadows upon collective memory. Among the vanished birds of the United States, one of the most unique was Conuropsis carolinensis, the country’s only endemic parrot. Though named for the area where it was first studied, the Carolina Parakeet was common throughout the lands east of the Rockies, noted for its tolerance of snow. It seems impossible that such a remarkable creature could have been forgotten within the span of a human life, yet only 84 years after the declaration of its extinction, few people today are aware that an American parrot ever existed. The purpose of this project is to investigate the distinctive characteristics of C. carolinensis, with the aim of constructing a compelling, multi-faceted portrait of this lost species. In-depth research will be conducted into the cultural and natural history of the bird and the causes of its disappearance, comprising an examination of first- and second-hand historical accounts and contemporary ornithological scholarship, as well as preserved biological specimens. Following in the strong tradition natural history illustration, the findings of this research will be synthesized as a series of paintings, executed in gouache on paper; original works of prose poetry will provide context for the images. Collectively, this body of work, presented in the exhibition format, will encourage consideration of the countless creatures which today face oblivion, and invite deeper contemplation of the precarious position held by even the most exceptional of species.

Abstract Name: Herculaneum Opened Scroll Database

The Herculaneum Papyri are among the most iconic and inaccessible damaged manuscripts in the modern world. Carbonized and buried by the eruption of Mount Vesuvius in 79 CE, the ~1,100 papyrus scrolls excavated from the ancient city of Herculaneum in the late 18th century, offers us a unique window into the classical world. EduceLab has been working on collecting 3D scans, spectral images, and descriptive data of over ~3,500 opened scroll fragments; this information is currently stored in google sheets, csv files, and metadata files. With all of this information scattered across multiple different files there is no way to easily organize, view, and navigate through the data. Our project focuses on making this information easily accessible and navigable to researchers by developing a relational database, available through a secure website, that allows for users to query the data. To accomplish this task a script needs to be developed to automatically collect the information that is being stored in the different files and use their information to develop and update a dedicated database. A website then needs to be developed to allow for users to access the database through the use of queries, and display the resulting information in a user-friendly manner. With the help of user feedback, we are hoping to develop a tool that allows papyrologists and fellow researchers access to scans, images, and descriptive information in order to study the opened scrolls without having to travel to the libraries which house the scrolls.

Abstract Name: Total Synthesis of Pestalamine A

Pestalamine A is a secondary metabolite that is naturally found in the mangrove-derived endophytic fungus, Pestalotiopsis vaccinii. It contains various structural features including a cis-alkene, primary aniline, and a furoate ester. This molecule exhibits moderate degrees of cytotoxicity against multiple human cancer cell lines, including MCF-7, HeLa, and HepG2. As such, pestalamine A has potential as a lead compound for cytotoxic cancer therapies and is an attractive target for total synthesis. The current research was conducted to identify synthetic routes for the production of Pestalamine A. The formation of the aromatic core, which represents half of the overall molecule, was constructed through SN2 esterification. The second half of the molecule, which contains a cis-alkene and both a cis-1,2-diol derived furoate ester, is still in the process of being formed. The aromatic core and the second half of the molecule will be combined through Sonogashira Coupling. This reaction requires the use of an alkyne of which will be formulated through a Weinreb amide derived from ethyl-(S)-lactate. Noyori Asymmetric Hydrogenation will be utilized to formulate the second hydroxyl group. Finally, the furoate ester group of Pestalamine will be attached through the chemoselective acylation reaction previously disclosed by us.

Abstract Name: Question Creation as a Tool to Help Students Understand Mathematics

This study applied a cognitive tool to math education to see if it increases positive output in students. Specifically, we were testing whether creating and answering questions related to the topics students were learning would help them perform better on tests and assignments. The self-generation effect is a phenomenon in cognitive psychology in which subjects are more likely to remember items that they generate rather than those provided. The self-generation effect has been used to help memory in multiple situations. Recall and recognition are generally higher for stimuli that subjects generated than for stimuli that was only viewed. In the current study, a group of seventh graders were separated into a control group, who for two weeks went home every night and answered two questions from their assigned homework, and an experimental group, who for two weeks went home every night and created and answered 2 questions related to material from class. Both groups completed a pre- and post-experience assessment with the same questions and two questionnaires related to math anxiety. After compiling, the data showed the hypothesis did come back statistically significant. Students significantly improved in both their completion of the math test but also in how much of it they got correct after the two-week period. The experimental group performed significantly better on the tests.

Abstract Name: Ashwagandha and Sexual Health on Women with Hyposexual Desire Disorder

Hypoactive Sexual Desire Disorder (HSDD) affects 40% of women and potentially decreases their quality of life. Currently, the primary treatment for HSDD is Flibanserin, which is a serotonergic agonist and an antidepressant. However, the limited efficacy of Flibanserin encourages the exploration of the utilization of traditional drugs such as Withania somnifera, otherwise known as Ashwagandha, as an alternative treatment for HSDD. Minimal studies examine ayurvedic medications or the symptoms of illnesses that traditional Western medicines are unable to treat. This comprehensive literature review investigated the efficacy of Ashwagandha in improving sexual function in women with HSDD. The paper evaluated how Ashwagandha may positively influence mental health, sexual desire, and overall physical health, potentially resulting in improved sexual health. The evaluation was conducted by analyzing and synthesizing a combination of human and clinical studies. This paper aimed to observe how Ashwagandha's phytochemicals may positively improve sexual health by improving sleep quality and mental function, as well as increasing sexual desire. In addition to the improvement in sexual health, Ashwagandha has minimal adverse effects which may allow it to be a better treatment in comparison to Flibanserin overall. This review proposed that Ashwagandha may improve sexual health for women struggling with HSDD. However, further research needs to be conducted on the long-term effects of the administration of Ashwagandha as many of the trials completed thus far have only occurred for a short period of time.

Abstract Name: Enhancing IoT Security with QDPC variant of McEliese: A Post Quantum Cryptography Approach

In the era of quantum computing, traditional cryptographic methods may face obsolescence due to advancements like Shor's algorithm, which can efficiently break widely used cryptographic protocols. This research focuses on IoT devices that face issues while adopting cryptographic protocols designed for classic computers because of their limited computational power and communication bandwidth.We propose a Post quantum cryptographic solution with Quasi-cyclic Moderate Density Parity-Check (QDPC) variant of the McEliece System for securing IoT communication against quantum attacks.The research methodology encompasses a theoretical development phase, where the algorithm design is followed by a practical implementation phase involving simulation and analysis in an IoT environment. The algorithm will be tested for quantum resistance, computational efficiency, and practical deployability in IoT devices. Comparative analysis with existing cryptographic solutions will be conducted to evaluate performance enhancements and security fortifications.The expected outcome is a robust, quantum-resistant cryptographic algorithm tailored for IoT devices, demonstrating a balance between high-level security and operational efficiency. The conclusion will discuss the implications of this research for future IoT security protocols and the broader field of post-quantum cryptography, emphasizing the need for proactive measures against quantum computing threats.

Abstract Name: Review of the Efficacy Study Deficit in Anxiety Aid-Claiming Mobile Applications

Anxiety mobile applications on the current app store are misleading users through advertising claims, whilst lacking transparent, published efficacy studies that support their supposed clinical foundations. Broader findings have indicated that a limited number of available mental health apps have peer-reviewed, empirical sources to substantiate their services. However, this line of research has not extended into nor specifically evaluated apps that market themselves on the distinct psychological concern of anxiety. Therefore, this study will address the deficit in the current literature on anxiety-themed applications that purport their effectiveness in managing anxiety and/or alleviating anxiety symptoms. 7 free-to-download mobile apps that are titled using anxiety-specific phrasing (i.e., "anxiety", "fear", "panic attack") and that are common across the iOS and Google Play store will be reviewed on the following: whether they have published efficacy studies that support their services' tools, the content of those studies, and if that information was accessible to users. The findings aim to shed light on the deceit apparent in the mobile market, one that persuades users into downloading apps and making in-app purchases on tools that may not elicit long-term, positive mental health trajectories, due to their lack of scientific evidence. Moreover, a discussion on how transparency lends itself to the mental health of users is necessary, as it will ultimately assist them with mindful downloading, as well as discerning between which apps are effective for their anxiety and which are simply schemes.

Abstract Name: Effect of Linker Modifications on Cis versus Trans C-F Activation with Bis-Bidentate Nheterocyclic Carbene Nickel Complexes

Fluorine plays a massive role in developing effective pharmaceutical drugs, however selectively fluorinating organic molecules is extremely challenging. A common route to installing fluorine involves C-F bond cleavage. C-F bonds are among the strongest bonds in organic chemistry, with a bond dissociation energy of at least 130 kcal/mol and are typically cleaved by second or third row transition metals. A more facile, sustainable, and less expensive approach for C-F activation may be in using base metal catalysts. Monodentate N-heterocyclic carbene (NHC) nickel complexes have been reported to undergo C-F activation, however bis-bidentate NHC (RNHC2R1; R, R1 = alkyl or aryl) analogs have not been reported. This work examines a novel series of RNHC2R1 nickel(0) complexes with varying R1 linkers to determine the effect of linker on C-F activation of hexafluorobenzene. Comparisons include a reference nickel(0) complex with two monodentate NHC ligands, and results show that low valent nickel NHC complexes easily break the C-F bond in C6F6 via oxidative addition. Crystallographic and NMR characterization demonstrate that ligand design and denticity affect the cis versus trans orientation of the final product, with possibility for additional ligand C-H activation. Cross coupling, and mechanistic studies are in progress.

Abstract Name: Examining the Ethics and Governance of Generative Artificial Intelligence

Our interdisciplinary research poster examines the ethical and societal implications of Generative Artificial Intelligence to propose recommendations for lawmakers and AI companies to help society safely adjust to this new era. This research is motivated by concerns associated with potential risks of confidential

information leakage and the generation of faulty recommendations with discrimination, led by a team of students from underrepresented groups. From this multidisciplinary perspective, we apply intersectionality and distributive justice theoretical frameworks to understand the complex processes of AI/ML models ("black box"). We provide policy recommendations for policymakers and AI companies to advocate for diverse and unbiased datasets, put emphasis on ethics, and improve transparency in AI with users and clients. Our methodology is a comprehensive literature review approach to critically assess academic journals, current headlines, and white papers. Our research focuses on three key dimensions: 1. Transparency & Bias in AI: To what extent do hidden biases within AI models contribute to ethical concerns and reinforce social inequalities? AI can be viewed as a black box because of its lack of transparency and explainability, which we aim to clarify. 2. Lack of Diversity in AI Talent: What are the consequences of the demographic disparities in individuals maintaining AI datasets and how does the lack of diversity contribute to bias? 3. Role of Data in AI Models: How does the collection of user data for AI datasets impact privacy? Our research examines the fundamentals of data privacy and how AI datasets produce outputs with biased or insufficient data. We will also analyze how a user's everyday use of the internet is collected to feed datasets and the implications that has on privacy, exploring the relationship between datasets and personal information. Our research aims to ensure politically neutral and ethical AI development to accommodate AI's exponential growth while in its early stages.

Abstract Name: Linguistic Relativity as Prose: The Hopi and the Sapir-Whorf Hypothesis in Christa Wolf’s Stadt der Engel oder The Overcoat of Dr. Freud

Christa Wolf is considered one of the most acclaimed writers of former East Germany who wrote prolifically from 1961 to 2011. She wrote with particular emphasis on the role of language in literature. However, there exists a lack of scholarship surrounding her work from a distinctly linguistic perspective. The metalinguistic choices Wolf makes in her writing as a part of the framework of what she calls Subjective Authenticity is closely aligned with Linguistic Relativity or the Sapir-Whorf Hypothesis. One is a literary framework while the other is a linguistic theory. By examining them together through a close reading of a passage exploring the Hopi Tribe in her novel Stadt der Engel oder The Overcoat of Dr. Freud and Benjamin Whorf’s original research on the Hopi Tribe, I reveal how Wolf’s inclusion of the passage on the Hopi is a key space for her own linguistic literary theory of prose.

Abstract Name: The Effect of Oral Microbiome on Blood Plasma Nitrous Oxide Levels and Blood Pressure

Cardiovascular diseases are the leading cause of death globally, with elevated blood hypertension being a significant risk factor. Nitrate, nitrite, and nitric oxide in the blood have been shown to be important mediators of human blood pressure. Dietary nitrates are reduced in the oral cavity by bacteria in the oral microbiome, and studies where saliva has been expectorated or where antibacterial mouthwashes have been used after consumption of nitrates have demonstrated a lessened effect on blood pressure, demonstrating the importance of bacteria in the bioavailability of nitrous oxide species. Minimal research has been done on specific bacterial species indicated in elevated blood plasma nitrous oxide species levels. The goal of this research is to associate specific bacteria with elevated levels of blood plasma nitrate levels by taking oral, saliva samples and venous blood samples from volunteers, as well as collecting blood pressure measurements. Specific oral bacterial species will be assessed by quantitative PCR, while blood plasma nitrites will be analyzed using a fluorescent assay read by a microplate reader. If successful, specific bacterial species will show a positive association with plasma nitrite levels; this would be especially informative as microbiome therapies are developed and evolve to treat patients, particularly hypertensive patients.

Abstract Name: A Deep Learning Approach for Pain Detection in Mice

Identifying pain in mice may be a crucial or fundamental part of an experiment in a lab setting. The Mouse Grimace Scale was developed to classify the pain in mice based on different body parts including their eyes, ears, whiskers, and nose. Similar grimace scales were developed for other animals such as rabbits, cats, rats, and other common animals used in lab settings. Despite the usefulness of this type of pain grading scale, grading images can be time consuming and requires trained humans to recognize signs of pain. To address this issue, a couple of different approaches are taken. Since the input data may be too complex for machine learning models, a more appropriate approach for classifying raw images is deep learning-based models. These models are a popular option due to the accuracy of convolutional neural networks (CNNs) such as InceptionV3 or Resnet50. Despite the mass amounts of data needed to train deep learning models, they are good for handling data with high dimensions. They are also capable of seeing non-linear relationships, which can be useful when dealing with datasets that hold complex features. In this study, we take a deeper dive into looking at the use of autoencoders for dimensionality reduction and feeding the prepared data into fully connected layers for binary classification of pain in Siamese neural network architecture. We also looked at a model using InceptionV3 and compared it to the previously mentioned model. Our aim is to visualize which model can classify mouse pain better and to determine if deep learning grimace scale models can classify mouse pain as good as human raters. We plan to clean up the dataset to only have front-facing mice images trained and use a crop, rotate, and brighten method to images in the dataset to make the model more robust.

Abstract Name: AN ANALYSIS OF MUTANTS PROMOTING BASAL SPREADING AND MIGRATION OF ENTEROBLASTS IN THE ADULT DROSOPHILA MIDGUT

Epithelial tissues in animals represent monolayers of cells which act as barriers between compartments, and also mediate exchange of substances across the barrier. The cells comprising the epithelium are polarised along the apical-basal axis and partake in homophilic interactions with neighbouring cells via adherens junctions, and heterophilic interactions with the ECM via integrins. Junctional contact between epithelial cells differentiates their apical-basal polarity from other polarised cells as their cortical domains are divided into the apical domain, adherens junction, tight/septate junction, and basolateral domain. This polarity is important for the integrity and function of epithelial tissues as loss of polarity contributes to tumourigenesis in various cancers. The adult Drosophila midgut epithelium is a model of alternative cellular polarity as it polarises by a mechanism that is different from other Drosophila epithelia, and has several features that resemble vertebrate epithelia. This study investigates the role of novel proteins previously identified in a forward genetic screen for mutants that disrupt midgut enterocyte polarity and/or epithelial homeostasis. Reverse genetics was employed to generate mutant MARCM cellular clones and immunofluorescence methods were used to analyse the phenotypes of cellular midgut populations mutated for the five candidate proteins. We show that certain mutant alleles do not contribute to defects in enterocyte polarity, but they potentially regulate the proliferation and differentiation of progenitor stem cells within the midgut. These findings provide a strong start to analyse other proteins that may regulate polarity within the adult Drosophila midgut.

Abstract Name: Modeling the Lattice Vibrations of a Debye Solid

Einstein’s model of specific heat is commonly taught to understand the vibrational frequency of atoms in a solid. This model claims that the frequencies are independent of one another. However, the Debye model states that the atoms are considered coupled together, and therefore, the overall vibrations of the solid are quantized with a range of frequencies. Using conventional transmission 57Fe Mössbauer Spectroscopy, the temperature dependence of the isomer shift is extracted from the spectral analysis for two solid state systems. This phenomenon is understood to be due to an effect called second-order Doppler shift and is approximated by assuming the material to be a Debye solid. The Debye integral is used to evaluate the Debye temperature to understand the second-order Doppler shift further. The approximation of the Debye integral is evaluated with a Fourier series. The extracted isomer shift data sets are analyzed through a Python code built on the Colab platform. A line shape analysis is performed assuming a Lorentzian function to accomplish the least squares fitting of the data. Details of the integral, the modeling approach, and the experimental data will be presented. This work is supported by the LSAMP award and the NSF PREM – Emergent Interface Materials, Grant 2122147.

Abstract Name: Discerning Key Predictors in Positive PCOS Diagnoses of Gynecological Patients

IntroPoly cystic ovarian syndrome, primarily known as PCOS is a hormonal disorder in which ovaries present larger than normal with cysts on the outside of the ovary. This syndrome can present in women through symptoms such as irregular menstrual cycles, excessive hair growth, and infertility due to imbalanced androgen hormones. The present study aims to explore factors related to a positive PCOS diagnosis and quantify the relationship between variables. The dataset was collected on 541 gynecological patients with their respective ages, hormone levels, menstrual cycle regularity, and physical manifestations of PCOS symptoms. The variables specifically analyzed were Anti-Mullerian hormone levels, age, BMI, Luteinizing hormone levels, Vitamin D3 levels which were all continuous. Three binary variables were also observed; weight gain, menstrual cycle, and hair loss.MethodsSAS was utilized to generate descriptive statistics for continuous variables and frequency tables for binary variables. A logistic regression was performed through SAS with eight potential PCOS factors to quantify the relationship between the variables. Out of the eight variables, 4 were found to be significant predictors of a PCOS diagnosis.ResultsThe findings demonstrated Anti-Mullerian hormone levels (p = 0.002), weight gain (p = < .0001), age (p = 0.004) and an irregular menstrual cycle (p = <.0001) were statistically significant predictors of PCOS. These results provide a better understanding of the etiology of PCOS in women's health. ConclusionThis study identified age, Anti-Mullerian hormone levels, weight gain, and an irregular menstrual cycle as significant predictors of PCOS. Comprehending these results can lead to more treatment plans for and earlier screenings to determine if a patient will have a positive PCOS diagnosis.

Abstract Name: Neural Network Solver for Transient State Incompressible Flow on Arbitrarily-Shaped Geometries Defined using Bezier Curves

Computer models for simulating turbulent fluid flow have many industrial applications. However, these models often rely on numerical methods, which are accurate but slow. The aim of this research is to use neural networks to simulate fluid flow much faster than can be done with numerical methods. To enable aneural network to predict the fluid flow around any arbitrary shape, e.g., an airplane or house, the prevailing method is to input the simulation grid into the neural network in the form of a point cloud or image. In this research, we propose a new approach that is simpler and faster. Instead of a point cloud, we define the boundary of an arbitrary obstruction using a handful of points. We then train the neural network to interpolate all intermediate points using Bezier curves to produce a closed shape. Using fewer points allows for

improved training time, inference time, and neural network size. We trained an ensemble of five neural networks for 90 epochs. The resulting ensemble was able to predict transient-state turbulent fluid flow for up to 2000 time steps with a mean squared error of 1.162E-05. Using ensemble stacking, our ensemble had an inference time of 6 seconds, which is a hundred times faster than typical fluid solvers. Our approach is applicable to modeling fluid flow over 3D topographic maps, which can be interpolated using radial basis functions or planes. The lasting impact of this research is that it will move us closer to modeling in real-time or better.

Abstract Name: Characterization of RBMS3 as a regulator of RNA stability in breast cancer metastasis

Cancer metastasis uses a diverse set of processes with post-transcriptional regulation playing a major role. Because these regulatory pathways have been difficult to study, REMBRANDTS-PRADA is a computational framework that was developed by our lab to predict master regulators of RNA stability. From cell line and patient-derived models of breast cancer, REMBRANDTS-PRADA predicted the RNA binding protein RBMS3 to be a novel regulator of RNA stability. CLIP-seq was then performed to determine the binding preferences and targets of RBMS3, verifying REMBRANDTS-PRADA predictions of target regulons of RBMS3. We hypothesize that RBMS3 suppresses breast cancer metastasis by post-transcriptionally facilitating gene regulation through maintaining RNA stability of its targets, determined by CLIP-seq, by binding to their 3' untranslated regions (3' UTR). To dive deeper into this hypothesis and validate RBSM3 targets, I cloned an mCherry/GFP dual-reporter system with 13 different RBMS3 binding sites and corresponding scrambled control sequences in the 3' UTR of GFP. The pooled reporter library was then expressed in MDA-MB-231 breast cancer cells with RBMS3 knocked down versus control cells to measure differential GFP expression when RBMS3 binds to these 3' UTR. Library preparation of DNA and RNA reporter sequences, followed by sequencing on the Illumina NextSeq platform, will be used to measure the effect of RBMS3 expression on the stability of the target GFP mRNA. It is expected that RBMS3 binding is required to maintain the RNA stability of its targets and suppress breast cancer progression through this mechanism.

Abstract Name: Analyzing the Effects of MobileNet as a Model Backbone on Model Training Time and Computational Resource Usage

MobileNet presented itself as the solution to the problem of a constant trend of making computer vision models deeper and more complex to achieve higher accuracy. The increase in complexity has a large effect on the amount of resources a machine will use in training and deployment. The true number of resources used remains unclear and should be well documented for future reference. This paper aims to provide that information by comparing the number of resources used and performance between FasterRCNN, FasterRCNN with a MobileNet backbone, and SSD with a MobileNet backbone on a relatively large handgun dataset along with a comparison of the performance of SSD with a MobileNet backbone on the same dataset with and without data augmentation. The results of the experiment show that FasterRCNN uses more system memory compared to MobileNet backbones and the MobileNet backbones had a decrease in the number of

GPU usage and VRAM usage compared to FasterRCNN. Along with this, for a nonaugmented dataset passed through SSD with MobileNet it used around the same amount of resources but performed 3% better than the same MobileNet model that uses an augmented dataset.

Abstract Name: Global Navigation Satellite Systems Observations of the Ionosphere During Strong Thermal Emission Velocity Enhancement

Global Navigation Satellite Systems (GNSS) signals experience phase and amplitude fluctuations known as scintillation when traveling through density irregularities in the ionosphere, a layer of plasma in the upper atmosphere. Precise point positioning (PPP) is a positioning method which relies on highly-accurate GNSS signal carrier phase measurements to achieve centimeter-precision: however, scintillation degrades these signals, leading to errors in positioning accuracy which negatively impact communication and navigation networks. Herein, we report the first observations of GNSS total electron content (TEC; a column integration of the ionospheric density) and PPP variation associated with Strong Thermal Emission Velocity Enhancement (STEVE) emissions, a recently-discovered, aurora-like arc characterized by a signature mauve glow, enhanced temperatures, and enhanced ion flow speed. In this study, we used optical imaging data from the Time History of Events and Macroscale Interactions during Substorms all-sky imagers to determine the spatial and temporal dynamics of STEVE. We additionally used GNSS receiver data from the University Navstar Consortium to determine TEC and PPP during STEVE. Although the theory suggests that TEC decreases during STEVE, interestingly, we found an unexpected enhancement of TEC associated with STEVE. TEC enhancement closely followed the path of STEVE longitudinally and was localized to STEVE. PPP exhibited enhanced variance locally around STEVE, indicating that the GNSS positioning error increased significantly. We suggest that the TEC enhancement during STEVE creates local TEC structures in the ionosphere that degrade the performance of GNSS. The TEC enhancement is likely created by energetic particle precipitation and plasma drift across STEVE. These results establish STEVE as a previously unidentified source of high-latitude scintillation and quantify STEVE's impact on ionospheric dynamics and GNSS navigation.

Abstract Name: Streams of Profit: Replaying Spotify's Crescendo to Success in the Post-Modernist Epoch

The transition from record players and cassette tapes to predominantly digital forms of musical media can be attributed to rapid digitalization in an increasingly technologically-reliant society. Compact discs became critical to the transition of music to convenient storage formats and portable media players provided listeners with entire music libraries they could access at any time. Similarly, the advent of illegal file-sharing services, such as Napster, a peer-to-peer network, allowed users to directly share and download music files–leading to copyright infringement claims. Napster's downfall paved the way for Spotify to revolutionize the music industry: changing the modus operandi of music consumption to streaming (Rahimi & Park, 2020). Despite the resulting rise in popularity for music streaming services, the effect of algorithms and product features on Spotify's revenue, in addition to differentiation from competitors in the industry, has been under-researched. This literature review seeks a better understanding of Spotify's brand positioning, analyzing key performance indicators, market share, and other measures of profitability to identify possible factors contributing to its success. Secondary data was obtained from public sources, including quarterly investor relations calls, SEC (Securities and Exchange Commission) filings, journal articles and the Spotify "For The Record" podcast, which provides insider insights on the company's latest earnings and business developments. The results of this study suggest Spotify's diversified product ecosystem creates greater user engagement and customer satisfaction (Gibbons, 2020), improving its value proposition. Furthermore, its data-driven algorithms create music recommendations specifically customized for listeners, which may offer the business a competitive advantage over other music service applications. Potential avenues of research in the future include investigating the effectiveness of marketing segmentation based on immutable demographic factors–in contrast to marketing campaigns launched by Spotify, which utilize behavioral segmentation to group listeners with similar streaming habits.

Abstract Name: The Interplay of Social Norms and Legal Systems: Unraveling the Complexity of Domestic Violence in China and Paving the Path for Change

This research investigates the perpetuation of domestic violence (DV) in China, a context where the interplay of social norms, institutional practices, and legal frameworks presents unique challenges. Despite the implementation of China's Anti-domestic Violence Law in 2016, its effectiveness has been subject to scrutiny among researchers. The primary objective of this study is to illuminate the intricate nature of DV in this context, identifying obstacles to achieving justice and reducing harmful behaviors. The hypothesis of this research centers on the idea that deeply ingrained social norms emphasizing family harmony and non-interference in family affairs hinder the Law's efficacy in protecting individuals from DV. Employing a framework rooted in social norms theory, leveraging previous political and sociological research, and analyzing primary sources related to traditional Chinese ideologies, this study examines specific instances of DV in China. The findings indicate that entrenched social and gender norms influenced by Confucianism and traditional Chinese cultural values are closely linked to law enforcement officers' perceptions and responses to the violations of the Law. Institutional norms within the police force regarding handling DV cases also play a pivotal role in law enforcement practices. This research underscores the significance of adopting a social norms approach to effectively address this problem and the need for a transformative shift in societal attitudes and behaviors. It contributes to a comprehensive understanding of DV in China, potentially influencing public discourse and empowering proactive efforts to promote meaningful change.

Abstract Name: Investigating the Impact of COVID-19 on Sustainment of an Evidence-Based Practice for Adolescent Substance Use

Nearly 1.6 million U.S. adolescents meet criteria for substance use disorders (SUDs. Evidence-based practices (EBPs) to treat SUDs can help address this pressing public health issue. However, the sustained delivery of EBPs in communities has been difficult within the context of the COVID-19 pandemic; therefore, we need to better understand factors that contribute to sustainment. One important factor for sustainment is the type of organization implementing EBPs. Private organizations tend to demonstrate greater support and more positive attitudes from staff for EBP implementation, compared to public (i.e., government-operated) organizations. It remains unclear, however, whether these organization types showed differential sustainment of EBPs for adolescent SUDs during the pandemic. This study, conducted at the RAND Corporation through the NIDA Summer Research Internship Program, compared the impact of COVID-19 on the sustainment of an EBP for adolescent SUDs between private versus public organizations. Using a cross-sectional observational design, clinicians and supervisors (n = 62) were recruited from organizations that received SAMHSA grants to scale up the Adolescent-Community Reinforcement Approach (A-CRA), a well-established EBP, in 17 states. Participants completed a web-based survey in which they reported organizational characteristics (including private vs. public status) and rated the extent to which COVID-related changes affected their organization's ability to sustain A-CRA on a scale of 1 (much harder to sustain) to 7 (much easier to sustain). A t-test was used to compare ability to sustain by organization type; on average, respondents in private organizations reported significantly greater ability to sustain A-CRA during COVID-19 (t=2.00, p<.05) . A chi-square test was used to test dichotomized (i.e., high vs. low) ability to sustain, but this test did not indicate a significant difference (X^2=2.36, p=0.12). These findings suggest a need to increase support for public organizations working to sustain EBPs through strategies that target facilitating factors like organizational support.

Abstract Name: Role of TCP19 in Regulation of Plant Growth and Development

The circadian clock allows organisms to synchronize their physiological functions with daily rhythms in environmental cues to optimize their development. In plants, the clock contributes to plant growth, defense, and other critical survival traits such as flowering. Plant growth and developmental responses are mainly initiated by cell differentiation-controlling mechanisms at the shoot-apex, thus we predicted that the regulation of the shoot-apex clock function should play an important role in controlling plant biomass and flowering time. We have identified that the transcription factor TCP19 specifically regulates the clock function at the shoot-apex. Thus, we hypothesized that TCP19 misexpressions would affect plant biomass

and flowering time. Indeed, our data indicates that TCP19-overexpression resulted in reduced biomass and delayed flowering time. However, plants carrying a tcp19-loss-of-function allele did not result in any notable phenotype suggesting that other factors may redundantly regulate plant biomass and flowering together with TCP19. Given that TCP19 regulates the expression of a core clock component, CCA1, but not a functionally redundant component, LHY, we hypothesized that the function of LHY may mask phenotypes in the tcp19-mutant background. In fact, double tcp19/lhy-mutant plants showed a significant flowering time delay in short days (but not long days) compared to the single tcp19 or lhy-mutants. These results indicate that TCP19 is a regulator of plant growth and flowering. Given that flowering time was only affected in tcp19/lhy-mutants and only short-day but not long-day conditions, our results are consistent with the notion that TCP19 only regulates CCA1 expression and further indicated that TCP19 is functionally redundant to LHY and regulates plants' ability to measure day length.

Abstract Name: The Impact of Schools Sustainable Infrastructure on Students' Academic Performance and Mental Health.

This research aims to examine the correlation between students' academic performance, mental health, and sustainable school design. The study focuses on the Gwinnett School of Mathematics, Science, and Technology (GSMST) in Lawrenceville, Gwinnett County. GSMST is the highest-achieving high school in Georgia, ranked 19th nationally in 2023 and declared as The National Blue Ribbon School of Excellence in 2016. According to the Georgia Department of Education (GADOE), GSMST leads Georgia's 2022 Standardized Test (SAT) with an average of 1386 score. The school prioritizes high academic achievement and brings out the potential of all students that attend with their boasted 100% graduation rate for the 2021 - 2022 academic school year. The interior of the building consists of natural lighting, enabling motivation and dynamic space. The research inquires if and how this public school is designed to enhance the abilities of students by including spatial features of universities such as collaborative learning environments, focused study areas, and lecture halls. The team utilizes a multi-faceted methodology, including literature reviews, interviews (i.e., with school officials), and analysis of building data. Despite the high-quality sustainable spaces, according to GADOE, in the 2023 Georgia Student Health Survey while the performances are high, the students' mental health is low. The Research Center for Sustainable Communities (RCSC) at Kennesaw State University (KSU) has been conducting analytical studies on how to enhance sustainability and reduce the carbon footprints of school infrastructures statewide in GA. The RCSC seeks ways in which the state could advance healthier and more sustainable, equitable, and cost-effective learning environments. Rooted in this initiative and funded by the KSU Office of Undergraduate Research, the research underlines how the GSMST educational built environment impacts the students' performance.

Abstract Name: Colliding Identities: Understanding the Influence of Multiple Stigmatized Identities and Intersecting Identities on College Students' Mental Health and Self-Rated Health

Approximately three-fifths of college students have met the criteria for at least one mental health problem. As mental health is associated with poorer academic performance and future unemployment, it is important to identify college students that may be more at risk for poorer mental health outcomes and self-rated health (SRH). The Double Jeopardy Theory and the Intersectionality Framework are two approaches that may help to identify those most at risk. In this study, we first explore how the number of stigmatized identities play a role in mental health outcomes and SRH for college students (i.e., Double Jeopardy Theory). We hypothesize that more stigmatized identities will be associated with poorer mental health and SRH. Next, we use an Intersectionality framework to investigate if specific intersecting identities (i.e., race/ethnicity, gender, and socioeconomic status) are associated with mental health and SRH. We hypothesize that race/ethnicity and SES independently and their interaction will be associated with poorer mental health and SRH, such that non-white and low SES participants will have poorer outcomes. In exploratory hypotheses, we will test the main effects of gender and its interactions with race/ethnicity and SES on mental health and SRH. Lastly, we will test for a three-way interaction between race/ethnicity, gender, and SES. In an online survey, participants (n=200) will complete demographic questions, report their number of stigmatized identities, and complete questionnaires assessing depression, anxiety, perceived stress, eating disorders, substance use, and SRH. Data collection is ongoing. Data will be analyzed using linear regression models. Results may highlight the benefit of using these two theoretical frameworks to identify at-risk college students and inform college counseling and outreach services

Abstract Name: An Examination of the Impact of Whitetail Deer on Industrial Fiber Hemp Cultivation

The purpose of this study was to investigate the impact of white-tailed deer (Odocoileus virginianus) on the growth of industrial hemp in East Central Illinois. A controlled burn was completed, and two plots, one enclosed (east) and one open (west) were identified. and the exclosure was built. The exclosure was built with wooden posts and fencing that started approximately 15 cm above the ground to allow for small animals to still access the plot. Two separate types of seeds were then planted in equal amounts in each plot (north and south). Once the seeds were planted, wildlife cameras were placed on the northwest and southeast corners to observe possible cervid interactions with the plot. The plots were observed weekly throughout their growing season and then harvested once fully mature. The average height and total mass of each plot and seed type were recorded and analyzed via a 2x2 factorial ANOVA. The industrial hemp that was contained within the enclosed plot had a statistically significantly higher average height and mass when compared to the industrial hemp that was harvested from the open plot. The North seed variety had a total harvested weight of 29.02 kg in the open plot and a 33.11 kg harvested weight in the closed plot. The South seed variety had a total harvested weight of 18.58 kg in the open plot and a 19.96 kg harvested weight in the closed plot. The closed plot had an average height of 259.33 cm while the open plot had an average height of 206.45 cm.

Abstract Name: Cartoon Viewing & Coping

The purpose of this study is to investigate if watching children's cartoons is effective as a way of coping. Data collection will begin in Fall 2023 and end Spring 2024. During the last 30 minutes of two different class periods, participants will do the following: (1) complete measures of stress and affect, (2) view approximately 20-minute cartoon or informational video, (3) and complete measures of affect and coping .The goal of the study is to understand coping tactics in college students who experience daily stressors. This form of coping branches from escapism, utilizing other things to be a distraction from reality, like watching cartoons. This study was developed by an observation as a student overhearing other student talk about the show Bluey, a newly popular Australian children's show about an Australian shepherd family and their daily lives. Many claimed that watching cartoons is their way of relieving stress. This study will explore the role that children-marketed animated cartoons can serve as a form of coping from stress in adults. Though there is a potential way this might work is through nostalgia within one's childhood.

Abstract Name: SPOTs — High-Throughput Synthesis and Screening for Transition Metal Nitride Catalysts

Since the industrial revolution, the world's unprecedented population growth has led to a high demand for fertilizers derived from ammonia. However, the primary synthesis method for ammonia, the Haber-Bosch process, is the most energy-intensive industrial chemical process, responsible for 1-2% of the global energy consumption and 1.44% of the global CO2 emissions. One promising alternative is to use mixed-metal transition metal nitride catalysts, which have shown remarkable selectivity and efficiency in heterogeneous catalysis under ambient conditions. While the numerous possible metal combinations and ratios among mixed-metal nitrides can become quickly overwhelming, it lends itself well to a high-throughput approach to catalyst discovery and optimization. In this work, a high-throughput method for synthesizing and screening mixed-metal nitride catalysts under ambient conditions has been developed. To generate a library of mixed-metal precursors, a novel liquid handler — surface-patterned omniphobic tiles (SPOTs) — has been designed and created using MATLAB and a CO2 laser. The procedure was optimized by varying the concentration of the metal suspensions as well as the operating conditions of the CO2 laser. The mixed-metal precursors could then be nitrified into metal nitride catalysts using pulsed laser synthesis (PuLS), followed by catalytic performance testing utilizing electrochemical methods. PuLS is a promising technique for synthesizing metal nitrides as the successful generation of vanadium nitride in liquid nitrogen has been verified with X-ray diffraction and X-ray photoelectron spectroscopy. The optimized SPOTs procedure has been able to print metal precursors precisely and uniformly as confirmed by microscopy. The integration of SPOTs into mixed-metal nitride catalyst syntheses with PuLS under ambient pressure has enabled the discovery and optimization of catalysts and ultimately paves the way for greener ammonia production.

Abstract Name: Assessing the Effects of a Mutated Human JAG2 gene on Muscle Stem Cell Functionality

The evolutionarily conserved Notch signaling pathway is essential for the development and maintenance of a variety of tissues. In skeletal muscle, the Notch pathway is involved in the myogenesis and self-renewal of muscle stem cells. The JAG2 gene is associated with muscular dystrophy, an inherited muscle disease; this protein product, also called JAG2, is a membrane protein that interacts with Notch1 in its intracellular domain as a ligand for Notch-mediated transcriptional activation. There are many mutations that can cause Muscular Dystrophy and understanding mutations in JAG2 more in depth will help to continue research and analysis of other mutations and diseases. The question that our research will answer is how mutations to the JAG2 gene affect muscle stem cell function and therefore aid in accomplishing our goal of understanding more about the dysfunction JAG2 mutations cause in humans. Currently, I am constructing retroviral human JAG2 expression vectors with wild-type and point mutations. To make a mutation that models the mutations of patients with muscular dystrophy, I altered the DNA sequences to cause the 243th or 728th amino acids. My research goals are to understand the function of the JAG2 gene and the dysfunction caused by mutations in muscle stem cells. The results of this study will help us achieve our goal of better understanding the dysfunction that JAG2 mutations cause in humans.

Abstract Name: Student Research Circle - A Bottom-Up Approach to Undergraduate Research

Close mentorship between faculty and students has been linked with a plethora of positive learning outcomes. Undergraduate research (UR), senior capstones, and service learning also enhance student retention and persistence to graduation. Past research highlights UR's role in developing critical thinking, problem-solving, and communication skills, crucial for competitive employment. Employers value recent graduates with diverse perspectives and effective communication skills. The demand for graduates skilled in cross-disciplinary communication accentuates the need for interdisciplinary research. This session proposes a bottom-up approach, shifting from traditional top-down faculty-led mentoring to empowering students in research initiation. At this Public Liberal Arts university, UR is one of the designated High Impact Learning Practices (HIPs) integral to graduation. Students learn about HIPs in their first-year seminar, exploring diverse laboratories. The university supports UR by facilitating conference presentations, such as at the National Council on Undergraduate Research (NCUR). A student-initiated, multidisciplinary Student

Research Circle (SRC) emerged from this support, encompassing STEM and humanities majors with consistent mentors. This session explores SRC's student-led model, emphasizing peer mentoring and fostering a sense of belonging for student researchers. With the growing emphasis on teamwork and communication in the workplace, this initiative equips students with interpersonal and knowledge-sharing skills. These mentors will share insights into the student-led program, emphasizing its implications for peer mentoring and fostering a sense of belonging among student researchers. Recognizing the increasing prevalence of teamwork in the workplace, this session highlights the importance of interpersonal skills and effective knowledge communication through undergraduate research. The SRC model contributes to preparing students for collaborative, interdisciplinary work environments. This session aims to inspire a new cohort of researchers by highlighting a model of a student-led approach, emphasizing its impact on peer mentoring, interdisciplinary collaboration, and cultivating a supportive research community.

Abstract Name: TMEM94 Haploinsufficiency Limits ER Mg2+ Uptake and Perturbs Ca2+ Cycling in Cardiomyocytes

Mg2+ and Ca2+ are the two primary divalent cations in eukaryotes. While Ca2+ and Mg2+ have distinct roles, they exhibit functional interdependence. Intracellular Mg2+ acts as a physiological antagonist of Ca2+ by controlling voltage and ligand-gated Ca2+ channels, impacting processes such as cardiomyocyte contraction. In cardiomyocytes, Ca2+ travels in repetitive and synchronized fluctuations known as Ca2+ oscillations which are crucial for coordinated heart muscle contraction. While Ca2+ has been thoroughly studied, Mg2+ and its dynamic still majorly remain a mystery. Our recent findings revealed that TMEM94 is an ER-localized Mg2+ uptake machinery. TMEM94 is a highly conserved P-type ATPase protein that contains a signature Mg2+ binding motif (GMN). Remarkably, human molecular genetic analysis revealed that mutations in TMEM94 lead to severe developmental detriments including congenital heart malformations, neurodevelopmental disorders, and facial dysmorphism. Based on preliminary data, we hypothesize that the absence of TMEM94 perturbs Ca2+ cycling in cardiomyocytes as a consequence of limited ER-Mg2+. Here we evaluated the physiological importance of TMEM94 by studying Ca2+ and Mg2+ oscillations in isolated wildtype and TMEM94 heterozygote murine primary cardiomyocytes, as well as siRNA knockdown in human induced-pluripotent stem cells derived cardiomyocytes (hiPSC-CM). TMEM94+/- cardiomyocytes exhibited high frequency in Ca2+ oscillations but failed to display synchronized Ca2+ waves as seen in WT cardiomyocytes. Further, iPSC-generated cardiomyocytes transfected with TMEM94 siRNA demonstrated the absence of Mg2+ oscillations suggesting that suppression of TMEM94-dependent ER-Mg2+ uptake likely leads to aberrant Ca2+ cycling and cardiac dysfunction.

Abstract Name: Essentialist Thinking and Affirmative Action Policies in College Admissions

Affirmative action policies aid in providing equal opportunities for marginalized groups. Previous research has shown relationships between biases and attitudes towards affirmative action, which factors affect attitudes on affirmative action more heavily, and differing viewpoints of affirmative actions in various countries. However, little research has focused on the relationship between essentialist beliefs and attitudes towards affirmative action policies in the United States. This study proposes that essentialist beliefs held by an individual will affect their attitudes towards affirmative action policies in college admissions. We will recruit 100 college students from Kennesaw State University's research participant system, SONA. The study will be conducted online via Qualtrics. We will use a 9-point Likert scale to measure social essentialist beliefs on both naturalness and cohesiveness dimensions. We will conduct regression models to test the relationship between essentialist scores and support with affirmative action policies. We hypothesize that higher essentialism in individuals will lead to greater negative attitudes towards affirmative action policies in college admissions. Results from this study may broaden the research on the social consequences of essentialist beliefs towards affirmative action.

Abstract Name: Understanding how changes in precipitation intensity will affect vegetation in the western U.S.

Precipitation events are becoming more intense as the atmosphere warms, but it remains unclear how precipitation intensification will affect plant growth in arid and semiarid ecosystems. There is conflicting evidence suggesting that larger precipitation events may either increase or decrease plant growth. Here, we report the growth responses of herbaceous and woody plants to experimental manipulations of precipitation intensity in a cold, semi-arid ecosystem in Utah, USA. In this experiment, precipitation was collected and redeposited as fewer, larger events with total annual precipitation kept constant across treatments. Results from the first two growing seasons revealed that more intense events 'pushed' water deeper into the soil, leading to an increase in woody plant growth. To provide a longer-term and more mechanistic understanding of this response, here we will be analyzing an additional two years of shrub stem radius growth, soil water content, new root growth, root area, and herbaceous plant growth. Additionally, we performed a depth-controlled water tracer experiment to describe grass, forb, and shrub rooting distributions in different treatments. Results have implications for understanding the increase in woody plant abundance around the world in the past 50 years, a phenomenon known as shrub encroachment, and for forecasting semi-arid ecosystem responses to climate change.

Abstract Name: Investigating the Causal Role of the Motor Cortex on the Coupling of Breathing and Volition

Do physiological signals play a role in movement-onset? Previous research suggests the initiation of a movement in humans is coupled with their phase of respiration, with movement more likely to be initiated during the expiration stage of breathing. Following that research, our study has two goals. First, we aim to replicate these previous results. Second, we would like to investigate the neural sources of this coupling between respiration phase and movement onset. We simultaneously used theta-burst stimulation (TBS; repeatedly stimulating using a focal magnetic field, a brain region to lower excitability temporarily) and respirometry (the measurement of respiration). Using TBS, we disrupted the neural sources of the brain's electroencephalographic signals associated with movement initiation and analyzed whether the expected respiration cycles remained consistent after this disruption. We applied TBS to the primary motor cortex (M1) and the supplementary motor cortex (SMA) in 15 participants, who completed 100 trials of a standard self-initiated movement task (i.e., the Libet task) before and after stimulation.We successfully replicated the coupling phenomenon, though the phase of breathing-action coupling was not as strong in our study (suggesting a lower effect size). We also found a trending effect of the region of TBS breathing-action coupling (p < 0.05). We plan to gather more participants to solidify the effect of the TBS target on the breathing-action coupling.

Abstract Name: Environmental Racism at the Heart of Extraction: Chemical Usage in LA County Oil Fields with Respect to Community Demographics

Los Angeles has a long history of oil extraction that has been linked to segregation and redlining. Oil fields like Inglewood, Beverly, and Cheviot Hills have been extracting resources for nearly a century. However, residents living near these oil fields have different sociodemographic circumstances that may affect oil extraction practices and contribute to environmental racism. Oil extraction uses chemicals in well maintenance and stimulation that maintain the integrity of the well and promote oil extraction. Some of these chemicals are known to be hazardous to human health. To evaluate the correlation between sociodemographics and chemical usage in LA County oil fields, I will construct Geographic Information Systems (GIS) generated maps using R to analyze the sociodemographic distribution of oil field adjacent residents and the chemical distribution of LA County Oil Fields. I will evaluate the South Coast Air Quality Monitoring District (SCAQMD) chemical usage from 2015 to 2019 based on chemicals per oil field event. I will utilize statistical tests to argue if chemical usage in oil fields adjacent to lower-income BIPOC communities will be higher than in more affluent white neighborhoods. This research will be essential for environmental epidemiology as LA County plans to phase out oil extraction by 2042. The county must

efficiently clean oil operations to ensure LA communities that have experienced environmental racism are treated equitably.

Abstract Name: Linguistics and Belonging: Exploring Gender Inclusive Language for Non-Binary Identities in Spanish

In English, gender-inclusive language has been adopted relatively quickly, while in other languages, like Spanish, an attempt to be inclusive usually collides with confusion and conflict, both socially and grammatically. New expressions of gender and gender identities are gaining recognition and acceptance by many communities around the globe, however not all languages are built equal regarding the linguistic rights and visibility of non-binary people. In the way that language reflects society, the words we use about gender-nonconforming people can shape their sense of belonging, as well as other people's perspectives. This can be difficult for languages like Spanish that at their core rely on a gendered perspective, and require new ideas for encouraging inclusivity. Based on the review of the theory, literature, and institutional programs, I will present the outcomes of my research by taking into consideration the needs of non-binary Spanish speakers and their linguistic rights. In this paper, first, I aim to identify and explain what exactly is gender-inclusive language and which arguments support or oppose it. Second, I will analyze what strategies and programs Spanish-speaking countries have enacted up to now. Finally, I will make recommendations on how gender-inclusive language can be promoted within these Spanish-speaking communities. I had the opportunity to spend a semester learning Spanish in Latin America, where I met a non-binary Spanish speaker. Throughout the time I spent with them, I observed their interactions with others, and despite it being provided, few people seemed to respect their preferred subject pronoun. It is important for people to feel like they have a place in their own language, and moreover their community. By educating others on the importance of gender-inclusivity in all languages, we can make our society more inclusive and change the way it views non-binary people.

Abstract Name: To What Extent Does Gene Flow Occur Among Earthworm Populations?

Earthworms are not native to Minnesota, but are now common across the state. Earthworm feeding diminishes the duff layer of forest floors and alters soil conditions in ways that can be detrimental to the growth of native plants. While now widespread, little is known about the extent to which earthworms naturally disperse. To investigate this, we sampled earthworms from areas of differing distances apart in

Itasca State Park (in northwestern Minnesota), and used allozymes to genetically analyze individuals to assess the extent of gene flow among populations. Gene flow is an important process promoting genetic diversity in populations from migration of individuals and introduction of alleles among populations. Populations with greater genetic variation are more resilient to environmental/ecological change. Typically, populations further apart or isolated from each other by a physical barrier experience less gene flow. We sampled earthworms from plots at various distances along a 16 m transect, and from at two other sites several km away (one near the shore of a lake, and one on an island within the lake), and assayed the worms for two allozyme loci. Allele frequencies were used to calculate genetic distances among areas sampled. Consistent with expectations, the island population was the least genetically diverse and the most genetically distant from the other sites. 'Populations' sampled along the 16 m transect differed from each other somewhat, but not to the extent that they did to the two other populations (lakeshore and island). These results imply that dispersal and gene flow maintains relative genetic homogeneity at distances within 16 m, but that genetic differentiation occurs at further-spaced distances, especially when physical barriers inhibit dispersal (e.g. mainland vs. island). Future research will extend the transect sampling to try to determine the geographic distance at which earthworm populations become distinct from each other.

Abstract Name: Low-Cost Shortwave-Infrared Spectroscopy (SWIRS) for Stroke Risk Screening in Pediatric Sickle Cell Disease: Computational Study

Sickle cell disease (SCD) has a profound effect on the brain. In sub-Saharan Africa, where most SCD patients (~75%) live, access to medical care is limited and ~11% of SCD children will develop a stroke by the age of 20. Although early identification is critical to treatment, transcranial doppler ultrasound (TCD), the standard screening tool, is not widely available due to its high cost and need of trained personnel. Speckle contrast optical spectroscopy (SCOS) may provide a user-friendly and cost-effective solution to this unmet need. SCOS is an emerging optical technique that can quantify blood flow in deep tissues at an inexpensive instrumental cost. However, the technique suffers from insufficient signal-to-noise ratio (SNR) and the detected signals are significantly contaminated. Therefore, we propose SCOS operating in the shortwave infrared (SWIR, 900-1700nm) region rather than its traditional near-infrared (NIR, 700-900nm) light source for enhanced depth penetration. To investigate the feasibility of SWIR SCOS, we performed computational verifications to compare against the NIR SCOS system. Both wavelengths were simulated with Monte Carlo Simulation MC Extreme (MCX) onto a two-slab layered model mimicking scalp-skull, and brain layers. The results indicated that SCOS data at 1064nm with an added noise model was less noisy compared to SCOS data at 785nm, and had more photons detected. The overall estimation accuracy of estimating blood flow for 1064nm SCOS was also higher than 785nm SCOS. These initial results give a basis for developing a more realistic MRI-based human head atlas model. As a next step, we will set up a benchtop SCOS system for experimental verification and initiate the design of a low-cost prototype based on these results.

Abstract Name: Physics Informed Neural Network for Solving the Shallow Water Equations on Grids of Arbitrary Geometry

Many physical phenomena exhibit wave behavior, including fluids, acoustics, and electromagnetics. When simulating wave behavior, one difficulty that is often encountered is wave reflections, which can lead to numerical oscillations, especially on grids with complex geometries. In this research, we investigated if a neural network can accurately model wave behavior when extensive reflections are involved. If proven true, such a neural network would be very useful, as neural networks are amongst the fastest techniques for solving mathematical models. To test this idea, we trained a neural network to simulate the shallow water equations on a grid where the right boundary is fitted to a 5-point, 8-point, or 11-point spline. The simulation scenario called for a wave to be given an initial velocity in the right direction, causing it to impinge upon and then reflect off of the right boundary. To make the task even more difficult, we allowed the initial wave location to be a random point on the grid. Our training methodology involved both supervised learning with sample data points and unsupervised learning with the residuals of the shallow water equations acting as a loss function. Throughout the course of five experiments, the neural network learned to model wave reflection with a mean squared error of 9.7797E-06 for the simplest scenario and 1.6595E-05 for the most complex scenario. We have proven that a neural network is capable of learning wave behavior with reflections, with applications in computational acoustics to the modeling detonation wave reflection.

Abstract Name: An Oral Microbiome Portable Analysis Device, LifeSmile, Can Indicate Symbiosis or Dysbiosis Using CRISPR-Cas12a and CANTRIP in a Two-color Bacterial Abundance Ratio Readout

Keystone bacteria within an oral microbiome can be indicators of gum health and diseases. Preterm labor, cardiovascular disease, cancers, and neurodegenerative illness are tied to two keystone species. The LifeSmile, an oral microbiome diagnostic device, is designed to rapidly generate an “abundance ratio” of the number of Fusobacterium nucleatum, an anaerobe to Streptococcus sanguinis, its facultative partner bacteria. Tooth microbiomes collected from individuals with Next Generation Sequencing (Nextgen) surprisingly had easily measurable levels of the abundance ratio. Nextgen sequencing is not a portable or rapid method. Previously the LifeSmile technology approached the problem of determining the abundance ratio with DNA extraction, LAMP, and CRISPR-Cas12a with two offsite color FRET targets. This portable, palm-sized device, displayed the abundance ratio, indicating positive dysbiosis. We hypothesize that a new compatible technology, CRISPR-Cas12a and Activated Nuclease poly-T Reporter Illuminating Particles (CANTRIP) could be run in parallel in the same reaction, giving two individuals signals (Fusobacterium on CANTRIP red fluorescence channel and Streptococcus on green fluorescence Cas12a offsite cleavage target). The addition of CANTRIP as a second signaling detection assay is hypothesized to serve as a faster, more efficient method to generate the keystone bacteria ratio due to its dual detection system from combined enzymes (CAS12a and terminal deoxynucleotidyl transferase TdT), which generate easily visible green fluorescence and red copper dual signals. The LifeSmile, a project developed by student researchers, is envisioned to be a robust point of care oral healthcare diagnostic device to provide patients with on demand, preventative assessment of oral symbiosis or dysbiosis.

Abstract Name: Pathways to Undergraduate Research Success: Voices from a Qualitative Researcher and Mentees in Educational Research

The benefits of undergraduate research embedded in courses for academic excellence is well known. However, mentors' and mentees' experiences with qualitative education research, which typically has challenges involving undergraduate researchers, is scarcely researched. My presentation has two foci. First, I will share my insights gained through mentoring undergraduate researchers from diverse disciplines on my interconnected research, Supporting Multilingual Learners and Their Teachers, Parents, and Communities (MLTPC) at a public R2 university. I will present my mentoring strategies by qualitatively analyzing materials that I have developed and reflections that I have kept for the last two years. Second, I will examine experiences of 10 undergraduate researchers who have engaged with me on the MLTPC project. I will qualitatively analyze their research logs, which include their reflections, conversations in meeting recordings, and other pertinent artifacts produced by them. Furthermore, three of the students as co-presenters will reflect on their research experiences with me from their own perspectives. Individual and focus group interviews will be conducted to generate the focal students' voices in the research process. Preliminary findings of the data sources will likely include students' deepened connections with their own immigrant parents through the research and increased critical understanding about linguistically minoritized populations in their country of origin and in the U.S. The students will also draw connections between their experiences in educational research and potential contributions to their fields. The mentees and I, the mentor, will also share what has worked and what has not, which will have implications for future directions. This presentation will be beneficial to all students, faculty, and/or staff involved in undergraduate research. It will particularly be inspiring for mentors who conduct small-scale qualitative research in fields known as soft sciences and who do not have much experience with undergraduate research mentorship.

Abstract Name: Predicting Social Anxiety Symptoms: Examining the Varied Impact of Brooding and Self-Reflection

Brooding and self-reflection are interrelated rumination processes, but they are distinct constructs. Brooding (or rumination) refers to repetitive, negative thoughts, which do not help generate a solution for a given problem. In contrast, self-reflection involves acknowledging strengths and weaknesses, and learning from mistakes and is generally a growth-oriented process. However, there is little research on whether the two

different rumination styles are associated with social anxiety disorder (SAD). This research aimed to examine whether brooding and self-reflection predict various aspects of social anxiety symptoms after controlling for demographic features and general emotional distress. As a part of a larger clinical outcome study, participants underwent a diagnostic interview and were divided into two groups based on their SAD diagnostic status: social anxiety disorder and non-socially anxious. All participants completed the Rumination-Reflection Questionnaire, which assesses brooding and self-reflection. Additionally, measures of social anxiety-related symptoms were assessed, including overall fear and avoidance of social situations (LSAS-SR), fear of evaluative situations (BFNE), and negative interpretations of social situations (ASC). Results of hierarchical regression analysis showed that brooding and self-reflection were significant predictors of social anxiety symptoms in the non-socially anxious group, particularly cognitive symptoms such as fear and concern about negative evaluation. However, brooding and self-reflection style did not predict social anxiety symptoms among those diagnosed with social anxiety disorder. These findings indicate that for those who are developing social anxiety symptoms, self-reflection may function as a protective factor whereas brooding may serve as a risk factor. Further research is warranted.

Abstract Name: Chemical and Optical Characterization of Produced Water from the Permian Basin Oil Field

Oil field-produced water is generally a mixture of petroleum, dissolved organic matter, rare metals, and contaminants. For recycling and metal recovery, knowledge about the chemical matrix of this produced water is indispensable. Forty samples were collected from the largest US petroleum basin and analyzed for major ions, dissolved organic carbon (DOC), and chromophoric and fluorescence dissolved organic matter (CDOM and FDOM). Concentrations of major ions (mg/L) ranged from 4,101-63,953(average 17,490±14,338) for Na+, 920.4-11,334.9 (4,054±2300) for Ca+2, 57.6-719.2 (403±184) for K+, and 128-1850 (689±421) for Mg+2, surpassing those of Na+ and Ca+2 in seawater and similar for K+ and Mg+2. Molar ratios of Mg+2/Ca+2 ranged from 0.21-0.56 (average 0.28±0.06), which are much lower than those in contemporary seawater (4.9-5.3). Concentrations of DOC ranged from 7.6-96.5ppm (average of 38.3 ± 23.3ppm), while CDOM (absorption coefficient at 254nm, a254) varied from 59.72-480.1m-1 with an average of 156.2±97.1m-1. There exists no significant correlation between DOC and CDOM, indicating that this produced water contained different sourced DOM. Specific-UV-absorbance at 254nm (SUVA254), an indicator of aromaticity, ranged from 0.0027-0.0933 L/mg-C/m, with an average of 0.024±0.019L/mg-C/m. Spectral slope (S275-295), inversely correlated with molecular weight, varied from 0.0013 to 0.0604nm-1. Parallel-factor analysis (PARAFAC) on fluorescence-EEM identified 4 major fluorescent components: three protein-like or oil-like (C1, C3, C4) and one terrestrial humic-like (C2). Fluorescence-index (FIX), humification-index (HIX), and biological-index (BIX) varied widely, indicating diverse DOM sources (terrestrial, microbial and oil), consistent with the poor correlation observed between DOC and CDOM. Our results provide an improved understanding of sources and properties of oil field-produced water and scientific bases for better disposal, recycling, and metal recovery.

Abstract Name: Impacts of diapause on blood-feeding behavior and fecundity of the invasive Asian tiger mosquito, Aedes albopictus

The Asian Tiger Mosquito, Aedes albopictus, is a public health threat because it transmits mosquito-borne pathogens (MBP), exhibits aggressive diurnal biting, and is highly invasive. MBP are transmitted by the bite of an infected female mosquito during blood-feeding. The invasion of Ae. albopictus in temperate regions can be attributed to the survival of eggs in cold conditions through a slowed metabolic state known as diapause. Diapause is induced by shortened photoperiods, after which females lay diapause eggs that are cold and desiccant-resistant. These eggs require greater metabolic resources. Given the greater metabolic requirements and biological differences of diapause eggs, this study was designed to evaluate how blood-feeding behaviors differ between non-diapause and diapause-induced female Ae. albopictus from a colony of mosquitoes that originated in Illinois, USA. We reasoned that increased resource demands placed on females preparing to lay diapause eggs could prompt an increase in feeding events, contributing to greater pathogen transmission potential. Non-diapause (27℃, 85% RH, 16:8 L:D) and diapause-induced (21℃, 80% RH, 8:16 L:D) Ae. albopictus adults were offered a blood meal and allowed to feed for 45 minutes. Feeding was videoed and the number of feedings and engorgement were recorded at five-minute intervals. Using Tracktor software, videos were analyzed to quantify the total time spent feeding in each trial. Non-blood-fed control and post-blood-fed mosquitoes were cold anesthetized, weights and wing measurements were recorded. After blood-feeding, female mosquitoes were provided with paper as an egg-laying substrate for seven days. The papers were photographed and the eggs were counted. The data suggest that inducing diapause changes blood-feeding behaviors, which could have implications for seasonal risk of pathogen transmission by Ae. albopictus in temperate regions.

Abstract Name: The extent to which creative art interventions can help mitigate symptoms of anxiety in adolescents with a focus on generalized anxiety disorder and social anxiety disorder

In this systemic review, the central questions are (1) to identify literature concerning effectiveness research on creative arts expression on adolescents with social anxiety and generalized anxiety disorder, (2) to review the results of this research, and (3) to draw conclusions on the effectiveness of creative arts expression in the treatment of anxiety levels in adolescents. The review reports the extent to which art therapy and creative art interventions can help mitigate symptoms of anxiety in adolescents with a focus of diagnosis of social anxiety disorder and generalized anxiety disorder.To access the effects that creative art interventions can have on anxiety levels a cross sectional quasi-experimental design was implemented in order to compare the mitigating effects that creative art interventions can have on an adolescent's anxiety levels. Additionally, a pretest and posttest design were also implemented into order to compare participants anxiety levels before and after the creative art intervention. A separate analysis on adolescents with generalized anxiety disorder and social anxiety disorder was also completed within the same study.It was concluded that adolescent's

anxiety levels did decrease as a result of the creative art intervention. It was further concluded that adolescents with generalized anxiety disorder and social anxiety disorder had even more decreased levels of post anxiety scores.

Abstract Name: Natural Language Navigation for Robotic Systems: Integrating GPT and Dense Captioning Models with Object Detection in Autonomous Inspections

Autonomous Unmanned Aerial Vehicles (UAVs) are rapidly transforming industries requiring inspection and surveillance. However, conventional UAV systems often require complex control schemes and lack adaptability, limiting their efficacy in variable environments such as indoor inspections. This paper introduces an innovative system integrating the cutting-edge Generative Pretrained Transformer (GPT) models and dense captioning models for autonomous navigation and fault detection in indoor environments. Our approach, displaying human-like flexibility, allows the drone to interpret and respond to natural language commands, vastly enhancing its accessibility and user-friendliness. Simultaneously, the drone utilizes object dictionaries derived from dense captioning of its captured images, facilitating an advanced understanding of its surroundings. These capabilities equip the drone to adapt its behavior and effectively handle unexpected scenarios, significantly enhancing the efficiency and accuracy of indoor inspections. This research contributes to revolutionizing building inspections, making the process more user-friendly, and localizable to a broader user base.

Abstract Name: Psychological Factors, Social Factors, and Potential Barriers Related to the Non-Use of University Writing Services

Our current research seeks to inform the ongoing development of first-year academic intervention at the University of Texas Permian Basin and add to the larger body of research regarding use of tutorial services. Our university is a public 4-year Hispanic-serving institution in a small southwestern city. Writing centers have often struggled with extreme underuse of their services, especially within academically at-risk populations. The factors contributing to this under usage is an oversight within composition and writing center studies. Looking at the psychological and social factors, and potential barriers involved within non-use

of writing tutorial services can help to increase their utilization. As writing consultations correlate with student success outcomes, understanding these factors can help improve first year retention, reduce academic probation cases, and increase graduation rates. Our research will take the first step in accomplishing this by collecting both qualitative and quantitative data on undergraduate students. Quantitative self-report data will be collected on writerly self-efficacy, academic help-seeking behavior, student self-determination, writing apprehension, self-stigma, accessibility, service satisfaction, awareness of services, and academic motivation via a survey. Additionally, differences in native language, socioeconomic status, first-generation status, and other demographic variables will be examined. Focus groups will collect qualitative data concurrently to supplement the survey with practical examples of student experience and discover potential unseen factors. The researchers are all previous or current student mentors, writing tutors or supplemental instructors within the university's student Success Center. The current study has a recruitment goal of 180 undergraduate participants at the University of Texas Permian Basin. Special emphasis for recruitment will focus on non-users, specifically those in their first or second year of university, and those in remedial English classes. Data collection will be complete by March 2024.

Abstract Name: Exploratory Study of UWEC/UWEC-BC Students in Recovery

This exploratory study builds on earlier research conducted in 2020 by Dr. Aaron Willis at Salisbury University. The present study was created to build off the findings from three years ago and begin the process of understanding the unique needs of UWEC/UWEC-BC students who identify as being in recovery from drugs or alcohol. The purpose of this study is to estimate the number of UWEC/UWEC-BC students who identify as being in recovery from substance misuse and if they would benefit from having recovery-related resources available on campus. An online anonymous survey through Qualtrics was used to gather results. An email was sent campus-wide and included the study information and a link to the survey. Posters with the same criteria were posted around popular campus buildings as well. The survey is still open and we have not analyzed the current results yet. The findings from the previous study indicated that 16.4% of Salsibury students identify as being a person in recovery from drugs and/or alcohol. The 2020 study also concluded that only 25.6% of Salisbury students believe that there are adequate resources available at Salisbury University for people in recovery. The anticipated results would support the previous findings. We expect there to be concerns regarding recovery-related services on the UWEC/UWEC-BC campuses. The upcoming results will either confirm or contradict with the previous study’s findings. Depending on the findings, there may need to be some changes in the way the University of Wisconsin-Eau Claire approaches support and services for those in recovery.

Abstract Name: Analyzing Security on IoT-based IP Camera Systems

With millions of devices connected in cyberspace, attackers now have many opportunities to exploit Internet of Things (IoT) systems. Most IoT vendors do not consider implementing security mechanisms in the devices that they produce, whether it be due to cost or resource restrictions.Threat modeling systematically identifies possible attack vectors against a system or device and then prioritizes the issues based on their severity. Once the system is implemented, vulnerability assessments are done periodically to identify potential exploits or weaknesses in a system. The result of the process allows cybersecurity experts to propose solutions that can mitigate these risks. The purpose of this project is to use forensics methodologies that are normally used in information technology (IT) enterprise intranets, in the context of IoT systems.Surveillance camera systems are now considered to be IoT-based due to the possibility of integrating cameras over an internet or local area network. This project presents a test implementation of an IoT-based camera system using open-source technologies and protocols commonly implemented in commercial solutions. The prototype monitors a given area in a remote location using servo motors that are connected to Raspberry Pis to support pan and tilt (PT) functionality for the cameras. In this project, we use OWASP's Risk Rating Methodology to identify and rate the likelihood and technical impacts of potential risks on our IoT surveillance network. We used well-known and trusted vulnerability assessment tools to assess vulnerabilities in our implementation of the system. Based on the results of the vulnerability assessment, we performed a series of attacks on the system to compromise the confidentiality, integrity, and availability of the system and data. Using forensics methodologies, we collected and analyzed data including logs and network traffic to identify who performed the attacks, how they were conducted, and what data, if any, was compromised.

Abstract Name: The Cognitive Effects of Birding as A Recreational Activity on Mood, Stress, and Anxiety

Participating in birding results in a decrease of stress and feelings of anxiety within individuals as well as an increase in the rate of experiencing a positive mood. To test this hypothesis, the researcher designed a quasi-experimental study which administers a survey which analyzes the mood, stress levels, and anxiety levels of both birders and non-birders in the form of a birdwalk. At the conclusion of the birdwalk, the participants completed a post-test in the form of the same survey as the pre-test minus the demographics' assessment. The data was analyzed using a related samples T-test. The birdwalk did not have a significant difference on the moods, and stress levels of the participants. Due to the small size of the data set used in this study, the findings of this study are not necessarily accurate. This procedure needs to be replicated and repeated more times to provide more reliable findings in response to this research question.

Abstract Name: The Influence and Impact of Content Creation in Public Relations: Influencers, Consumers, and Brands

Content creation has become one of the most powerful forms of communication in our current era of digitalization and media. It is essential to understand content creation's impact within public relations, as it is an entirely new way of connecting with people, particularly when it comes to our existing environment. Content has the ability to convey messages, which bolsters engagement with publics and stakeholders and overall helps to maintain brand image and reputation. When creating content, creators have the ability to tell a story, which has proven to be much more engaging in video form as opposed to other forms of media such as text or advertisement banners. Short-form content such as TikTok videos has the ability to foster a strong and reputable relationship with viewers, in turn creating a positive brand image.

Abstract Name: Predisposition Gene Identification for Obesity-Associated Melanoma

The potential links between various cancers and severe obesity (BMI≥35 kg/m2) have long been investigated. Previous studies of the heritability of both obesity and melanoma independently suggest that the genetic components outweigh the environmental components. Utilizing a unique approach with rare resources, potential rare, shared coding variants to likely predispose individuals to both melanoma and obesity were identified. Currently, Genetic Epidemiology has 400 melanoma cases with whole exome sequence (WES) data with some in pedigrees. 30 of these cases also have severe obesity. The sequence data of cousin pairs with both melanoma and BMI≥33 was analyzed to generate a list of 120 candidate variants. All cousins belonged to high-risk melanoma pedigrees that were identified using Utah genealogy data that has been tied to multiple public and medical records. Using the data of other family members with both melanoma and obesity where available segregation was assessed. The association of each candidate variant with obesity and melanoma was assessed through previous Genetic Epidemiology predisposition studies, Ingenuity, and UK Biobank. 2 variants in genes POMC and KLHL29 were carried together in one other affected individual in the same family. Both the POMC and KLHL29 genes have been independently associated with melanoma and obesity separately. Taking this unique approach has identified several candidate predisposition variants for both obesity and melanoma including the POMC and KLHL29 variants that segregated with both obesity and melanoma in the pedigree it was observed.

Abstract Name: Tuning Drug Release from PLGA Particles

Nanoparticles have been used in various biomedical applications including drug delivery. Particle size influences critical factors such as cellular uptake and drug release. However, the current laboratory protocol for poly(lactic-co-glycolic acid) (PLGA) particle synthesis yields a broad particle size distribution, leading to inconsistent results. Here we developed a protocol to isolate particles of various sizes and assessed the relation between particle size and its drug release kinetics. Particles were synthesized using the double emulsion method and separated by size via centrifugation. Using Dynamic Light Scattering (DLS), we verified that particles were separated into 50 nm increments using the newly developed method. Preliminary data show that smaller particles display a higher drug release at early timepoints than larger particles. In addition, we also observed that same-size particles with higher Molecular Weight (MW) exhibit a slower drug release. These findings improve particle synthesis and expand our ability to tune particle properties. We are currently investigating the effect of particle size, and therefore drug release kinetics, in macrophage phenotype using Drug 1, a potent anti-inflammatory drug as the cargo.

Abstract Name: Worms like Coffee too: Mapping the Sensorimotor Circuits That Coordinate Coffee Sensation

The coffee industry reaches over 80 billion US dollars in revenue partially due to the numerous chemicals that allow for coffee's highly attractive aroma and flavor. Many people integrate coffee into their everyday routine; therefore, understanding why people are attracted to coffee can allow us to 1) characterize its attractive nature and 2) better understand how humans interpret a complex smell and taste on a molecular and cellular level. Although many are coffee consumers, the mechanism and characterization of coffee attraction have yet to be fully understood. We report that the model worm, C. elegans, with only 302 neurons, can smell and perform strong attraction behavior towards various coffee types. Using the model worm, we have identified worms to be strongly attracted to coffee. We have also characterized the neural architecture that drives this sensori-motor behavior. Ultimately, we provide a platform to thoroughly understand the mechanisms and future neuronal circuits that mediate sensory-guided behavior to a complex human-sensed stimulus

Abstract Name: Jet Optimization Using a Hybrid Multivariate Regression Model and Statistical Methods in Dimuon Collisions

Heavy ion collisions, in this case, muons, result in jets and noise. Jets are crucial event-shaped observable objects that are used in high-energy particle physics, i.e., they are one of the many objective variables that we can measure to determine the properties of a collision. However, many ionic collisions result in large amounts of noise, taking away from the jets' energy, increasing the energy lost, and thus reducing the efficiency of collisions with heavy ions. Our focus is specialized to dimuon collisions and improving the efficiency of said collisions. The purpose of our study is to analyze the relationships between properties of muons in a dimuon collision to optimize conditions of dimuon collisions and minimize the noise lost. We used principles of Newtonian mechanics and their use cases at the particle level, allowing us to further analyze and conjecture different models and equations. Tools we used were simple Python algorithms as well as linear regression models with tools such as sci-kit Learn, NumPy, and Pandas (1 & 2). Our hypothesis: the invariant mass, the energy, and the resultant momentum vector play a large role in determining the noise in a dimuon collision. If we constrain these inputs optimally, there will be scenarios in which the noise of the heavy-ion collision is minimized.

Abstract Name: Association Between Area Deprivation Index and Outcomes After Subarachnoid Hemorrhage

Subarachnoid hemorrhage (SAH), a type of life-threatening hemorrhagic stroke caused by bleeding in the arachnoid space of the brain, often results in long-term disabilities and poor quality of life (QOL). Individuals living in more advantaged neighborhoods report higher levels of QOL post-stroke, but little has been reported about QOL and neighborhood data after SAH. This study examined the relationship between neighborhood data using the area deprivation index (ADI), measures of functional outcomes, and QOL at 3- and 12-months after SAH at a single stroke center. General outcome was assessed using modified Rankin scale (mRS), where 0 is no deficit and 6 is death. Physical QOL (PCS) was assessed using 20 items of the 36-item short form survey (sf36). The ADI was obtained using the University of Wisconsin School of Medicine

Neighborhood Atlas and patient zip codes, where higher scores indicate increased deprivation. Demographic and clinical data was obtained from the patient, chart, or caregiver.Outcomes were obtained by interviews with the patient or caregiver. A retrospective analysis of 215 SAH patients (mean age 54 years, 76% female, 84% white) used logistic and linear regression models to examine ADI measures (state decile, national percentile) and outcome variables controlling for stroke severity, age, race, and gender. Significant relationships were identified between ADI measures and PCS at both 3 and 12 months after SAH. For each one unit increase in ADI, the change in 3 month PCS was -3.711 (p<0.001). For each one unit increase in ADI, the change in 12 month PCS was -4.364 (p<0.001). There was no relationship between ADI measures and MRS at 3 or 12 months.This analysis suggests that individuals from areas of higher deprivation report poorer physical QOL as measured by the sf36. Targeted interventions for patients in areas of higher deprivation warrant investigation.

Abstract Name: The Impact of Exercise on ADHD Phenotypes in Zebrafish

Diagnoses and prescriptions for attention deficit hyperactivity disorder (ADHD), a human disorder prevalent in children, have increased dramatically in the last decade for unknown reasons. Currently, medication is the most common treatment for ADHD, and the most commonly prescribed medication, methylphenidate, is a stimulant with many adverse effects. However, some studies show that exercise is beneficial in managing signs and symptoms of ADHD, both in addition to and instead of medication, depending on the severity of ADHD. This research used zebrafish as the model organism to examine the effects of lead and exercise on a behavioral variable to measure ADHD severity due to their gene conservation and easily monitored behavior patterns. To conduct this research, a swim tunnel was constructed to exercise the zebrafish for 30 minutes daily for 10 consecutive days to represent chronic exercise. The behavioral variable, thigmotaxis, is the percentage of time spent on the outer edge of a petri dish. Thigmotaxis data was collected from video recording fish from above after interventions were implemented, including lead exposure at 1 milligram per liter to induce ADHD-like behaviors as well as exercise to combat them. The values for thigmotaxis of all the fish in three groups (control, exercised, lead-exposed) were averaged and the percentages from each intervention were compared using ANOVA analysis, followed by paired t-tests when statistically significant. Analysis revealed decreased thigmotaxis with lead exposure compared to control and exercise groups, both in the acclimation period ($p = 3.7 \times 10\text{-}3$) and the thigmotaxic period ($p = 1.3 \times 10\text{-}5$). No significant differences in thigmotaxis were observed in either the first minute or the last minute across groups or within any particular group.

Abstract Name: The Role of Nursing in Preventing Ventilator-Acquired Pneumonia Through Oral Care: An Evidence-Based Project

Abstract:Objective. This work undergraduate project sought to evaluate the potential impact of nurse-led oral hygiene practices on the incidence and outcomes of ventilator-acquired pneumonia (VAP) in adults in the intensive care setting.Background. Despite the availability of guidelines and protocols, there is a lack of consistency and adherence among nurses in performing oral care. This project attempts to address this issue by identifying possible barriers to oral hygiene practices and proposing strategies for improvement. It provides a comprehensive review of the evidence on the effectiveness of performing oral hygiene and its impact on VAP incidence and outcomes.Methods. This evidence-based project answered the question of "What role do nursing-led oral hygiene practices impact the incidence and outcomes of ventilator-associated pneumonia in intensive care units?" The databases utilized were from the University of Central Oklahoma Chambers Library using keywords about the topic. With many of the barriers being lack of education, accountability, and inadequate technique, a solution of enrollment of competencies, skills review, proper documentation, and follow-up surveys will be utilized as preventative measures. Conclusion. The results of this project are based on the literature and indicate that when oral hygiene is performed consistently and correctly, the incidence and outcomes of VAP in ICUs will be significantly reduced. Some barriers to implementation by the staff include lack of knowledge, lack of training, time constraints, and lack of readily available resources. The findings from this project will be used to influence evidence-based guidelines, create standardized oral assessments and documentation, enhance education and communication among staff, and propose further research to close any gaps in the literature. Overall, the goal is to improve the quality of care and outcomes for ventilated patients in ICUs.Key words. critical care, mechanically ventilated adults, nurse education, oral care, oral hygiene, compliance, ventilator-acquired pneumonia.

Abstract Name: Locating a Mass Execution Trench From The Holocaust/Shoah: Subsurface Imaging Within a Coastal Dune System, Šķēde, Latvia

Unmarked graves within conflict zones have been a prevalent occurrence in all parts of the world. In the present day, the precise locations of many of these burial sites' remain uninvestigated. One such site is in Šķēde, Latvia, where 2,700 women and adolescent Jewish residents were killed by Einsatzgruppen Group A and complicit Latvian collaborators during the Jewish Holocaust in 1941. The goal of the research is to utilize ground-penetrating radar (GPR), a geophysical tool that can image the subsurface, to aid in locating one of the trenches depicted in the 1945 Polish Commission Report. According to archival photos of the execution, the Jewish citizens were shot and fell into a trench dug parallel to the Baltic Sea. Data was collected using a Sensors and Software_ pulseEKKO® GPR Pro system with an antennae frequency of 500 Megahertz (MHz). Traces were collected every 0.02m triggered by an odometer wheel. Lines within the grid were collected

0.25m apart. Three grids were collected in the summer of 2023, with the primary focus of the project interpreting the northernmost grid measuring 14x15m. The grid was collected behind an established foredune, in an area of continuous low herbaceous vegetation. Within the grid, an elongated depression is apparent on the surface, evident of anthropogenic influence.The lines within the grid were collected towards the east, while the elongated depression was oriented north and south, parallel to the shoreline. On the profile, reflections depict dipping starting on the 9 meter mark on the y axis. Dipping reflections can be seen bordering both sides of the elongated depression declining inwards. The disturbance within the stratigraphy appears to be human influenced. With that, and what has been documented in historical imagery, it can be insinuated that the elongated depression is associated with the Šķēde executions.

Abstract Name: Emma

Created from a found object (a porcelain doll), a microcontroller connected to a speaker and a proximity sensor, and an original sound file, Emma is an interactive sound sculpture designed to express how my mind felt during my recent struggles with anxiety and grief—that seemingly unending feeling of dread, the sadness, and the inability to think clearly inspired this piece. The sound used is from an original composition made using VCV Rack. That composition was then edited in Adobe Audition until it became a sound that felt like it could have been the soundtrack to my experience with dealing with grief. I chose to use a doll because dolls usually evoke thoughts of childhood; however, this doll has a haunted air and a darkness accentuated by the sound that starts as a person approaches her. This piece is influenced by Graphite Ground by Liz Phillips, an interactive sound installation that used natural conductors to create sound based on proximity. I chose to work with electronics as I’m interested in how software and coding can further my art pieces, and I wish to experiment with incorporating my sound art pieces into sculptures. While working on this piece, I learned more about coding and the use of electronics in art, including the complexities of wiring a project. I also learned how attaching a sensor to a project can change the entire feel of the piece.

Abstract Name: COVID-19 Impact on Children’s Social Emotional Behaviors Mediated by Various Factors

The impact of COVID-19 on young children has significant social-emotional implications. Studies currently show mixed findings with limited post-COVID data. Young children missed essential experiences early in life relating to social, emotional, and language development due to COVID-19, which is correlated with worsened adult-child relationships in children under six years of age (Erwin & Frey, 2023). Schooling disruptions led to negative parental mood, worse child behavior, and increased loss of temper in children aged 3-8 (Gassman-Pines et al., 2022). However, a potential positive emotional effect was found on mental

well-being for children 7-11 due to reduced academic stress and increased attention from caregivers, but this same study also indicated significant somatic, cognitive, and worry reactions, especially in older children (Larsen et al., 2022). Still, other studies found no significant behavior effect in financially stable parents of 3–5-year-olds, although hyperactivity and loneliness were slightly elevated (Linnavalli & Kalland, 2021). Another factor related to social-emotional behavior and peer interaction is language. Recent studies showed that preschool children affected by COVID-19 are experiencing significant problems with verbal language and social communication, likely due to distance education, limited exposure to the social environment, and lower family interaction (Erbay & Tarman, 2022). Children with already-known language delays experience a higher decrease in language production due to COVID-19 (Hsu & Wong, 2023). However, research indicates speech therapy can contribute to positive social-emotional outcomes. Past studies showed intensive speech therapy increased confidence and social participation, leading to more successful conversations with people in various environments (Pennington et al., 2020). The current project aims to examine COVID-19's impact on social-emotional behaviors in young children (ages 3-4) in various programs, including speech therapy. Data consists of ratings from teachers using Social Competence Behavioral Evaluation forms (LaFreniere, et at. 1995) and observations. Detailed results and implications will be shared at the conference.

Abstract Name: Methods for Designing XR Multi-User Experiences

The research objective is to identify and generate a design methodology for creating digital galleries by using interactive experiences in virtual reality (VR) multi-user environments. This research integrated accessible User Experience (UX) and Extended Reality (XR) as theoretical and technical foundation (Bustos, et all 2021). The resulted methodology has three-phases: I. [Conceptualize] We used established 3D architectural modeling programs, developing 3D scanning technologies, as well as traditional physical design methods to create a conceptual model. Student's physical models were scanned using photogrammetry and were formatted for import into the conceptual model. II. [Visualize] The model was converted, using plug-ins specially developed for the 3D-design program, into a virtual and augmented reality (AR) platform which allowed us to examine visual aspects of the design and make adjustments. III. [Implementation] The converted concept model was placed into a meeting room, using the platform, for students to participate in a multi-user experience. The experience was then evaluated from two sets of perspectives, evaluators (students) and observer (creator). Students utilized virtual reality headsets and controllers to move around the gallery and view the models on display. Feedback was positive and provided insight for areas to adjust the model and user experience. Developments in XR environments and technologies have created more opportunities for galleries and museums to extend their reach with larger audiences, facilitate community engagement, display artworks from museum archives, provide additional revenue streams, empower the knowledge ecology (Sibley, 2019), enhance the perception of interactive space, and increase the viewership of curated exhibitions. Successful implementations would provide desirable experiences for a wide audience and have a greater level of accessibility than the physical environment could allow. KEYWORDS: Digital Accessibility; Virtual Museums; Extended Reality, User Experience, MUVE (Multiuser Virtual Environment)

Abstract Name: Effectiveness of Social and Academic Resources In Low-Income Neighborhoods

The purpose of the study is to assess the effectiveness of social and academic resources in low-income neighborhoods. Cresson Pods was established in 2019 as housing for low-income households. The housing pods provide a secure living space for 275 households. However, the pressing issue was the houses were in the middle of nowhere and left many families with nothing to do outside of the home. United Way partners with various agencies to provide youth with resources such as dinner events, game nights, festivals, and spring break camps that are also enjoyable for parents. They wish to create a safe space that also promotes a healthy environment. Student researchers reviewed a total of 12 scholarly journal articles. The journal articles represent thousands of people who reside in similar size rural areas. All of the articles include how important community centers, and their academic and social activities are to rural neighborhoods and their residents. This research helps our study by highlighting what services are helpful for rural community centers to provide their residents, and how the services can help the population of rural communities. The student researchers use the information gained from the programs to understand the effectiveness of community centers in lower income areas. The study is focused on active members of the Cresson Pod community and their families. The group's research question is, "What is the effectiveness of social and academic resources provided by community centers in low-income neighborhoods?" The student researchers developed a survey with close ended and open-ended questions. Their target sample size is 100 participants. They will use the data to better advocate and support the needs of low-income neighborhoods through community centers.

Abstract Name: The Math Guidebook for Educators: Helping Students Who Struggle In Math

"93 percent of Americans indicate that they experience some level of math anxiety" (Blazer). The fear of math is a prevalent issue in today's society, and needs to be addressed. The goal of this project was to create a comprehensive, accessible Math Guidebook for Educators of all grade levels. The finished product explores the main topics of math anxiety, math specific disabilities, accessibility tools, and helpful strategies. The primary method of research for this project was an extensive literature review using textbooks, relevant videos, and scholarly articles. The Math Guidebook for Educators will spark the conversation about math anxiety and math specific disabilities while educating teachers and students about this subject. During the Fall 2023 and Spring 2024 semesters, further work will be done to add more information to the Guidebook, creating and implementing a survey for higher education students and k-12 teachers to ask questions related to math anxiety, and ultimately resulting in a math discussion conference during the spring semester.

Abstract Name: Understanding Oxygen Movement and Catalytic Properties of Cobalt Doped Perovskites: LaFe1-yCoyO3-δ

Various oxygen transport membranes (OTMs) have been synthesized for their potential in industry for pure-oxygen generation by separation from air or for production of renewable energy such as syngas. Oxygen transport membranes provide a cheaper alternative to current industry practices, in addition to being a reusable and more eco-friendly catalyst. Often these membranes are perovskites, ABO3, with different amounts of A and B-site doped metals. In this work, perovskites of varying amounts of cobalt doped on the B site, LaFe1-yCoyO3- (LFCO), will be synthesized and their purity analyzed with x-ray diffraction. These iron and cobalt perovskites will be analyzed using the programs Soft BV and Vesta to calculate where oxygen can move through the structure and how much energy is required to do so. The various structures of LFCO will then be tested for syngas production via Gasboard-3100. If these perovskites are deemed viable for use as an OTM, further experimentation can be done on a larger scale for their uses in industry.

Abstract Name: Strong Roots, Flowering Legacies: The Importance of Nurturing Community-Facing Student Research in Special Collections

Implementing sustainable practices that support undergraduate research is imperative for faculty mentors and administrators invested in supporting student learning through these high-impact, engaged opportunities. As community-engaged scholars and public historians have emphasized, methods critical to research with external constituencies and partners require acknowledgment of the contributions and expertise of all parties, as well as, continual reflective practice of shared inquiry. Recent scholarship emphasizes the need to consider power differentials between and among participants, organizations, and communities. Furthermore, collaborative efforts to make special collections more accessible are valued as stewardship to a global audience of researchers. Giving student researchers the autonomy to select, preserve, and contribute to the sharing of primary sources empowers them as active voices in scholarly conversation. Using our mentorship experiences in two Council of Independent Colleges Humanities Research for the Public Good grants and the Community Engaged Alliance Faculty Fellow Program, we examined how faculty can sustain student research that maximizes accessibility of special collections to benefit student learning, institutional advancement, and the surrounding community. With assistance from the Indiana Historical Society and Private Academic Libraries Network of Indiana (PALNI), undergraduates researched multiple campus citizens making substantial contributions to the college and public good, cataloged archival materials, and conducted oral histories to intentionally preserve and emphasize a diversity of campus voices. Students organized their research in ways that make it more widely accessible to local, state, and the broader public.

Throughout this exercise, we have found several ways to expand the reach of these initiatives so they enhance the learning of more students, fit better within existing faculty efforts, augment institutional resources, strengthen community partnerships, and offer public access to information. Through practice, we have developed successful strategies that increase the sustainability of these high-impact, high-effort undergraduate research projects

Abstract Name: The Effects Social Media has on the Quality of Relationships

The purpose of this study is to test the theory of how social media impacts the relationship of young men and women that compares the time spent on social media to the quality of relationships, both platonic and romantic, for students studying psychology at Clark Atlanta University. Past research on generation Z adults indicated that there has been a great decrease in interest in being in a monogamous relationship. This study is unique because not only does it focus on romantic relationships, but it includes friendships and how social media may play a significant factor in the decline. The hypothesis of the present study were that students who utilize their phones, or social media, at an excessive rate will not be in serious relationships or friendships with a strong foundation compared to those who do not utilize social media excessively. The participants were Clark Atlanta students studying psychology. The data collection method was a survey created on Qualtrics. The results indicated that the participants do love their partners; however, desire more. Research shows that they are not necessarily satisfied in their relationships and that it does not meet their original expectations. Within their friendships, they have disagreements every so often, but they are able to maintain a healthy relationship as they practice good communication between one another. The majority stated that their most used application is a social media platform with an average of 15 hours a week. The expectations were thus confirmed. Implications of the results for future studies include new generations consumed by social media do not long for commitment. The results of this study can contribute to the field of psychology and help initiate positive change for young adults and adolescents who are consumed by social media and false realities they acquire due to their excessive usage.

Kaitlyn Clemenceau

Discipline: Education

Authors:
#1 Alan Fletcher

Abstract Name: Alan Fletcher: An In-Depth Study of Graphic Design Excellence

Alan Fletcher, a luminary in contemporary design, revolutionized graphic design with his distinct style, communication, and originality. He is well-known for his expressive typography, color, perception, pattern, style, and illustrations. These are all great traits for a graphic designer. His influence has touched the minds of many other designers, new or old, and has changed their perspective on concepts through impactful visuals. It has inspired them to embrace diversity and experimentation in their work. Many designers struggle with and seem to repeat the same thing they have already made or are stuck. It is essential to seek help and inspiration from others because the human mind constantly thinks of new ways to improve something. It might be outstanding or bizarre, but it is better than nothing.

Abstract Name: Community Connectedness: Flagstaff Family Food Center

Project Purpose: This intervention aims to decrease feelings of loneliness, increase feelings of connectedness to loved ones, and increase feelings of community togetherness for recipients of Flagstaff Family Food Center (FFFC).Background: Northern Arizona has a large amount of its population facing negative mental health issues. These outcomes disproportionately impact people who have low SES and live below the poverty line.Methods: Our Northern Arizona University (NAU) HS403C team has collaborated with the FFFC to provide resources and support to food-insecure individuals to build social connectedness to improve mental health outcomes. To accomplish this, we connected these individuals with loved ones through mailing, emailing, texting, and calling programs, as well as signing them up for email addresses.Conclusion: Through a pre and post-social isolation survey, we found that 62.5% of program participants felt more connected to their community post-intervention. Even with our promising results, further interventions may prove beneficial as nearly 40% of participants said they often feel socially isolated post-survey. This demonstrates a need to continue similar interventions.

Abstract Name: Effects of Methyl Jasmonate and Jasmonic Acid Loaded Nanoparticles on Defensive Secondary Metabolites in Hairy Root Cells

Secondary metabolites in plants help with defense mechanisms against pathogen infection and abiotic stresses, including drought, extreme temperatures, etc. While an increase in these metabolites will benefit plants, they also provide potential benefits to humans as possible therapeutics. Methyl jasmonate (MeJ) and jasmonic acid (JA) are both known to elicit defensive secondary metabolites when delivered to plant cell cultures. Amine functionalized mesoporous silica nanoparticles (MSNPAs) loaded with these elicitors are hypothesized as carriers for delivery into the plant cell. This work focuses on the delivery of methyl jasmonate and jasmonic acid into Lobelia cardinalis hairy root cells using high surface area MSNPAs (with 2.5 nm diameter pores). Synthesis and amine functionalization of these nanoparticles are performed first, resulting in a porous particle with a positive surface charge, confirmed by zeta potential. Using evaporative loading techniques, MeJ/JA is loaded into the pores and quantified using thermogravimetric analysis (TGA). Hairy root cell cultures are then treated with one of five different treatments of elicitor and particle combinations. The control group contains hairy root cells in plant media. Other treatments include root cells with elicitor in media, nanoparticles in media, elicitor loaded nanoparticles in media, and unloaded

nanoparticles and elicitor suspended in the same media. Ultra high-performance liquid chromatography (UHPLC) coupled with electrospray mass spectrometry (ESI-MS) is used to analyze the metabolites synthesized with each treatment. Focusing on jasmonic acid as the elicitor, data manipulation is performed to determine which secondary metabolites are elicited in significant amounts. T-tests are then performed to determine which treatments are statistically significant from the control group. Current work focuses on analysis of each metabolite and determining which treatment showed the greatest impact on area counts.

Abstract Name: Embracing Saidar: How Women are Represented in Robert Jordan's The Wheel of Time Series

Robert Jordan is one of the bestselling fantasy authors of the early twenty-first century. With fifteen books in his The Wheel of Time series, he was able to create a new world with scores of imagined countries and cultures. Although women have historically been poorly represented throughout literature, there is a noticeable deficit of well-developed female characters in fantasy. Robert Jordan set about to create a world in which women and men were equal. This thesis examines the portrayal of women in Robert Jordan's The Wheel of Time series and studies how Jordan included powerful women in his series while allowing his female characters to experience challenges similar to those faced by contemporary women. Examined are the Aiel Maidens of the Spear; queens and other female rulers; local women leaders; and finally, the Aes Sedai, the organization of women magic wielders.

Abstract Name: The Harrowing of Hades in Christian Apocrypha and the Controversy over Universal Deliverance

The Harrowing of Hades is an under-discussed event in Biblical circles today. There are several places in Scripture where the Harrowing is mentioned. Matthew 12:30 claims that Jesus was kept in the "heart of the earth" for three days. Ephesians 4:9 claims that Jesus descended into "the lower parts of the earth." The most detailed mention of the Harrowing is in 1 Peter 3:18 where it is said that Jesus preached to the spirits in prison during the period between His crucifixion and resurrection. However, this final text is notoriously ambiguous on who in Hades was preached too and who accepted the gift of salvation. Contemporary scholarship has taken an interest in how Christian apocryphal texts like The Questions of Bartholomew and The Gospel of Nicodemus approach the Harrowing. Specifically, the question is whether Jesus saved all or only some prisoners in Hades. In this paper, I argue that the earliest manuscripts of both texts teach that Jesus delivered everyone from Hades. Over time, due to evolving theological concerns of Christian scribes, this narrative was edited out to fit a limited eschatology of deliverance. This shows that ideas of universal

deliverance were very common at the time these traditions were first formed around the second-third century but by the later manuscripts, these ideas had become purposefully edited out in favor of narratives that do not teach that Jesus saved everyone. Christian orthodoxy had moved on from the belief in universal deliverance and sought to erase prior history that associated it with this.

Abstract Name: Investigation of the toxicity of coriander oil as an alternative to synthetic pyrethroids to non-target aquatic organisms

Mosquitoes are insect vectors of deadly and harmful diseases to humans; these insects are most frequently controlled using synthetic pesticides known as pyrethroids. Although these pesticides are lethal to mosquitoes, they also can kill, or sub lethally harm non-target species that serve key functional roles in aquatic ecosystems. Essential oils are often cited as a “greener” alternative to synthetic insecticides, but in order to be truly “green”, these compounds must not harm non-target organisms at concentrations that are lethal to mosquitoes. By conducting 48-hr toxicity assays on non-target organisms including the common water flea (Daphnia magna) and a crawling water beetle (Peltodytes sp.), it was assessed whether essential oils derived from the coriander plant (Coriander sativum) can act as a greener alternative to synthetic pyrethroids. The synthetic insecticide permethrin was toxic to Daphnia magna (LD50 = 0.33 ppb) and Peltodytes sp. (LD50 = 0.21 ppb) at concentrations of staggering magnitude lower than the coriander oil (Daphnia magna LD50 = 117 ppm, Peltodytes sp. LD50 = 42 ppm). Compared to the non-target organisms, literature estimates of LD50 for mosquito (Aedes aegypti) larvae were higher for permethrin (LD50 = 1.3 ppb) but lower for coriander oil (LD50 =27 ppm) Therefore, coriander oil can be considered a “green” alternative to permethrin since the concentration needed to kill mosquitoes was lower than that required to kill non-target organisms. Using coriander oil rather than permethrin as a mosquito larvicide may therefore simultaneously prevent mosquitoes from spreading deadly diseases while also protecting aquatic ecosystem diversity.

Abstract Name: Chlorophyll in Spearford Gully: An Analysis of Chlorophyll Trends Relative to Rainfall

This research examines the relationship between rainfall events and chlorophyll present in the water at Spearford Gully on the Lone Star College-University Park campus in order to assess the impact of pollution in precipitation runoff on water quality. Previous scholars in the fields of biology and ecology (Smith & Schindler, 2009) have found direct links between the pollution of water sources and the use of pesticides and fertilizers in gardens and corporate agriculture due to surface runoff. Furthermore, additional studies note a

positive correlation between rainfall events and the growth of chlorophyll α levels, which in excessive amounts can disrupt aquatic life and produce harmful toxins within a water source. Research for this project involved collecting data over a span of 28 days in the month of February 2022 by utilizing a water sonde that measures chlorophyll submerged within the gully and a Harris County rain gauge. The water within the gully was analyzed for chlorophyll α levels and depth changes with additional visual confirmation from campus cameras. Results indicate no positive correlation between rainfall events and the growth of chlorophyll α levels within the gully thus showcasing a contradiction from previous existing research. However, the analysis showed a growth of chlorophyll α and depth change unassociated with rainfall. These findings suggest the growth of chlorophyll α observed was potentially a result of a nutrient-rich discharge that entered the gully upstream and was deposited downstream where the water sonde was located. Future research is needed to determine the source of the pollution runoff entering upstream. Results of this study emphasize the importance of analyzing water sources located in urbanized areas to identify potential sources of pollution from human activity and seek methods to advocate for reducing these harmful behavior

Abstract Name: Relationship Between Annual Girth Growth and Water Stress in Quercus garryana (Garry oaks): A Species of Conservation Concern

Quercus (oak trees and shrubs) are important for maintaining biodiversity worldwide. In the Pacific Northwest, Quercus garryana (Garry oak trees) are the most abundant species in this genus, but have declined substantially in the past few decades. To support oak conservation, and protect the mammals, fungi, and plants dependent on Q. garryana, we need to understand how environmental stressors affect the growth and physiology of this key species. In this study, we investigated the relationship between the annual girth growth of Q. garryana and both short-term water stress (Ψp) and long-term water stress (δ13C). We collected branch samples from the canopies of 47-64 mature Q. garryana in the Willamette Valley of Oregon. Samples were collected each year from 2019 to 2023 in late summer during the daytime (the diurnal period of maximum water stress) and nighttime (the diurnal period of minimum water stress). Immediately following collection, Ψp was assessed on the healthiest leaf. Samples were transported on ice to the laboratory where leaves were homogenized and assayed for δ13C using isotope ratio mass spectrometry. We used linear regression to model the relationship between annual girth growth and water stress. Greater tree water stress was significantly associated with greater annual girth growth. Long-term water stress assessed as variation in δ13C explained a higher proportion of variation in annual girth growth (R2= 0.297, p < 0.05), than short-term water stress assessed as Ψp (R2= 0.193, p < 0.05). These results indicate that Q. garryana will tolerate water stress associated with habitat restoration measures and future climate change in the Pacific Northwest. Future conservation efforts should focus on minimizing other environmental stressors such as shade suppression to promote growth of mature Q. garryana which have the highest value for conservation of biodiversity in the region.

Abstract Name: Synthesis of Two Novel bis-Imidazolium Bromide Salts as NHC Precursors

N-heterocyclic carbenes (NHCs) are a useful moiety for stable organometallic species due to their strong σ-donation ability. Three potential imidazole derivatives were investigated for their ability to link together via a methylene bridge. These derivatives were then refluxed in toluene and methylene bromide for several days, which, by previous work, should allow the formation of a linked salt product. Two novel bis-imidazolium salts with methylene bridges are reported, and the synthesis of one potential bis-imidazolium salt was attempted but was not successful. Both synthesized salts have been characterized by 1H NMR and 1H-COSY NMR spectroscopy. Although a low yield was obtained for the syntheses, it was proven possible, adding to the library of possible NHC ligands. Further research will consist of searching for more efficient reaction conditions, and the synthesis of bidentate NHC transition metal complexes using these bis-imidazolium salts.

Abstract Name: Having it's Cake and Eating it Too: The Case of AfricaMuseum and it's Prevailing Colonial Legacy

The Royal Museum of Central Africa (RMCA) was founded with the profits King Leopold II collected from the Congo Free State. The RMCA opened in 1910 by King Arthur I after King Leopold's death. The RMCA was a colonial museum that sought to glorify Belgium's role in Congo. Responding to critics, the museum underwent a renovation from 2013-2018 with the goal of decolonizing the museum's narrative. The museum opened under the name AfricaMuseum in December of 2018. My analysis of the reopened exhibits and museum reveals that AfricaMuseum has continued the colonial legacy they promised to condemn.

Abstract Name: Chimeric PD1 Expressing T cells as a Therapy for Squamous Cell Carcinoma and Lewis Lung Carcinoma

Currently, the overall 5-year survival rate for lung cancer is 23% in the United States. Treatments for lung cancers can have many harmful side effects including nausea, vomiting, fever, infections, and exhaustion. Therefore, a new treatment option to increase survival and reduce side effects is desperately needed for individuals with these cancers. Using immune cells to treat cancer is quickly becoming a new option. One

type of immunotherapy uses chimeric antigen receptor expressing T cells (CAR T cells). CARs are modified receptors that use genetic engineering to create a novel receptor that targets tumor-associated antigens and enhances T cell responses. We developed a CAR, chimeric-PD1 (chPD1), with the Programmed Death 1 (PD-1) receptor as the tumor-targeting domain attached to CD3 zeta activation and Dap10 costimulatory domains. Since the ligands for the chPD1 receptor are expressed on most tumor types and not on healthy cells, they are ideal for CAR T cell therapies. Previously, chPD1 T cells were shown to effectively treat murine models of pancreatic, colon, prostate, and other cancers. The purpose of this study was to test the anti-tumor efficacy of chPD1 T cells against squamous cell carcinoma and Lewis Lung carcinoma. Flow cytometry and RT-PCR were used to determine that the tumor cell lines expressed PD-1 ligands. Therefore, these tumor cells were potential targets for our chPD1 T cells. Using LDH cytotoxicity assays, we demonstrated that chPD1 T cells increased lysis of tumor cells compared to control T cells. ELISAs and LEGENDplex assays were used to assess cytokine secretion by chPD1 T cells. For all tumor types tested, chPD1 T cells secreted pro-inflammatory cytokines, including IFN-γ, TNF-α, and GM-CSF, but did not secrete the anti-inflammatory cytokine IL-10. Based on these results, chPD1 T cells could provide an effective treatment alternative for squamous cell carcinoma and Lewis Lung carcinoma.

Abstract Name: Redefining the Will of God: From Christian Polygamy in Utah to Islamic Polygamy in Senegal

In the United States, the concept of polygamy is a taboo that contradicts the normative relationship pattern of monogamy. However, in some West African countries such as Senegal, polygamy is common practice, and legal. Despite its illegality in the United States, polygamy continues primarily in Mormon Christian communities in Utah. In contrast, polygamy in Muslim countries like Senegal is regulated not only through the government but also through the Quran. The validity and ethics of polygamous relationships come into question as women often bear the brunt of hardships in terms of jealousy, heartbreak, divorce, and gender stratification. Not only are typical binary gender roles performed and stereotypes visible but they are amplified in this situation where women often have no choice but to accept the desires of their husbands. This can be seen in the novel Une si longue lettre (So Long a Letter) by Senegalese author Mariama Bâ who writes of the trials of women in the 1970s as they navigate their familial relationships in connection to polygamy. My research, supported by existing scholarship, critically yet thoughtfully discusses this sensitive topic in the context of America and Africa. The two-fold objective of my work is to deconstruct the nuanced realities of polygamous relationships and to attempt to revisit and redefine the normalization and regulation of polygamy by Mormon Christianity and Islam of the perceived equal treatment of co-wives. Lastly, this paper, supported by existing literature, will thus shed new light on the pitfalls of polygamy as it pertains to women in both the United States and Senegal.

Abstract Name: Using GIS techniques to test a model of coexistence between two montane ground squirrels

Predator-prey interactions extend beyond direct predation and can influence prey behavior and habitat use. This “ecology of fear” has been studied in a variety of taxa, and differences in perceived predation risk have been demonstrated to impact species coexistence. Previous research on the golden-mantled ground squirrel (Callospermophilus lateralis) and the least chipmunk (Tamias minimus) indicated that these species have differing foraging efficiencies at different distances from cover; T. minimus is more efficient close to cover, and remains close to safety, while C. lateralis is able to exploit “riskier” habitat in the center of a meadow. The aim of this study was 1) to test the continued coexistence of C. lateralis and T. minimus to determine if their patterns of meadow usage are stable and 2) to use geographic information systems (GIS) to refine methodologies used by Smith (1991) and Baas (2011). Raster analysis was utilized to locate meadows with appropriate habitat and determine the distance from cover and area of each meadow. Meadows were observed visually and with camera traps to record the presence of one or both species. Both distance from cover and area of a meadow were found to contribute to species composition. Results are consistent with past studies, indicating that the coexistence of these two species is stable. This research provides further evidence that non-consumptive effects of predators promote species diversity.

Abstract Name: Impact of Average Daily Rate on Hotel Cleanliness in Game Theory

Despite the acknowledged influence of the Average Daily Rate (ADR) on hotel cleanliness, establishing a definitive connection between the two in both suburban and resort destinations during high and low seasons has remained inconclusive. Hotel managers tend to prefer having specific cues to guide their decision-making rather than being overwhelmed with excessive information, making it challenging to arrive at a decision. In this study, two matrices were constructed based on various indices, and game theory strategies were applied to predict the outcomes of the relationship between ADR and cleanliness.A sample of ADRs and cleanliness in suburban and resort hotels in the US was retrieved from Smith Travel Research and TripAdvisor during the 6-year period from 2018 to 2023. Using vector error correction model, the study has conducted the game theory to examine the impact of the ADRs on the cleanliness in the yearly seasonal cycle of the high season (April to September) and the low season (October to March).Findings indicate that during the peak season, when the ADR rises in resorts and falls in suburban areas, cleanliness standards are at their best in both types of accommodations. During the off-peak season, the highest levels of cleanliness are achieved when both resorts and suburban accommodations increase their ADRs. This suggests that cleanline can draw both leisure and business travelers to suburban areas during the low season and more leisure travelers to resorts during the high season. Further research should be conducted to other areas of the United States. The contributions of the study are (1) Game Theory would be used to develop hotel strategies. (2) When hotels in suburban and resort destinations set their prices in opposite directions for customers, an equilibrium of mutual benefit can be reached depending on whether it is the high or low season.

Abstract Name: A Clean Slate: Public Art and Ecological Science in Contemporary Appalachia

The rugged hills of Appalachia have supplied the United States with a large percentage of the country’s energy in the form of coal for generations, but the poorly regulated industry has left the region with scarred landscapes, damaged towns, and ecological devastation affecting the lives and health of millions. Where most see an impossible problem, AMD&ART, a small nonprofit of historians, engineers, and artists sees opportunities to repair the landscape, provide recreational opportunities, and spur economic development. Utilizing the archival collection AMD&ART, 1994-2005, at the University of Kentucky Libraries Special Collections Research Center, research will focus on the artistic interventions used at one site chosen for remediation in Vintondale, Pennsylvania. The collection contains photographs, plans, and correspondence that provide a detailed look into the art objects created as part of the project. The research project includes an analysis of archival documents, photographs from an in-person site visit, and other primary source materials. It uncovers the impact of the three public art installations that AMD&ART brought to the surrounding community and exemplifies how environmental art can be used at similar sites in need of revitalization. These three artworks respectively commemorate the past, guide the present understanding, and instill hope for the future of ecological partnership in the arts and sciences. Such installations inform how contemporary art practices intertwine art, history, and science into the larger contemporary art world. Vintondale’s reclamation of not only its water but also its cultural heritage serves as a model for future projects that aim to rehabilitate and advance the beautiful landscapes of Appalachia and beyond. The interdisciplinary approach of the project demonstrates how the humanities and technical aspects complement each other to achieve goals deemed unreachable.

Abstract Name: Resurgence of Latina and Chicana Women’s Murals in Mexico and the United States in the 21st Century

Murals by me have received considerable attention in scholarship. However, murals by women have been seldom addressed. This research examines murals by Latina and Chicana women in Mexico (Paola Delfin, Adry Del Rocio and Tahnee Flohr) and the United States (Las Mujeres Muralistas, Judy Baca, Celia Rodriguez, Rosalinda Palacios, Antonia Mendoza, Irma Lerm Barbosa and Barbara Desmangles) in the twenty-first century. This study's significant questions are as follows: What social and political events in each country generated interest in murals by Latina and Chicana women? How has the safety, sexism, acceptance, and subject matter of the murals by Latina and Chicana women in each country differ, if at all, and why? Research determined that the United States support of the Deferred Action for Childhood Arrivals (DACA)

and the Development, Relief and Education for Alien Minors Act (DREAM) generated interest in the restoration of the 1970s and 1980s murals by the Latina and Chicana artists aformentioned. On the other hand, in Mexico, the feminist movement culminating in the National Gender Equality Policy (2013-2018) provided a more accepting environment for female muralists. However, in both countries, Latina and Chicana women continue to experience discrimination, unequal opportunities to produce murals, and unequal compensation. Unsurprisingly, murals in Mexico and the United States have the same underlying theme of female activism. This study, based a formal examination of the murals within the cultural and political context of the respective societies, is significant considering the most recent attacks on the DACA and DREAM policies, and the Latina/o and Chicana/o population in general.

Abstract Name: Determining the Molecular Function of PDH1

Putative 2-methylcitrate dehydratase (PDH1), is a Saccharomyces cerevisiae mitochondrial protein that plays a role in respiration. It is known to be involved in the propionate metabolic process, but its specific molecular function has not been identified. To determine this function, cells deleted for PDH1 deletion cells were grown on a series of medias to test its fitness. Glycerol media is a non-fermentable carbon source and is used to identify whether a deletion mutant can withstand the diauxic shift, which is when the yeast undergoes cellular respiration instead of glycolysis, the preferred energy generating mechanism in high glucose. Additionally, another fitness treatment that was employed in this study was exposure to ultraviolet radiation, which is known to trigger DNA damage checkpoints. Some reports have shown that oxidative stresses from UV can hinder the growth of mitochondrial proteins resulting in a defect. Interestingly, our results indicate that cells deleted of PDH1 are able to grow on glycerol media, which was surprising given most mitochondrial proteins show defects on non-fermentable carbon sources. Additionally, we found an increase in fitness when exposed to UV. Further research is required to identify the mechanism by which cells deleted for PDH1 are unaffected by glycerol media and display an increase in fitness upon UV exposure.

Abstract Name: Microbial Diversity: Evaluation of Microbes in Soil Within Close Proximity of Beech Trees

Understanding the relationship between trees and soil microbes is essential for evaluating its microbial diversity. In this study, we employed bioinformatic analyses to unravel the microbial communities in the soil near the base of American beech trees (Fagus grandifolia). Soil samples were collected from soil near the base of beech trees at Bowie State University campus. DNA extraction was prepared for metabarcoding of fungal (ITS data) and bacterial (16S data). Our bioinformatic analyses revealed a diverse bacterial and fungal

communities within the soil samples collected. Our analysis also highlighted the relationship between the bacterial and fungal components. Fungal communities were dominated by Eurotiomycetes and bacterial communities by Acidobacteria.

Chartise Coleman

Abstract Name: Microbial Communities in American Beech (Fagus grandifolia)

Studies have suggested that the microbes found in the surrounding environment of a plant will likely colonize those plants via horizontal transmission. The objective of this class project was to compare the microbial communities in the soil, bark, and healthy beech leaves. We hypothesized that leaf and bark tissues would host some of the microorganisms also found in the soil, and that the closer the soil to the tree, the more similar the communities. We characterized the microbial communities using metabarcoding of nrITS (fungi) and 16S (bacteria) markers. Results show that plant tissue communities are different from soil communities, with little overlap. This suggests a possible substrate and tissue specialization.

Abstract Name: Soil Aggregate Analysis

Soil aggregates are coherent groups of soil particles that are held together by organic matter, roots, and fungal hyphae. An aggregate breaks along the lines of structure inside the soil, and assists in indicating how much structure a soil has which directly correlates with soil health. When soil particles occur as aggregates, the soil experiences many benefits including an increased capacity to infiltrate and store water, resistance to erosion, better management and delivery of nutrients, and much more. When a soil has more structure it creates pathways for root growth as well as animal and microorganism activity. The stability of soil aggregates when they are wet has become an important indicator of soil health, but the quantitative measurement of wet aggregate stability requires a labor-intensive laboratory analysis. Recent advances in image recognition approaches for aggregate stability may provide a promising means of evaluating the stability of soil aggregates with less laboratory time and equipment. Image recognition of aggregate stability may also provide a simple way for farmers and others who are concerned with soil health to provide visible demonstrations of soil health indicators that are also quantitative. Here we compare the results from a laboratory aggregate stability method with image recognition methods on several soil types from Minnesota.

Abstract Name: How Agricultural Productivity is Effected by Broadband Access in Rural Areas

Technology plays a pivotal role in the evolving landscape of the agriculture industry. However, with the digital divide present in rural areas, farmers cannot fully utilize the technology available to them. This research aims to understand the effects a lack of internet access has on farming operations' productivity. These efforts and results will serve as a guideline for grant money allocation, advocacy efforts, and legislation moving forward. Amid the challenges brought on by the COVID-19 pandemic, rural areas have become the focus of research in terms of healthcare, education, and age-related implications of the digital divide. These understandings have helped shape this study of agricultural productivity as it relates to broadband in rural America. Preliminary interviews show that internet access is crucial to farming operations as it allows farmers to order equipment, research innovative practices, and access available resources. Even daily tasks such as record-keeping rely on internet-based programs. Results from a comprehensive survey and an extensive literature review will allow us to fully understand the importance of broadband on farming operations. This research contributes to the goal of fostering productive and sustainable agricultural practices by offering practical suggestions and opportunities to improve connectivity in rural areas across the Southern United States.

Abstract Name: The History and Implications of Presidential Executive Orders

This paper conducts an in-depth analysis of presidential executive orders (EOs) in three different eras, ending with a discussion of the implications that are faced in the modern United States political atmosphere. First, an analysis of the U.S. Constitution and the Framers' intentions for the executive branch are discussed using transcripts from the Constitutional Convention. This discussion leads directly into the first executive orders issued by presidents from the Colonial Era, considering how many were issued, how they were used, and what circumstances drove their usage. Comparisons between different presidents are used to understand what situations prompted higher usage of EOs in the early years of the United States. Next, the purpose and frequency of executive orders shifted during and after the Civil War, and a case study of Abraham Lincoln and his unprecedented use of executive orders is analyzed to understand why and how this shift occurred. Finally, the Modern Era of executive orders is discussed, specifically looking at President Franklin D. Roosevelt's heavy usage of executive orders along with some analysis of how recent presidents have considered executive orders such a President Barack Obama. After these analyses have been conducted, implications of this research are discussed, including how the use of executive powers in the current political environment has shifted the balance of power between the three branches of the government. This research concluded that while Presidential executive orders have a much larger scope in modern politics as compared

to the Colonial Era. In their modern implementation they are used as a relief valve for the gridlock and institutional imbalance that partisanship has created within the other branches of the federal government in the 21st century.

Abstract Name: The Ordinary Price of Zero

The standard economic model is a key player in Shampanier et al.'s Zero is a Special Price: The True Value of Free Products published in 2007. The authors argue that consumer behavior, when presented with a price of zero, or free, is irrational and inconsistent with the standard economic model. This research claims the standard model presented by that work is an inaccurate characterization of consumer theory and that their experimental research design cannot differentiate between the model they presented and the concept of utility maximization restricted by a budget constraint. Shampanier and colleagues propose a correction to their model that, upon further examination, can easily be accounted for when the research design allows for substitution and income effects. This research demonstrates these effects using mathematical programming to simulate consumer decision-making with various utility functions, such as the Cobb-Douglass functional form. The results show that standard economic theory does an exceptional job of predicting consumer behavior when one good is free. The predictive power of these models relies on their ability to include both income and substitution effects, which are excluded from the "standard" model. Our study shows that Shampainer and colleagues' model is a special case of standard consumer theory and confirms why the literature has been able to reliably verify their results.

Abstract Name: The Effect of Excess CO2 Exposure on Brassica rapa (Wisconsin Fast Grower) and Its Chemical Composition

Increasing atmospheric CO2 levels in recent years have raised concerns regarding the future of plant health. Many new studies predict atmospheric CO2 levels to rise to nearly 1100ppm by the year 2100. The aim of this research is to further understand the relationships between plant biochemistry and elevated atmospheric CO2 levels. Researchers predicted that if Brassica rapa was exposed to 1100ppm of CO2, plant tissue would have increased amounts of protein and chlorophyll. In this research, two groups of Brassica rapa (Wisconsin Fast Grower Plants) field mustard plants were grown in controlled environments. Two groups of plants were grown, one labeled the 'experimental group' and one the 'control group'. The experimental group was subjected to elevated CO2 treatments of 1100 ppm, while the control group was subjected to CO2 levels

consistent with 2023 atmospheric levels. After the plants were grown, plant samples containing both stems and leaves were obtained and subjected to a series of extractions and tests. Mechanical breakdown using pestle and mortar paired with a 95% acetone solvent were used to isolate the plant proteins. Chemical analysis of plant tissue using spectrophotometry and electrophoresis revealed that Brassica rapa plants exposed to elevated CO2 levels have increased concentrations of chlorophyll and decreased concentrations of protein. Elevated chlorophyll concentrations could suggest increased rates of photosynthesis and energy demand. Decreased protein concentrations could suggest increased plant efficiency, with less demand for proteins to facilitate photosynthesis. These results point to the possibility of higher energy demands, and more efficient use of CO2 when exposed to 1100ppm CO2 levels.

Abstract Name: Psychophysiological Measures of Stress and Fatigue in Air Traffic Controllers

Due to increasing frequency of near miss aircraft events, a burgeoning area of research is in the efficacy of air traffic control (ATC) and pilot communication. ATC personnel must continually monitor ever-changing runway and air traffic conditions and make split-second decisions. Currently 3 of the 313 ATC facilities around the country are fully staffed; understaffing can lead to increased fatigue and stress being experienced by ATC personnel. Previous research has found that stress and fatigue can lead to poor decision making. This current study seeks to use previously identified physiological markers of stress and fatigue to determine if these markers can predict increments or decrements in performance on ATC tasks. In this study, we will employ BIOPAC technology (a means of recording changes in the sympathetic nervous system via electrodes on the skin) to identify markers of stress and fatigue including heart rate variability, electrodermal activity, and brain waves during simulated ATC scenarios. These scenarios include standard procedures about airfield clearances, issuance of traffic advisories, managing wake turbulence separation minima, course deviation and alterations, and making altitude adjustments. Anticipated outcomes include data illustrating that decreased heart rate variability and increased electrodermal activity, both of which are associated with increased sympathetic arousal, and increases in alpha wave activity, indicating a lack of attention, during periods of stress and fatigue, will result in poorer performance on the ATC tasks. By identifying if these markers of stress are impacting ATC performance, it would allow this technology to be used, in real time, to pinpoint when ATC controllers are likely to make an error, potentially avoiding the near miss aircraft events that have been occurring and provide evidence for potential safety regulation changes within the Aviation industry leading to potential legislative changes issued by the FAA.

Abstract Name: The Creative Mind of Paul Rand

Paul Rand was one of the most influential designers because of his innovative branding ideas and creative thinking. Starting from the bottom and working his way up, Paul was loved by most people who knew him. He even went on to become a professor at several universities, such as Yale. During this time, Rand was becoming an even bigger sensation in the design community. In the early months of the 1960s, this is where he would start to become the famous man we know and love today. Paul Rand was working commercially when he helped create the logos for several top-rated companies. The first was Westinghouse, then ABC (American Broadcasting Company), followed by UPS (United Postal Service), and lastly IBM (International Business Machines Corporation), plus many others. These designs are still used and loved today. I think that shows how much of a success Paul Rand truly was. Once he grew older, he chose to write several books off of all the "chicken scratch" he had written down throughout the years. Paul was nothing but an encouragement to young artists who wanted to spread their wings and enter the design field. He did many interviews and was always open for a conversation. Paul Rand passed away in November of 1996. After a lifetime of hard work, Paul inspired millions of people and is still a design hero.

Abstract Name: The Body Positivity Movement: Bettering College Women's Body Image and Health

Body image concerns among college-aged women continue to be an immense issue across college campuses. As technology advances, it has become more common for young girls and women to edit their social media photos and ultimately focus more on their flaws. Body image has a substantial impact on mental and physical health, therefore, it's vital that these concerns are addressed and fought. One movement that has been used recently as a possible way to combat this concern is the body positivity movement. For this research project, a Qualtrics survey was sent out to 9,175 female students attending Middle Tennessee State University with the intent to better understand how the body positivity movement is impacting college women's body image and health. The survey questions focus on body positivity movement advertisement campaigns and social media. Specifically, the questions concentrate on the respondent's self-image and awareness of the body positivity movement. Attitude-based scales were pulled from existing research studies and literature and the results were analyzed using SPSS data analysis software. The main differences found in this study show that younger women tend to struggle with body image more than older participants. The attitudes of the survey respondents were recorded before and after watching two body positivity advertisements. The increase in acceptance and satisfaction with one's body and flaws after watching the two advertisements was significant. Many respondents expressed an interest in seeing more body-positive content especially when it comes to the brands that they love. Recommendations based on the data collected from the research were provided to direct further advancement of the body positivity movement to continue to improve college women's body image and health.

Abstract Name: Amyloid Beta (1-42) Aggregates in the Presence of Insulin

Alzheimer’s disease has been correlated with the build up of amyloid-beta plaques due to aggregation of these amyloid peptides. The amount of aggregation of amyloid-beta (1-42) has been shown to increase more substantially over time when in the presence of insulin, leading to a higher risk for the development of Alzheimer’s disease in patients with diabetes. The interaction of amyloid-beta (1-42) and insulin was examined under a variety of conditions to investigate aggregation patterns. Through SDS-PAGE and western blot techniques, the aggregation of amyloid beta was studied over various time intervals with combinations of polyethylene glycol (PEG) and insulin to mimic a physiolgically accurate system in which the aggregation levels were observed. Additionally, Thioflavin T assays and Bradford assays were used to quantify the aggregation under each condition. Aggregation was found to be the highest when amyloid-beta was combined with PEG and insulin, in comparison to lower values when aggregated separately. Further research will be done to understand the effects of drug therapies added to an environment in which aggregation levels are the highest.

Abstract Name: Foreign Intervention in Laos: A Political and Economic Development Handicap

This research sets out to explain how two pivotal eras of intervention in Laos, the French Colonial Era and the contemporary Chinese Influence Era, have negatively impacted the country’s growth politically and economically. This research aims to fill the gap where the small amount of preexisting literature that is relevant to Laos fails to connect Laos’ history and colonial ties to its modern issues. As such, this research compares and compiles a variety of primary, secondary, and tertiary sources and puts forth unique arguments about the state of Laos. The French, driven by imperial ambitions, viewed Laos merely as a strategic tool for Indochinese expansion, hindering economic progress and education. The legacy of French rule left Laos underdeveloped and economically stagnant. In the present, China's influence, particularly through hydroelectric dam projects and the Laos-China Railway, presents a new form of dependency. Burdened by insurmountable debt, Laos experiences environmental degradation, agricultural challenges, and social upheaval. Chinese investments, ostensibly for economic cooperation, mirror historical patterns, serving China's interests while perpetuating a cycle of external control. Comparatively, French and Chinese interventions prioritized their goals over Laos' development, strained regional relationships, and suppressed democracy. The paper underscores the parallels between these historical periods, emphasizing that lessons from history are crucial for Laos to shape a more balanced relationship with external partners. Acknowledging its historical roots, Laos must prioritize self-determination, equitable development, and caution in foreign entanglements to transcend the shadows of its past and emerge as a sovereign nation. A renewed commitment to agency and autonomy is imperative for navigating the complexities of its relationship with China.

Abstract Name: The Effects of Minimum Wage on Teenage Pregnancy Rates in the U.S.

The effects of minimum wage on teenage pregnancy is a relevant research topic that explores whether changes in minimum wage laws have any influence on the incidence of teenage pregnancy. It raises important questions about the economic and social factors that can impact the reproductive decisions of teenagers. Minimum wage is the legally mandated lowest hourly wage that employers must pay their workers, and teenage pregnancy refers to pregnancies of individuals who are 19 or younger. A study by Lindsey Bullinger (2017) showed that a $1 increase in the minimum wage decreased teenage pregnancy by 2%, or by about 5,000. Another research article stated that raising the minimum wage to $15 an hour could reduce the number of adolescent births by 35,000 per year. If further research shows that minimum wages influence teenage pregnancies, then policy makers might consider raising the minimum wage to reduce teenage pregnancy rates. Other policy implications may include healthcare access, and support services for those teens that do get pregnant. The data used in this study is from the U.S. Census 2011 and 2014. These years were chosen to determine if there is a significant effect from the passing of the Affordable Care Act in 2012 that requires insurance companies to cover the costs of birth control. All 50 states and Washington D.C. are used in the dataset. Minimum wages for each state were taken from the U.S. Department of Labor website. To determine the effect of minimum wage on teenage fertility, regressions will be run with teenage fertility rate as the dependent variable, and minimum wage as the independent variable, among other demographic variables, such as income and poverty rate. It is expected that the higher the minimum wage, the lower the teenage pregnancy rate.

Abstract Name: Oxylipin Biosynthesis Pathway Encoding Genes, Lipoxygenase 1 and 2 Expression Profiling

Lipoxygenases (LOXs) (EC 1.13.11.12) catalyze the oxygenation of fatty acids and produce oxylipins, including the plant hormones jasmonic acid (JA) and its methyl ester, methyl jasmonate (MeJA). A novel LOX gene family was identified comprising nine LOX genes in the aquatic plant, duckweed (Spirodela polyrhiza) (Upadhyay et al., 2020). The 13-LOX subfamily, with seven genes, predominates, while the 9-LOX subfamily is reduced to two genes, an opposite trend from known LOX families of other plant species. We were interested to know as why this 9-LOX sub gene family is reduced to 2 genes contrary to land plants. To further use these two genes in genetic engineering, the first task is to find out if the genes are expressed or comparatively more expressed than the other one. Our results from this CURE project indicates that both LOX1 and LOX2 genes express but at a varying levels. LOX1 gene expresses approximately 3-fold higher than the LOX2 indicating its early activation or requirement.

Abstract Name: Drawing on the Depth of Processing: Does Drawing Improve the Memory Trace?

The purpose of this study is to examine memory processes drawing on the research of Clark and Tulving (1975). Clark and Tulving demonstrated that episodic memory, rather than being an automatic by-product of operation, is a cognitive process that increases the durability of the trace (called “depth” of processing) which refers to a greater degrees of semantic involvement with the item. Multiple experiments were run to understand the relationships between degrees of semantic involvement and memory. Participants were induced to process words to different depths by answering various questions about the words: shallow encoding was achieved by asking questions about typescript, intermediate levels of encoding was accomplished by asking questions about rhymes, and deeper levels were induced by asking whether the word would fit into a given category or sentence frame. Clark and Tulvin concluded that the deeper encoding took longer to accomplish and were associated with higher levels of performance on memory/retention tests. The second experiment performed was designed in which a complex but shallow task took longer to carry out but showed lower levels of recognition than an easy, deeper-level task. The authors concluded that a minimal semantic analysis is more beneficial than an extensive structural analysis.The purpose of the present study is to determine if encoding is better when using a deeper level of processing (Clark & Tulving) that involves drawing a picture. In the “Board Game” study, participants were shown a 12 item word list and given 30 seconds to study the list, followed by a recall task. After, they were given a second list on a whiteboard and given 30 seconds to draw a picture of each word - again followed by a recall task. Using the whiteboard resulted in better recall, supporting the notion that drawing requires deeper processing then simple memorization.

Abstract Name: Refined Violence: Dualities in Cy Twombly’s Fifty Days at Iliam (1978)

Depictions of war and violence have been a part of the traditional art historical canon for many centuries. This paper examines the works of Cy Twombly, who challenged traditional and modern perspectives and illustrations of violence. Contemporaneous expressionist artists often portray violence as a gendered dichotomy: violence is an act you perpetrate, seen as masculine, or it is an act you receive, seen as feminine. Twombly subverts this dichotomy, and addresses both gendered perspectives on the depiction of violent art in the grand message of cyclical aggression as seen in his Fifty Days at Iliam series (1978).This paper will dissect Classic and contemporary definitions of masculinity and femininity to further nuance the discussion of violence in art. This paper does not attempt to offer a novel definition of violence but will offer several multidisciplinary constructs to address the impact of violence on constructions of gender. From this

framework can a deeper analysis of Twombly's contemporaries be conducted. Francis Bacon, Chaim Soutine, and Ana Mendieta will be discussed to establish a contextual framework that strengthens the understanding of gendered dichotomy in art. I will also discuss violence within the context of dynamism and the act of artistic creation. This study focuses on The Fifty Days series, with the Shield of Achilles and Ilians in Battle highlighted to illustrate Twombly's approach that blurs gendered conceptions of violence. This paper suggests his evocation of the phallus, his method of artistic production, and his reference to complex symbols from Alexander Pope's translation of Homer's Iliad are tools with which Twombly enacts this strategy.

Abstract Name: Infinite Accessibility: Star Trek and the Shifting Portrayal of Physical Disability in American Culture

This study traces the shifting depiction of physical disability in Star Trek from the 1960s to the 1990s with the aim of examining the portrayal of disabled people within American science fiction. Using a comparative analysis of the portrayal of disabled characters in inclusive settings it may be possible to discern a shift in popular attitudes toward disability. This analysis focuses on examples from Star Trek: The Original Series, The Next Generation, and Deep Space Nine featuring a character with a visible physical disability whose impairment is directly tied to the episode's plot. Each episode's examination relies upon two main conceptual frameworks: Ilana Lehmann's detailed studies of disability which showed their general acceptance and Ashley-Marie Maxwell's literary analysis of popular culture found a removal of all impairments. The episodes under review are based upon the guidelines of Shepard's Portraits of Individuals with Disabilities in Star Trek which evaluated the characters based upon their ability to educate about disabilities. This study revealed that the limitations each character faced evolved from a situation in which disabled people were deprived of choice (1960s), to one in which coping mechanisms and assistive technologies better equipped the disabled (1990s). Additionally, the level of agency and self-advocacy of the disabled character also reflects the shift. This paper delineates the significance of how science fiction, a genre with roots in medical and technological advances, depicts and may even mirror the public views of disability. Furthermore, this study highlights the significance of more research into the changing portrayals of disability in popular culture, such as other long running television series and the effect on public changing attitudes towards disability inclusion and accommodation.

Abstract Name: Associations among dimensions of friendship quality, accountability, and sport commitment

More recently, sport commitment has garnered increased attention among sport and exercise psychologists.

Previous research suggests athletes are committed to sport in two forms: enthusiastic commitment (EC – ‘want to’) or constrained commitment (CC – ‘have to’). In tandem with sport commitment literature, sport peer relationship research has flourished with findings suggesting peers are motivationally salient members of the sport context. Friendship quality (positive & negative aspects of friendship) and accountability (the condition of an individual being responsive to and responsible for their actions towards important others) play a role in our understanding of peer relationships. Despite this knowledge, sport peer relationship research is understudied. The purpose of this research was to gain a nuanced understanding of the complex relationships teammates share. More specifically, we examined sport friendship quality and accountability as predictors of sport commitment. Collegiate athletes (N = 100; Mage = 21.0 years) from 10 separate sports provided demographic information and completed established measures of sport friendship quality, accountability, and sport commitment. Canonical correlation analyses showed a multivariate relationship emerged (p < .05) indicating a moderate association between the predictor variables (friendship quality dimensions & accountability) and criterion variables (EC & CC). Higher reported positive sport friendship quality and accountability were associated with higher EC and lower CC. Negative sport friendship quality was not related to sport commitment. Our work also helps showcase the relevance of the accountability construct in understanding athlete’s sport commitment. In essence, examining a robust social tapestry of an athlete seems to best enrich our understanding of social relationships in the sport context. The significant relationship found between accountability and the two forms of sport commitment is informative for future work.

Abstract Name: Everybody Wants to be Black, but Nobody Wants to be Black: Redefining Our Influence, Stereotype, and Perception.

In the age of globalization and interconnectedness, the exposure to and sharing of cultures are becoming increasingly normalized. The internet and social media have changed culture by putting everything at our fingertips. With today’s easy access to the once-known-as far-away customs and ways of life of foreign countries, fellow humans are revamping and broadening their social interests as they get accustomed to cultures other than their own. Existing literature shows that Black people, in particular, have been pioneers in many fields throughout history and are known to have many rich and attractive cultures. From educational figures like Booker T. Washington to entertainers such as Josephine Baker and Aretha Franklin, the list of legends that epitomized black influence is long and traceable not just in the United States but all over the world. Hip-hop was and is still a tangible example of black culture in America, a genre of popular music that originated in the early 1970s by African Americans in the Bronx, which took the world by storm and still has a palpable influence mainly on the youth worldwide. Despite the obvious infatuation with black culture, there are still negative perceptions and evident stereotyping of black people within other communities. How could one explain such worldwide infatuation with black cultures concurrently with such discomfort vis-a-vis black people? This research will first explore the many ways in which black people are imitated throughout other cultures and how black culture is relevant to others. Then, we will dive into black stereotyping and attempt to redefine the misperception of blacks by others despite their fathomable rich culture that connects us all as humans.

Abstract Name: Seasonal Snacks: Invertebrate Diet Shifts between Wet and Dry Seasons in the Mara River, Kenya

Invertebrates in the Mara River in East Africa play a crucial role in the cycling of nutrients, including nutrients egested by hippopotamuses. However, little is known about the food-web dynamics in this important river. Mara River invertebrates fall into three established functional feeding groups based on their ecological role and primary feeding strategy: scrapers consume material off of rock and sediment, collectors capture and ingest food suspended in water, and predators prey on invertebrates and other animals. This study aims to better understand the common food sources of Mara River invertebrates, with consideration for seasonal changes and the number of hippos present in the river. Gut contents of invertebrates collected upstream of hippo activity during different seasons were analyzed using ImageJ software to compare the food sources of scrapers, collectors, and predators during the wet and dry seasons. Invertebrates were found to cumulatively consume a more diverse diet during the wet season than the dry season. Scrapers and collectors consumed more insect material and other autochthonous (food from within the river) sources during the wet season than in the dry season. Predators exhibited the opposite behavior and consumed more insect material during the dry season. These data can be compared to that of river invertebrates affected by hippo activity further downstream to determine how hippo dung can change the food-web dynamics of the Mara River.

Abstract Name: Revolutionizing Sustainable Architecture: Biomimicry and Digital Tools

This research focuses on leveraging advanced digital tools to drive eco-friendly architectural innovation, aligning with the growing need for environmental sustainability, By blending architectural design, computational modeling, and biomimicry, the study aims to usher in an ecological age. The core hypothesis centers on imitating nature's organic structures to enhance sustainability in architecture. Two key approaches are implemented: computational modeling of organic forms and the structural analysis of these forms. Computational modeling, powered by Autodesk's Dynamo software, involves simulating and refining biomimetic structures. The goal is to analyze their tensile and compressive strengths, expecting improved structural integrity. Autodesk's Robot Structural Analysis software will be used for experimental validation. The study explores designs inspired by natural elements like hollow tubes, shells, exoskeletons, tension structures, woven structures, and planar surface transformations. A complimentary component of the research will explore the construction of a cost-effective bioprinter to democratize bioprinting technology. Utilizing readily available 3D printers, such as the 'Ender 5', open-source bio-extrusion modifications like the

‘Replistruder v3.0’ are integrated to facilitate the printing of non-plastic materials. Detailed assembly instructions and firmware programming are provided to make affordable experimentation with bioengineered materials, such as hydrogels, accessible for collaborative architectural applications. It envisions a new era in architectural design driven by ecological principles, fostering sustainability, resilience, and harmony in our world. Ultimately, this research seeks to redefine the relationship between the natural and the built environments. It envisions a new era in architectural design—one where ecological principle guides our creative process and innovation leads us to a more sustainable, resilient, and harmonious world.

Abstract Name: The Effects of Agrochemicals on Mosquito Life Histories and Immune Function

Anthropogenic perturbation of the environment can lead to unforeseen consequences. An area of concern is the overuse of agrochemicals; while important for food production, off-target biological impacts are unknown. The most widely used herbicide, glyphosate (Round-up™), has been shown to impact animal nervous systems. In the African malaria mosquito, Anopheles gambiae, glyphosate reduces immunity and increases malarial transmission risk. Immunity can be reduced by inhibiting phenoloxidase (PO); a component of insect defense against many parasites including bacteria, protists, and viruses. Agricultural lands are excellent breeding grounds for mosquito species, many of which transmit arbovirus diseases, suggesting glyphosate has profound impacts on vectored disease dynamics. However, there are potential limitations with previous studies, accounting for only one species vectoring a protist and using unrealistic doses. To investigate, more research conducted in environmentally realistic conditions on arbovirus vectoring species is needed. We address the hypothesis that agriculturally relevant doses of glyphosate delivered in an environmentally meaningful manner impact mosquito immunity and life histories. We use the southern house mosquito Culex quinquefasciatus, whose larvae develop in agricultural run-off and vector arbovirus diseases including West Nile, St. Louis encephalitis and Western equine encephalitis. We exposed larvae and adults to increasing glyphosate doses, assessed their PO activity, immune gene transcription, and life histories. We found glyphosate negatively impacts larval survival and development time. Further, adult mosquitoes exposed to small amounts of glyphosate in the larval environment showed impaired PO activity as adults. We found no effect of glyphosate on adult immune gene transcription. This experiment provides insight on negative impacts agrochemicals have on mosquito life histories and immune function at agricultural doses. Future research should assess the effects of agriculturally relevant glyphosate doses on arbovirus transmission rates. If these have an impact, new policies addressing the use of agrochemicals in disease hotspots should be implemented.

Abstract Name: The Role of Progranulin Deficiency and TDP-43 Pathology in Prefrontal Cortex Dendritic Degeneration: Implications for Frontotemporal Dementia

Frontotemporal Dementia (FTD) is one of the most common forms of early-onset dementia, and it is characterized by prominent behavioral symptoms like impaired social dominance. Half of FTD cases exhibit TAR DNA-binding protein-43 (TDP-43) pathology. In FTD, TDP-43 mis-localizes from the nucleus to the cytoplasm, leading to insoluble TDP-43 aggregates within the neuron. Mutations in the GRN gene, which codes for progranulin, a growth factor that regulates lysosomal activity, cause FTD with TDP-43 pathology. Our research aims to answer the following question: How do mutations in GRN, which cause a loss of progranulin, and the existence of TDP-43 pathology cause impaired social behaviors in FTD? To address this question, GRN heterozygous mice were crossed with TDP-43 overexpressing mice to represent pathological aspects of FTD, including impaired social dominance behavior. I hypothesize that loss of progranulin with TDP-43 pathology will induce degeneration of dendritic spines in the medial prefrontal cortex among layers II and III pyramidal neurons. Through a combination of iontophoresis microinjection of fluorescent dye, high-resolution confocal microscopy, and innovative morphometry analysis I tested this hypothesis and discovered that GRN heterozygosity coupled with TDP-43 pathology drove a reduction in mushroom spine density in the prefrontal cortex. Loss of mushroom spines is consistent with the exhibition of aberrant social behavior in this mouse model. These studies yielded a deeper understanding of the mechanisms that drive cognitive impairment in FTD.

Abstract Name: Nanostructured Zinc Oxide Gas Sensors

Metal oxide semiconductors are used as gas sensors in a variety of applications to detect the presence of various gases. Here, we report the synthesis, characterization, and sensor development of nanostructured zinc oxide (ZnO) semiconductors for gas sensing of CO2 and O2. Using a general hydrothermal reaction between zinc precursor salts (zinc nitrate, sulfate, acetate, and chloride) and a base (hexamethylenetetramine) at concentrations between 0.05 and 1.0 M, we show that nanostructured zinc oxide crystals can be grown directly onto glass substrates. The nanostructures generated vary significantly in size, morphology, and surface area depending on reagent and concentrations used, including nanorods (zinc acetate), nano-honeycombs (zinc nitrate), and nanoplates (zinc sulfate). We also report improvements to the adhesion and film homogeneity via spray pyrolysis, wherein substrates are pre-treated with an aerosolized spray of zinc salt precursors at high temperature. Lastly, we present the development of ZnO-coated substrates as CO2 sensors via preliminary resistance measurements in air and under CO2.

Abstract Name: How Accessible is My Website?

It is important that websites are accessible for everyone. Some people have trouble processing speech or printed text due to a sensory deficit. It can also be difficult or impossible to click the mouse button while holding it still and to use the keyboard for someone with limited use of their fingers or limbs. Designers should design websites and other tech with people with disabilities in mind. The Web Content Accessibility Guidelines recommend that websites be made perceivable, operable, understandable, and robust.However, most designers are healthy with good vision, hearing and dexterity, and it could be hard for designers to know how accessible their sites are. We want to make it easier for designers to know if their websites are accessible for people with disabilities. Therefore, in this project, we will develop an automated system that will quickly check websites for accessibility issues based on the Web Content Accessibility Guidelines, evaluate scores and give feedback about how to improve the website in terms of accessibility. The user will enter a website address into a textbox, press a button, and our website will generate a report for accessibility issues. We expect that this project will also raise awareness around accessibility on the web.

Abstract Name: Kantian Critique of the Development of Obstetrics and Gynecology

Throughout history, medical researchers have conducted ethically questionable experiments, with some resulting in severe harm or death to the subjects. Despite the abuse of medical test subjects, immoral medical experimentation was often justified because it led to medical discoveries that benefited the rest of humanity. Specifically, women's healthcare has historically been an underdeveloped field based upon insufficient and sexist research, and its genesis is fraught with ethical concerns. The catalyst for developing the modern field of obstetrics and gynecology in America was Southern slaveholder's desire to increase the birthing capabilities of enslaved people after Congress ended the transatlantic slave trade. James Marion Sims is lauded as the "father of modern gynecology," but he gained this title by performing experiments on enslaved women of color without pain medication or any semblance of ethical regard for the humanity of his subjects. Sims' experiments, namely his revolutionary method for repairing vesicovaginal fistula, form the basis for gynecological practices today. Contemporary scholarship discusses these issues in texts like Medical Violence, Obstetric Racism, and the Limits of Informed Consent for Black Women from the Michigan Journal of Race & Law and Medical Bondage: Race, Gender, and the Origins of American Gynecology from the University of Georgia Press. I analyzed these sources using Immanuel Kant’s Groundworks on the Metaphysics of Morals to argue that the obstetric practices of Sims are immoral through a Kantian ethical framework. The severity of Kantian ethics provides an immovable framework to expound upon the atrocities used to develop today's modern gynecology.

Abstract Name: Working with Natural History: Commemorative Materialities and the Developing Visual Language of Nahua Christianity

The Hearst Chalice, housed at the LA County Museum of art is a liturgical object made in late 16th century colonial Mexico whose fabrication combines featherwork, miniature boxwood carvings, lapidary art, and silversmithing. Previous scholarship has asserted its status as a work possibly commissioned by a Nahua Christian elite in colonial Mexico and outlined some of the artistic traditions relevant to its exquisite design; however, a more contextualized analysis of the object that explores its specific production in the 1570s had not been undertaken. By engaging closely with the materials of the chalice, Nahua and Spanish primary sources, as well as art-historical scholarship on Postclassic Mesoamerica and colonial Mexico, this paper proposes that the chalice is tied to the crisis of the Franciscan Millennial project in the mid sixteenth century and the related burgeoning of the field of natural history. In the 1570s, the Franciscan Bernardino de Sahagún and a group of Nahua intellectuals spearheaded a considerable expansion of Book 11 of the Forentine Codex, devoted to "Natural Things," under the idea that natural history was a more inert terrain in which Nahua knowledge could be recorded. This paper contends that the chalice served as a refined visual expression of that knowledge, which, through the specific selection of materials, further articulated a Nahua Christianity. These findings are consequential because they bring together the study of natural history with the field of art history and shed light on the visual traditions of the first endemic Christianity to the Americas.

Abstract Name: Environmental Life Cycle Assessment for Solar Canals in the San Joaquin Valley

Earth's climate continues to experience unprecedented impacts from climate change creating challenges for communities and ecosystems, affecting the San Joaquin Valley (SJV) with no exception. The SJV has recently experienced extreme heat waves during their summers and floods from heavy rains, which affect communities and their agriculture. With the agricultural industry being the largest in California in the SJV that produces a substantial portion of U.S. and global food commodities, SJV farms rely heavily on water provided by irrigation canals. Another important aspect is energy, which the communities in the SJV use for power. California has ambitious goals to decarbonize across all sectors by the year 2045, which calls for an increase in renewable power sources. As a result, constructing solar panels over irrigation canals (referred to as Solar Canals) and aqueducts have been proposed as a solution and a pilot project will be installed in Turlock, California. Solar Canals have multiple potential benefits to (1) generate electricity, (2) reduce water evaporation through shading, (3) reduce aquatic weed growth with less exposure to UV light, and (4) reduce land use by placing solar panels over pre-existing infrastructure rather than other land. We will employ cradle-to-gave Life Cycle Assessment (LCA) method to quantify the environmental impacts and co-benefits of Solar Canals. Preliminary results will consist of baseline fuel usage and CO2 emission calculations of canal cleaning to determine potential reduction from Solar Canals that may reduce aquatic weed growth and need for as frequent cleanings from shading the canals.

Abstract Name: Ernest Hemingway: The Snowball Effect of Stress-Inducing Circumstances

“Just then, death had come and rested its head on the foot of the cot and he could smell its breath” (Hemingway). Hemingway demonstrates his fascination with death using the character of a soldier in a hospital from an unpublished work, exemplifying how his fiction has been shaped by his experiential mental states. This research is built on other studies regarding Hemingway’s biographical aspects as they apply to his fiction. However, other studies do not address the parallel themes between his life and his short story work in relation to suicide. The analytic techniques used by Hemingway scholars are reconstructed to reveal how Hemingway’s life affected his writing. I will argue that the impacts left on Hemingway by his involvement in World War I and the impact that his father had on him are contributing factors to Hemingway’s suicide in 1961, and these circumstances have been fictionalized by Hemingway either subconsciously or intentionally. Hemingway reflects on his experiences of isolation and loss in the following primary short stories: “A Way You’ll Never Be” and “In Another Country.” Hemingway’s experiences from the impact his father had on him are recorded in the following primary short stories: “Indian Camp,” “Fathers and Sons,” and “My Old Man.” In exploring what led Hemingway to end his life, key father-son moments and wartime experiences will be considered both in light of specific settings (including liminal zones) that impacted him personally and how such moments of trauma contributed to his decision (as shown through movement).

Abstract Name: Informal Actors in The Commercial Sector El Hueco - Medellín 2016-2023

This research falls within the domain of business history but also seeks support from other disciplines within the social sciences. Its objective is to characterize informal actors in the commercial sector of El Hueco - Medellin, individuals who are integral to the city's business milieu and have engendered logics of action and practices contributing to the construction of sustained economic, social, and political trends. From this perspective, there arises a need to investigate, characterize, describe, understand, analyze, and comprehend how informal actors in this commercial sector influence the economic development of the city, constituting a group with high adaptability that has managed to thrive in a globalized world.The study is carried out between 2016 and 2023, a period where we will demonstrate the practices given around informality in the El Hueco-Medellin. Currently this place has an appropriate space for 4,500 street vendors, but according to Guillermo Giraldo, national president of the General Union of Workers, there is a tripling in number from 12,000 to 35,000 since early 2022. This context, exacerbated by the lack of implementation of public policies to guide informal traders and their families, underscores the relevance of the research (Zuleta, 2022).The project is qualitative in nature with hermeneutic analysis supported by the prosopographical method, incorporating interviews, surveys, participant observation, and group sessions with individuals associated with the sector. It will be complemented by a documentary review of public and private archives. Support will be provided by Centro Unido, a major entity that brings together most entrepreneurs and traders in the sector, as well as the Union General de Trabajadores Informales (UGTI), and by seedbeds at EAFIT University. This process will facilitate the understanding of an economic, political, social, and cultural phenomenon experienced by the city, contributing to various fields of study.

Abstract Name: A Tale of Two States: Comparing the Impact of Alcohol Regulation on Suicidality in Two Midwestern States

While the toxicological effects of alcohol on the human body are widely known and studied, intersecting regional patterns of alcohol use and mental health trends are less understood despite their synergistic impact on human health. The State of Wisconsin, known for its infamous relationship to alcohol, is characterized by legislative practices and cultural attitudes which are widely considered to be at blame for high rates of alcohol dependency that are distinguishable from many other U.S. states, including its neighbor Minnesota. Likewise, Wisconsin’s rising rate of suicide outpaces its neighbors despite robust investment in mental health

treatment and prevention services throughout much of the state's history.Using publicly available State and Federal health data from the start of 2006 to the start of 2018, the authors seek to investigate, on a biennial basis, if the rising rate of suicide in Wisconsin over the last decade is connected to its statewide rate of alcohol consumption. To accomplish this, the authors of this study first seek to systematically quantify, on a biennial county-wise basis, state and county legislative policies that regulate alcohol consumption, distribution, and production in Wisconsin or Minnesota, two states that experience similar trends in health outcomes despite their cultural and legislative differences. Second, the authors seek to determine how, on a biennial county-wise basis, prevalence of suicide over a decade-long period correlates with: a) access to mental health and substance abuse treatment services, b) state and county alcohol-related ordinances, and c) prevalence of alcohol consumption. Finally, we will draw inter-state comparisons using the resulting trends and discuss if they reflect observed differences in legislation and cultural attitudes concerning alcohol.

Abstract Name: Illicit Market Impact: The Dollar and the Economic Fall Out of Argentina's Educated

This study investigates the impact of the black market for U.S. dollars on Argentina's urban populace from 2003 to 2015, marked by hyperinflation and political instability. We focus on hourly wages across different educational levels, which can reveal that stringent government regulations on the foreign currency market led to increased black-market activities. The existing research suggests that the rising black-market rates disproportionately affected the urban workforce, particularly those with lower education, due to limited access to stable financial resources. This economic burden was more pronounced for the less-educated group, while the middle-educated group faced increased costs for essentials and restricted upward mobility. This project employs open databases from Argentina to analyze economic indicators and develops a multivariate model using survey data to assess the dependence of various socioeconomic groups on dollars. Categorizing urban populations by education levels, this study explores the interplay between these levels and economic factors. Our contributions include insights into the black market's impact on labor markets. This research adds depth to the understanding of government actions on the populace, especially in foreign exchange markets, enriching knowledge about wage stagnation during hyperinflation and informing future efforts to stabilize monetary policies.

Abstract Name: Exploring Subsurface Weathering and Chemical Depletion Fraction in Yosemite's Sequoia

Groves: Implications for Nutrient Dynamics and Ecosystem Sustainability

This project explores subsurface weathering in Yosemite's Sequoia groves, aiming to measure the extent of soluble element loss, focusing on rock-derived nutrients affected by weathering processes. Understanding the influence of weathering intensity on nutrient availability for tree growth is vital for ecosystem sustainability, as Sequoias play an integral role in the park's ecosystem. The study links weathering processes to carbon sequestration, exploring two distinct rock types—metavolcanic rock, prevalent in the grove, and granite. The investigation assesses whether metavolcanic rock supplies different or more nutrients than granite. Fieldwork in Mariposa Grove at Yosemite required using a hand trowel to collect two soil samples at each location from depths, one about 10 centimeters and the second about 10-20 centimeters. Surface rock outcrops were sampled using a hammer, chisel, and gas-powered rock drill. Subsequently, lab work was conducted at UC Merced, where rocks and soils were pulverized to a fine powder, organic matter was removed by heat treatment, and samples were analyzed for elemental geochemistry using a Bruker X-ray Fluorescence Spectrometer. Comparing the elemental chemistry of fresh bedrock and weathered soils was done using the Chemical Depletion Fraction to assess the extent of soluble element loss due to weathering processes. Increased weathering intensity may lead to increased rock-derived nutrient levels due to the breakdown of rocks and minerals, thereby contributing to the nutrient shed. Thus, understanding these dynamics is essential for preserving and managing Sequoia ecosystems, particularly in the face of prolonged drought conditions and climate change. It highlights the importance of tailored conservation strategies considering the specific geological substrates underpinning these magnificent forests.

Abstract Name: Vibrotactile versus Visual Stimulation in Learning the Piano

Vibrotactile stimulation has been explored to accelerate the acquisition of motor skills involving finger movements (Gemicioglu et al. 22, Markow et al. 2010, Seim et al. 17). This study evaluates the effectiveness of vibrotactile stimulation compared to visual feedback in learning a 14-note one-handed tune on the piano. In the experiment, 14 subjects with no prior piano experience were exposed to both vibrotactile and visual stimulation to determine which was more effective. Subjects were randomized 1:1 in a group that first receives vibrotactile stimulation, then visual stimulation or in a group that first receives visual stimulation, then vibrotactile stimulation. Effectiveness was measured by evaluating the timing error and accuracy. Results from our study indicated that the timing error for vibrotactile stimulation was 12.1% (SD 6.0%), while the equivalent for visual stimulation was 22.3% (SD 10.3%). The accuracy for vibrotactile stimulation was 69.2% (SD 27.2%), while the equivalent for visual stimulation was 91.3% (SD 13.5%). It was observed that vibrotactile stimulation was generally more effective at minimizing the timing error at which the notes were hit compared to visual stimulation, and no statistically significant differences were found in accuracy.

Abstract Name: Analysis of Paraben Induced Caspase-3 Activation in Human M624 Melanoma Cells versus Normal HaCat Epithelial Cells

Paraben, a common antimicrobial agent used in a wide variety of industrial, cosmetic, and pharmaceutical products, has been used for many years due to their ability to maintain a neutral pH and their odorless and colorless properties. While parabens have been found in everyday products for a number of years, controversies over their use have arisen as they have been linked to adverse effects and multiple skin cancers including malignant, melanoma, and contact eczema in the last several years. In this study, human melanoma cells and human normal epithelial cells were treated with 0.05-10mM paraben solution, consistent with IC50 values. Parabens were dissolved in ethanol or methanol solvent and added to complete DMEM for cell treatment. Methylparaben (methyl 4-hydroxybenzoate) and two paraben derivatives, mononitroparaben and helptylparaben, were used. A colorimetric Caspase-3 microplate assay kit was used to assess the ability of these compounds to induce apoptosis. Previous research has shown parabens have induced apoptosis in human melanoma cells, while this study will assess parabens' ability to induce apoptosis in normal human epithelial HaCat cells versus human melanoma M624 cells and provide support for the continued study of paraben as a possible topical treatment for melanoma.

Abstract Name: Advancements in Culture Microscopy to Characterize Nematode Parasitism in Multicellular Organisms at the Molecular Level Consistent with Disease Tolerance and Resistance

Nematodes, or roundworms are among the most diverse but least studied organisms on Earth. They occur as parasites in animals and plants or as free-living multicellular organisms in soil, freshwater, and marine environments. In microbial and agricultural settings, nematodes contaminate pastures and mammalian species, and in medicine, serve as model organisms to the study of cancer and emerging tolerant parasitic diseases. Thus, relevant research options are necessary. We hypothesized that developing techniques against nematodes may be a promising alternative treatment. As such, we generated microbial environments and manipulated pathways to understand the roles of individual environmentally occurring microorganisms' abilities to interact and disrupt the impact that nematodes ultimately hold. Nematophagous fungi are a versatile carnivorous group of organisms that specialize in trapping and digesting nematodes. Our main goal is to compare the interactions of nematodes against various isolates of nematophagous fungi, and evaluate the possibilities of these molecular interactions to treat surfacing contaminations and parasitic disorders. Our research has resulted in the modification of environmentally occurring processes of fungi associated in conjunction with nematodes. In the future, we hope to produce biological control outcomes against different types of roundworm isolates.

Abstract Name: Rosebud Watershed: Stream Contamination and Cumulative Risk in Human Health

The purpose of this research was to analyze ground and surface water contamination within the Rosebud watershed, with the intended purpose of calculating the cumulative risk between the mean and median level of contaminants as it relates to human health. I chose this watershed because it had a very high level of lead contamination, which interested me, because of the recent high levels of lead contamination found in drinking water in Montana schools all across the state. I speculated that it could be possible that the high lead levels in public school drinking water could perhaps be a symptom of contamination from mines. The Rosebud watershed has two major active coal mines; one is in Rosebud County and the other is in Big Horn County. Using data from the Ground Water Information Center (GWIC), I carefully selected the data that would allow me to investigate ground and surface water contamination and cumulative health risks. Surface water poses risk to humans because we get our drinking water from surface water. Within the watershed, arsenic and uranium have levels above the EPA standard of 1.0 or greater, meaning that the water is unfit for lifetime consumption. It is fair to assume that these contaminants may influence the health of those who consume these waters. Rosebud County has a life expectancy rate of 74.93 years which is lower than both Montana (79.1 yrs.) and the United States (79.09 yrs.). Mortality rates are high in Rosebud. We can postulate that arsenic could be a determining factor in the high rates of chronic illnesses in Rosebud County. Environmental Health is a great field because I feel people must know what they are putting in their bodies. People have a right to make decisions about their health.

Abstract Name: Measuring the Impact of an RNA Stem-Loop on the HTLV-1 gag-pro Frameshift Efficiency

Many viruses use programmed -1 ribosomal frameshift (-1 PRF) sites to permit the synthesis of viral proteins encoded in alternative reading frames. The HTLV-1 gag-pro frameshift site includes a slippery sequence, a spacer, and an 11 base-pair stem-loop. While the slippery sequence and frameshift site function were previously established, its frameshift efficiency is unknown and the role of the downstream RNA structure is unexplored. There is substantial conservation in sequence and structure between the HTLV-1 and HTLV-2 gag-pro frameshift sites. Thus, we hypothesized that the HTLV-1 gag-pro frameshift efficiency is similar in magnitude to the corresponding site in HTLV-2 and its stem-loop is critical to frameshifting. To achieve the objectives of the study, we cloned p2luc plasmids encoding for the HTLV-1 wild type, HTLV-2 wild-type, and HTLV-1 no stem-loop frameshift sites. This involved the design of DNA inserts that encode each frameshift site, the ligation of a restriction enzyme digested insert to the p2luc vector, transformation of that DNA into E. coli, and the purification and sequencing of the cloned DNA. Presently, we are synthesizing and purifying reporter RNAs for each construct. These RNAs will be used in a dual-luciferase assay to measure

each frameshift efficiency. The frameshift efficiency of the HTLV-1 gag-pro frameshift site with and without its stem-loop will be compared to HTLV-2 to evaluate our hypothesis and fill important gaps in knowledge related to HTLV-1 -1 PRF.

Abstract Name: Movie posters through the 60's till now

Movie poster design as well as poster design has been around for many years as early as the 1800s, but throughout time especially in the 1910’s through 40’s, it has changed a lot in the United States. Starting with propaganda posters and advertisements for recruitment for war. With the collage style of art that was used in films like Casablanca, there has been a change from the circus-like movie posters to the more graphic design-based illustrations that we're now starting to show a lot in the 1960s. The main thing to remember is that throughout the decades designs that are on movie posters change in conjunction with the style or trend of that decade based on the imagery and text.

Abstract Name: “Medicalized Racism in Black Mental Health”

Over the last several decades psychology as a discipline has grown and prospered. With many advancements in the diagnosis of illnesses and acceptance of mental health, the field has progressed making mental health more acceptable to discuss. While the field has shown such great progress in providing proper care to patients, Black psychology is often not discussed and is often missing from academia within the psychology field. Westernized psychology often “generalizes” how the mind works based on Eurocentric perspectives. The Black experience is very different from the white one, therefore, there should not be a generalized, white, approach to the understanding of the mind. Institutional and medical racism has prevented the ability of Black and African people to receive care for any conditions that an individual might have. Through analyzing Black literature and research articles, we can see that there are large discrepancies such as a lack of research opportunities, lack of mental health care, and discriminatory practices within medical institutions when it comes to Black and African individuals. These discrepancies have led to individuals experiencing high levels of depression and suicidal ideation. Depression is a major health concern for Black and African individuals aged 12 years and older (Madubata et al. 2018). By reviewing the evidence that previous research has shown and analyzing the work that Black psychologists are currently doing within the field, we can recognize the discrepancies that are currently taking place. We can then look to the past to discover how history has led us to medicalized racism and the historical context of racism in medicine. Finally, we can review the solutions and resources that we can make present within the field to make it so Black and African Americans can reach out for care and also feel more welcome as practitioners and care providers.

Abstract Name: Environmental Factors of Reporting Agencies and Their Effect on the Likelihood of Sexual Assault Crimes Being Reported

Past research has shown women ages 18 to 24 are the most at-risk population to experience sexual assault. This research will specifically focus on responses from this age group. When sex crimes go unreported to the police, victims may not be able to obtain necessary services to cope with victimization, offenders may go unpunished, and law enforcement and community resources may be misallocated due to a lack of accurate information about local crime problems. This research focuses on the environmental factors of government agencies that affect the likelihood of sexual assault crimes being reported. For purposes of this study, a government agency focuses on a police environment specifically the rooms where sexual assault crimes are reported. The student researchers also observed how the Vulnerability Theory and the Standpoint Theory informed their research. They developed a 41-question survey with demographic, quantitative, qualitative, and 3 are Likert scale questions. This exploratory research included a sample size of 80 participants using purposive sampling techniques. They ran qualitative and quantitative data through Statistical Package for Social Sciences (SSPS). The purpose of this study is to create an understanding of how environmental factors of government agencies affect whether sexual assault crimes are being reported. In the case that sexual assault crimes are not being reported, the student researchers would like to examine if it is the environment of the governmental agency itself that is keeping individuals from reporting. In the case that environmental factors of government agencies are impacting the reporting of sexual assaults, the student researchers would like to encourage government agencies to be mindful of the emotion being cultivated by their agency. This research has the potential to impact interventions that are being created and to get an idea of the accuracy of the number of crimes being reported.

Abstract Name: Parental Influence on Atheist Rhetoric in Czech Republic

Czech Republic has a conflicted history with atheism due to the way the Communist Party enforced a non-religious regime. This study explores the relationship Generation Z Czech Republic citizens have with atheism due to parental influence. The research will connect to previous studies by evaluating the current religious affiliations and rhetoric of a younger generation, as opposed to people alive during the Communist

Party's rule. Parental influence has likely affected young people's feelings toward atheism through church, education, or other variables. The study will use Zoom interviews to acquire first-hand data and to compare the opinions and ideas towards atheism of people aged 18-26 in the Czech Republic. To analyze the data, thematic coding will organize key words together like "non-religious," "religious education," and "faithful" to discover influences and opinions towards atheism. The study could signify parent influence has shaped atheist belief through choice of education or parenting styles, but also other influences such as religious presence on social media (positive or negative) could appear. In the study, findings will create framework for future research on the relationship between children and religious parental influence, politics and religion, and the relationship young people have built with religion in a post-communist society, as compared to the relationship older generations had built in a different world.

Abstract Name: Examining the Relationship Between Athletic Participation and Academic Success in Athletes and Non-Athletes

For many students, athletics are a major part of their college experience. In 2022, over 500,000 students were members of the NCAA (Statista, 2023). Despite this, research documenting the effects of sports participation on college students, the results are mixed. For example, Bradly et al. (2012) reported that the academic achievement of males who participated in rowing was higher than for peers not involved in sports, but rugby and soccer were not. More broadly, Maloney & McCormick (1993) reported that athletics negatively affects academic performance, while Deere et al. (2019), reported the GPA of athletes is higher than the GPA of non-athletes. These conflicting results are typical of research on how sports participation affects academic success.The purpose of this study is to examine differences in academic success between athletes and non-athletes. The hypothesis of this study is: There will be a significant difference in academic success between athletes and non-athletes. It is hoped that the results will shed some light on this important issue and help college students to better understand how participation in sports impacts their college experience.For this study, an online survey will be conducted using Qualtrics to examine the relationship between athletic participation and academic success. Participants will be recruited using the SONA system. Athletes scores on the Subjective Academic Achievement Scale (Stadler et al., 2021) will be compared to scores from students who do not participate in athletics using t-tests.I previously explored this topic through a classroom project. The results indicated that athletes performed better academically than non-athletes. However, the sample size was insufficient to draw any definitive conclusions. I predict that with a larger sample size, I will be able to obtain results that are both statistically significant and meaningful.

Abstract Name: Chemotherapy Treatment Alters Ki67 and Ankyrin Expression in Response to Strain and Hyaluronic Acid in Ovarian Cancer

Nearly 20,000 individuals are expected to be diagnosed with ovarian cancer within the next year; many of these will suffer from recurrent or late-stage disease that will develop resistance to chemotherapies. First-line treatments include chemotherapy drugs, Cisplatin, and Paclitaxel, which have different mechanisms of action. However, even with the varied treatments, chemoresistance remains a significant problem in ovarian cancer. Patients have less than a 50% five-year survival rate, making it essential to uncover the mechanism through which chemoresistance develops. The tumor microenvironment (TME) may play a significant and yet poorly understood role in developing drug resistance. Key components of the TME include cancer-associated fibroblasts (CAFs), which exert micro strains on the matrix, and hyaluronic acid (HA), an overexpressed glycoprotein. We hypothesize that CAF-generated strains and the increased presence of HA enhance chemoresistance. Samples were exposed to either vehicle controls, Paclitaxel, low dose (LD) Cisplatin, or high dose (HD) Cisplatin after exposure to combinations or absence of strain and HA. The ovarian cancer cell line OVCAR-8 non-modified or wild type (WT), shSCR, and shCD44 were exposed to strains on a Flexcell system (10% elongation, 0.3Hz, 24hr). Through quantifying immunofluorescence images for the proliferation marker, Ki67, and a cytoskeletal protein, Ankyrin this study investigated the role of tensile strain and HA on the development of chemoresistance. Our results display a strong association between strain and HA to increase expression of both Ki67 and Ankyrin. In the WT samples, these levels are further increased and observed when cells are treated with Cisplatin. Taken together, this suggests that the tensions exerted on the TME and the increased exposure to HA influence the development of chemoresistance and are pivotal in encouraging malignant behaviors.

Abstract Name: Reframing Virginia Woolf's Mrs. Dalloway

Virginia Woolf’s Mrs. Dalloway remains a novel that stubbornly refuses literary critics’ definitive interpretations. Since its publication in 1925, critics have struggled to identify its central purpose, resulting in sharp disagreement over the ways in which they interpret the novel. Because Woolf chose to tell Mrs. Dalloway’s story largely through the inner monologues of its characters rather than an omniscient, objective narrator, readers receive little guidance on how to respond to the novel’s events. Instead, they must rely on the characters’ incomplete, subjective—and thus biased—projections, often leading critical responses grounded in close readings to favor unfairly one character’s perspective over another’s. But these readings risk short-circuiting the novel’s tightly interlocking world of lived experience in which the past informs the present. To do so means to miss the macro point about the subjective nature of reality Woolf was establishing. This paper argues that critics must give equal consideration to the often contradictory points of view presented by Mrs. Dalloway’s characters in order to fully apprehend the novel. By examining the substantial critical disagreement around some of these characters, this paper emphasizes the notion that the novel’s meaning must attend to the irreconcilable differences between characters’ mental worlds rather than relying on close readings of particular characters. In weaving together a story with contradictory points of view, Woolf deliberately requires the reader to consider a multiplicity of perspectives, and thus establishes the subjectivity of human experience as the controlling theme of the novel.

Abstract Name: Identification of the Antifungal Mechanism of EIPE-1 against Cryptococcus Neoformans

Cryptococcus neoformans is a fungal pathogen found worldwide in soil and bird droppings that causes disease in immunocompromised and immunocompetent hosts. Cryptococcal meningitis has received global attention and is credited with 152,000 annual cases of cryptococcal meningitis in the HIV/AIDS population, killing approximately 112,000 people yearly. Treatments for fungal infections are limited, many treatments are toxic, and fungal organisms are becoming resistant to current treatments. Therefore, the discovery of novel antifungal therapies is critical for fighting these deadly infections. Previous studies in our lab showed that a eumelanin-inspired compound, EIPE-1, has antifungal activity against C. neoformans. EIPE-1 treatment led to misshapen cells, and transcriptional data showed differential regulation of fungal genes involved in cell wall synthesis, membrane assembly, and cell stress. Therefore, we hypothesized that fungal strains with mutations in these signaling pathways will be resistant to EIPE-1 treatment. For this, we have screened mutants from the C. neoformans mutant library for those that are available for transcription factors, kinases, and phosphatases. Mutants were mixed in competition with an m-cherry fluorescent cryptococcal strain and were treated with EIPE-1 or were left untreated as a control. Following a 24h incubation, cells were analyzed on a flow cytometer to evaluate resistant mutants. Data show that the mutants tested so far are more susceptible to EIPE-1 treatment than wild-type cryptococcal cells. Additional studies will examine further mutants to uncover those more resistant to EIPE-1 treatment. These data will be verified by incubating mutant strains with increasing concentrations of EIPE-1, which will verify their importance in EIPE-1 resistance. Finally, we will examine the how EIPE-1 interacts with the signaling pathway(s) where these genes are located by Western blot by examining phosphorylation of proteins in the identified pathways. These studies will enable us to pinpoint the mechanism of action of EIPE-1 against C. neoformans.

Abstract Name: History and Development of Italian Piazzas: Comparing Piazza della Signoria and Piazza del Popolo

Piazzas are an integral part of the Italian culture and history. They date back to Greek, Roman and Entrust scan civilizations. Piazzas can have various purposes. Through our travels in Italy, we got to see many different piazzas, that had different purposes, sizes, shapes and aesthetics. This essay analyzes Piazza della Signoria in Florence and Piazza del Popolo in Rome, to compare them and see how the idea of these piazzas changed through the history of Italy. Piazzas or squares are planned and used differently in the United States compared to how they are planned in Italy. This essay then aims to compare piazzas to ideas of squares and urban planning in the United States. We have a very different culture than Italy. We use a lot more vehicular transportation, lessening the need for these open spaces to take breaks on commutes, that the Italian piazzas provide. The question is also asked how technology has influenced the use of piazzas in our modern life. As the United States is a much younger country than that of Italy, we don't have the same rooted history to the use of piazzas. Some guiding questions for this essay were how do Piazza della Signoria and Piazza del Popolo compare in terms of planning and purpose? How does the planning of piazzas compare to the planning of squares in the United States? How do piazzas in Italy stand up to modern urban planning theories in relation to squares?

Abstract Name: DECARBONIZED DESIGN; ANALYZING HOW MASS TIMBER CAN SUPPORT DECARBONIZATION AND GROWING COMMUNITIES

The rise of carbon in our atmosphere is a leading cause of climate change, and one of the biggest threats to our planet. Though not the most toxic greenhouse gas, it is the most durable, therefore lingers much longer in our atmosphere. This leads to higher atmospheric temperatures, causing natural disasters such as melting ice caps, hurricanes, wildfires, and rising sea levels which leads to displacement of people and loss of biodiversity. The global building industry emits almost half of the annual carbon emissions. My thesis aims to understand how mass timber can be a leading building material to lower carbon emissions and reduce existing carbon. My project will be in downtown East Point Georgia, as Georgia is the number one state for forestry in the US and is a leading timber and paper industry in the country. Atlanta has the highest percentage of canopy coverage of any major US city. Trees are a staple of our community. With existing forestry conditions Georgia could be a leader of mass timber for the Southeast region of the United States. Also, with the proximity to Atlanta, the rail lines, and Hartsfield-Jackson International Airport, East Point has a central location to be an example site for promoting mass timber. My project aims to develop a demonstration pavilion which educates on the issues of carbon emissions, and how the building industry and mass timber can work to lower carbon emissions in our atmosphere. It also aims to show how we can push the limits of mass timber construction for the building industry, and support decarbonization by lowering

embodied carbon. Some of my guiding questions are how does mass timber support decarbonization? How will the mass timber industry support East Point and Georgia? My goal is for prosperity in East Point and globally through decarbonization.

Abstract Name: Testing Reciprocal Within-Person Changes in Aversive Reactions to Emotions and Skill Use in the Unified Protocol

Emotional disorders are thought to be maintained in large part by the experience of frequent and intense negative emotions and aversive reactions to these emotions. The Unified Protocol for Transdiagnostic Treatment of Emotional Disorders (UP) was designed to teach patients skills to manage aversive reactions and reduce the frequency and intensity of negative emotions. However, it is unclear how skill use and aversive reactions are related to each other in this treatment. Participants (N = 70; Mage = 33.75, 67% female, 74% White, 74% heterosexual) completed measures of aversive reactivity, skillfulness, anxiety and depression before each session. We used hierarchical linear modeling to explore if within-person changes in aversive reactivity predicted residualized session-to-session changes in skill use and if within-person changes in skill use predicted residualized session-to-session changes in aversive reactivity. We then used multilevel mediation analyses to test whether aversive reactivity or skill use mediated the effect of the other construct on changes in anxiety and depression. Within-person increases in skillfulness significantly predicted session-to-session improvements in cognitive skills and mindfulness but did not predict improvements in any aspect of aversive reactivity. Within-person changes in aversive reactivity did not significantly predict changes in skillfulness. Between-person changes in skillfulness were significantly related to changes in between-person aversive reactivity. Only the indirect effect of skillfulness through mindfulness on anxiety/depression was significant. These results suggest that aversive reactivity and skillfulness may be relatively independent constructs.

Abstract Name: Predictors of Language Learning Anxiety in the Japanese Classroom

This research investigates the intricate relationship between Japanese language learning anxiety and various key variables, building upon the framework established by Han Luo (2018) but tailored to the unique characteristics of the Japanese language. Unlike Latin-based languages, Japanese employs three distinct writing systems—Hiragana, Katakana, and Kanji—adding a layer of complexity to the language learning process. The central inquiries focus on understanding the correlation between Japanese language learning

anxiety and selected variables, assessing the relative contributions of these variables to anxiety prediction, and exploring potential interactions among them.Survey methods were employed, targeting participants from Japanese 111 (first semester) and Japanese 231 (third semester) classes. The study examined seven variables: age, motivation (read/write/comprehend/speak), perception of the Japanese language's difficulty, self-perceived achievement, self-perceived language learning ability, self-expectation in the Japanese classroom, and perception of the Japanese language's importance.Among the variables, self-perceived language learning ability and self-expectation in the Japanese class exhibited negative correlational relationships in predicting anxiety, while the perception of the difficulty of the Japanese language demonstrated a positive correlation. Additionally, the motivations for learning to speak, comprehend, and write exhibited a negative relationship with grade expectations. Notably, motivation and grade prediction yielded significant ANOVA results (0.036 and <0.001, respectively) among the multiple variables examined, suggesting their pivotal roles in influencing anxiety levels.This research extends Luo's framework to the Japanese context, providing valuable insights into the nuanced dynamics of language learning anxiety. By elucidating the interplay of these variables, the study contributes to a more comprehensive understanding of the challenges faced by Japanese language learners, paving the way for tailored educational interventions and support systems.

Abstract Name: Neurological Links to Home Design Preferences: A Comparative Study using Eye-Emulation Software

This study seeks to understand the visual elements of home design that attract the human eye. Specifically, it aims to compare the visual appeal of traditional homes to modern homes using eye-tracking software. However, this study focuses solely on visual analysis, leaving the exploration of emotional and cultural factors for future research. The purpose is to understand the neurological connections between architectural design and human preferences, shedding light on which elements make homes visually appealing. In the mid-20th century, the architectural landscape shifted towards modernism, characterized by functionalism and minimalism. However, recent research suggests neurological links to architectural preferences that challenge modern design's dominance. This study is relevant today as it explores why people are drawn to traditional homes, considering the current preferences of professional architects. This research contributes to the understanding of how architectural aesthetics impact individuals and communities and offering insights into the neurological aspects that influence architectural preferences. The methodology involves analyzing six homes, three traditional and three modern. The analysis will be conducted using 3M Visual Attention Software individually on each home by tracking participants' eye movements, and then given a numerical ranking of 1-6 based on their visual appeal. Subsequently, a comparative analysis will identify the most and least visually attractive homes. Anticipated results from the software suggest traditional homes will score higher due to the "character," or the details where the eye looks, which are missing in modern architecture. The discussion will explore the idea that contemporary homes, by incorporating traditional elements such as proportion, may achieve higher appeal and last for generations of homeowners. Contemporary designs can evolve into "traditional" homes by aligning with the preferences discovered. By understanding what elements people are naturally drawn to, architects can create more appealing and lasting designs, thereby bridging the gap between modern and traditional aesthetics.

Abstract Name: Understanding the effects of accessible medically-tailored food boxes containing fruit and vegetables on cardiometabolic markers in immigrant Hispanic/Latine individuals with hypertension

Background/Objective: The Dietary Approaches to Stop Hypertension (DASH) diet recommending 8-10 servings of fruits and vegetables (F&V) daily is known to lower blood pressure. This project aims to measure the effect of improved access to culturally-appropriate F&V on cardiometabolic markers such as systolic and diastolic blood pressure (BP), skin carotenoid status, and markers of adiposity in immigrant Hispanic/Latine individuals with hypertension. We hypothesize that increased access to F&V will reduce cardiometabolic markers for hypertension and increase skin carotenoid levels after 28 days. Methods: Twenty Hispanic/Latine participants with hypertension were enrolled in a 28-day clinical trial. Participants received a weekly food box with 8-10 daily servings of F&V. Pre- and post- measurements of BP, weight, waist circumference, and skin carotenoid levels were collected. T-tests determined significant changes in measures at p<0.05. Results: Average age of the 11 women and 9 men completing the intervention was 49.5±9.3 and 65% of participants migrated to the U.S. from Mexico. Significant mean differences in systolic BP (3.4± 7.3 mmHg; p<0.05), diastolic BP (3.0±5.6 mmHg; p<0.01) and waist circumference (-0.8±1.0 inches; p<0.01) were found. While difference in weight (-1.5±4.6 lbs) and skin carotenoids (25.2±75.7) changed, results were not significant. Before the study, 81% of participants indicated they couldn't afford to eat balanced meals “often” or “sometimes”, whereas the intervention reduced this to 57%. Conclusion: Improved access to F&V supported significant changes in systolic BP, diastolic BP, and waist circumference, showing the DASH diet can help lower cardiometabolic markers. This provides formative contributions to research regarding access to culturally-appropriate F&V interventions for hypertension in the Hispanic/Latine community as little research displays work encompassing cultural food preferences.

Abstract Name: Soil Salinity: Can Ionized or Deionized Water Mitigate the Negative Effects of Salt Stress on Root and Shoot Growth of Brachypodium distachyon?

Soil salinity is one of the most severe environmental factors impeding crop plant productivity and is an ever-increasing threat to worldwide agricultural production. Interestingly, some studies have shown that various forms of water may reduce salt accumulation in soil. We hypothesized that it may be possible to mitigate the effects of salt stress on plants with the addition of ionized or deionized water, and proposed the following research question: Can ionized or deionized water mitigate the negative effects of high soil salinity on root and shoot growth of Brachypodium distachyon, a small grass plant used to study biofuels? To test our hypothesis, B. distachyon seeds were germinated and transplanted into fabricated ecosystems (EcoFABs) in different growth environments, including a control group (normal growth media), and test groups with

normal growth media, high salt concentration, and either ionized, deionized, or tap water. The root and shoot growth of each plant was measured weekly over four weeks. The results of our experiment were consistent with our hypothesis. Specifically, we found that in high salinity with ionized water groups, the shoot length was ~76% greater, and root growth was ~240% greater compared to controls. Additionally, plants in high salinity and ionized water were visibly healthier when compared with test groups. Similar results were observed in the deionized-treated high salinity group, but they were not as robust as with ionized water. Based on these results, we concluded that it may be possible to mitigate the effects of high soil salinity on plants with the addition of ionized water. We recommend repeating our study and increasing the number of replicates per group to confirm these results. By scaling up the experiment we hope that future studies will affirm that ionized water is the best option for optimizing root and shoot growth in salinized soil conditions.

Abstract Name: Barriers and Motivators for Joining the Midwifery Profession in Black and African American Nursing Students

Purpose: The purpose of this study is to explore factors that influence African American nursing students' decisions to pursue midwifery careers.Research Context: Research suggests that greater diversity and integration within the maternal health field significantly reduces the risk of poor maternal outcomes for women of color. However, there is a shortage of midwifery students of color and midwives of color in clinical practice. According to the 2021 American Midwifery Certification Board Demographic Report, only 7% of certified nurse midwives identify as Black or African American, compared to 84.95% who identify as Caucasian. A recent study by Mehra et. al (2020) found that racism is a motivator and barrier for people of color aspiring to become midwives in the United States. However, more research is needed to understand other factors that contribute to nursing students' decisions to pursue a career in midwifery to address this gap.Methodology: This study extends the Mehra et. al (2020) findings by only surveying current undergraduate nursing students and expanding upon the potential motivators and barriers of joining the midwifery field. Using a descriptive cross-sectional design, participant responses to an anonymous survey asking questions regarding personal factors and barriers, family factors and barriers, community factors and barriers, and societal factors and barriers that may affect a student's decision to become a midwife will be analyzed. Data collection is in progress and will be completed in January 2024. Data analysis will be completed in February 2024, using SPSS software. Expected Results: This study provides insight into the barriers that students might face when considering midwifery as a career choice. These findings will provide nursing programs valuable insight that can be utilized for recruiting and educating a diversified workforce to help improve patient outcomes and address the maternal health crisis in the United States.

Abstract Name: Focus on Power: A Qualitative Analysis for the Development of a Lifestyle Behavior Prehabilitation Program for Soft-Tissue Sarcoma Patients.

Common treatments of soft-tissue (ST) localized extremity and trunk sarcoma include radiation, surgery and chemotherapy. These treatments result in excellent local disease control, however, during the post-treatment period, ST sarcoma patients experience high rate of wound complications (about 35% of patients). Evidence indicates poor preoperative functional status and malnutrition are associated with longer hospital stays which leads to higher complication rates and worse functional outcomes following treatments for ST sarcoma. Preoperative exercise training and proper nutritional intakes have shown to reduce hospital stay and reduce postoperative complications. Additionally, interventions in preoperative exercise (prehabilitation) and nutrition interventions have demonstrated benefits for other cancer populations and non-cancer orthopedic surgery patients. However, to date, there is no data to support the development of a lifestyle prehabilitation program in ST sarcoma patients. Therefore, the purpose of this study is to obtain feedback from soft tissue sarcoma survivors on their experiences with lifestyle behaviors pre- and post-diagnosis and how their ST sarcoma treatment affected their lifestyle behaviors. The final goal of this project is to use a patient-centered approach to adapt current prehabilitation programs for a ST sarcoma population. Through this study we will be collecting feedback and preferences via one-on-one interviews on the participants experience with physical activity and nutrition programing pre- and post-diagnosis, as well as their feedback on preferences for a lifestyle prehabilitation program. The results from this study will be used to develop a lifestyle prehabilitation program for ST sarcoma patients to be tested in a future pilot study.

Abstract Name: Comparative analysis of nonribosomal peptide synthetase protein expression under control of different inducible promoters

Epoxomicin is a natural proteasome inhibitor and the structural inspiration for the multiple myeloma drug Carfilzomib. While Carfilzomib is produced through chemical synthesis, epoxomicin is produced by Actinobacteria in nature via a biosynthetic pathway including a nonribosomal peptide synthetase (NRPS). NRPSs are massive modular enzymes used by bacteria to build anticancer, antibiotic, and other bioactive peptides in an assembly-line fashion. By modifying the gene sequence of the epoxomicin NRPS and expressing the engineered enzymes heterologously in E. coli, we propose that the pharmacophore of Carfilzomib can be created biosynthetically, hopefully lowering drug cost and increasing production efficiency. To effectively express the large (>150 KDa) engineered NRPS enzymes in E. coli, we tested protein overexpression under the control of three different inducible promoters (araBAD, lac, trc). Plasmids were cloned via Gibson Assembly containing NRPS-encoding genes in combination with each of the inducible promoters, and transformed into BAP1, a derivative of E. coli BL21. Small scale expression tests of induced and uninduced cultures were analyzed via SDS-PAGE and Western Blot to compare expression of NRPS enzymes in terms of inducer control, and amount of overexpression of full-length protein. We found loose inducer control of NRPS expression in multiple vectors, even those under control of the arabinose operon. Additionally, high titers of full-length protein were typically correlated with expression of other protein fragments. With optimized expression, we will next purify these enzymes and test for their ability to

biochemically produce the Carfilzomib pharmacophore. Continued optimization of modular protein expression and purification in E. coli can provide a template for the conditions by which large, engineered NRPS enzymes are effectively produced outside of their host organism.

Abstract Name: “The Gay Plague”- Analyzing the Effect That the Reagan Administration Had on the Hypersexualization-Stereotype in the LGBTQ+ Community

“The Homosexual Disease.” “The Gay Disease.” “The Gay Plague.” All of these terms have been used and are still actively utilized to describe the HIV/AIDS Epidemic. This epidemic has been a prime talking point in many conversations about LGBTQ+ equality, acceptance, and access to basic human rights. The first reported cases of domestic HIV appeared in 1981, which continues to affect and take the lives of not only the LGBTQ+ community, but all people across the world. According to hiv.org, the leading organization dedicated to HIV/AIDS awareness and research, “approximately 1.2 million people in the U.S have HIV, and about 13 percent of them don’t know it and need testing.” Notice how in the wording of the statistic they only say “people” and no other term relating to the LGBTQ+ community. It is important to recognize that HIV affects all people and also acknowledge that this affects LGBTQ+ and racial minorities, all of which are not mutually exclusive. LGBTQ+ hatred has always existed due to government and public figures using their harsh rhetoric to create horrendous stereotypes, terrible responses to LGBTQ+ societal acceptance, and ignorant attitudes toward Queer healthcare. The Reagan Administration is one of the biggest perpetrators for not only utilizing these said terms, but also exploiting them to portray harsh stereotypes and false information to the general public of America about the LGBTQ+ community during the rise of the HIV/AIDS epidemic.

Abstract Name: The Rococo and Victorian Eras: Art, Architecture, and Graphic Design

The history of art is vast and expands across the entire globe. Some of the earliest works of art can be seen in cave drawings that date back to the Paleolithic Period between 30,000 and 10,000 BCE. Since then, art has evolved and transformed. Today the broad term art includes a variety of media ranging from painting to photography, installation to architecture, printmaking to graphic design. As the media of art evolves through history, styles and standards evolve as well. Analyzing and comparing different time periods of history allows for a better understanding of art and the purpose for them. This essay will compare paintings, architecture, and graphic design from the Rococo art movement (1720-1770) and Victorian era art (1850-1900) focusing on the characteristics, styles, and ideals of each movement. Although the Victorian style, primarily in graphic design, was influenced by the Rococo style, the two movements have many key differences between their painting and architectural styles. Comparing these two movements shows the progressive and retrospective

choices of artists and, in turn their societies, through the expression of their art. Looking and analyzing specific aspects of art movements gives context and a better perspective of what the world was like in different periods of time throughout human history. By analyzing the Rococo style and Victorian style, key differences are evidence of the progressive changes of a developing world.

Abstract Name: Women on the Grid: Barriers Between Female Motorsport Athletes and a Seat in Formula One

While Formula One Grand Prix racing has been hosting competitions since 1950, only five women have ever qualified for a Grand Prix race and, of those five, only two actually competed. Motorsport is classified as a unisex sport in that the sex of an athlete has no impact on the athlete's ability to compete, meaning female athletes are theoretically just as capable as men. However, they lack the support needed to break into professional motorsport. The lack of female drivers may be attributed to four main barriers: the historical masculinity of car culture, gender stereotyping, over-sexualization of female athletes, and lack of parental support. In addition, female athletes are compared to physical beauty standards set by NASCAR driver Danica Patrick and Formula One hostesses the Grid Girls, which causes drivers to be oversexualized and tokenized. This paper analyzes a number of peer-reviewed sources regarding each of these specific barriers, as well as an interview of anonymous female drivers to get specific reports about their personal experiences. Supporting evidence also includes firsthand accounts from racers, analysis of advertisements and photoshoots, and self-reported stereotyping regarding female drivers. This paper cross-references sex differences in F1 with those in the similar unisex sport of esports and online gaming to see if the same discrimination exists in other male-dominated sports. This analysis demonstrates that that female racers are more sexualized, more underestimated, and less valued than their male counterparts. Finally, this paper examines F1's new gender inclusion program Formula One Academy, launched November 2022, to predict the impact that it may have in the future. With Formula One's international fan base and popularity, if they are able to successfully sex integrate, they have the potential to influence other unisex sports and set an example for how to create a gender-inclusive environment.

Abstract Name: Physiological Implications of Exclusion in Individuals with ADHD Symptomatology

Attention-deficit/hyperactivity disorder (ADHD) is an interference in the brain's internal communication system connecting the areas mediating attention, arousal, and emotion. An example of emotional interference is rejection sensitive dysphoria, the feeling of emotional pain due to a failure or rejection. There is limited

research addressing whether this interference presents as a physiological response. We investigated the physiological responses of individuals with ADHD symptomatology during an exclusion task. Participants were 18-38, N = 60; 26.7% male, 73.3% female. Self-reported measures of ADHD symptomatology were reported using the Adult ADHD Self-Report Screening Scale (ASRS). For an objective measure of behavior, participants completed the Go/No-Go task. The Cyberball task was used to manipulate exclusion. During this task, heart rate was measured as beats per minute (BPM), using electrocardiogram (ECG) technology. Self-reported measures of exclusion were reported using the Need-Threat Scale (NTS) after the task. We found that 21.7% of participants reported a current ADHD diagnosis; 61.7% of participants scored a four or more on the ASRS, expressing symptoms that are highly consistent with ADHD. Findings showed that counterintuitive to previous literature, there was a significant time effect across ECG measures where BPM decreased from baseline during the task and increased during the post measure, F (2, 214) =11.034, p <.001. Further, we found associations between NTS total scores and ADHD symptoms to be negatively correlated, r (57) = -.444, p < .001. Finally, participants with self-reported ADHD diagnoses had greater impulsivity errors (responding on no-go cue) as compared to participants without it. These findings suggest ADHD symptomatology and physiological responses during exclusion are not associated. Additionally, after the task we found higher rejection sensitivity in those with higher ADHD symptoms. Further physiological research in rejection sensitivity, specifically in individuals with a current ADHD diagnosis is needed.

Abstract Name: Jeremy Soule: An Innovator in Video Game Music

Music has played an important role in the video game industry since its advent in the late twentieth century, helping to guide and shape it into what it is today. From the days of the arcade to present-day gaming systems, this new, relatively fledgling industry has taken off as an industry that is wholly worthy of artistic respect. This is thanks to the work of several different video game composers, whose efforts are quite difficult to go unnoticed. One such composer is Jeremy Soule, who, in his career spanning nearly three decades, has become one of the most important, prolific, and influential composers in the world of video game music. Soule's artistic efforts have helped to innovate an entire industry and bring it to new and greater heights. Alongside the advent of new computer technology, Soule has bridged the gap between early and modern video game music, and his prominent role in how video game music has developed cannot be understated. Soule was one of the earliest composers to utilize orchestral music in video games and, as such, became an important pioneer for it. Due to his efforts, what was previously impossible to do in video game soundtracks is now very possible, and Soule has served to pave the way for other composers to write grand orchestral scores for the games they work on. Transforming video game scores from very simplistic computerized sounds into rich orchestral works that rival film scores has served to elevate the status of video games as an artform, in a manner quite similar to film in the early twentieth century. With the grand, sweeping melodies and rich polyphony of an orchestral soundtrack, video games can be appreciated by the general public as a form of art rather than just entertainment.

Abstract Name: Fringe Media Consumption and Perceived Intelligence of the Opposite Gender: Are They Related?

The cohabitation of gender stereotypes and political ideology in America has been observed within various spheres (Eagly et al., 2020; Eagly & Mladinic, 1994; Nathanson & Young, 2012). While these stereotypes can take different forms and influence different types of behaviors and opinions, the relationship between them and the mainstream media is consistent. Past studies, however, fail to consider the advances in social networking platforms over the past decade, including an influx of more unregulated content, such as YouTube and podcasts. In this project, I expand on this topic by exploring the relationship between ideologically extreme, or fringe, media consumption and perceived intelligence of the opposite gender among students at the University of Wisconsin - Stout. I surveyed 301 students and completed 12 in-depth interviews to study this relationship. Both modes asked a battery of questions about personal engagement with fringe media and relative intelligence of the opposite gender. Results indicate that overall engagement with these sources is low, although even minimal engagement does statistically correlate to a slightly higher belief in certain gender stereotypes about intelligence while interviewees mentioned more profound influences from these sources. Furthermore, women felt their intelligence to be higher than that of men, contradicting past literature on the topic. The significance of this study lies in its support for the idea that participating within these spheres does play a role in how each gender thinks of the other's intelligence. With this information, individuals can become more aware of how this engagement may influence personal biases and may actively work against them to break down these stereotypes.

Abstract Name: The Influence of Trust in Science and Political Leaning on Perceptions of Drinking Water Quality

A combination of climate change and land usage practices has raised the issue of clean drinking water. What was a purely environmental issue has become one garnering widespread attention from both the public and governments alike. At the same time, partisanship has been increasing, with some researchers documenting that trust in science can sometimes fall along party lines. However, individual belief in science is influenced by a multitude of factors. While the influence of trust in science on concern with other environmental issues has been studied, it has yet to be applied to policy issues surrounding drinking water. This study aimed to understand the potential relationship between trust in science and perceptions of drinking water quality along political divides in rural Wisconsin. A mixed methods approach, including a mail survey and several interviews, revealed that while there is a partisan divide when it comes to trust of institutionally generated scientific information, Dunn and Barron County residents are not as partisan about drinking water concerns as they are on other environmental issues. Furthermore, residents were generally unconcerned with the quality of their own drinking water but were concerned with drinking water on a broader level. This can be used to improve communication between scientists, government officials, and the public regarding potential drinking water concerns. However, further research into how belief in science impacts other facets of environmental policy in rural areas should be conducted in order to create and mold effective communication to support strong environmental policy in a variety of areas.

Abstract Name: Ciprofloxacin- An antibiotic derivation and antimicrobial study

The purpose of this study is threefold: to prepare ciprofloxacin analogs via amide formation synthesis; to examine the analog's antimicrobial activity; and lastly, to design experiments with the aim of comparing their permeabilities. By changing the amide functional group on the molecule, the membrane permeability, polarity, and effectiveness of inhibiting bacterial growth in gram-negative bacteria (E Coli.) can be exhibited. Synthetic reactions are performed through amide formation with two varying acid chlorides. Through these reactions, acetyl chloride and cyclopropanecarbonyl chloride are used to derivate from the ciprofloxacin molecule. The antimicrobial effectiveness of the ciprofloxacin analogs is tested with a zone of inhibition on BL21 and DH5α E.coli sample strains. Experimental designs and results are to be presented in detail.

Abstract Name: Comparing the Presence of Antibiotic Resistance Bacteria in Wastewater Systems to Assess the Population Health of Kansas Counties

The development and spread of antibiotic resistance, as well as the emergence of novel human pathogens, are progressively limiting the treatment and prevention of bacterial infections. This poses a threat to critical components of modern medicine. The emergence of antibiotic-resistant microorganisms that evade all water treatment technologies poses a growing threat to community health. Research has shown that water in sewer systems can serve as an early warning system for disease outbreaks (Hutinel et al., 2019). Surveillance and tracking of microorganisms in wastewater play a crucial role in this early warning system (EWS). Furthermore, analyzing sewage samples has the potential to complement clinical surveillance systems for antibiotic-resistant bacteria efficiently. Thus, it is important to establish the relationship between resistance rates in sewage in different part of United States. In this study, influent and effluent wastewater samples, along with municipal water samples, were collected from Hays and Colby, KS for a period of ten months. Each sample underwent a viable plate count technique, bacterial isolation and an antibiogram profile analysis. A total of 22 resistant microbe isolates were identified. Ten Gram-negative isolates appeared in treated water. An ANOVA analysis of the rate of antibiotic resistance between Hays, Colby and nationwide was performed.

Results showed there is no significant difference in the rate of antibiotic resistance when compared to nationwide (F2, 15 = .411, p>0.05).

Abstract Name: The Town Square: A qualitative approach in understanding how public green spaces and main street design affect resident downtown utilization

This qualitative study investigated the impact of public green spaces and main street design on resident downtown utilization. Two different Iowa downtowns with similar demographics were chosen for a comparative analysis, one featuring a downtown with a strong public green space and one without. Polk City (IA) was chosen as the primary case study because its “town square” downtown features a prominent public green space at its core. Nevada (IA) was chosen as a town of comparison because its downtown contains a traditional main street with little to no public green space. Individual qualitative surveys were conducted to gather data in respective downtown areas on three separate Thursdays and Sundays from 11:00 am to 6:00 pm in September 2023. Participants were randomly chosen for a face-to-face interview, and responses were either filmed or recorded depending on participant consent. The survey questions aimed to ask how, why, and how often residents spent their time in downtown areas. Digital transcriptions were made of all interviews and analyzed post hoc to examine any differences in resident downtown utilization. Findings from this study show increased community engagement in the downtown with greater public green space, as, on average, Polk City residents spent more time downtown, utilized it for more purposes, and visited it more frequently compared to Nevada.

Abstract Name: Automated Parking Space Vacancy Detection Utilizing Spatial Grid

In primarily populated areas, locating available parking can take time and effort, posing an environmental problem. Depending on the time of day, many drivers may face this issue due to the high volume of other drivers attempting to find parking. In most instances, urban drivers are forced to search for available street parking or vacant spaces in public parking lots. This behavior can often lead to traffic jams in local areas, often seen in populated cities such as Los Angeles and New York. Solutions to this public parking problem introduced the idea of smart parking systems. In this research, we propose a novel approach to video-based parking space detection by utilizing a spatial grid to introduce localization to the scene. Our approach

essentially utilizes a spatial grid that serves as a map of the scene, including only the road as cells within the grid. Once the grid is established, it encompasses the entirety of the parking lot, allowing our approach uses a network specialized in Monocular 3D Object Detection to map each vehicle's location more accurately within the scene with respect to the available parking spots identified during grid generation. To leverage the use of our system, we also built a demo application using a database to record the status of each parking space. By leveraging the duration of occupancy of each space, our system also has access to historical occupancy data, which can be used in tandem with other factors, like time of day and day of the week, to provide more valuable predictions and information that can assist drivers in finding parking more efficiently. We plan to continue thoroughly evaluating the accuracy and reliability of our system's predictions through comprehensive testing and comparisons with existing state-of-the-art systems to ensure its practicality in real-world scenarios.

Abstract Name: From Barbie to Battleship: Analyzing Brand Marketing for Films Based on Existing Toy Properties

With the cultural zeitgeist captured by the movie Barbie in 2023, the floodgates for films based on existing toy properties have been unleashed. Barbie was touted for its aggressive marketing campaign and its subsequent success at the box office, but why did this sensation come to be? Can it be replicated? And how did its marketing play a role in its success?In my research, I will conduct case studies of six theatrical wide-releases where the subject matters of the films are based on existing legacy toy properties. I will seek to examine the marketing strategies employed by each film and analyze how these marketing strategies connected to the toy's well-known brand identity. Qualitatively, I will analyze the impact of these marketing strategies through established brand marketing frameworks. I will also conduct thematic analysis on social media posts around the film's theatrical window to determine general audience reception, noting indications of brand connection and nostalgia as factors. As a quantitative framework for brand impact, I will analyze weekly box office returns in comparison with weekly toy sales to establish the impact of the film's theatrical release on the toy brand's continuing business. Final box office figures and toy sales post-film release will provide conclusions on the impact of each film on their toy brand. Through this research, I expect to uncover the importance of authentic brand marketing for films based on beloved brands. As toy brands look to profit off the success of Barbie, I want to establish a marketing framework for companies to use in order to honor the brands they seek to adapt on screen. I expect to find a connection between brand authenticity and successful film performance, which would substantiate the importance of brand authenticity in the making and marketing of films based on existing toy properties.

Abstract Name: Understanding the Link between Moral Foundations and Cyberdeviance

Recent studies have found evidence for a correlational link between moral values and the decision to engage in deviant behavior. While this work has primarily focused on deviance in offline spaces, this study expands on these findings by focusing specifically on deviance that occurs in online spaces, especially in the way people interact with others and present themselves online. Through the lens of psychological and criminological theory, this research aims to investigate the impact that one's morals have on their willingness to engage in deviant activity online. Preliminary findings suggest that there are some similar patterns in the way our moral systems impact deviant behavior in both online and offline spaces.

Abstract Name: Readmission Patterns of Adolescents with Severe Lung Injury from Vaping (EVALI)

Electronic cigarettes were initially introduced as a smoking cessation tool in 2007, but their widespread availability and appeal have led to a surge in use among adolescents and young adults. This led the Surgeon General of the United States Public Health Service to declare youth e-cigarette use an "epidemic" in 2018. E-cigarette, or Vaping Product, Use Associated Lung Injury (EVALI) was termed by the Center for Disease Control in 2019 after many young patients began presenting with acute lung injury and organizing pneumonia. There have been continued admissions among adolescents for EVALI (unpublished data), which raises significant public health concerns about the medical harms of vaping. Although clinical characteristics of adolescents with EVALI have been well described, there remains a knowledge gap as to whether adolescents with EVALI have been readmitted to the hospital after the initial insult for medical reasons related to e-cigarette use. The aims of this study include determining whether adolescents with a history of hospitalization for EVALI required readmission to the hospital for vaping-related medical illness or for any other reason related to e-cigarette use and characterizing factors that contribute to readmission within this population. To investigate how these factors influence readmissions, I will conduct a retrospective chart review of medical records of adolescents aged 13-21 with a history of admission to the hospital for EVALI at Children's Medical Center Dallas from 2019-2023 and closely examine demographic (i.e. age, gender, ethnicity), clinical (i.e. severity of lung injury; hospital course including admission diagnosis, treatment, and laboratory analysis; vaping history), and social (i.e. family environment, level of education, and access to health and support services) factors. By the end of this research project, I hope to identify common characteristics associated with adolescents with a history of EVALI compared to those who did not have readmissions in the medical record.

Abstract Name: Investigating Hospital Floor Tiles to Mitigate Bacteria by using a DBD Plasma Hoover

Surface sanitation is important in medical settings to avoid contamination. This work investigates plasma techniques to mitigate bacteria on the floor tiles that are traditionally used in the hospital environment. For this purpose, a Dielectric Barrier Discharge (DBD) plasma torch was designed along with a robotic hoover that held the plasma torch to scan the floor tiles in an automated fashion. The plasma hoover can travel at a speed of 2-3 mph and can hold a load of 80 pounds including the gas cylinder, power supplies, and motors. Calculations were performed for the wheels to make sure that it could carry 80 pounds net weight of the robot, while operating at a speed of 440 feet per minute and a stopping accuracy of 0.5. A PS4 controller was used to operate the robot in a remote fashion and operating software was developed. Rubber and vinyl tiles were used to simulate hospital flooring as these materials are commonly found in hospitals. The trial runs were conducted at various operating speeds with a plasma torch to eject the plasma sheet to scan the bacteria over the floor tiles. Before plasma scanning, the bacteria (E. coli) was cultivated on the floor tiles that were dried for 24 hours before swabbing for the trials. The trial runs were conducted at various speeds at various plasma operating conditions (10-15 slpm Helium/Argon, 8-13 kV, 20-40 kHz). The plasma torch generated a plasma sheet with a dimension of 25mm length, 50 mm width, and 2mm thickness. Preliminary results indicate a significant reduction in bacterial colonies that is strictly a function of plasma exposure time to the targeted area on the floor. Our presentation will include the details of our experimental setup and results on bacterial mitigation.

Abstract Name: The effect of arena size on outcomes of mixed martial arts competitions in the UFC

Mixed martial arts (MMA) is a combat sport in which two competitors fight in what is often an octagonal cage. The Ultimate Fighting Championship (UFC) is one of the more popular organizations that organize MMA events, using an octagonal cage as the setting of each contest. UFC has been organizing events since 1993, and recently, in an effort to save costs, created the UFC Apex in 2019, a smaller, company-owned arena in Nevada. The UFC Apex uses a smaller diameter octagon that has been the subject of a folklore claim often said by commentators, competitors, and fans; precisely that the results of events that take place in the UFC Apex are often more exciting and favor certain types of fighters. In this paper we investigate this commonly heard but unverified claim. For some perspective, the diameter/area of the two octagons are 25 feet/518 ft^2 and 30 feet/746 ft^2 (respectively). The CEO of the company has denied claims (vehemently) that the smaller octagon changes the nature of the contest.In our investigation, we employ statistics to test whether the claim is true. We use web scraping to extract the past contest results from publicly available sources and afterwards, we define the different styles of fighting (e.g. wrestling, striking, etc.) using metrics that incorporate fight statistics such as ground control time, total strikes, etc. We finalize by using statistical hypothesis testing.The number of contests in the UFC Apex and other venues is large, often one event per week consisting of upwards of ten matches. We believe that the data set is large enough that a definitive conclusion can be made about the claim and that it would be a novel start to an investigation into the underlying statistics of this relatively new sport.

Abstract Name: The 'Sustainable Development' of Capitalist Extractivism: The Continuity of Post-War Development in Oro Legal and Tierra Dorada

In this paper, I explore the question “How are sustainable development projects Tierra Dorada and Oro Legal continuations of post-war international development constructions?” “Development” as a concept is elusive, and has transmogrified to fit market demand and U.S. interests. The international development industry, composed of a network of U.S. government institutions, NGOs, practitioners, and implementers, evolved from the construction of post-WWII hemispheric divides and Global North capitalist interests. A rich post-development literature has argued that the promises of the development industry and its endless failures can be attributed to an industry designed to promote United States foreign policy interests and the propagation of capitalism. This stands in stark contrast to the global altruism promoted by the international development industry. International development implementers have tweaked their messaging to respond to the growing critique of development. Now, the international development industry centers the pursuit of “sustainable development,” responding to global calls for environmental justice. Decolonial scholars decry development projects as inherently neocolonial, while implementers promote sustainable development projects as a new era of development policy that centers on indigenous justice, biodiversity conservation, and locally-led development. I argue that sustainable development projects promote Western capitalist ideology and extractivism, in a continuity of post-war development under the guise of sustainability and global altruism. To make my case, I examine the sustainable development projects Tierra Dorada and Oro Legal, which aim to formalize artisanal gold mining in Colombia, mitigate environmental risk from cyanide and mercury use, and promote alternative livelihoods through market-based solutions. Relying on qualitative methods and interviews with development practitioners, I craft my argument by first examining the lineage of extractivism in Latin American development. I conclude with an examination of non-extractive alternatives to development, centering Latin American scholarship on Buen Vivir.

Abstract Name: Understanding COVID-19 Vaccination Behavior: Analyzing Equity and Factors Impacting Uptake

The MAVEN (Multidisciplinary Analysis of Vaccination Games for Equity) project addresses the global health threat of vaccine inequity in the fight against emerging infectious diseases. The work presented here aims to provide a comprehensive understanding of vaccination coverage and identify key drivers of vaccine uptake. The COVID-19 pandemic has shed light on differences in vaccine behavior across the country and the state of California, and past research studies have identified various individual, social, and structural factors associated with vaccination rates in different communities and geographic regions. In the study presented here, we used data from public sources, including Google Health, the Center for Disease and Control Prevention (CDC), California Department of Public Health, California Healthy Places Index, and Carnegie Mellon University. Different statistical tools were used to analyze the data with software such as Python, SQL, JMP and R. Throughout the United States, associations between ethnicity and vaccination hesitancy were observed. With a focus on zip codes throughout the state of California, the analyses found strong associations between economic, social, education, and housing indicators and COVID-19 vaccination measures like percentage of fully and partially vaccinated individuals. Following these analyses is the construction of an ARIMAX (Autoregressive Integrated Moving Average with Exogenous Variables) forecasting model that aims to track future trends ahead of time so that institutions, and society as a whole, can be better prepared during a pandemic. Exploring different factors associated with vaccination behavior can reduce the risk of future pandemics by enabling targeted interventions in communities that display certain characteristics and have shown a previous history of struggling with vaccine distribution and implementation.

Abstract Name: Relationships Between Orthorexia, Exercise Dependency, Body Dysmorphia, and Decision-Making

Chronic concerns over accessing and consuming healthy food can produce problematic eating behaviors—these behaviors are being increasingly categorized under the term orthorexia nervosa (ON; REF). Individuals exhibiting ON symptomatology express a disruptive obsession with eating healthy foods. Although not part of the formal DSM-V or ICD-10 classification schemes, considerable research exists that suggests that ON is a unique and maladaptive set of eating behaviors that may be linked to formally recognized eating disorders and/or obsessive-compulsive disorder (Dunn & Bratman, 2016; Novara et al., 2021). Similarly, unhealthy and maladaptive behavioral patterns related to excessive exercise (exercise dependency) are also widely documented in the sport and health science literature (Oberle et al., 2017; Landolfi, 2012). Although there is considerable debate around the concept of exercise “addiction,” excessive exercising appears to share at least some behavioral and cognitive patterns with substance use disorders (Oberle et al., 2017). Past research has also demonstrated that ON and exercise dependency frequently co-occur and may share common neurobehavioral substrates (Freimuth, Moniz, & Kim, 2011). This research confirms previously documented relationships between ON and exercise dependency and investigates how these phenomena might be related to negative components of body image associated with body dysmorphia. It was hypothesized that individuals scoring high on traits or behaviors linked to ON and/or exercise dependency would also express decision-making strategies that are similar to those documented in the literature as being common to substance use disorders. Additionally, factors linked to ON and exercise dependency are related to decision-making patterns that are commonly expressed in individuals with substance use disorders.

Abstract Name: Classifying Road Debris Using Deep Learning Technique In Artificial Intelligence

According to a study done by AAA Foundation for Traffic Safety in 2016, road debris was a factor in an average number of 50,658 police-reported crashes between the years 2011-2014. This work addresses the critical problem of road debris detection and classification, a major threat to road safety, especially on highways. Road debris, such as barrels, car parts, puddles, salts, and trees, can cause accidents. Leveraging deep learning, we explored three pre-trained convolutional neural network (CNN) models - VGG16, MobileNetV2, and InceptionResNetV2 - to classify five types of road debris. We divided our dataset into training, validation, and testing sets, initially with 146, 73, and 49 images. After augmenting the dataset, we increased it to 875 training thermal images, 375 validation thermal images, and 114 testing thermal images. We evaluated the models' performance over various epochs with a learning rate of 0.0001, an Adam optimizer, and a batch size of 10. The VGG16 model emerged as the top performer, boasting a 100% training accuracy and a 96.65% validation accuracy. In testing, it correctly classified 90.35% of the images. Visualized confusion matrices showed consistent superiority for the VGG16 model across all debris types. This work underscores the efficacy of deep learning models in detecting and classifying road debris, with VGG16 as the most accurate and efficient model. It also emphasizes the importance of image augmentation, significantly improving model performance by expanding the training dataset's size and diversity. These findings have substantial implications for road safety. Implementing deep learning models for road debris detection can substantially reduce accidents, making roads safer for all users. Road authorities and safety organizations can leverage this research to develop automated systems for timely debris detection and removal, enhancing road safety.

Abstract Name: The Deaf Experience in National Parks with an Emphasis on Rocky Mountain National Park

The purpose of this research is to investigate the experiences of Deaf visitors to the Rocky Mountain National Park (RMNP).The lack of research and desire from the Deaf community to conduct this research shows its significance. The little research that exists in this field focuses on how National Park workers interact with Deaf people, rather than how Deaf people interact with the Park and its members. A study regarding Deaf visitors in Yosemite National Park found that many of these visitors were invisible to its employees. This analysis is crucial to the human experience as quality of life is improved with access to outdoor recreation. Whether people identify as a cultural and linguistic minority or as living with a disability, everyone should have equitable access to the National Parks. The approach of a narrative analysis from a first-person perspective of those who are Deaf and have spent time recreating in RMNP is the best way to secure this qualitative data. We are using a purposive sampling technique to identify participants who fit the necessary criteria, as we are strategically selecting informed participants. Participants will be interviewed with open-

ended and semi-structured interview questions on Zoom, using an interpreter. All meetings will be recorded and transcribed. After individual interviews, a focus group with all interviewees will be created to be collectively interviewed, using an interpreter. This interview will also use the same question structure and will be developed based on the initial responses of the participants. Thus, the research will be triangulated, creating greater validity of this research. Data will be collected and analyzed through a thematic analysis with a minimum of three interviewees. We are eager to uncover the significance of the Deaf perspective in National Parks to gain knowledge and understanding of this human experience.

Abstract Name: Analysis of APEH Enzyme Activity in Saliva Samples of Patients Exposed to Photobiomodulation.

Photobiomodulation (PBM) therapy, or low-laser/light therapy, is a non-invasive therapy thatuses red or near-infrared light to stimulate changes in the body. Although PBM has been usedfor decades, its physiological effects on the body are still being elucidated. In this work, wehypothesized that PBM therapy would cause measurable physiological changes in patient'ssaliva. Saliva was selected because it's easy, safe, cheap, non-invasive, and has beendemonstrated to be a promising bodily fluid for biomarker detection. Patients donated salivasamples following PBM therapy over six sessions. Each saliva sample was tested in triplicate fortotal protein, uric acid concentration, and Acyl Peptide Enzyme Hydrolysis (APEH) activity.These markers were selected as they are related to oxidative stress and present in saliva. In thiswork, we show how three different biochemical markers change with PBM therapy. This isimportant because it adds to the body of work showing physiological changes relating to lowlight treatments.

Abstract Name: Anti-tumor Mechanisms of Mitochondria-Targeted Compounds

In the United States pancreatic ductal adenocarcinoma (PDAC) is the fourth leading cause of cancer death with a five-year survival rate of ~10%. PDAC is highly resistant to radiation and chemical therapies, including immune therapies. New therapeutic approaches focus on targeting PDACs energy metabolism system to disrupt tumor progression with the use mitochondria-targeted inhibitors mito-metformin (MMe) and Fluorinated mito-metformin (FlMMe). These analogues possess the capability to preferentially accumulate within cancer cells and disrupt mitochondrial respiration. Published data from the laboratory indicate that MMe and FlMMe decrease mitochondrial respiration, inhibit complex I, and thereby decrease overall ATP levels. MMe has shown promise at inhibiting growth both in vitro and in vivo. Although 1000x more selective than its parent compound Metformin, MMe is not easily trackable. Our novel analogue FlMMe has proven to be more cancer selective, and safer, maintaining the same functional capacity while increasing detectability in vitro and in vivo. We asked if MMe and FlMMe anti-tumor effects were mediated through comparable molecular mechanisms. We hypothesized that inhibition of OXPHOS energy metabolism with mitochondria-targeted inhibitors inhibits cell proliferation and stimulates apoptosis in PDAC cell lines. We measured the antiproliferative and apoptotic effect initiated by MMe and FlMMe in a dose dependent manner via the Incucyte Live-Cell Analysis system. Using the Incucyte system we simultaneously measured changes in confluency as a surrogate for cellular proliferation and activity of the apoptosis effector caspases 3/7 intreated PDAC cells. We measured a statistically significant increase in apoptosis followed temporally by decreased cell proliferation. Moreover, we determined that FlMMe has a greater apoptotic effect on PDAC compared to MMe in both mouse and human PDAC cells. Therefore, the progressive development of triphenyl-phosphonium cation (TPP+) conjugated mitochondria targeted inhibitors may lead to new immunotherapeutic treatment options in PDAC.

Abstract Name: Mathematical Approaches of Modeling Obesity Trends

The prevalence of obesity has drastically increased over the past several decades. The rise in obesity has caused strain within the healthcare system, as obesity puts individuals at an increased risk for a variety of diseases and conditions. This project aims to compare various mathematical approaches of modeling obesity trends within the United States. The ideal model would mimic the overall obesity trends in the United States, be modifiable to fit the obesity trends in different regions of the United States, and take into account how obesity varies due to societal factors. Factors such as socioeconomic status, income, race, ethnicity, geographic location, and personal connections have all been shown to contribute to one's likelihood of experiencing obesity. This project first looked at the overall trends of obesity and how they have changed over time utilizing linear regression models. Additionally, since the rise in obesity levels has been theorized

to mimic the spread of infectious diseases, an SIR-type model was created. Finally, agent-based modeling strategies were employed to create a probabilistic model of obesity trends. It was discovered that each of these models have their own strengths and weaknesses in their ability to capture obesity trends. Developing these and similar models could enable the investigation of various intervention strategies to reduce obesity levels within the United States.

Abstract Name: Circadian Contributions to Nighttime Blood Pressure Variation in Black Adults

Blood pressure (BP) follows a diurnal rhythm, meaning that it varies over a 24-hour period. BP that dips 10%-20% each night in healthy adults is a dipping BP pattern. The absence of a decrease in nighttime BP is characteristic of a non-dipping BP pattern, which is prevalent in the Black American population and is correlated with higher risk of cardiovascular disease. While previous studies have examined circadian rhythm contribution to nighttime BP variation, this study focuses on circadian contribution to nighttime BP variation in Black adults by analyzing biomarkers of the circadian clock, including salivary melatonin. Each study participant completed a constant routine (CR) protocol–a gold standard method in human circadian rhythm research–over a 30-hour period in which entrainment cues (i.e. lighting, meal timing, and physical activity) were held constant to analyze participants' natural circadian rhythms. Saliva samples were taken hourly, and melatonin levels in samples were measured using radioimmunoassays and analyzed with cosinor analysis. The study included a total of 22 participants, 11 (50%) females. The mean age of participants was 37.1 years, and the average BMI was 32.0 kg/m2. There were 16 (72.7%) non-dippers as determined by 24-hour ambulatory BP monitoring prior to the CR protocol. There were no statistically significant differences in sex, age, or BMI between dippers and non-dippers, but there were significant differences in nighttime systolic BP (p=.018) and diastolic BP (p=.041). Cosinor analysis revealed significant circadian rhythms in salivary melatonin in both groups (p<.001) and a significant difference in the mesor of melatonin concentration of dippers and non-dippers, t(465)=3.34, p<.001. However, there was no difference in circadian amplitude or phase of salivary melatonin between groups. Thus, environmental and behavioral factors may contribute more to nighttime BP variation than circadian rhythms and can be targeted in future research.

Abstract Name: The Synthesis of Mesalamine and Curcumin Capped Metal Nanoparticles for the Treatment of Inflammatory Bowel Disease (IBD)

Silver nanoparticles are innovative materials which have been found to have applications in antiseptics and drug delivery systems. IBD (Inflammatory Bowel Disease) is a term used to describe the series of chronic illnesses that are characterized by inflammation of the intestinal track lining. The two main diseases are Ulcerative Colitis (UC) and Crohn's' disease (CD). UC affects mainly the entirety of the colon while Crohn's affects the entirety of the digestive system (from mouth to anus). To aid in the remission, 5-ASAs (Mesalamine, balzalaside etc.) and curcumin are beneficial, alongside corticosteroids (prednisone) and biologics (Adalimumab and Infliximab). 5-ASAs (Mesalamine) are used to halt and avert flare-ups within the digestive tract while steroids and natural supplements such as curcumin assist in the management of inflammatory and oxidative conditions. An effective synthesis of silver nanoparticles involves the use of silver nitrate, a capping agent (such as mercaptosuccinic acid) and a strong reducer (such as sodium borohydride). UV-Vis was utilized to verify the presence of mesalamine and curcumin capped metal nanoparticles. Signals around the 350-400 nm area confirmed the presence of silver nanoparticles in the two experiments. This research explores conditions that are used to synthesize these nanoparticles, that could be beneficial someday, in the delivery of therapeutic agents straight to intestinal lesions in the colon or digestive track. Pre-liminary results on the synthesis of a mesalamine stabilized copper nanoparticle are also introduced.

Abstract Name: Precision Medicine: Electrospray/Spin Techniques for Fine-Tuned Anti-Inflammatory Release

Nanofibers, an innovative technique for drug delivery, hold immense potential for addressing current medical challenges across health-care domains. These materials boast a versatile range of applications due to their tunable physical properties, dictated by the choice of polymers used during fabrication, allowing for a tailored approach to design, whether for enhanced filtration, biomedical scaffolds, or targeted drug delivery systems. Current research efforts aim to develop drug-delivery systems which serve to provide efficient, targeted treatments through cost-effective means. In the aerospace field, researchers seek to revolutionize modern medicine for the treatment of immune and physiological disruptions experienced by astronauts under the effects of micro-gravitational conditions. Noting both the applications for conventional healthcare settings and the aerospace industry, this research focuses on developing pH-sensitive nanofibers for oral drug delivery, with interferon-β (INF-β) as a targeted treatment for multiple sclerosis. By tailoring the nanofiber-based drug delivery system to be pH-sensitive, the study aims to optimize drug release in specific

physiological conditions, ensuring precise and controlled administration. The engineered nanofibers are designed to exhibit pH resistance in the gastric environment, maintaining their integrity/stability, while demonstrating solubility at intestinal pH levels. This strategic formulation aims to enhance the absorption of anti-inflammatory agents, optimizing their bioavailability for therapeutic effectiveness. The study aligns with broader applications in inflammation treatment through the advancement of astronaut health and supports efforts to establish optimal strategies for the treatment and prevention of the progression of multiple sclerosis.

Abstract Name: Darkness and Light: The Connection between Personality and Conspiracy Beliefs

Conspiracy theories have become a large part of the modern cultural zeitgeist. Past research has shown connections between conspiracy belief systems and several types of personality traits, from the Big 5 Personality Traits to HEXACO. Connections have also been found between event-specific conspiracy beliefs and the Dark Triad of Personality—Narcissism, Machiavellianism, and Psychopathy. However, no published studies have examined conspiracy beliefs in connection to the Light Triad of Personality—Humanism, Kantianism, and Faith in Humanity. The present study examined both Light and Dark Triad traits as potential predictors of generic conspiracy beliefs. Eastern Kentucky University students (n=144) completed surveys on these beliefs and traits. Results indicated that Dark Triad traits were significant positive predictors of generic conspiracy beliefs. Interestingly, Light Triad traits showed no significant connection with generic conspiracy beliefs but were negatively correlated with Dark Triad traits. This suggests that while Light Triad traits negatively predict Dark Triad traits, they are not predictive of generic conspiracy beliefs. Further research examining the connection between generic conspiracy beliefs and event-specific conspiracy beliefs, as well as how personality factors relate to each, should be done to understand the complexities of this topic.Keywords: Conspiracy Beliefs, Dark Triad, Light Triad, Personality, Conspiracy Theories

Abstract Name: The Impact of YAP-Mediated Hippo Signaling in Obesity and Triple Negative Breast Cancer

Obesity is one of the most prevalent and modifiable risk factors for chronic diseases such as cancer. Recent meta-analyses suggests that breast cancer-specific death among obese women is elevated 1.3-fold in comparison to normal weight woman. There is also an increased risk (OR of 2.3, CI 1.4-3.6) of developing triple negative breast cancer (TNBC) in women with a higher waist/hip ratio (WHR). However, the

underlying pathophysiology linking obesity, adiposity, and TNBC needs further investigation.This study establishes a mechanistic link between obesity-altered metabolism and dysregulated proteasomal pathways, specifically the YAP-mediated Hippo cascade. This pathway is used to regulate cellular events during tumor progression and metastasis, and its proteolytic malfunction can cause a variety of diseases, including cancer. Previous results suggest that use of an adipocyte conditioned medium (ACM) promotes colony formation of human breast cancer cell line HCC1806 and BT549 in comparison to stromal conditioned medium (SCM), as well as mouse breast cancer cell 4T1, through YAP-mediated Hippo pathway hyperactivation.Results show that EIF3H is an upstream regulator of YAP and is highly expressed in obese mice (LMNA LCS) in comparison to normal controls (WT), as supported by RNA-sequencing. Over 150 of these genes are present in oncogenic metabolic pathways, which has been indicated by KEGG data. Furthermore, there is an association between the use of ACM and breast carcinogenesis. Data from clonogenic assays on three TNBC cell lines treated with ACM show increased cancer cell colony number and size, suggesting that adipocyte secretome has the ability to increase tumor growth. Western blot results also show that ACM increases both YAP and EIF3H expression as compared to SCM. Thus, this study uncovers the clinical relevance of the EIF3H-YAP axis in regulating obesity-related breast cancer.

Abstract Name: The Effects of Bans on Communist Parties and Their Successor in Post Communist States

Since the Eurasian collapse of communism from 1989 to 1991, each state that has been affected by a revolution, coup, or party collapse that ended the communist monopoly of power, has seen some kind of communist successor party. Often times, these parties find some success, but not typically in democracy. Successful successor parties are typically either a rebranding of the old party, having never lost power, a puppet party used by authoritarians to claim either opposition or bipartisan support, or a center-left social democratic party. It is this paper’s purpose to find out why bans on communist parties have led to both healthy democratic systems and instable authoritarian regimes, while also to determine if the bans on communism were simply used to protect the state’s sovereignty from threatening neighbor. This will be done by analyzing data from Variants of Democracy (VDEM), along with examining election results since the communist collapse in the Baltic States, Mongolia, Montenegro, Czechia, Slovakia, Poland, Turkmenistan, Tajikistan, Russia, and Belarus.

Abstract Name: Development of Kappa Opioid Receptor Antagonist Through the Use of In-silico

Technology

The opioid crisis presents a concerning public health challenge in the United States, characterized by the devastating consequences of opioid addiction. It is crucial to address this crisis by the development of selective antagonists targeting the kappa-opioid receptor (KOR). These antagonists, characterized by their capacity to bind to KOR and inhibit its activity, hold the potential to reduce the addictive properties of opioids and reduce the associated risk of overdose. By utilizing molecular modeling simulations via AutoDock, this study has undertaken rigorous investigations into potential ligands that exhibit the requisite binding affinity to the KOR binding pocket, with a specific focus on achieving a binding energy exceeding -9 kcal/mol. Promising compounds, most notably the JDTic ligand, have been identified as displaying a high affinity for the KOR binding site. To gain deeper insights into the real-world behavior of these ligands, molecular dynamics (MD) simulations are planned, which will afford a comprehensive understanding of the stability and dynamic interactions characterizing the ligand-receptor complex over extended periods. In employing computational chemistry tools to specifically target KOR, this research contributes significantly to the broader campaign against opioid addiction. The potential discovery of non-addictive opioid alternatives holds promise for combatting the escalating opioid crisis, thereby offering relief to afflicted individuals and society as a whole, while concurrently paving the way for safer and more efficacious pain management strategies.

Abstract Name: The Incorporation of Therapy Dogs in Physical Rehabilitation and the Improvement of the Emotional Well-Being of the Patients

Physical rehabilitation continues to incorporate new approaches to ensure the best outcome for the patient. It’s known how mentally deteriorating the experience of physical rehabilitation is after an injury, so it’s important to constantly seek new designs for the patient's wellness. In this literature review, I will report themes from research that examine the relationship between incorporating therapy dogs in physical rehabilitation and an improvement in patients' emotional well-being. I conducted an article search and selected six peer-reviewed articles that were published within the last 10 years, obtained from peer-reviewed journals, and empirically derived. Studies had to include the following criteria: addressed mental health post-injury, inclusion of therapy in physical rehabilitation, and discussion of canine companionship. After reviewing and synthesizing the articles, the following themes emerged. Physical rehabilitation was found to impact the participants by resulting in a downward shift in their mental health during the recovery process. It was also found that dog interaction can alter the emotional well-being of individuals through building relationships that provide a sense of purpose which can lead to positive or negative feedback. Gaps were found in the literature discussing the benefit of a relationship with a dog, as well as most of the participants being women. In conclusion, the literature explains that having a therapy dog during physical rehabilitation can improve emotional well-being while in the recovery process. Gaps in the literature can be further researched to gain a better understanding of the negative experiences of participants with dogs. This topic is important because it can be used by different professionals in physical rehabilitation to help their patient stabilize their emotional well-being. It can also motivate therapists to expand their thinking when it comes to the inclusion of uncommon practices in rehabilitation.

Abstract Name: The Investigation of Extraversion's Impact on the Job Satisfaction of People-Oriented Professions

Kapur (2022) described job satisfaction as a compilation of multiple factors: attitudes toward a job, work environment, type of work done, compensation, and social relationships. The current research aims to investigate job satisfaction. Understanding job satisfaction is important as it is a basis of wellbeing in adult life. In the workplace, extraversion may influence job satisfaction based on the individual's social needs and on the requirements of tasks to be completed. Extraversion may also influence an individual's ability to speak up during task confusion, or speak out in the face of challenges. Although the literature indicated that extraverted individuals within clerical settings reported a preference for cognitive tasks and both extrinsic and intrinsic rewards, lower satisfaction levels were reported when such tasks were completed in cubicle or office space with limited social interactions (Sterns et al., 1983). The literature's focus on clerical workers of an older age created a gap that the current study will cover by recruiting individuals from a variety of jobs. The current study will implement two scales to survey individuals of varying ages with differing levels of extraversion, and are current employees in different workplace settings. For the measurement of extraversion, the current study will be using the BFI-2-XS scale (Soto & John, 2017) and will measure job satisfaction using the Basic Psychological Need Satisfaction at Work Scale (Eriksson & Boman 2018) which has three subscales: autonomy, competence, and relatedness. The current study will investigate how well extraversion predicts facets of job satisfaction through multiple regression analyses and path analyses. We hypothesize that extraversion will significantly predict the social aspect of job satisfaction and that individuals from the health care industry will interact with extraversion to increase job satisfaction. Limitations and practical implications will be discussed during the presentation.

Abstract Name: Bridges to Belonging: Utilizing Small Scale Classroom Intervention to Improve Classroom Inclusivity

Students in introductory engineering courses face challenges communicating and integrating their ideas fairly and equally during work in team projects. Often, these challenges with team communication fall along gendered lines, where women students experience marginalization in team settings that decreases their sense

of belonging in the engineering program. While these issues could, and have been, attributed to implicit gendered communication practices (Robertson, Adams, and Rea, et al. 2022) explicit ideological bias (Potvin, 2018), our current research looked to test concrete ways educators might create small-scale interventions to incentivize more inclusive learning environments. Our prior research (Robertson, Adams, and Rea et al. 2022) not only demonstrated this communicative gender bias within introductory engineering classrooms, but also provided feedback from the students and faculty that we could then use to guide our research in this study. With this guidance, we strove to alleviate gender discrimination in engineering classrooms. Using this prior research, we created an intervention for the following year's students involving a short group competition followed by a survey. This intervention would allow us to group students together intentionally, which our previous research implied would have the greatest impact on a student sense of belonging. In the months following the intervention, these groups worked on a large-scale engineering project together and reported their experiences within the group using a classroom survey.By analyzing the survey responses and interviewing the professors for the course, we uncovered insights into how we may increase belonging for women in engineering. Our results demonstrated how small-scale classroom intervention benefited women in engineering harmful classroom interactions, and made for a more accessible learning environment for all students.

Abstract Name: The Phytoestrogen, SDG, and its Potential to Reduce HIV-Induced Neuroinflammation and Oxidative Stress

Human Immunodeficiency Virus or HIV, is an aggressive virus that attacks the immune system. When HIV compromises the blood-brain barrier, it can cause neuroinflammation and develop into neurocognitive disorders known as HIV-Associated Neurocognitive Disorders or HAND. The ongoing absence of a cure increases the need for therapeutics for individuals living with HIV cognitive impairment, as current antiretroviral treatments are unable to cross the blood-brain barrier. A potential therapeutic we are interested in is Secoisolariciresinol diglucoside or SDG. SDG is a plant lignan and phytoestrogen. SDG can cross the blood-brain barrier, and activate antioxidant pathways. It has been shown to have anti-inflammatory and antioxidant properties potentially through the non-classical estrogen receptor. Estrogen signaling is known to be neuroprotective and the loss of its signaling may exacerbate neurological impairment during HIV. Therefore, we hypothesized that SDG would reduce HIV-mediated neuroinflammation and oxidative stress. To test this hypothesis, human macrophages were stimulated with SDG and HIV for one hour or one day. Protein Lysates were collected for western blotting to explore changes in antioxidant proteins. We also collected media from the stimulated macrophages to access macrophage-induced neurotoxin production. The media was placed onto neurons for one day, followed by map 2 staining to quantify the loss of neurons in culture. We found that antioxidant proteins were decreased with HIV after one hour and one day stimulation. Pretreatment of SDG before HIV infection increased the proteins after day one compared to untreated and HIV alone. Also, HIV-conditioned media reduced the number of neurons present after being imaged with immunofluorescence microscopy. Given this data, our results showed that the pretreatment of macrophages and neurons with SDG, reduced HIV-induced neuroinflammation. SDG increased antioxidant protein expression during the HIV infection, and from this it can be concluded that SDG may be a therapeutic for neuroinflammation.

Abstract Name: When Every Vote Counts: The Erosion of Conformity's Impact on Voting Behavior

This project examines the relationship between social conformity, information about aggregate turnout, and how pivotal an individual's vote is. Building on previous research by Blais and Hortala-Vallve (2020), which argues that the degree of social conformity of individual voters plays a pivotal role in how they respond to turnout information, this study proposes that increasing how much voting matters may negate the observed differences in voting behavior between conformists and nonconformists. An economic experiment in the form of a simulated election is conducted to test this hypothesis. The results of this research have the potential to offer new insights for increasing voter turnout without resulting to mandatory voting, especially in the United States where how much individual votes matter changes from state to state.

Abstract Name: “You need to resign”: The Effects of Social Media Commentary and Gender on Incumbent Candidate Evaluations during Political Campaigns

As social media becomes a dominant tool in political campaigns, it is important to analyze how candidates and voters interact over social media and how this impacts elections. This study aims to uncover whether Instagram comments - a key tool voters use to interact with candidates - have an impact on voters’ perceptions and whether or not there are differences in these impacts based on the gender of the candidate. Due to bias against women in politics, I hypothesize that respondents will evaluate female candidates more harshly than male candidates after viewing negative Instagram comments associated with them. To test this hypothesis, I randomly separated a sample of 435 undergraduate students into four groups. Each group was assigned a hypothetical incumbent Senate candidate (male or female) and shown a candidate biography. The biographies were identical, save for the names/genders of the candidates. Additionally, the two experimental groups were shown negative Instagram comments associated with their candidate. Each group was asked to evaluate their candidate's viability, favorability, competency, leadership ability, and qualifications, in addition to scoring the likelihood that they would vote for them. I found that the male candidate had lower scores than his female counterpart for all six traits evaluated, meaning he was evaluated more harshly. This persisted in both the control and experimental groups, as well as both before and after the stimulus was presented to the experimental groups. However, the respondents’ evaluation scores for the female candidate dropped by a larger margin after viewing the negative comments than the scores for the male candidate did. This persisted for five of the six traits evaluated. Voters’ perceptions, then, are impacted by negative Instagram comments for male and female candidates, although there is some evidence to indicate that they have a larger negative effect on the perceptions of female candidates.

Abstract Name: Quick Fit Prosthetic Leg Socket

Introduction: Prosthetics, tailored to individual needs, enhance the lives of amputees globally. Traditional fabrication takes weeks to months, posing challenges. Our innovative approach involves patients directly in the process, using a specially designed socket attachment. This involvement accelerates production, empowers individuals in their rehabilitation, and yields superior outcomes.Methods and Materials: The molding method takes time and the stump can change size over time. We used 3D printing to start making a prototype. Inflatable knee sockets will have an outer carbon fiber layer to hold the socket structure in place and withstand high pressure. The inner layer will be a silicone material to hold the residual skin in place, prevent slipping, and provide cushioning and comfort for users. As silicone does not absorb sweat, the socket will have proper ventilation to protect the skin and regulate the inner temperature.Testing:. We are testing different ideas to see which will inflate better, the first is a blood pressure cuff design and the other involves using silicon. We found the cuff is more firm but has a risk of pain on the skin. The silicon design will help to alleviate pain on the skin however it might not hold as firm. Our idea is to combine the two.Results: Additional components are slated for incorporation into the socket, thereby finalizing the comprehensive design. Subsequently, upon achieving a finalized and steadfast product iteration, our focus will shift towards initiating the procedural steps for commencing clinical trials. This strategic progression will encompass the inception of the FDA application process alongside navigating the complexities associated with securing insurance coverage.Conclusion: Our inflatable knee socket serves as the right solution for amputees. It displays features that allow users to adjust the socket to their desired fit. It allows muscle activities and prevents pain and pressure injuries.

Abstract Name: Let's Work Out the Kinks: Processing Arousal for Neurodivergent Individuals

Sex is a social activity that the majority of humans will take part in over the course of life, but for some, it may be difficult to navigate due to the fluid social cues. Recent literature suggests that neurodivergent individuals, like those with attention deficit hyperactivity disorder or autism spectrum disorder, tend to have problems with navigating social situations, and may even experience increased anxiety or stress in these situations. To offer increased accessibility to a pleasurable sexual experience, it’s theorized that the introduction of kink practices to a neurodivergent individual could allow them to personalize a framework for

navigating sexual situations. Kink practices are structured by negotiation, communication and consent of all participants, which allows these participants to know what is expected of them at the time of the sexual situation. These clearly dictated expectations can make pleasure accessible for neurodivergent individuals as they navigate sexual experiences. Through a digitally delivered survey to the students, faculty and staff of the University of Central Oklahoma and interviewing participants who were selected through purposive sampling, we hope to find a correlation between kink practices and increased pleasure for neurodivergent individuals during sexual situations. In finding these correlations, we hope to increase accessibility for neurodivergent individuals.

Abstract Name: Filipino/a/x Americans Navigating Predominantly Campus Climates

This study shows that in the culture of a predominantly white campus culture, these Filipino/a/x Americans (n = 9) feel a sense of “otherness” visually, within their intersecting identities, and/or within the Filipino community on campus. This study is framed by the seven tenets of Asian American Critical Race Theory to contextualize the impact of the White Supremacist narrative of Asian Americans in American history. To further our understanding of how Filipino/a/x American students navigate predominantly campus climates, this study examines the stories and experiences of 9 Filipino/a/x Americans' perspectives in a predominantly white campus climate. The study finds that the participants lacked a sense of belonging due to a lack of diversity and culturally specific resources. Their university’s failure to meet the needs of the Filipino/a/x Americans forced the students to assimilate, join a community by membership, or isolate to cope with the realities of a predominantly white campus culture. These findings are similar to the research on students of color's experiences on predominantly white campuses.

Abstract Name: Single-Family Housing Design for Corneal Scarring Visual Impairment

The purpose of the design of “Grove Nest” was to design a single-family home that promotes independent living for the young daughter of a couple who suffers from corneal scarring. The young daughter of the couple contracted measles as an infant which ultimately led to her corneal scarring. The measles virus in the cornea causes irritation in the eyes and a dislike of bright lights. Some of corneal scarring’s symptoms include cloudy vision, blurred or decreased vision, seeing “halos” around lights, and eye pain. The site of the home has a view of the ocean, and the design aims to create a meaningful connection to the landscape and encapsulate all the rich sensory experiences it has to offer. The findings of this design were gathered from various sources including meeting with a specialist of the vision impairment organization, review of articles, and analysis of case studies. The final design strategies incorporated research findings such as logical space

layout, tactile cues, smart home, lighting flexibility, color contrast, and accessibility features. The logical layout of the home was organized so occupants can navigate through the spaces in a logical and functional manner according to their day-to-day routines. Smart home technology such as smart lighting systems and appliances serve to enhance daily tasks and allow for a more comfortable and independent lifestyle. The color contrast found in the finish and material selections serve to enhance visibility and contribute to the overall safety of navigating the home. The final design aimed to integrate inclusive design solutions researched, while remaining aesthetically pleasing for the family.

Abstract Name: Beyond Borders: Unveiling the Diversity of Latin American Design

Latinx and Hispanic designers have played a significant role in shaping the design landscape throughout history. With their powerful and influential graphics, rich cultural history, and compelling visual storytelling they continue to have a lasting impact. Despite these contributions, design within Latin American and Hispanic communities is persistently marginalized. Unjustly labeled as "exotic and loud," it is unfortunately perceived through a narrow lens, neglecting to appreciate the bold beauty and historical depth inherent in the style. This disparity can be attributed to a complex interplay of environmental, religious, and political factors, which contribute to the persistent marginalization of Latinx designers. I aim to raise awareness of the challenges Latinx designers face. A central hurdle is the lack of representation, unequal opportunities in the community, and political/religious bias. By discussing these issues and advocating for a more inclusive and appreciative recognition of their artistic endeavors, we can initiate a transformative shift into an interconnected design landscape. This involves dismantling barriers to success, fostering equal opportunities, and challenging ingrained biases that have perpetuated the marginalization of Latinx designers. In doing so, we not only amplify the voices of these designers but also enrich and educate the design discourse with the vibrant and diverse perspectives they bring to the table.

Abstract Name: Cultural Learning Strategies in Elementary Education: A Comparative Study of Practices in the United States and Ecuador

The intersection of culture and education in elementary classrooms is a pressing concern for teachers, parents, and policymakers. The need is driven by evolving demographics and the need for culturally responsive teaching practices. This study, "Cultural Learning Strategies in Elementary Education: A Comparative Study of Practices in the United States and Ecuador," investigated how schoolteachers in these two diverse countries incorporate cultural learning strategies to respond to unique student populations. The problem statement underscored the necessity of addressing cultural diversity in educational settings to

provide equitable and effective learning experiences for all students. As demographics shift, understanding pedagogical responses to cultural diversity is imperative. The significance of this research extends beyond the classroom. In today's multicultural world, educating students from diverse backgrounds is crucial for our society. Incorporating cultural learning strategies carries profound implications for social inclusivity, peace, heritage preservation, and more. The study's potential to inform policies, curriculum, and teacher training programs emphasizes its broader societal impact. Methodologically, this research reviewed literature on culturally responsive teaching and cultural learning strategies in both countries, ensuring provocative findings. The predicted result was that educators in Ecuador will exhibit teaching strategies focusing on the nation's internal cultural diversity, while US educators will adopt strategies influenced by the international and multicultural nature of their student body. These insights will foster more inclusive and culturally aware teaching practices, benefiting students and society. This project's implication is clear: it has the potential to transform how we approach multicultural education. By comparing practices in these two diverse nations, we can adapt and refine strategies to better suit today's students and the future of our society. This research is a step towards a more inclusive, harmonious, and culturally enriched world.

Abstract Name: Sex differences in the effect of exercise on the cognitive consequences of methamphetamine abuse

Methamphetamine (METH) is a widely used psychostimulant drug, and its use in the United States has reached a near-epidemic in the past 15 years. METH use costs billions per year through crime, foster care, lost workplace productivity, and other social problems, in addition to causing destructive effects in the lives of users. In humans, METH abuse has been shown to result in long-lasting brain injury as well as significant cognitive impairments. METH interacts with catecholamine nerve terminals which results in the initial euphoria after taking the drug but then leads to long-lasting brain injury for the user. The neurotoxic effects of the drug are responsible for inducing the cognitive consequences associated with abuse, which include impairments in memory, attention, executive functioning, and decision making. The memory impairments caused by METH are the most prominent and persistent cognitive problems, because they interfere with the user’s ability to adhere to and benefit from addiction treatment. Therefore, it is of utmost importance to find ways to attenuate these cognitive deficits and thereby improve treatment outcomes for METH users. The impacts of exercise on the rodent brain, such as induction of synaptic plasticity, increased production of neurotrophins, and enhanced neurogenesis, have been extensively characterized, and the beneficial effects of exercise on cognition are well-documented. Here we investigated whether exercise can improve performance on two memory tasks known to exhibit METH-induced deficits in rodents: object recognition and odor recognition. Notably, work on this question has historically left out a critical portion of the population – females. Women are just as likely as men to develop substance use disorder, but women often use and respond to drugs differently. Here we demonstrate critical sex differences in the ability for exercise to attenuate METH-induced cognitive deficits, as evidenced by variability in scores on object-in-place and odor recognition tasks.

Abstract Name: The Effect of Field-Related Hyperbaric Oxygen Therapy on Skeletal Muscle Regeneration

Background. Skeletal muscle trauma necessitates timely and efficient recovery mechanisms to prevent long-term complications. Additionally, muscle trauma can occur in geographic locations lacking specialized medical facilities. Yet the initiation of intervention in these locations would promote timely and efficient muscle recovery. Clinically, hyperbaric oxygen (HBO2) therapy has positive effects on crush muscle injuries. The underlying mechanism is that 100% oxygen delivered under pressure leads to the delivery of more (dissolved) oxygen to hypoxic tissue. In preclinical studies, HBO2 therapy at 2.5 atmospheres absolute (ATA) positively affects muscle mitochondria and physiological performance and regenerating fiber properties. However, clinically, this pressure level must be delivered in a specialized medical facility, which is one reason that HBO2 therapy is not widely used. A lower pressure, such as 1.5 ATA, could be delivered in a general medical facility. Purpose. To test the effect of HBO2 therapy at 1.5 ATA on muscle regeneration. Methods. The regenerating fiber properties of crush-injured muscle treated with HBO2 therapy at 1.5 ATA or 100% oxygen from male and female C57BL/6 mice will be examined. Specifically, fiber cross-sectional area and the number of regenerating fibers positive for developmental myosin heavy chain and galectin-3 at 4 and 8 days postinjury will be quantified. Immunohistochemistry will be used to detect these properties. Expected Results. If HBO2 therapy at 1.5 ATA has a positive effect, then we expect the fiber cross-sectional area to be greater at 4 or 8 days postinjury compared to treatment with 100% oxygen. Additionally, a higher number of regenerating fibers positive for developmental myosin heavy chain and galectin-3 will be detected at 4 days postinjury in HBO2-treated mice. Overall, anticipated results could unveil the effectiveness of field-related HBO2 therapy in accelerating muscle regeneration, possibly offering a viable option for non-hospital or non-specialized settings.

Abstract Name: DO NATURAL HABITATS SUPPORT BETTER BIVALVE HEALTH RELATIVE TO HUMAN-INTRODUCED HABITATS?

Estuarine habitats worldwide have been extensively modified by human-introduced structures such as seawalls. Human-introduced structures may favor non-indigenous species (NIS), but few studies have directly compared species health (i.e. condition index) on various habitat types. NIS Mytilus galloprovincialis is a dominant space-occupier bivalve, a mussel, which occurs on seawalls throughout Southern CA estuaries including Newport Bay. In a preliminary study, it had better condition on natural cobble vs. human-introduced seawall (2-way ANOVA, site*habitat, p=0.0001) but tidal elevation was not controlled,

confounding our ability to discern a habitat effect. Lower tidal elevation should improve species condition due to longer immersion time, so for this follow-up study, we hypothesized that condition index (CI) would vary both across habitats and among tidal elevations. M. galloprovincialis were collected from a seawall and cobbles at a site in upper Newport Bay, CA, and on the north and south-facing surfaces of an outfall pipe in San Diego Bay, CA, while recording tidal elevation for each individual. M. galloprovincialis experienced a nominally significant habitat*elevation interaction (2-way ANOVA, elevation*substrate, p=0.0595) with higher CI at lower elevations on seawalls only, and higher CI on cobble versus seawall but only at higher tidal elevations. Data from the outfall pipe have been processed and the poster has been updated. Understanding habitat and tidal elevation effects on the health of a broader selection of both native and non-native bivalves will inform future management decisions about the use of natural and anthropogenic habitats.

Abstract Name: CHRIST'S IDENTITY AND PORTRAYAL BY CARAVAGGIO

How is Christ Jesus portrayed and identified in Caravaggio's paintings? Caravaggio's portrayal and identity of Jesus is prevalent throughout his religious works with a heightened sense and perception of reality. He uses tenebrism or Chiaroscuro, notions of good and evil, and many other dimensions to interpret imagery that brings forth a calling of the divine in the everyday. The realistic approach and life-like paintings of Christ done by Caravaggio have since impacted the way we perceive the religious and spiritual aspects of Jesus. Caravaggio was revolutionary in his approach to painting since he understood and was able to capture the human side of the divine. In particular Caravaggio was able to have a keen focus on human emotions and physicality in his paintings. It's almost as if Caravaggio knew that we the viewer are able to know the emotional state of mind that Jesus might have been in with the depicted biblical stories that unfold with immense palpability before our eyes in his paintings.

Abstract Name: It Would Be Great If They Could Read: Educator Values and Students With Complex Communication Needs

Understanding reading and writing as the most foundational life skills is a critical shift to make in understanding intervention for people with communication and language disorders. Not infrequently, professionals may differentiate life and job skills from literacy skills in a way that deprioritizes literacy skills. For example, a teacher may be advised or permitted to focus more on teaching a student common phrases or job skills in favor of foundational literacy skills. Understanding the discrepancies and conflicts between what educators state are their personal values, the goals they create and work towards with their students, the environments they teach in and the techniques they choose to implement are all key to understanding the

ultimate outcomes for the students they work with and the context within which students are or are not gaining the critical literacy skills they need to support their independence. The central aim was to elicit information about educators' views and mindset around the connections between language and literacy, and the barriers they face in effectively implementing the project's curricular components. The project required classroom educators (defined as teachers, aides, and speech language pathologists) to implement: (a) Readtopia (Building Wings, Inc.) as the comprehensive literacy curriculum, (b) at least the 36 Universal Core vocabulary as the Tier 1/Class wide aided language solution (on paper-based to high-tech platforms) so students could access curricular lesson materials, and (c) Aided Language Input as the communication partner language-learning strategy.

Abstract Name: Estrous Cycle Regulation of Neuronal Ensembles Encoding Threat Memory within the Central and Lateral Amygdala Following Cued Threat Acquisition and Recall

Women are more vulnerable to stress- and fear-based disorders, including anxiety and post-traumatic stress disorder (PTSD), than men. Dysregulation of emotional memory is a core feature of these anxiety disorders, and these emotional memory processes are regulated across the menstrual cycle. Although auditory threat conditioning is the most well-established preclinical model of emotional memory, most studies using this model have ignored the role of the rodent estrous cycle. We hypothesized that threat memory processes are modulated across the estrous cycle through regulation of neuronal ensembles during acquisition and recall of cued threat memory. We first established behavioral differences in threat memory processes across the estrous cycle, with any exposure to low ovarian hormone phases during either threat conditioning or recall resulting in enhanced recall in females as compared to males. To investigate the mechanisms behind this behavior, we measured c-fos protein expression as a postmortem neural activity marker in the central (CEA) and lateral amygdala (LA), two regions required for threat memory processing, following the acquisition or recall of a cued threat memory across high (proestrus) and low (diestrus) hormone states. We found effects of both sex and estrous cycle on CEA activation. Mice in proestrus had higher c-fos levels than those in diestrus, but both were higher than those in male mice. LA activation was sensitive to estrous cycle with increased c-fos in diestrus compared to proestrus females. We next questioned whether these differences at memory acquisition would persist at memory recall, providing evidence of estrous cycle regulation of memory ensembles. Ongoing work is quantifying regional c-fos expression in the CEA and LA after memory recall. Overall, our data demonstrates that cycling reproductive hormones modulate threat memory within the CEA and LA and suggest the importance of considering estrous cycle as a variable when studying threat memory dynamics.

Abstract Name: Optical Data Transfer Around Opaque Occlusions Using Electronic Encoding and Diffractive Decoding

We introduce a free-space optical communication scheme for transferring spatial information, e.g., an image, around arbitrarily shaped, fully opaque occlusions that partially or entirely block the line-of-sight between the transmitter and receiver apertures. In our scheme, an electronic neural network encoder and an all-optical diffractive network-based decoder are jointly trained using deep-learning methods. Diffractive network is an all-optical computing framework that comprises parallel diffractive surfaces separated by free space to perform a learned transformation on the input optical field dictated by the desired task. The electronic neural network produces an encoded phase representation of the optical information to be transmitted. The phase-encoded wave, after being obstructed by fully opaque occlusions, is decoded by the diffractive network at the receiver. This jointly trained encoder-decoder pair can communicate any arbitrary optical information around opaque occlusions, and the information decoding occurs at the speed of light propagation through passive light-matter interactions. We experimentally validated our framework in the terahertz spectrum by communicating images around arbitrarily shaped opaque occlusions using a 3D-printed diffractive decoder. This framework is scalable for operation at any wavelength and can be adopted for numerous applications, e.g., in emerging free-space communication systems.

Abstract Name: Sensory Overload

At the age of 20, I was diagnosed with both ADHD and Autism. I became fascinated with how and why late diagnoses of neurodivergence are so common. My years of research led me to one main conclusion: misinformation about neurodivergence is accepted as standard, and the stigma surrounding disability keeps it from being discussed and accepted by society. I use my art as an accessible medium for sharing my research. This led to Breaking the Stigma around Autism: an Interactive Art Exhibition. This body of work is about simulating aspects of the neurodivergent experience within my viewers to promote education and understanding. I am submitting one of these works: Sensory Overload. For neurodivergent people, sensory overload, or complete overstimulation caused by sensory input, can lead to meltdowns, anxiety, and even physical pain. Though neurotypical people cannot fully experience it, I wanted to simulate the feeling at a minor level. Sensory Overload is very pleasant and unpleasant textures dispersed across a panel. Via the gallery plaque, the viewer is asked to become a participant and touch the piece. The participant has to reach behind a piece of frosted plexiglass that obscures the textures to touch the work. The lack of visual information creates an element of surprise, disorientation, and discomfort within the participant that mimics the experience of sensory overload.Many who attended my show said this piece helped them experience an aspect of autistic life they otherwise could not understand. Ableism, stereotype, and misinformation are still extremely present in society. These things need to be combatted by starting healthy and honest discussions about neurodiversity. Within my own community, I saw how people’s perceptions of autism shifted upon

viewing my work. NCUR would help my message reach a large, prestigious audience, an opportunity often out of reach for neurodivergent people.

Abstract Name: Use of Place Preference Testing to Determine Rewarding Properties of N_2O

Opioid analgesics are used to treat pain, but approximately 3 million people in the U.S. have suffered from opioid use disorder. Nitrous oxide (N2O), also known as laughing gas, is an inhaled anesthetic with analgesic properties commonly used in dentistry and other minor surgery procedures. We are currently investigating analgesic efficacy of a liquid formulation of N2O that can be used as an alternative to opioids to treat pain. We found that the liquid N2O administered by oral gavage decreased sensitivity to mechanical and heat stimuli in mice. We then used a Place Preference test to assess the risk of dependency with N2O. Mice were placed in a dual-sided chamber with different visual cues and were restricted to one side of the chamber after receiving the drug daily for 5 days. After this 5-day conditioning with N2O, mice were given access to both sides of the chamber. Mice treated with N2O failed to show preference towards either side of the chamber. These results suggest that the liquid N2O given by oral gavage is not rewarding and may therefore not produce dependence. If true, N2O may be an effective alternative to opioids.

Abstract Name: Examining How Family Honor and Loyalty Affect Perceptions of Risk in Individual Decision-Making

Families play crucial parts in the overall preparation of individuals to become independent adults. Yet the effects of what an individual feels to be “owed” back to their families, in response to family honor and loyalty, varies immensely. The perception of what should be done may influence how appealing different choices appear and the decisions made might differ from the individual’s true preferences if placed under different circumstances. Whether those choices arose from being instilled in familial values or holding family honor in such high regard, the decisions took into consideration different pressures (personal, family preferences, external pressures: peers and society) in their lives. A gap exists in the current studies when analyzing family loyalty, risk-taking, and decision-making-- treating each of these dimensions in its own respective realm of psychology rather than as a whole. We can see these ideas being played in palliative care decisions or blended family situations. Most existing literature focuses on cross-cultural approaches (de Valk & Schans, 2008, Sovet & Metz, 2014), but my project also examines within-culture variability in the role of family honor and individual decision-making. The project aims to bridge that gap and explore family relationships and obligations by investigating the extent to which people weigh perceptions of family

honor in making those personal decisions. This study looks deeper into how family honor affects how people think about how to make– and perceive-- choices. A detailed survey will allow me to discern an individual's perceptions of what family honor is; participants recounting decisions made would give insight into how risky the choices seemed. We expect to see family honor as some sort of default in individuals given the closely intertwined nature of families and individuals.

Abstract Name: Brick by Brick: Building Academic Success for Student Parents - Guardians Hall

This project delves into how architectural interior design influences the academic success and well-being of student parents at the University of Central Oklahoma, with a particular focus on optimizing Guardian’s Hall to meet the needs of these students and their children.Student parents in higher education face distinct challenges, often achieving higher grades but experiencing lower graduation rates compared to their non-parenting peers. This discrepancy is linked to a lack of supportive infrastructure and resources tailored to their unique situation. As higher education evolves, there's an increasing need to reassess campus facilities to better support these students. Guardian’s Hall aims to fill this gap by integrating historical architectural styles with modern amenities, fostering an environment that nurtures academic achievement and personal well-being.The study conducted interviews and surveys with student parents to gain an in-depth understanding of their needs and experiences. The research findings were crucial for evaluating how different design elements can positively impact their academic outcomes. Case studies of similar facilities enriched the overall understanding of the building design considerations for these students. Guardian's Hall design aims to fill this gap by integrating the historical architectural styles of a university located in the southeast region along with modern amenities. This facility fosters a living and learning environment that nurtures academic achievement and personal well-being by providing spaces such as on-campus daycares, interactive study rooms, and family-friendly on-campus living. A well-designed space like Guardian’s Hall will significantly enhance the academic and personal lives of student parents. The project aims to demonstrate that a synergy of historical aesthetics with modern functionality can create a supportive environment, likely leading to improved retention and graduation rates. These results will offer valuable insights into how architectural design can address specific educational needs, potentially shaping the direction of future campus developments.

Abstract Name: Reconstructing the Experiences of Foster Children in Mid-20th Century New York City: Narratives of Agency, Empowerment, and Intersectionality

Children’s stories are as absent from written histories as their voices. In part, this marginalization is due to the lack of records that shine a light on children’s realities. However, even records that center adults can offer

glimpses into children's lives. Relying on the adult-centric sources I have available to me, I set out to reconstruct the experiences of foster children during the mid-20th century in New York City. This period was the inflection point when the percentage of foster children placed within home settings, as opposed to institutions, reached a majority. The results of this turning point profoundly affected the most vulnerable and resilient children, yet, the few historians who have addressed this topic have largely made arguments that concern systems, structures, and institutions. That is to say, while they write about children, children are still just outside the focus.Shifting the focus away from the systems themselves, my research aims to answer how foster children asserted their agency and subjecthood in situations where they were made to feel powerless. Relying on graduate theses from the New York School of Social Work (1948) and Fordham University (1953) as my primary sources, I write narratives of foster children to demonstrate how they were agents of their own lives. In doing so, I illustrate the principal themes of their experiences, analyzing their narratives through the application of interdisciplinary social theory. I expand on issues of liminality, labeling, and intersectionality while connecting the children's lives to their broader historical context. Each story shines a light on what it was like to be a foster child in the mid-century, uncovering details about a child's personality, struggle, and victories. Through these narratives, it is clear how children are active in creating their reality, rather than passively accepting the reality dictated to them by adults.

Abstract Name: STAB2 and PLD4 Expression in Anolis Carolinesis

The green anole (Anolis carolinesis) is a reptile that goes through morphological changes during certain periods of the year. During the breeding season the brain and gonads of the green anole go through morphological changes. The purpose of this study is to determine whether certain genes become more active during the breeding season of the green anole lizard compared to the non-breeding season. The two genes being studied are STAB 2 and PLD4. The STAB 2 gene has been observed in humans to create a protein that aids in multiple functions of the body. One of these functions is angiogenesis, otherwise known as the synthesis of blood vessels. With the gonads increasing in size during the breeding season, it is thought that the STAB 2 gene might become more active to aid in the increased need for blood flow by synthesizing new blood vessels. The second gene we have been studying is the PLD4 gene. The PLD4 gene is a protein coding gene involved in the cytokine production that occurs during inflammatory responses. It is thought that PLD4 might become more active in breeding males as the bright red dewlap of the males is an important part of mating displays for green anoles. The activity of each gene was determined by running multiple PCR tests as well as PCR cleanups and qPCR tests. With this knowledge we would be able to tell if our hypothesis are supported by our results.

Abstract Name: Development of Whey Protein-Lignin Based Film Materials for Dairy Food Packaging Applications

Whey protein (WP) and lignin are by-products of cheese production and the pulp and paper industry, respectively. This project aims to combine WP, glycerol, and lignin to develop biodegradable films for food packaging applications. WP solutions underwent denaturation at temperatures between 60-90°C with glycerol and lignin. SDS-PAGE showed that the film-forming solution prepared at 90°C resulted in 88.7% WP denaturation, 51.1% for WP made by mixing 20°C and 90°C in a 1:1 ratio, and 12.3% for WP prepared at 60°C. Results revealed that WP denaturation increased available thiol groups, which were likely responsible for forming the polymeric structure of WP films. With altered polymeric structures, different levels of WP denaturation altered film properties such as water vapor permeability, water solubility, glass transition temperature, and mechanical strength. Water solubility, glass transition temperature, puncture force, and tensile strength were inversely correlated with the percent denaturation of WP. The 90°C WP film had the highest tensile strength (5.77 ± 0. 31 N.mm-2), and puncture force (67.57 ± 6.88 N.mm-1). The addition of lignosulfonate and alkaline lignin (at 5% w/w of WP) provided antioxidant functionality equivalent to 6.25 ± 1.00 mg ascorbic acid/g film and 6.71 ± 1.12 mg ascorbic acid/g film, respectively. The thermal stability of WP films was improved with the addition of lignin as indicated by the increased glass transition temperature (Tg with alkaline lignin = 77°C, Tg with lignosulfonate= 80°C vs. Tg of 90°C WP film = 62°C) Adding lignosulfonate improved water barrier properties by 10%. WP films with alkaline lignin demonstrated improved light barrier properties than those with WP only. Overall, the results highlight the importance of WP denaturation in film properties and the potential benefits of different types of lignin for improving film properties.

Abstract Name: Analysis of PHYB Mutations Identified in a Genetic Enhancer Screen in Arabidopsis thaliana

The plant Arabidopsis thaliana contains the genes LRB1 and LRB2 (Light-Response BTB 1 and 2) that encode proteins functioning as target adaptors in complexes that initiate degradation of the phytochrome red/far-red-light receptors. Plants containing mutations of both the LRB1 and 2 genes are hypersensitive to red-light. In several of the lines there is a putative enhancer point mutation in regions of the PHYB gene, which encodes the phytochrome acting as the major red-light receptor in Arabidopsis. Screens were conducted to identify mutations that increase red-light hypersensitivity of LRB1 and LRB2 double mutant plants, which was successfully done. Recent work has focused specifically on the E2-1-2 and E11-6-5 mutant lines to characterize the effects of these mutations on light responses and phytochrome action. Backcrosses were done to focus on these mutations, backcrossing of the E2-1-2 line has been completed, and the E11-6-5 line is undergoing the backcrossing process. Genotype/phenotype analysis has been done to see how the TDNA insertion mutations in the LRB1 and LRB2 genes, along with the PHYB point mutation works together to affects red-light hypersensetivity. We have also looked at enhancer E2-1-2 lines which are blue-light hypersensitive and conducted genotype/phenotype co-segregation experiments which determined that the PHYB point mutation in that line may also be responsible for the blue-light phenotype and for the mutant lines themselves.

Abstract Name: Positive Self-Talk versus Brooding and their Relationship with Creativity

PosterTITLEPositive Self-Talk versus Brooding and their Relationship with CreativityData collection is in progress. Many studies have established a relationship between depressive symptoms and creative thought. However, the relationship is not robust and can be found in both directions. Here, researchers wish to further investigate why this occurs. It is likely because studies have examined multiple symptoms of depression, some being related to creativity and others unrelated. We hypothesize that different types of self-talk will be correlated with creativity. Specifically, we predict a positive relationship between positive self-talk and creative thinking, and a negative relation between brooding and creative thinking. Participants from a college sample will be instructed to respond to a self-report measures of self-talk and brooding. Additionally, the ability of the participants to produce creative thinking will be measured using an alternative use task. To assess research question 1: Does positive self-talk predict creativity, we will run a regressional analysis where positive self-talk is the predictor and creativity is the outcome. Covariates include gender and age. To assess research question 2: Does brooding predict creativity, we will run a regressional analysis where brooding is the predictor and creativity is the outcome. Covariates include gender and age. This study is important due to the connection between creativity and depression potentially providing an individual an outlet for understanding one’s emotions. This outlet can lead to increased ability to problem solve and make decisions.

Abstract Name: How Meditation and Preconceived Notions Could Effect Test Anxiety

This study will analyze how meditation can decrease test anxiety, and whether a person’s pre-existing beliefs can affect this relationship. It is suggested by research that test anxiety comes from two different components: Worry and Emotionality. The Worry aspect is described as cognitive concerns regarding the exam and exam performance, while Emotionality is described as the physiological and autonomic arousal during a testing situation. It is hypothesized that meditation could target both these aspects through lowering the sympathetic nervous system and reducing ruminating thoughts. The goal of this project is to expand on the previous research in two main ways. First, the current work would target test anxiety specifically, as opposed to more generalized or clinical anxiety. Second, this research will also investigate whether a person’s biases toward or against mindful meditation may impact how helpful it can be. Findings from this study can provide an understanding of how meditation can affect test anxiety depending on a person’s established assumptions. This has implications for students at all levels who struggle with test anxiety.In order to test this, a simple

experimental design will be conducted at the University of Central Oklahoma, in which particpants will be randomly assigned to two groups. Participants recruited will be told they are taking an exam. They will then complete 10 minutes of meditation (meditation group) or sit quietly for 10 minutes (control group). After the exam, both groups will answer questions that assess their test anxiety levels. Finally, they will be given a quick survey to determine their general views on meditation. It is predicted that the meditation group will report less test anxiety than the control group, but that benefit will be diminished for those who hold negative views on meditation.

Abstract Name: Substance Use and Avoidance Attachment in Hispanics and Non-Hispanics

Mary Ainsworth, an American-Canadian Psychologist formed the Strange Situation Procedure in 1969 to measure mother-child attachment and created a foundation for attachment styles that is still used by attachment theorists. The information collected has helped gain understanding of attachment throughout different points in life (Berlin et al., 2022). This research focuses on substance use between Hispanics and Non-Hispanics who have an avoidant attachment. The purpose of this study was to acquire substantial knowledge about the association between attachment and substance use, in Hispanics and Non-Hispanics. Due to the insufficient research done with Hispanic participants and avoidant attachment, it was key to have this population included. The use of attachment helps individuals learn about themselves including knowing how to navigate ways to form relationships with others. Attachment impacts all relationships throughout an individual's life (Fitton, 2012). Participants in this study were adults who took an anonymous online survey and were asked about their attachment tendencies such as their ability to get close to others and fear of abandonment. Attachment style was determined using the Adult Attachment Questionnaire (AAQ) created in 1996. Additional questions regarding relationships with biological parents and substance use were also asked. The results of this study indicate Hispanic participants had relatively the same frequency levels of substance use regardless of their attachment style. Non-Hispanic participants reported lower levels of substance use frequency with high levels of avoidance attachment, and higher levels of substance use frequency with lower avoidant attachment.

Abstract Name: Mitochondrial Dysfunction in Striated Muscle Is Related to Muscular Dystrophy

Background: Duchenne muscular dystrophy (DMD) is a genetic disorder lacking the dystrophin protein, causing muscle deterioration and weakness. The standard of care is glucocorticoid therapy, focusing on

delaying complete muscle function loss. Although the cause is genetic, recent studies using a novel and more relevant mouse model of DMD, the D2-mdx mouse, suggest mitochondrial dysfunction is an early event in the disease process. However, the mechanism through which the cytoplasmic protein's loss disrupts the electron transport chain is poorly understood. Rpl3l is a paralog of the ribosomal protein, Rpl3. Rpl3l is only expressed in skeletal and cardiac muscle tissue. Current literature hypothesizes that Rpl3l may serve as a negative control of muscle growth. The aim of this study was to investigate how mitochondrial dysfunction is related to weakness in the D2-mdx mouse, and the potential relationship between expression of Rpl3 and physiological characteristics of the D2-mdx mouse model.Methods: Muscle function was assessed by measuring plantarflexion in vivo. Mitochondrial function was assessed using high resolution respirometry. Protein expression levels were measured using Western blots. Results: Consistent with the literature, we found that D2-mdx mice were significantly weaker, and muscle mitochondrial function was decreased, compared to the control, DBA/2 mice. Further, we found that in D2-mdx dystrophic mice, peak torque was significantly reduced by 44%, which was associated with muscle-specific changes in Complex I and II activity and maximum electron transport chain capacity. Preliminary data showed an increase in protein expression levels of Rpl3 in D2-mdx dystrophic mice, compared to the control, as expected. Conclusions: Cardiac and skeletal muscle in the D2-mdx murine model of Duchenne muscular dystrophy exhibit lower mitochondrial oxygen consumption capacity and higher reactive oxygen species production. These changes may worsen muscle weakness already present due to loss of the dystrophin gene in Duchenne muscular dystrophy.

Abstract Name: Aqueous Synthesis of Polyelectrolytes (Ionomers) using Non-metal Based Reducing Agents

Sustainable and green water purification methods are increasing in demand worldwide today. Some current water purification techniques deal with filtration, ion exchange, and osmosis processes. There is an increase in demand to create safer purification methods as many new harmful contaminants are still present at extremely low levels. Current literature about ion-exchange purification methods focuses on ways to grow polymers on scaffoldings, which bind to toxic compounds and purify the water. Yet, these efforts must be revised when looking at residual contaminants due to the synthesis process of the polymer. Current synthesis techniques focus on creating these polymer chains through activators regenerated by electron transfer (ARGET) atom transfer radical polymerization (ATRP). This research focuses on finding procedures using inexpensive and safe reducing agents that do not contain heavy metals. Ascorbic acid and similar reducing agents are of interest as they allow for the same type of polymerization needed to create polymers of interest but are also safer. The reaction is maintained at a pH of 9-10 to ensure that the reducing agent and amine are deprotonated. The polymer is synthesized as a pseudo-first-order reaction, the basis for calculating the rate constant and percent conversion. Our most successful non-metal-based polymer synthesis reaction, with ascorbic acid, had a rate of 0.050 ± 0.007 h-1 and a 97.7% conversion. This reaction still falls short compared to the Sn(Oct)2 reducing agent polymer synthesis, as it has a rate of 0.067 ± 0.008 h-1. Unlike the metal-based synthesis, our non-metal-based reactions change to a dark red color once exposed to oxygen. Preliminary results show that non-metal reducing agents work to synthesize the polymers, but further research and kinetics must be done to determine the reaction's efficiency.

Abstract Name: Characterization of poly(vbTMAC) through Extinction Coefficient and Radius at Various Lengths and Solutions

Creating sustainable sources for water purification and clean drinking water has become a global priority. Of the current water purification techniques, ion exchange resins are of interest as they purify the water by removing contaminant ions and exchanging them with safe ions. Our group focuses on synthesizing anion-exchange polymers used to functionalize our nanomaterials. However, analytical characteristics are needed to evaluate the synthesis and performance of these nano resins. The study focuses on UV-Vis analysis to characterize the absorptivity of our polymer in various conditions. The polymer matrix gives the resin stability and ion exchange capabilities; quantifying the polymer concentration is crucial to understanding our materials' performance. Through the Beer-Lambert Law, the extinction coefficient directly correlates polymer concentration to light absorption, allowing rapid characterization of our resin synthesis. Recent studies have determined the extinction coefficient on other common ion-exchange polymers. The extinction coefficient of the monomer and polymer, where n=292, in ddH2O, were determined to be 79.3 ± 2.8 mL mg-1 cm-1 and 1.59 ± 0.05 mL mg-1 cm-1, respectively. Shorter polymers with a length of 225 and 30 had an extinction coefficient of 2.149 ± 0.006 mL mg-1 cm-1 and 2.3 mL mg-1 cm-1, respectively, in ddH2O, indicating that extinction coefficients are negatively correlated with polymer lengths. Our polymers must also be tested in different solution conditions as certain resin synthesis reactions are carried out at varying pH levels. Accurately determining polymer concentration by extinction coefficient is crucial for optimizing resin synthesis and the durability of materials. Current work is being done to determine the size of the polymer as a function of time through DLS. Future work should expand on the scope of the polymer studied and test the extinction coefficient in practical applications.

Abstract Name: Comparison of Asthma Healthcare Outcomes by Patient Demographics Before COACH McLungsSM Implementation

This study aims to summarize the demographic characteristics of asthma-related patient visits over the past five years before the implementation of COACH McLungsSM. COACH McLungsSM is an iPad-based program that uses shared decision-making between the patient and the provider to generate a treatment plan. 21 family medicine and pediatric practices in the Charlotte, NC, area were recruited in 2022. Baseline utilization data, such as emergency department visits, inpatient hospitalization, and oral steroid prescriptions, along with demographic data, such as race, sex, ethnicity, and race for patients aged 5 to 17 who were patients at these practices, were collected. The analysis of race showed that White/Caucasian patients and Black/African American patients had a similar proportion of patients in the baseline database, with 44.3% vs. 44.5%, respectively. White/Caucasian patients had an average of 5.0 outpatient visits, while Black/African American patients had an average of 5.7 visits (p = 0.100). White/Caucasian patients had an average of 1.883 visits to the ED and 0.1623 Hospitalization visits, while Black/African American patients had an average of 3.057 visits to the ED and 0.2679 Hospitalization visits. A further analysis of this observation shows a significant difference by race between ED (p < 0.001) and hospitalization visits (p = 0.023). Additional

disparities present themselves when comparing oral steroid prescriptions between the two cohorts. Black/African American patients had an average of 3.44 prescriptions, while White/Caucasian patients had an average of 2.60 prescriptions. The differences observed in the prescription and usage of steroids to treat asthma are significant (p < 0.001). In conclusion, a series of disparities with patients living with asthma by race are present when observed by patient visit type.

Abstract Name: Nudging Gym Use

We are interested in researching the effect of interventions to increase exercise behaviors. This project aims to encourage gym use by utilizing the economic theory of sunk cost fallacy. The sunk cost fallacy describes a phenomenon where an action is motivated because of a cost that has already been incurred. At the University of California, Riverside, fees for using the Student Recreation Center (SRC) are integrated into tuition costs and make up approximately 3% of the quarterly tuition. Our research hopes to understand whether reminding students of the inclusion of gym fees in their paid tuition will create a perception of sunk cost and encourage them to attend the gym more frequently.The American Medical Association outlines recent trends in growing healthcare prices and disease morbidity, emphasizing the importance of preventative health in managing health outcomes. Studying whether providing university students with information regarding “sunk” gym fees within their tuition costs increases their gym attendance can help researchers better understand how to encourage preventative health behaviors. This information can be valuable for applications within the medical and public health sectors to target improved community health and health autonomy. We hope to identify mechanisms to increase the frequency of exercise behaviors to understand methods of promoting preventative health through behavioral economic principles. Our research may be extended beyond exercise behaviors to encompass a variety of preventative health measures, including improved diet and reduced alcohol consumption to understand effective interventions to increase preventative health behaviors in society. As the healthcare industry grows, preventative health is increasingly important for patient autonomy and to reduce costs and burdens on the healthcare system.

Abstract Name: Exploring the link between hurricane-induced rainfall and nutrient pulses on Florida's West Coast

Blooms of the dinoflagellate Karenia brevis are recurrent along the west coast of Florida and lead to ecological damage and risks to public health through the release of brevotoxins. The availability of nutrients

is a significant factor in stimulating algal growth. This study examines the role of rainfall-induced nutrient pulses, particularly ammonium, nitrate, and phosphate, and their association with algal blooms. Water samples collected monthly along Florida's west coast were analyzed using absorption-based spectrophotometry techniques and employing an Autoanalyzer 3. Our findings establish a direct correlation between hurricane-induced rainfall and nutrient flux, exemplified by notable nutrient spikes during events like Tropical Storm Elsa and Hurricane Ian. These results emphasize the importance of addressing land-based nutrient pollution for long-term red tide impact reduction.

Abstract Name: An Analysis of the Controversy Surrounding ABA to Promote More Ethical Practice Among Occupational Therapists Treating Children with Autism

In recent years advocates within the autistic community have challenged applied behavioral analysis (ABA) due to alleged harmful practices, such as extinction and punishment, which some claim have led to long-term trauma in children with autism spectrum disorder (ASD). ABA and occupational therapy (OT) are two of the most popular therapies that work with children who have been diagnosed with ASD. While they are two very distinct therapies, they overlap in many ways. Due to this overlap, it is important to see if any of the complaints surrounding ABA can also be applied to OT as this can indicate that OT is also potentially harming children with ASD. However, there has been very little research investigating whether there are any areas of concern in how OT approaches treating children with ASD. The purpose of this research is as follows. First, the controversy surrounding ABA is explored. Next, the practices of occupational therapists and behavioral therapists are analyzed and compared through a survey of practitioners in Lubbock and Fort Worth, Texas with the purpose of determining if any of the complaints raised against ABA could also be applied to OT. This analysis and identification of concerning areas of overlap can provide a framework to then propose more ethical practice among occupational therapists working with children with ASD. These results can be used as a way to reconstruct certain practices in OT to better align the field with the modern values of inclusion and diversity, while also reengaging occupational therapists with the foundational values the practice was built upon.

Abstract Name: The Paradox of Tragic Art

Tragic art involves the complex interplay of negative and positive emotions, leading to physical and psychological changes within the viewer--such as chills, tears, and feelings of being moved (Hanich et al., 2014; Wassiliwizky et al., 2015). Negative emotions expressed within art are even considered to be an

essential resource, allowing artists to create pieces that engage viewers emotionally and are highly memorable (Menninghaus et al., 2017). But, if we often seek to limit negative emotions within real-life situations, why do we seek them out when viewing art, and why do we enjoy it? My study aims to investigate the paradox behind tragic art, addressing why we may leave an experience viewing tragic art feeling emotionally positive. Furthermore, this study explores whether tragic art has the ability to change our perspectives, specifically from an unsympathetic to a sympathetic view towards a marginalized group: refugees. Participants will be 150 adults who identify as politically conservative, suggesting an initial unsympathetic view towards granting entry to refugees fleeing to the United States. Participants will watch two videos illustrating sculptures depicting the tragedies faced by refugees when fleeing their countries, and will then be asked to rate their negative and positive affect, how moved they felt after watching the video, and how meaningful they found the art. Finally, participants will be asked to identify whether their opinions regarding refugees entering the United States have changed--and if so, how. I expect participants to demonstrate a mix of positive and negative affect following the tragic art video, and that these emotions will be mediated by the feeling of being moved, an overall positive emotion (Hanich et al., 2014). Additionally, it is expected to see that participants, who were originally unsympathetic to refugees migrating, will be more sympathetic to the cause.

Abstract Name: Regulation of Glucose Homeostasis by GFA-015

Glucagon (GCG) is a 29-amino acid peptide released from alpha-cells of the pancreatic islets. Glucagon is best known for its counterregulatory actions against insulin-stimulated hypoglycemia via hepatic glycogenolysis and gluconeogenesis. However, glucagon also regulates a range of actions like amino acid catabolism, lipolysis, ketogenesis, fatty acid oxidation, satiety, thermogenesis, energy expenditure, and bile acid metabolism, which are seemingly desirable improvements in patients with metabolic syndromes. Consequently, glucagon-receptor (GCGR) agonism has been added to classic incretin hormones in single-molecule, multi-receptor co-agonists that elicit superior therapeutic efficacy in metabolically compromised rodent models and emerging clinical trials, without impairing glucose metabolism. Thus, studies herein interrogate GCGR agonists of various pharmacodynamic length to test for maximum metabolic benefits while minimizing adverse effects on glucose homeostasis.Comparison of native glucagon to the long-acting GCGR-agonist with enhanced solubility, IUB288, revealed a distinct glucose response. GCGR agonists stimulate a similar glucose excursion within 60 minutes of administration in lean C57Bl6 mice. However, unlike the native peptide, IUB288 treatment induced a subsequent period of reduced glycemia. To confirm the effect of IUB288, we used GFA-015, a novel long-acting GCGR-agonist with enhanced engagement and extended pharmacodynamics allowing for once-every-72h dosing. After a 5-hour fast, GFA-015 was administered to C57Bl6 mice and observed over a 4-hour period. GFA-015 stimulated a smaller glucose excursion than IUB288 as well as a prolonged period of reduced glycemia, resulting in significantly lower blood glucose levels compared to the vehicle. GFA-015 treated mice exhibit increased insulin levels after the initial dose, further rising by day 4 and aligning with timepoints displaying reduced glycemic levels in the mice. A mixed-meal challenge on day 7 highlighted improved glucose tolerance in GFA-015 treated mice as compared to vehicle-treated controls. These data support that long-acting GCGR agonists increase circulating insulin and stimulate periods of enhanced glucose homeostasis.

Abstract Name: Dancing Our Way Through Stress: A Pilot Study Illuminating Bharatanatyam's Potential as a Therapeutic Outlet

Bharatanatyam, an ancient classical dance form originating in India, transcends cultural boundaries to offer a holistic approach to well-being. This study delves into the fascinating intersection of Bharatanatyam and mental health, with a focus on stress, exploring its profound impact beyond its established physical benefits, i.e., increased physical fitness and improved flexibility, circulation, and muscle toning. Stress relief is not only attained from the endorphins produced by the cardiovascular exercise of Bharatanatyam. Relief additionally includes different pressure points of hand gestures, known as Mudras, the expression of different moods, known as Rasa, and different body postures, known as the Karnas. The practice of Bharatanatyam, thus, initiates the healthy unification of the body and mind, helping practitioners to tune into the body to find expression of thoughts and emotions. This study explored Bharatanatyam's impact on stress reduction and overall well-being through a preliminary analysis involving Bharatanatyam dancers from UAB's dance team, Natyam. Utilizing the Perceived Stress Questionnaire developed by the Perelman School of Medicine at UPenn, stress levels before and after Bharatanatyam practice sessions were measured, which integrated rhythmic movements, expressive gestures, and storytelling. Our hypothesis posited a decrease in perceived stress with the practice of Bharatanatyam. By examining the correlation between Bharatanatyam and perceived stress, this study provides a gateway to understanding the profound connection between the ancient art form and the growing field of mental health, thus revealing its potential as a holistic therapeutic outlet. Thus, the purpose of this piece is to elucidate an example of the method in which Bharatanatyam improves one's self-efficacy in a manner that mirrors a progression from external movements to an inward channeling of energy and consciousness. This piece depicts the transformative impact of self-awareness and understanding on healing anxiety and depression.

Abstract Name: Beyond Diagnosis: The Cognitive Demands of Stopping and Turning Behaviors Among Drivers With and Without Multiple Sclerosis and Implications for Driving Safety

Background: Multiple sclerosis (MS) commonly affects cognitive/motor abilities important for safe driving. However, limited research has examined the impact of MS-related cognitive compromise on cognitively-demanding driving behavior. Namely, turning and stopping at intersections are challenging driving situations that constitute a significant portion of road collisions. This study used virtual reality driving simulation (VRDS) to 1) investigate differences in stopping/turning behavior between adults with and without MS, 2) identify cognitive correlates of stopping/turning behavior, and 3) examine whether cognitive correlates differ

by MS status. Methods: 85 adult drivers (48 PwMS, 37 controls) completed cognitive assessments and a VRDS drive featuring right/left turns and stop sign intersections with varying cognitive demands. Linear/logistic regressions assessed driving behavior in relation to MS status, cognitive measures, and their interactions. Results: Group differences were minimal, except for controls executing sharper left turns than PwMS ($p=0.035$, $\eta 2=.08$). Additionally, PwMS tended to stop after the line at high-complexity stops ($p=0.07$, $phi=0.31$). In terms of cognitive correlates, weaker abilities in visuospatial ability/memory, cognitive/motor speed, and rapid working memory are related to less-safe turning behavior. Abnormal complex attention was associated with less-safe stopping. Associations between cognitive/motor variables and stopping/turning did not significantly differ by MS status. Conclusions: PwMS exhibited similar driving behaviors to controls at challenging intersections, with occasional exceptions such as increased caution in left turns and a trend towards less safe stopping at high-complexity stops. Cognitive/motor correlates included selective visual attention, visuospatial ability, working memory, and psychomotor speed, regardless of MS status. The results emphasize the importance of evaluating cognitive and motor capabilities for driving, rather than relying solely on diagnostic status when making driving safety recommendations. Findings may differ in other neurologic populations, which will be explored in future research.

Abstract Name: Development of an Economical Motion Sensing System Using IMUs for Real-Time Gait Cycle Estimation

The gait cycle, for human walking, is defined as the normalization of time between consecutive foot contacts from the same foot. The applications of the gait cycle have been well established, especially for clinical assessments and powered assistive devices. For real-time gait cycle analysis, implementing predictive models to do so can be challenging due to the high variability in human motion. Existing approaches yield accurate estimates, but often require expensive hardware, limiting the proliferation of this technology. As such, our goal aims to develop an economical motion sensing system for real-time gait cycle estimation and benchmark its performance against a higher-end system. Both the high-end (HE) and off-the-shelf (OTS) systems use two inertial measurement units (IMU), mounted on the thigh and the lower leg. Separate microcontrollers for each system process IMU output and use an algorithm developed by our group for real-time gait cycle estimation. Ten participants without neuromuscular impairments will be recruited to walk on a treadmill for 20 minutes at speeds ranging from 0.5-1.5 m/s at randomly assigned increments of 0.1 m/s, simultaneously wearing both systems. The root means square error (RMSE) of each system's gait cycle estimates will be compared to offline calculations. Regression analysis will be used to quantify system drift through the RMSE and a two-way ANOVA will assess differences in the effects of system performance and gait speed. We expect that drift will be observed in both systems, but occur earlier in our OTS system and with only marginally greater error compared to the HE system. Additionally, we do not expect differences with respect to gait speed. Overall, developing an affordable, yet adequate system can hold the potential to improve access to reliable biomechanical data, advancing both assistive device technology and real-world gait analysis outside of a lab environment.

Abstract Name: Assessing Website Accessibility Awareness Among University Students in the United Arab Emirates

The World Health Organization estimates that more than one billion people around the world live with a disability and face various challenges in digital environments. Since the invention of the World Wide Web, governments and businesses everywhere have moved their services to websites. In particular, the United Arab Emirates (UAE) aims to digitalize all services by 2023. Consequently, it is critical that these websites be accessible to all members of society regardless of their abilities. Several efforts have been made to promote accessible website design including the creation of the Web Content Accessibility Guidelines (WCAG). However, previous studies that numerically evaluated accessibility of different websites in the country have

demonstrated a widespread non-conformance with accessibility standards. This cross-sectional study aims to assess the level of knowledge, attitudes, and perceptions of website accessibility among Information Technology (IT) students in the UAE. A select sample of 70 Zayed University IT students completed an online questionnaire. Results revealed a high level of familiarity with the challenges faced by people with disabilities but a low awareness of web accessibility. Notably, while 58% of students had enrolled in web development courses, 92% reported that none of their courses covered website accessibility, and 78% were unaware of the WCAG. The findings suggest a need for further data to be collected from different universities in the country to reach a general conclusion and understand the implications of web accessibility awareness in a larger context.

Abstract Name: Explicitly Queer, Political, and Radical

This paper poses a queer intervention to the scholarship of Jacques Rancière; whose oeuvre has been centered around how art and politics are intertwined and how they shape the “distribution of the sensible,” what produces the system that determines what is permitted to be said, thought, and done within a society. Rancière posits that the distribution of the sensible establishes an aesthetic regime, but that art has the potential to challenge and disrupt this regime. Regarding this, Rancière writes extensively on cinema, analyzing high culture films such as La Haine (Mathieu Kassovitz 1995) and La Strada (Federico Fellini 1954); however, he has neglected a large body of films that practice the criteria he establishes.I focus on Gregg Araki’s Teen Apocalypse Trilogy of the New Queer Cinema movement as films that are radically political according to Ranciere’s theoretical framework. I express that the main political nature of the trilogy lies in their “explicit queerness.” In order to define what I consider art that is “explicitly queer,” I establish criteria as well as a timeline of radical queer art starting with Marcel Duchamp’s La Fountain, Andy Warhol’s Sex Parts, and Pier Paolo Pasolini’s filmography. Then, alongside my analyses of the films, I take a phenomenological approach based on Tarja Laine’s Feeling Cinema: Emotional Dynamics in Film Studies (2011), positing my personal experiences with each film in order to understand their political nature according to Rancière’s The Emancipated Spectator (2009). Through this paper, I assert that because of Araki’s unconventional style, his engagement and challenging of the spectator, as well as his subversion of traditional aesthetics and storytelling techniques, Araki’s Teen Apocalypse Trilogy reveals the epoch of America’s queer youth in the 1990s, giving voice those refused one within the dominant order and therefore being the political films as Rancière articulates.

Abstract Name: Dissecting the EGFR/MAPK/Ras pathway in NF1-mutant Ovarian Cancer Through Western Blot Analysis

Ovarian cancer ranks as the 8th most common cause of cancer-related deaths in women. High Grade (type II) Serous Ovarian Cancer (HGSOC) is among the most lethal forms of human cancer. In 14% of HGSOC cases Neurofibromin 1 (NF1), is mutated or deleted, and no specific targeted approach is currently available for this group of patients, who are generally treated with surgery and/or radio-/chemo-therapy.NF1 negatively regulates the MAPK pathway by functioning as a Ras-GTPase. The Ras/Raf/MAPK pathway is a signal transduction pathway that regulates cell growth, division, and differentiation. This pathway contributes to mitogenic and pro-survival signaling and is often implicated in many forms of cancer. EGFR is a receptor tyrosine kinase upstream of NF1 and the MAPK signaling pathway. Our lab hypothesizes that cells lacking NF1 are dependent on EFGR signaling. Therefore, by inhibiting the EGFR signaling pathway, we may be able to induce cell death in NF1-mutant ovarian cancer cell lines.We are currently utilizing 5 model cell lines: OVCAR4, OVCAR5, and HEYA8 are NF1- wild-type, whereas PEO1 and DOV13 are NF1-mutant. Western Blot Analysis will detail the impact of drug treatments (e.g., EGFR inhibitors) on downstream signaling targets in the NF1 pathway (e.g., AKT, mTOR), with the final aim to identify differential regulation and novel targetable nodes to treat this subgroup of ovarian cancer.

Abstract Name: Are Pell Grants Enough?

This study aims to examine how gender differences and socioeconomic status influences how each individual experiences a sense of belonging and hope. Using the lens of attachment theory, this study focuses on the sense of belonging and hope among Pell Grant recipients. It is hoped that this will assist the search for ways to increase belonging and hope on campus. This research will add to the discipline of psychology a better understanding of the factors that can potentially impact a sense of belonging and hope in an individual. Data was collected through an online survey that measured undergraduates' levels of belonging and hope and collected demographic information. The results showed that, for this sample, receiving Pell Grants has no correlation with belonging and hope. However, the results did show that gender has a significant impact. It can be concluded that women attending this institution tend to have a lower sense of belonging and hope in comparison to men. The results also showed how students living on campus were more likely to experience belonging and hope in comparison with those who don't live on campus. Implications for this are discussed.

Abstract Name: For God and Country: Death Anxiety, political violence, political alienation, and Christian nationalism.

According to the literature on Terror Management Theory, clashes in differing beliefs and worldviews can be seen as a threat and may motivate individuals to engage in aggressive or violent behavior. This study aimed to understand some of the contributing psychological and demographic dynamics of Christian Nationalism in regard to political violence and political alienation through the lens of Terror Management Theory. It was hypothesized that low death anxiety scores, high political violence scores, high political alienation scores, conservative political ideology, and high religiosity would predict Christian Nationalism. A correlational study was performed to understand the relationships between death anxiety, political violence, political alienation, political ideology, religiosity, and Christian nationalism. Through an online survey shared throughout the South Central region of the United States, 201 participants, primarily undergraduate students at an evangelical Christian university, completed surveys which measured all six variables. A linear regression analysis was used to predict Christian nationalism. Statistically significant results displayed that high levels of political violence, low levels of political alienation, high levels of religiosity, and a conservative political ideology predict Christian nationalism, while death anxiety was not statistically significant. The influence of the study's setting and context are discussed in light of the unexpected relationship between political alienation and Christian Nationalism. Additionally, the data revealed that religiosity interacted with progressive political ideology differently than with conservative political ideology. This study offers insight into the psychological dynamics of Christian Nationalism and its complex relationship with religion and politics.

Abstract Name: Associations between Threatening and Non-Threatening Adverse Childhood Experiences and Psychological Wellbeing: A Gender-Based Analysis.

There is evidence for an association between adverse childhood experiences (ACE) and mental health difficulties in adults. This study adds to this literature by identifying threat- and non-threat-related ACEs and investigating their effect on wellbeing. Additionally, we will examine the moderating effect of gender in these relationships. Participants (22.4 ± 4.5 years; 70% women, 28% men, 2% LGBTQI; 42% Latinx|e, 15% white, 37% Asian, 2% black, 4% Indigenous, PI, and mixed race) were N=412 students from a public, urban university who completed an online survey between the spring of 2022 - 2023.We ran multivariate linear regression models to investigate the effects of threat and non-threat-related ACEs on students' well-being. Next, we used multiplicative terms (thread-Ace * gender and non-thread-ACE * gender) to assess their interactive effects on well-being. In the final linear multivariate regression model, we adjusted for potential confounders and covariates, including demographics (age and race/ethnicity) and other potential stressors (first-generation student and perceived financial situation). We found significant differences in well-being by gender (Women=10.34; Men=13.40; t=5.51, p<0.0001) and perceived financial situation (Worse = 9.81, Same as others = 11.70, Better = 11.58; F=4.89; p=0.008). In the final regression model, male students in the higher category of non-threatening ACEs have significantly lower scores in well-being (β= -2.89 p=0.010) compared to men in the lower category and all women. No statistically significant effects of threatening ACEs on students' well-being were found. Distinguishing threat-related and non-threatening ACEs enables a comprehensive examination of the effects of ACEs on students' well-being. Our findings suggest that males with histories of non-threatening ACES may be at higher risk for lower well-being levels. Further research is

needed to identify gender differences that may reveal unique vulnerabilities or resilience factors to inform tailored interventions and support strategies to aid students with ACE histories to succeed in college.

Abstract Name: Understanding the Needs of Georgia's Hispanic/Latinx Population Regarding Adolescent Health

Georgia's Department of Public Health's Adolescent Health and Youth Development (AHYD) Program is based on the Positive Youth Development Approach as recommended by the Centers for Disease Control and Prevention. This approach engages youth within their communities, schools and organizations, peer groups, and families in a productive and constructive manner. Overall, the AHYD program aims at preventing HIV, STIs, and pregnancy among all youth. In Georgia, the Hispanic/Latino population has grown to over 10% of our total population. However, adolescent health programs within Georgia have not specifically focused on the cultural differences among the large Hispanic/Latino community. This study takes the existing AHYD programs and seeks to investigate how these program resonate with the Hispanic/Latino communities, including variability in countries of origin. First, a thorough literature review was conducted regarding Hispanic/Latino youth, at risk behaviors, and the cultural competency of current programs. More specifically, the AHYD programs were further analyzed for how they address the unique needs of the Hispanic/Latino communities, especially beyond just translations to Spanish. Finally, recommendations were provided in terms of best practices that are needed to be incorporated into the programming as well as any evaluation measures. As the Hispanic/Latino population continues to increase in Georgia, it becomes more evident that improving the health and well-being of Hispanic/Latino children in critical to the state's future. While existing state-funded programs have focused on largely oral health, obesity and nutrition, mental health, unintentional injuries, reproductive and sexual health have been ignored, often due to stigma and cultural expectations. More steps must be taking to ensure their safe passage to adulthood across all areas.

Abstract Name: Life expectancy by neighborhood: do lower-income households have worse health impacts?

It has been forty years since the landmark paper by Robert Bullard, known widely as the father of Environmental Justice, concluded that solid waste sites in the city of Houston were not randomly distributed but targeted communities of people of color. Over the past forty years, both Houston and the field of environmental justice have grown. My research revisits some of this work to identify to what extent there has been change and where we stand in our current condition when it comes to the relationships and connections between environment and health outcomes. I gathered data on six super-neighborhoods in the greater Houston area including Afton Oaks/River Oaks, Midtown, Kingwood, Greater Fifth Ward, Kashmere

Gardens and Independence Heights. I began with data from the US Census Bureau to measure factors such as life expectancy, income inequality and racial makeup of the census tracks these neighborhoods reside in. I then used the EPA's EJ Screen to measure data on hazardous waste proximity, toxic releases into the air, and lead paint exposure in the census tracks that include these communities. I then compared the information from these sources to test whether there was a correlation between the race/socioeconomic statuses of these communities and the health/environmental factors.

Abstract Name: Correlation of Dahlia Mosaic Virus Strains with Symptoms of Infected Dahlia Plants

Dahlia species, known for its vibrant and varied blooms, is popular in Utah's growing cut flower industry. However, some cut flower farmers encounter challenges with its cultivation due to its susceptibility to viruses. This study aimed to identify symptoms of Dahlia mosaic virus strains (DMV) in symptomatic dahlia plants, specifically focusing on the Holland, Portland, and D10 strains. Molecular biology techniques including polymerase chain reaction (PCR) and gel electrophoresis were employed to accurately identify and differentiate the viral strains. Samples were collected from dahlia plants exhibiting mosaic-like patterns, leaf distortion, petal discoloration, stunting, reduced flower production, and yellowing of leaves. DNA was extracted from these samples followed by PCR amplification using strain-specific primers. The resulting PCR products were visualized using gel electrophoresis. Preliminary results indicated a predominance of the D10 strain. The Holland strain was also frequently detected but was not universally present in all samples. In samples with necrotic flower buds or leaves, all three strains of the virus were identified. In certain varieties, the presence of all three strains prevented the production of flowers altogether. Leaves of plants only infected with D10 sometimes, depending on variety, will show a faint mosaic pattern whereas leaves from plants infected with the Holland strain display a brighter, yellow mosaic. This research advances our understanding of the symptoms associated with DMV strains for easier field identification in the future as well as sheds light on the prevalence and distribution of these strains. The findings will improve management strategies and inform cut flower farmers of what symptoms to look for in plants.

Abstract Name: Quality Assurance and Quality Improvement within the Child Welfare System

Organizations, such as public child welfare systems, often dedicate a large body of resources towards improving their systems, often with specific goals for their target audience: improving outcomes for children and families. However, within systems improvement efforts, there are two different approaches: quality

assurance and quality improvement. Quality assurance efforts often refers to compliance-based metrics within systems activities, and quality improvement focuses more on the improving the activities of broad systems to be more in line with the organizational mission. The National Partnership for Child Safety (NPCS) is a peer-to-peer learning and data sharing collaborative of over 35 child welfare jurisdictions in the United States, and members are focused on systems improvements. The main objective of this study is to learn more about the nature of quality improvement efforts in child welfare systems, using employees working within NPCS jurisdictions as a sample. The methods of this study include surveys and follow-up interviews with quality improvement professionals within these child welfare jurisdictions. Ultimately, the goal of quality improvement is to improve outcomes for youth and their families, to ensure that the most vulnerable children/youth are safe within their permanent homes. This research is currently in active data collection, thus results are still pending. However, a full description of the project development process, study goals, and preliminary data will be presented at the conference.

Abstract Name: Jack Kirby: The Unsung Revolutionary of the Comic

The goal of this presentation is to highlight the achievements of Jack Kirby and give credit where it is due. Jack Kirby's accomplishments as a graphic designer stem not just from his iconic illustrations themselves, but also the messages and emotions he was able to convey through them. He had a successful career with big name comic companies, namely Marvel and DC. During the time he worked at these companies, his job was as an illustrator, and he did it well. Many people admired and tried to emulate his work, from fellow colleagues to average comic fans. This happened to the point where other artists were highly encouraged to copy his style as much as possible. Jack Kirby was known for having a one-of-a-kind dynamic art style. Not only did Kirby's works look visually pleasing, with his bold and strong line art, but they also resonated with viewers on a deeper, symbolic and emotional level. His work helped convey powerful feelings and ideas, further inspiring people and instilling these beliefs within them. Whether they projected the notion of patriotism during a time it was more essential or challenged the audience to contemplate a character's hidden depths, Kirby's work more than achieved this effect, and did not stop there. In a time where Kirby himself struggled with his own internal conflict, he poured everything he had into his work, creating masterpieces full of reflected raw emotion. Yet despite all of this, Kirby never felt fully appreciated, neither when working with Marvel nor with DC, feeling as though his work was being profited off of by others.

Abstract Name: DOES BEING AEROBICALLY FIT RESULT IN APPROPRIATE VO2 MAX CLASSIFICATIONS?

The American College of Sports Medicine suggests that people should exercise three times a week, at a moderate to vigorous intensity for a minimum of thirty minutes. These proposed guidelines suggest that if one completes said recommendations, it is possible for one's overall VO2 max to result in an appropriate classification (≥ fair). PURPOSE: The purpose of the present study is to see if females who are aerobically trained per the ACSM guidelines will result in appropriate VO2max classifications. METHODS: The present study only included individuals who were in the following subcategory (20-29 years of age). Participants were young (age= 21.80 ± 1.30 years, height 162.77cm ± 7.40cm, mass 58.56kg ± 9.31kg females. The specific submaximal aerobic test to predict one's VO2max was the cooper 12- minute walk-run test, which was performed on a treadmill. An Independent sample T-Tests were used to assess VO2max values between each participants output and ACSM norms. An alpha of 0.05 was used for level of significance. RESULTS: Of the 6 participants in the study, five had VO2max values that were categorized as fair (34.6-38.9 mL.kg-1.min-1), and one had a classification of excellent (46.5-51.3 mL.kg-1.min-1). The present study suggests there are no significant differences between the current participants VO2max classifications and normative values (P = 0.916). CONCLUSION: The aim of the present study was to see if general exercise recommendations per the ACSM have a positive or negative impact on one's overall VO2max classification. The present findings do suggest that exercising aerobically a minimum of three times a week, for a minimum of 30 minutes at moderate to vigorous intensity can be beneficial to keeping a fair to excellent VO2max classifications.

Abstract Name: Computationally Probing the Light-Driven Chemistry of Two Model Brown Carbon Chromophores

This research investigates brown carbon chromophores (BrCCs) that are found in aerosols produced by biomass burning. These molecules have the ability to absorb visible and ultraviolet light. The impact of BrCCs on climate change is poorly understood. Moreover, the light-driven chemistry of BrCCs can affect the composition of atmospheric aerosols. In this study, we are focusing on two model BrCCs which have very similar chemical structures but behave very differently in experiments. Specifically, the BrCC, 2-phenyl pyrrole (2PhPy) produced a clear spectrum that abruptly terminated. In contrast, the other model BrCC, 2-phenyl imidazole (2PhIm) did not produce an experimental spectrum at all. Our goal is to use computational chemistry to rationalize why the two molecules behave very differently. We speculated that the cause of these differences involves the light-driven breakage of an N-H bond. Using computational chemistry, we mapped out how the energy changes as the N-H bond breaks when the electrons are excited. Our results show that as the bond is stretching to larger distances, the energy initially increases. However, at a large enough N-H bond length, the electronic character of the excited state changes and further stretching of the N-H bond lowers the energy. Overall, we are beginning to build an understanding of the light-driven chemistry of two model BrCCs and aid in the interpretation of existing experimental data.

Abstract Name: Bill T. Jones' Curriculum II: Transcending Movement through Visual Technology

In the era of ever persistent, always developing technology, how are artmakers to proceed? What technology is the contemporary choreographer to use in their practices and how does that aid or inhibit their work? In researching Curriculum II, by the Bill T. Jones/Arnie Zane Company, the discovery made was that there are many ways in which visual stage technology intertwines with the physical form of dance. Just as movement lexicon and conceptual ideas contribute to the story arc of a piece, visual technology can create meaning and narrative as well. Exploring the technological role in the piece, three company members were interviewed including Janet Wong (Associate Artistic Director, Choreographic Collaborator, and Video Designer), Megan Dechaine (Stage Manager), and Serena Wong (Lighting Supervisor). Direct correlation between themes and technology usage proved an integral part of the piece as it uses a high amount of technology. The technological aspects hold conversation with the physical bodies rather than a corroborative approach which is commonplace in Western contemporary dance. Notably, the video design and lighting design contribute to the atmosphere and narrative in a substantial way; each moment of the piece transports the audience to a specific feeling or idea. The incorporation of these elements is done in an informative and conversational way that supersedes conventional aesthetics. Janet Wong implores, “what is the technologies’ intervention into your work and what is your intervention into technology?” In considering this, contemporary choreographers should make informed decisions with intentionality to enhance the artistic voice of their piece. In establishing understanding of technology’s evolving presence, a work can transcend movement and imagine worlds beyond the status quo.

Abstract Name: Elevated Blood Pressure in College Students and an Assessment of Their Risk Factors

While hypertension is common in older adults, the disease process is related to unhealthy diet, insufficient exercise, and/or alcohol use, which are modifiable risk factors that are common among young adults (Whelton et al., 2022). Younger adults with elevated blood pressure (BP) are at higher risk of cardiovascular disease (Zhang et al., 2019). However, college students may be unaware of their risk factors for hypertension and disease-related complications. The purposes of this study were to assess for high BP in college students and support students in identifying their risk factors for hypertension.The Neuman Systems Model and the Fogg Behavioral Model (TFBM) framed our work. Neuman’s model addresses that both internal and external factors affect health (Neuman & Fawcett, 2011). Education regarding internal and external risk factors should prevent hypertension in college students. TFBM states that for behavior change to occur, motivation, ability, and prompts must be concurrent (Behavior Model, 2022). Providing education and encouraging lifestyle changes should support all elements of TFBM. Convenience sampling was used. Four assessments

of blood pressure were performed on a private midwestern college campus. BP and heart rate were assessed at initial screenings. Participants completed a Google Form that assessed overall health, knowledge of and risk factors for hypertension. Participants disclosed recent caffeine, food, and alcohol intake. Education was provided on how these impact BP. At later screenings, education on stress reducing methods was provided and body water, body fat, and BMI were assessed.Our results indicated that 52% had an elevated systolic BP and 30.4% had an elevated diastolic BP. Recent caffeine and alcohol intake had no significant impact on BP readings. Top stressful events, self-reported on the Google Form, were linked to college life. Our results illustrated that high BP is prevalent among college students, increasing their risk for future complications.

Abstract Name: It’s Not You, it’s My Attachment Style: How Attachment Styles Relate to Perceptions of Authenticity in Romantic Partners

This study investigates a correlational relationship between one’s own attachment style and perceptions of authenticity in one’s romantic partner. Perceiving a romantic partner as authentic is associated with better relationship outcomes, more trust, and decreased anxiety (Wickham, 2013). In addition, past research has shown that within one person, authenticity is related to more secure attachment (Gillath et al., 2010). We predicted that individuals with insecure attachment styles (anxious and avoidant) will perceive their partner as less authentic than people with a secure attachment style. In addition, we predicted that people with a secure attachment style will report having better quality relationships and greater life satisfaction compared to people with insecure attachment styles. Gathered through an online survey platform, participants (N = 120) in a romantic relationship completed a survey measuring demographics, personality, attachment style, perceptions of partners’ authenticity, self-ratings of authenticity, relationship quality, and satisfaction with life. A multiple linear regression analysis showed that, controlling for self-perceptions of authenticity, anxious and avoidant attachment were related to a lower perception of a romantic partner’s authenticity, supporting our first hypothesis, $F(3, 114) = 25.184$, $p < .001$, $R2 = .399$, $\Delta R2 = .177$, anxious: $sr2 = -.183$, $p = .050$ and avoidant: $sr2 = -.446$, $p < .001$. In addition, greater attachment security was related to better relationship quality ($r = 0.62$, $p < .001$) and greater satisfaction with life ($r = 0.52$, $p < .001$), supporting our second hypothesis. These results demonstrate that one’s own attachment style is related to perceptions of a romantic partner’s authenticity as well as self-perceptions of relationship quality and satisfaction with life. Understanding these relationships can contribute to well-being in relationships while laying the groundwork for further research to establish a causal relationship between attachment style, perceptions of romantic partners’ authenticity, relationship quality, and well-being.

Abstract Name: Associations between home environment, severity of distress, and unmet needs among family caregivers of women with gynecologic cancer

Approximately 49 million adults in the United States provide unpaid care to a loved one and commonly experience high levels of distress. The home environment is known to influence caregiver (CG) distress but has rarely been evaluated in gynecologic cancer. This analysis aims to examine the association between home environment, distress, and unmet needs in these understudied CGs. Gynecologic cancer CGs (n=782) who were offered support in an outpatient Family CARE Center completed a 20-item survey of demographic information, distress, and unmet needs. T-tests and chi-square analyses were used to compare distress level and frequency of unmet needs between 1) family caregivers who did or did not live with the care recipient and 2) caregivers with or without children living in the home. Mean CG distress was 4.41(SD = 3.08) on a 0 to 10 scale. CGs with children in the home reported higher distress (mean=4.8; SD=3.05) compared to those without children in the home (mean=4.17; SD=3.06; t(691)=-2.51; p=0.006). There was no difference in distress between CGs who lived or didn't live with the patient (p=0.47). The most common unmet needs were “managing patient symptoms” (n=216; 27.6%), “need for information about cancer treatment” (n=213; 27.2%), “maintaining your own emotional health” (n=187; 23.9%). Comparing unmet needs among different living situations, CGs with children in the home (compared to those without) were more likely to need information about cancer treatment and to report financial concerns, while CGs living with the patient, compared to those who didn't, were more likely to report difficulty finding time for themselves (all p<0.05). Having children in the home was associated with higher CG distress. Different CG living situations expressed different sources of distress. Identifying high risk caregivers based on living situation can lead to earlier interventions to address unmet needs and reduce distress.

Abstract Name: The Relationship Between the Way We Perceive Stress, Cognitive Flexibility, and Mood

Our study aimed to explore how perceived stress, mood, and cognitive flexibility come together in the lives of college students, using findings that helped us understand these interactions within the context of higher education. Recent research has underscored the growing psychological challenges college students face as they navigate academic pressures and life's demands. Our research contributes by delving into the connections between perceived stress, mood, and cognitive flexibility. The insights gained can guide strategies and support systems to benefit students in this complex environment. We collected data from 126 undergraduates at a small Southeastern private university (52.8% female, 46.3% male, and 0.8% other; 43 freshmen, 44 sophomores, 28 juniors, and 8 seniors), ranging in age from 17 to 34 (mean = 19.74; S.D. = 1.78). To gauge stress, we employed the Revised Perceived Stress Scale (PSS), while mood was assessed using the Positive and Negative Affect Schedule (PANAS). In addition, cognitive flexibility was measured through the Cognitive Control and Flexibility Questionnaire (CCFQ). Our results confirmed our initial

hypotheses. They revealed a positive correlation between cognitive flexibility and positive mood scores and a negative correlation with negative mood scores. Perceived stress showed the expected patterns, with negative correlations with positive mood and positive correlations with negative mood. We also found the anticipated negative correlation between perceived stress and cognitive flexibility. These findings underline the pivotal role played by cognitive flexibility in managing stress and promoting emotional well-being among college students. The discussions on how these results can shape practical interventions and support programs to enhance students' mental resilience within the challenging landscape of higher education are highly anticipated. While we acknowledge the limitations of our sample, primarily consisting of first-year and second-year students, we are eager for future research in more diverse academic settings to deepen our understanding.

Abstract Name: The Impact of Peripherally-targeting Interventions on Multiorgan Gene Expression in Aged Rats

The proportion of adults aged 65 and older is increasing in the United States. Due to this, there is a growing need for therapies to alleviate the deleterious effects of aging, especially decreased cognition. Peripheral interventions that exert system-wide effects are a promising field of therapy for ameliorating cognitive decline. One prior study examined the effects of a ketogenic diet and time-restricted feeding in aged male rats. The effects of these interventions on cognition and microbiome composition were investigated, and the results demonstrated the efficacy of these interventions in ameliorating aspects of age-related declines in function. This study provided valuable information about the impacts of these interventions on the targets described. Mechanistic insight as to how these interventions influence cognitive status, or how the resulting changes to the gut microbiome result in improved cognition, is still lacking. Further information about factors contributing to cognitive decline could be obtained by examining changes in gene expression in tissues from these studies, both within and outside of the central nervous system. Thus, this project evaluated several genes associated with possible contributing factors for decreased cognition with a focus on insulin signaling and glucose uptake. Brain, liver, and muscle tissues from the rats in the study were utilized in quantitative real-time PCR against 14 target genes. Tissue-specific effects were demonstrated for several genes in certain genes involved in insulin signaling pathways, such as significant differences in certain gene expression in CA1 and CA3 brain regions. These data are aligned with previous results from this study, indicating that these interventions result in brain-region dependent changes in gene and protein expression and further expands this work to include regionally specific effects beyond the brain.

Abstract Name: A Theoretical Evaluation of Measles-Unvaccinated Children Thresholds for Targeted Interventions

Despite being a vaccine-preventable disease, measles directly results in over 200,000 annual deaths. Identifying and vaccinating measles zero-dose children, children who have not received any routine measles-containing immunization, is a leading priority to control measles transmission. The focus of this research is to determine the threshold of measles zero-dose children that requires vaccine-targeted intervention to prevent an outbreak for 52 Gavi, the Vaccine Alliance-eligible countries. Prior work has examined the influence of age contact mixing patterns on the probability of measles elimination and potential outbreak risk. This project leverages age contact mixing matrices to investigate country-specific thresholds of measles zero-dose children. To estimate these thresholds, we simulate all possible age immunity profiles that would result in contact- and age-adjusted population-level immunity of at least 93%. Empirical analyses estimate that 93% population immunity is sufficient to prevent measles outbreaks. The simulation framework combines matrices of monotonically increasing immunity profiles for children aged 1-14 years, transformed country-specific age-contact matrices, and age-specific measles vaccine effectiveness rates to calculate the range of vaccine coverage profiles for children aged 1-14 years that will prevent an outbreak. We conduct data analysis to examine global and regional trends among these vaccine coverage profiles. Across all countries, median required vaccination coverage drops between age groups 1 and 2 years but increases from age groups 2 to 14 years to prevent measles outbreaks. However, uncertainty in required vaccination coverage decreases from age groups 2 to 14 years. Countries in sub-Saharan Africa require the highest age-specific median vaccination coverage to prevent outbreaks. Countries in the Middle East and North Africa demand the lowest age-specific median vaccination coverage. Overall, countries with higher age contact rates need higher vaccination coverage to prevent outbreaks. This study's findings may be used by international organizations to inform targeted immunization strategies and resource allocation.

Abstract Name: I'll Play It in the Background: The Impact of Media Multitasking on Academic Self-Efficacy and Self-Concept in Generation Z Undergraduate Students

Academic media multitasking (completing homework while simultaneously watching television, movies, or YouTube videos) is a prevalent tendency among Generation Z college students, despite the negative effects multitasking can have on focus and comprehension. This study examines college students' academic media multitasking habits and whether those habits detrimentally affect their academic self-concept and self-efficacy. 141 undergraduate students aged 18-24 completed a survey that presented three sets of questions: one that gauged their media multitasking habits, including frequency of multitasking with reading, writing, mathematics, and exam preparation tasks, respectively; one that measured their academic self-efficacy in a variety of scenarios; and one that measured their academic self-concept in a variety of scenarios. Students responded to each question on a five-point Likert-type scale, and their responses in each set were averaged to calculate a score of 1 to 5 points. 75% of participants (n=106) scored 3 out of 5 points or higher in self-concept, and 84% (n=119) scored 3 out of 5 points or higher in self-efficacy. These scores did not have a positive or negative correlation with the participants' frequency of academic media multitasking; students who had a high multitasking score had similar self-concept and self-efficacy scores as those who had a low multitasking score. Additionally, survey participants reported their grade point average (GPA), with 86% of

participants (n=121) stating a 3.0 GPA or above. There was no correlation between participants' frequency of academic media multitasking and their GPAs. Thus, despite existing literature that illustrates the negative effects of multitasking on comprehension and focus, this study suggests that media multitasking does not strongly impact Generation Z's academic performance, self-efficacy, or self-concept.

Abstract Name: History of Malayalee Catholics in Texas

When moving to Texas at a young age, I never imagined celebrating my culture here. I believed I would be leaving my favorite foods and traditions in Kerala. After living in Texas for over a decade, I learned how my thoughts were wrong. Here in Texas, I can celebrate my religion and culture freely with those who share them with me and those who do not. I have learned how our Malayalee Catholic traditions are still kept even in a different land. Through my traditions and religion, I have made many good relationships. Malayalee Catholics are unique in many ways. We have a special culture and traditions which have been well-kept throughout centuries. There are many other traditions that I didn't get a chance to explain in depth or at all. In terms of marriages, food, and musical traditions, I can go on and on. They are almost endless. Another unique fact about us is our lineage or where we actually come from. Due to the lack of historical evidence, there is a lot of debate on this. However, oral traditions and the little historical evidence we have help us learn about our own roots. Even among us there are many different ways on how we became Catholic. Our food is also amazing. The tradition of our food goes back. These flavorful Pesaha Appam, Kozhakatta, and Appam and Stew all make me more excited to celebrate my religious holidays. As I mentioned before, we are a minority in India. Recently, we have been getting more hate from North Indians. There is lots of Christian persecution in North India. Coming to Texas, I have seen the good sides of even North Indians. I have experienced many great things here.

Abstract Name: Impacts of US Interventionism on the Art and Artists of Iraq Post 9-11

Post 9/11 conflict between the US and many middle eastern nations, mainly Iraq and Afghanistan, was spurred by the 'War on Terror' as it was dubbed by George W. Bush and the American military. The main goal was to seek out and eradicate al Qaeda, which was the terror group that took responsibility for the 2001 attacks. This started in Afghanistan with the targeting of the Taliban governing structure, but eventually expanded throughout the region specifically targeting the government led by Saddam Hussein. Bush and the government cited human rights abuses as well as hoarding of WMDs or Weapons of Mass Destruction, and while this claim was later disproved, it was the basis for the 2003 invasion of Iraq. The impacts of this intervention on the art of the nation of Iraq is what this paper is seeking to explore. The invasion of Iraq had

immediate effects as well as longer-term ones, specifically being the destruction of major cultural sites and the exportation of stolen art from these sites to outside Western nations. There were also prisoners taken awaiting trial kept and tortured in the highly criticized Abu Ghraib prison that held mainly Iraqi nationals. These abuses among others committed to the Iraqi public impacted greatly the mindset and outlook of the nation and its people. This has and continues to have a surmountable impact on how Iraqi people express themselves artistically.

Abstract Name: Frenchy's Fried Chicken: A Houston Icon

Houston’s food culture is comprised of hundreds of restaurants with a variety of food that represents cultures from around the world. Frenchy’s Chicken is a Creole restaurant vital to the culture of the primarily African American Third Ward community. Percy “ Frenchy” Creuzot, Jr., began with one po-boy stand but grew the company to one of the top restaurants in Houston, recently being named the best fried chicken by the Houston Chronicle. The company now encompasses an eleven-restaurant franchise and a Sausage Company that sells products at local grocery stores.This paper is based on primary sources, in particular many articles in newspapers in the Houston area since its founding in 1969. In addition, the paper utilizes interviews with the business owners, describing the founding and growth of the company. Other sources included news reports and videos from the era. Each generation of the Creuzot family has fought to keep the business alive through economic ups and downs. As their business grew, the Creuzot family philanthropically used their wealth to give back to the Third Ward community. For over five decades, Frenchy’s Chicken has adapted and continued to prosper throughout the Houston area. The hard work of the Creuzot family has resulted in a successful Sausage Corporation, restaurant franchise, and valuable addition to the community.

Abstract Name: The Effects of Oral THC Exposure in Pregnant Rats on Maternal Behavior and Pup Neurodevelopmental Outcomes

In 2021, 7.2% of pregnant women reported past-month cannabis use - an increase of 3.8% since 2015 (SAMHSA, 2021). Data on the effects of cannabis use on maternal and fetal/neonatal outcomes is extremely limited. In preclinical research, most studies focus on exposure to the psychoactive constituent of cannabis, delta-9-tetrahydrocannabinol (THC). THC crosses the placental barrier and is secreted in maternal milk

thereby exposing the fetus/neonate. This study measured maternal behavior and neurotoxicity after Wistar rat dams were exposed to 5.0 mg/kg/day THC or an equal volume of sesame oil vehicle starting 14 days prior to breeding and continuing until offspring were 14 days old. Measures in the dams included maternal weight gain, gestational length, gestational weight gain, implantation sites (at necropsy), and brain and liver weight at weaning. Maternal behavior was assessed by collecting measures of nest quality and pup retrieval on PND 0, 2, 4, and 6. Neurodevelopmental outcomes in the offspring included birth weights, litter size, percent live births, percent male, postnatal day (PND) of eye opening, postnatal weight gain from PND 0-21, and brain and liver weights in one male and female at weaning. THC significantly decreased lactational weight gain in the dams and decreased postnatal weight gain in the pups. The brain:body weight ratio was higher among THC-exposed rats, especially in the dams. Pup retrieval and nest quality did not differ between the THC and control dams. These results demonstrate perinatal THC exposure does produce neurotoxicity and indicate that additional research examining the effects of perinatal THC on the brain and behavior are necessary. The results also suggest that any future negative effects observed in the brain or on behavior in THC-exposed offspring are likely not due to poor maternal behavior.[Supported by NSF #2051105]

Abstract Name: Through the Screen: Exploration of How College Students Perceive Mental Health Issues Based on Their Media Consumption

Mass media (i.e. television, social media, film, etc..) influences our expectations of others, establishing guidelines for conducting ourselves, and leading our lives. Media has the power to spread awareness of mental health issues, and simultaneously misinform, normalize, and glamorize them potentially resulting in unsound self-diagnoses (Jaramillo, 2023). Rather than exploring the impact of the media on college students' mental health state, this study assesses students' knowledge of mental health issues based on their media consumption. Between social media, film, and television, several studies have explored the implications of mental health portrayals for adults and adolescents (Diefenbach, 1998; Wahl, 2003; Stuart, 2006; Srivastava et al., 2018; Haddard et al., 2021). Many studies have analyzed the media contents of mental health portrayals, its stigma, and its effects. However, few have explored college students' perceptions of mental health issues, based on their media consumption. This study fills gaps in the literature by assessing how college students' knowledge of mental health issues is influenced by their media consumption. Surveys with college students were used to understand students' media use, where they gained mental-health-related information, and how mental health issues were depicted in media. Since the voices of mental health professionals have been lacking from these media conversations in scholarly work, mental health professionals were interviewed in this research to gauge their attitudes and beliefs on the intersecting field between media and mental health. This exploratory study will assist with comprehending the best practices to incorporate when students use media to learn about mental health issues with recommendations from practicing mental health professionals. Overall, this work hopes to strengthen the incorporation of media and mental health literacy universally.

Abstract Name: Monte Carlo models for eye plaque brachytherapy treatment of iris melanoma

Eye plaque brachytherapy is an effective treatment for eye cancer that uses radioactive seeds in an applicator. The purpose of this work is to model eye plaques used to treat iris melanoma and evaluate radiation dose (energy deposited per unit mass) using Monte Carlo simulations. The simulations are performed using the egs_brachy code using 125I (OncoSeed 6711) and 103Pd (TheraSeed 200) brachytherapy seeds. The plaques span 360°, 270°, and 180° arcs and are modelled at the center of a (30 cm)^3 water volume. Dose was scored in a (2.55 cm)^3 sub volume made up of (0.5mm)^3 voxels for simulations with 10^10 histories. Voxelized three-dimensional (3D) dose distributions for each plaque are calculated and compared to published BrachyDose data (Thomson et al., 2010). egs_brachy calculated doses are compared to BrachyDose considering absolute dose in gray, dose as a percentage of prescription dose, and dose relative to the TG43 approach currently used in hospitals (Rivard et al., 2004). Statistical analyses show agreement within a 95% confidence interval with published data at 6 points of interest in the eye (cornea, sclera, lens, eye center, macula, and optic disk). Along the plaque central axis, results agree within statistical uncertainties. In conclusion, eye plaques used for treatment of iris melanoma were successfully modelled and benchmarked. These models will be distributed (open source) with the egs_brachy code on GitHub enabling state-of-the-art dose calculations in hospitals that will improve patient treatments. Abstract Name: Adjunctive LAT-Activating CAR T-cell (ALA-CART) Targeting the B7H3 Antigen on Ewing Sarcoma Solid Tumor Cancer Cells

T-cells are an essential part of our immune system, protecting against infections, but they also hold promise for treating cancer. T-cell activity is based on attacking infections (“non-self”) while ignoring normal cells (“self”). Tumor cells originate from our bodies; hence T-cells naturally see them as “self” and ignore them. To overcome this, T-cells can be engineered with Chimeric Antigen Receptors (CAR) which target surface proteins on tumor cells, driving T-cells to attack them. CAR T-cells have been successful against leukemia, however, have not worked against solid tumors, such as Ewing Sarcoma (EWS), a difficult to treat cancer that has not responded to CAR T-cell therapy. The Kohler Lab found defects in CAR T-cell signaling through LAT, a vital protein for T-cell activation, leading them to create the Adjunctive LAT-Activating CAR T-cell (ALA-CART) to strengthen LAT signaling. This improved the metabolism and efficacy of ALA-CART cells against leukemia compared to standard CAR T-cells. As the metabolism of T-cells is important for surviving the harsh tumor microenvironment, we generated ALA-CART cells targeting the B7H3 protein on EWS and

compared them to standard B7H3-CAR T-cells. We stained B7H3-ALA-CART cells and standard B7H3-CAR T-cells with Mito Tracker to determine the mitochondrial mass, with TMRE to test for mitochondrial membrane potential and Rhod-2 to test for mitochondrial Ca2+ concentration. We tested B7H3-ALA-CART and standard B7H3-CAR T-cells for their ability to kill EWS cells in vitro and found B7H3-ALA-CART was functional but less cytotoxic than standard B7H3-CAR T-cells. However, we found that B7H3-ALA-CART cells eliminated established EWS tumors in mice, whereas the B7H3-CAR T-cells could not control the growth of the tumors. Collectively, our data demonstrate ALA-CART cells have improved metabolism and are more effective against EWS tumors in vivo and making this a promising strategy for treating patients with solid tumors in the future.

Abstract Name: Designing a Wearable Technological Ear Device for Individuals with Noise Sensitivity

How could a wearable ear device be designed to aid individuals with noise sensitivity and improve their quality of life? Noise sensitivity effects a wide range of individuals that can stem from a variety of psychological and physiological sources including PTSD, anxiety disorders, ADHD, autism, misophonia, auditory processing disorders, hyperacusis, etc. Noise sensitivity causes individuals to have a hypersensitivity to noise that greatly impacts quality of life. Each individual has specific needs and can be triggered in nuanced ways. Children are more susceptible to APD which can be difficult for guardians to manage. There's a rise of wearable ear technology, with headphones and earphones making up a large percent of the U.S. purchasing market. The device designed is aimed to rest within the ear canal similar to an ear bud with a sleek and ergonomic design. The design is discrete resting in the natural anatomy of the ear, aiming to prevent the stigmatization of individuals with hearing sensitivity. The ear device is paired with Bluetooth connectivity to a cellular device like a phone or tablet. From here the device is connected and managed through an app that allows for the user or parental figure to control noise input levels, noise cancelation, track triggers, and the ability to hear the outside environment. This allows for a customizable hearing experience for individuals at large. Visual language was inspired by the company Headspace. Through the design process of this device secondary research was conducted, ideation phases of sketching designs, CAD modeling and 3-D printing models to be user tested for ease of use and comfort. The design aims to create a culture centered around the user's well being and awareness to how their environment affects them allowing for individuals with noise sensitivity to find control and improve their quality of life.

Abstract Name: The impact of combined-neuromuscular electrical stimulation (Comb-NMES) intervention on muscle cross sectional area (CSA) and signaling for inflammation

PURPOSE: To determine the effect of a combined-neuromuscular electrical stimulation (Comb-NMES) intervention on muscle inflammation and size in individuals with acute spinal cord injury (SCI). INTRODUCTION: Traumatic SCI often results in extreme skeletal muscle atrophy and loss of motor and sensory functions. Studies have shown that NMES can increase muscle mass and impact muscle signaling pathways for muscle growth and regeneration in the chronic stages of SCI. Still, the impact of NMES on muscle atrophy and inflammation in acute SCI is not comprehensively understood. METHODS: 19 (16 M/3 F) acute SCI participants aged 30.9±9.3 years with injury levels of C3-L1, classification ASIA A-C were enrolled. Comb-NMES involved concentric/eccentric contractions of the quadriceps and twitch electrical stimulation applied to the quadriceps muscle via surface NMES. The control group received passive leg extension and twitch contractions induced by TENS. Vastus lateralis muscle biopsies were performed before and after 3-5-week Comb-NMES treatments in patients with acute SCI. Western blot analysis was implemented to quantify proteins for inflammatory signaling. Immunohistochemical analyses were performed to determine muscle fiber cross-sectional area (CSA). RESULTS: The comb-NMES group (n=12) increased the expression of proteins Jak1, Stat3, Traf6, IL-6, and TweakR/FN14 and myosin heavy chain (MHC) IIx isoform CSA. The control group (n=7) decreased muscle CSA for MHC Ia, IIa, and IIX. CONCLUSION: The increase in signaling for Jak-Stat pathway and muscle CSA in the CombNMES group suggests that Comb-NMES intervention may lead to muscle remodeling/growth in the acute stages of SCI.

Abstract Name: “You’re Doing That Wrong!”: A Comparison of Psychological Treatments from the 1930s and the Modern Era

It’s 1938 in Dayton, Kentucky and the beginnings of mental illness treatments are taking place. It’s her first day of her psychiatry course and she quickly files into the classroom along with her fellow nurses-in-training, taking a seat in the first row next to a woman with short hair done up in tight ringlets. The instructor comes in shortly after and places his hands on the podium. In response, she and the other women peeled open their new notebooks and pressed their pencil tips onto blank pages as words began to pour out of his mouth.Using a nurse-in-training diary from 1938 as inspiration, this short story will investigate the evolution in psychiatric care during the 20th century while capturing an intimate view into one woman’s experience at youth and old age. The Diary of an Unidentified Nurse, 1938, at the University of Kentucky Libraries Special Collections Research Center provides the genesis of this creative project. “You’re Doing That Wrong!” is the story of a young nurse in a modern memory care unit who receives a new patient, who is the woman who wrote the diary 85 years later. Due to the erosion of her memory, the patient has regressed to the time of her schooling, which allows one to make the comparison between the treatment of mental illness during the 1930s and the modern era because of the constant disagreements about treatments between the nurse and her patient.

Abstract Name: New Apprenticeships of Observation for Pre-service Teachers through Social Media

The concept of the Apprenticeship of Observation was developed by Dan Lortie (1975) in his seminal book Schoolteacher: A Sociological Study. This particular kind of apprenticeship describes the influences that prospective teachers' own K-12 student experiences have on their understanding of education. Future educators spend significant time as students in K-12 classrooms observing their teachers, and this affects their understanding of teaching and what kind of teachers they want to become. More recently, the Apprenticeship of Observation arguably includes new elements, as technology allows aspiring teachers additional opportunities to observe teachers. In particular, many teachers are on social media, and due to the amount of time teens spend on these platforms it is appropriate to investigate how pre-service teachers have been influenced by what they observe of these social-media-using teachers and their classrooms. The purpose of this study is therefore to explore new digital Apprenticeships of Observation for pre-service teachers. Through 28 semi-structured interviews with pre-service teachers, we identified some of the influences of social media on pre-service teachers' understanding of teaching. The participants reported learning about various topics related to teaching and teachers through their social media use prior to and during their teacher education program. Participants stated that they tended to follow practicing teachers who shared the same education philosophy, priorities, and values. Many of the participants said that those looking to learn more about the education profession should use social media, but also must do so with caution. We build on these findings to conceptualize how social media adds new facets to teacher development, and identify implications for pre-service teacher education. The results of this research will raise awareness of how outside influences affect pre-service teachers' understanding of their profession. This will allow teacher educators to adapt their class content to include surfacing and analyzing such influences.

Abstract Name: Conflicts of Identity in Bipolar Disorder

The purpose of this project is to visualize the conflict of identity that exists within Bipolar Disorder. My interest came from reading Dr. Kay Jamison's "An Unquiet Mind". In her memoir, she went into great detail about her disastrous highs and dangerous lows, showing vulnerability throughout her difficult journey. For those who suffer from Bipolar Disorder, the line between their chemically-induced symptoms and sense of self can be difficult to draw, and my work was made to visualize that struggle. My research methodology began with multiple close readings of "An Unquiet Mind". Specifically, I analyzed passages that demonstrated her conflict in finding herself, and in not knowing which thoughts and feelings were hers or a product of her disorder. I will create three different paintings representing an aspect of her inner conflict. The first will represent her inability to separate her creations from herself, her inability to determine if her instances of mania are truly her or a symptom of her illness. The second will represent her conflict with medication, how something meant to cure her is actively separating her from herself. The last will represent her resolution: how she is the destructive, the creative, and the self. I want my paintings to express the difficulty that people with Bipolar Disorder have in finding themselves in the vast space of their emotional distress. I have submitted previous samples of landscape art and portraits that I will draw inspiration from. I expect the results to confirm that identity exists on a spectrum. That people with Bipolar Disorder do not exist as people and entities outside of their disorder, but as a culmination of the ideas, emotions, and actions they take in response to it.

Abstract Name: Assessing Sex Differences in Stress-Induced Alterations of DNA Methylation

Stress has been identified as a significant factor influencing the brain and is thought to contribute to the development of mental health disorders and inflammation. One specific mechanism through which stress affects brain function involves epigenetics and gene methylation. Previous research has demonstrated that stress can enhance the expression of the epigenetic enzyme DNMT3a, responsible for DNA methylation, in the nucleus accumbens (NAc) of female mice, but not in males. This project aimed to investigate the impact of stress on gene-specific methylation in both the mouse NAc and the hippocampus (HIP), another brain region included to explore global differences, and to assess whether any sex-specific differences exist. Two cohorts of c57BL/6J mice were subjected to a 5-day stress paradigm, while a control group remained unaffected. Following the completion of the stress period, mice were sacrificed either two hours or one week later. Bilateral brain tissue samples were collected from the NAc and HIP, and DNA was extracted. The extracted DNA was then either left undigested or digested with restriction enzymes sensitive (HpaII) or non-sensitive (MspI) to methylation. Subsequently, real-time PCR was employed to quantitatively assess methylation levels using the ΔΔCT method. The results indicate that the previously reported increase in DNMT3a in the NAc of stressed females does not result in a genome-wide increase in DNA methylation. While stress did result in elevated methylation of the IKKB and PDYN genes in the NAc of females, consistent with the hypothesis, it did not lead to the same pattern of methylation alterations in other genes and in the HIP. Overall, the findings align with earlier studies suggesting that both stress and sex play a role in influencing DNA methylation. However, the site-specific effects of these factors underscore the intricate nature of epigenetic regulation and have strong implications for potential therapeutic treatments.

Abstract Name: CycPUF: Cyclic Physical Unclonable Function

Physical Unclonable Functions (PUFs) leverage manufacturing process imperfections that cause propagation delay discrepancies for the signals traveling along these paths. While PUFs can be used for device authentication and chip-specific key generation, strong PUFs have been shown to be vulnerable to machine learning modeling attacks. Although there is an impression that combinational circuits must be designed without any loops, cyclic combinational circuits have been shown to increase design security against hardware intellectual property theft. In this paper, we introduce feedback signals into traditional delay-based PUF designs such as arbiter PUF, ring oscillator PUF, and butterfly PUF to give them a wider range of

possible output behaviors and thus an edge against modeling attacks. Based on our analysis, cyclic PUFs produce responses that can be binary, steady-state, oscillating, or pseudo-random under fixed challenges. The proposed cyclic PUFs are implemented in field programmable gate arrays, and their power and area overhead, in addition to functional metrics, are reported compared with their traditional counterparts. The security gain of the proposed cyclic PUFs is also shown against state-of-the-art attacks.

Abstract Name: Deconstructing Nature Metaphors: Women's Representation from Shakespearean Eras to Contemporary Narratives

Language allows us to identify with others, and make sense of the world around us. Yet, as Friedrich Nietzsche has famously pointed out, we often forget that the language we use is highly metaphorical, and those metaphors can sometimes determine what we count as truth. As early as 1512, Erasmus of Rotterdam noted the power of metaphor in De Copia - a text book that taught readers to write and speak effectively through an abundance of rhetorical techniques and copiousness of expression. While Erasmus celebrated the enriching power of metaphors, emphasizing their role in amplifying speech and contributing to copia, he also cautioned against excessive use, highlighting the need for careful selection to ensure that metaphors enhance language without causing unintended consequences.Today, George Lakoff and Mark Johnson have long argued that metaphors shape our understanding of the world, often dominating our understanding of it. While Erasmus cautioned against an overabundant use of metaphor, perhaps he didn't quite anticipate that metaphor use can be ideologically problematic - especially in the way they constitute women. For instance, the way women are metaphorized as "earth." Variations of the metaphor perpetuate the underlying idea of women as objects to be cultivated, dominated, or subdued, depicting them as land, birds, soil, and more. Interestingly, Darren Aronofsky's film Mother! uses this metaphoric construction of women to critique this potentially exploitative figure of speech, drawing parallels between the metaphoric construction of earth and femininity that exposes the metaphor in terms of the nefarious work it can do. Drawing from both Erasmus and Aronofsky, my presentation will demonstrate how these natural metaphors of women have troubling consequences in terms of how women are viewed and how they view themselves - ultimately, "unearthing" the ethical concerns behind the use of nature metaphors to construct femininity.

Abstract Name: Empowering Undergraduate Researchers: A Mentor's Approach to Building Self-Efficacy and Engagement

Effective mentorship is pivotal in transforming undergraduate students into scholarly researchers. This process necessitates a deep understanding of students' interests and capabilities, coupled with strategies to

motivate them towards the benefits of undergraduate research. When students recognize these benefits, either directly or vicariously, their engagement and performance in research projects, both in and out of the classroom, significantly increase. Over decades of teaching Communication Research Methods, I have guided numerous undergraduates to present their research at regional and national conferences. Witnessing their public presentations, showcasing their analytical skills and research confidence, has been immensely rewarding. These experiences not only bolster students' self-confidence and competence in academic research but also contribute to their overall personal growth. In my presentation, I will highlight three key strategies employed in mentoring these students. First, understanding students' thoughts, interests, and abilities is crucial. This requires attentive observation, personal interaction, and direct communication. Second, building students' self-efficacy is essential. Conveying the message that they are capable and competent involves both verbal and nonverbal communication. Third, and most importantly, is assisting students in recognizing the benefits of their research endeavors. This recognition is a catalyst for them to think critically, engage deeply, and enjoy the process of scholarly inquiry. These methodologies not only advance students' academic trajectories but also lay a foundation for their future research endeavors, demonstrating the transformative power of dedicated mentorship in academia.

Abstract Name: What's that Building? Exploring Public Perceptions of Architectural Functionality Based on Form.

A building's function has historically been tied to its form. We see this in civic buildings, schools, churches, and homes. Many of those recognizable forms were abandoned with the modernist movement in the early twentieth century. Are these new forms still related to their functionality and can average people perceive a building's functionality based on its form. Learning the opinions of the general public will enhance the architect's ability to design for the people who will live and work in and around the buildings they design.This study aims to answer those questions by means of an online survey. To gain a wider demographic of survey takers, the survey is largely spread through social media where I have access to a wide variety of people across the globe and of differing generations and backgrounds. The survey has two types of questions. The first presents two pictures of buildings and asks the survey taker to tell which holds a specific function. The second question type presents a single building and four choices of building function. In both question types, all signage or other markings of building type were digitally removed from the photographs. The survey includes fourteen architectural functions ranging from single family homes to State Capitols. Each category includes traditional and modern examples. This variety in style will help to analyze whether there is a difference in the general public's ability to perceive a building's function if the building is traditionally designed or if it takes a more modern approach in design. Although this survey is still active, the expected results are as follows: Traditional forms are generally more easily discernable than modern designs. Some building forms are equally recognizable regardless of form. The stand outs from this list are schools and stores/shoppes.

Abstract Name: Degradation of Perfluorooctanoic Acid in Water by a Pin to Water Discharge Cold Plasma

This study focuses on the degradation of perfluorooctanoic acid (PFOA)-contaminated water by a Cold Atmospheric Pressure Plasma (CAP). Using PFOA as the choice of our contaminant is justified in today's ecosystem. PFOA is a "forever chemical" that does not break down easily and is toxic even at low levels, and its conventional treatment technologies such as advanced oxidation processes and activated carbon have scientific challenges. A 20-micromolar PFOA solution in conductive water was subjected to argon plasma at around 10 Watts in both positive and negative polarity respectively. The time of plasma exposure was varied from zero to two hours and the solution was analyzed with an LC-MS to quantify the percent degradation of PFOA over time using CAP. It was determined that PFOA degrades about 65% in an hour when CAP is run in positive polarity with Argon gas. The negative polarity trials provided evidence that about 40% of PFOA degrades in the same conditions mentioned above for positive. In the presence of a 1 mM solution of a surfactant cetyltrimethylammonium bromide, 75% of PFOA degrades in one minute in both positive and negative polarity. Scavenger experiments were carried out in both positive and negative polarity with a 7 mM solution of isopropanol, a scavenger of the H, and the OH radical. Results indicate an inhibition of PFOA degradation by around 55% in positive polarity and around 11% in negative polarity. This suggests that the H radical is most likely a probable species responsible for the degradation of PFOA as OH radicals are not supposed to be responsible for PFOA degradation as suggested in the literature. We will continue to probe similar scavenger experiments in the future to determine a specified pathway for degradation.

Abstract Name: Collaborative Memory and Stereotype Threat

Collaborative memory has garnered an influx of research within the last decade as cognitive psychology extended its exploration of cognition beyond a single individual. Although collaborative memory appears to have some improvements on memory retention, it also impairs initial performance, a concept referred to as collaborative inhibition (Weldon & Bellinger, 1997). Previous researchers have identified various mechanisms which could factor into group inhibition, such as social loafing or social contagion errors (Rajaram & Pereira-Pasarin, 2019; Weldon & Bellinger, 1997). Additionally, Pepe et al.'s (2021) study on collective inhibition in ethnically diverse settings suggests stereotype threat to be a factored mechanism.This study extends Pepe et al.'s (2021) collaborative memory study on ethnic composition by changing the uniform condition to Black Participants. The goal is to determine if stereotype threat contributes to collaborative inhibition and if so, to what degree.

Abstract Name: Narrative Inquiry of Undergraduate Student Experiences in a Gender Inclusive Living Community

Gender Inclusive Housing Communities have become more common at universities in recent years, however, Gender Diverse students continue to be regularly harassed, are discriminated against by students and faculty, and often do not feel supported by the university. There is a large unmet need for social, emotional, and academic support for this population, which could close emotional and physical gaps if solved. The purpose of this study is to capture the stories of undergraduate Gender Diverse students' living in Gender-Inclusive Housing Communities through narrative inquiry at Northern Arizona University. As programs continue to be put in place in an effort to support Gender Diverse students, few studies have been done to explore their experiences, making it difficult to understand whether they are working as intended. This project aims to document which part of these programs are beneficial and what gaps still exist according to those currently living in one. The study will use narrative inquiry to report the experiences of these students and questions will be asked to document the experiences, stories, and needs expressed. The university which will be the platform for this project is a large, public university, so this study is significant to programs intending to support TNBGD people globally. Additionally, the findings may be able to guide NAU in making changes which will benefit GIH students.

Abstract Name: Association Between BioKinetoGragh Accelerometers and NeuroCom® Balance Master®

Purpose: Determine the association between two validated measures assessing gait and balance; the BioKinetoGragh (BKG) Accelerometers and NeuroCom Balance Master, respectively.Methods: Seventy-six healthy volunteers’ overall balance was evaluated using the NeuroCom® Balance Master®. Participants completed three sets of randomized three walking trials for the BKG under different visual conditions (eyes open, blindfolded, partially inhibited vision). During these 9 trials, participants completed a 20-foot forward-and-return walk while securely holding a mobile device against the chest with both hands. Pearson correlations were conducted to examine the association between the total score on the NeuroCom Balance Master and the BKG variables representing the domains of power, speed, and balance.Results: NeuroCom scores positively correlated with BKG forward power (r =.09, p =.01), total power (r =.15, p =.0001), vertical power (r =.18, p <.00001), medio-lateral power (r =.13, p =.0004), vertical/mediolateral power (r =.17, p <.00001), and power strike force (r =.14, p =.0002), indicating increased gait power. NeuroCom scores inversely correlated with BKG stride/timing variables including double stance interval mean (r = -.11, p

=.006), double stance interval standard deviation (r = -.11, p =.005), double stance time (r = -.16, p =.00002), stance phase (r = -.19, p <.00001), and stride time (r = -.16, p =.00002), indicating faster gait. NeuroCom scores inversely correlated with BKG balance measures of anterior-posterior range of motion (r = -.21, p <.00001), middle range of motion (r = -.16, p =.00002), and turnaround range of motion (r = -.22, p <.00001), indicating less postural sway.Conclusions: Dynamic gait variables, assessed under diverse conditions, predict NeuroCom total scores, reflective of balance across varied scenarios. Practically, a brief, widely available mobile device-based gait assessment offers preliminary screening capabilities to identify individuals warranting comprehensive balance assessments in clinical or research settings.

Abstract Name: Investigating Plant Secondary Metabolites and Fungal Extracts for Acaricidal Activity

Our research project involves using underrepresented plant secondary metabolites to reduce the amount of Varroa destructor mites affecting European honeybees (Apis mellifera) within a beehive. Varroa mites are the leading cause of colony collapse disorder across the globe and spread diseases, such as deformed wing virus, to the bees. Current treatment methods involve using harsh synthetic chemicals to treat hives for varroa. The mites are becoming resistant to these chemicals, and that resistance has created a need for new treatment methods. Plant compounds such as thymol have successfully been used to treat varroa, but not many compounds have been tested. We assessed standards of natural plant products and fungal extracts to find additional compounds that may display miticidal effects. We collected varroa mites from the NMU Research Apiary during the summer of 2023. We used a brood frame that was designed to accommodate drone brood, as varroa mites prefer the much larger drones and would routinely uncap the cells and collect any varroa mites within. The mites were then placed in petri dishes containing bee pupae and stored at 30℃. Five mites were then placed in scintillation vials containing either 0.5 mL of a 1 mg/mL standard or a fungal extract. We then assessed the mite mortality every two hours over a period of six or eight hours. We found that extracts of Lion’s Mane mushroom in ethanol and cannabidiol (CBD) displayed substantial miticidal effects during our study. This is a significant finding, as cannabidiol has also been shown to boost honeybees' immune systems in low doses, so this compound could both benefit the honeybees and display miticidal activity. Going forward, we aim to investigate additional cannabinoids, such as THC-V, for miticidal effects and multiple concentrations of CBD to find the lowest effective dose that can be used.

Abstract Name: Validation of Golgi Isolation Utilizing Immunoprecipitation in Human Postmortem Cortex

Na+/H+ exchangers (NHEs) play a significant role in cellular and intracellular pH regulation and have been linked to numerous psychiatric and neurodevelopmental disorders. We are looking into the role that NHEs may play in the serious psychiatric illness schizophrenia, which affects around 1% of the population worldwide and is associated with significant morbidity and early mortality. Altered pH regulation of the intracellular compartments by NHEs may play a role in a common molecular disturbance reported in postmortem schizophrenia cortex, namely the disruption of protein modification and trafficking. Using cell fractionation of human postmortem dorsolateral prefrontal cortex (DLPFC), we previously were able to separate endosomes from plasma membrane allowing for the identification of the intracellular localizations of NHE6 and NHE9, normally targeted to early/recycling and late endosomes, respectively. We are also interested in the specific intracellular localizations of NHE7 and NHE8, which are normally targeted to trans-Golgi and mid/trans-Golgi stacks, respectively. However, we found our previous method of cell fractionation was not successful in separating Golgi from plasma membrane. Now, we are investigating the efficacy of Golgi isolation through a combined approach utilizing both traditional cell fractionation as well as immunoprecipitation/immunopurification of Golgi. We are currently working to validate the immunoprecipitation of Golgi in human postmortem DLPFC for the first time. Once verified, we will combine this approach with cellular fractionation and Western Blot analysis to investigate and more accurately measure the true intracellular localizations of the NHE7 and NHE8 exchangers in schizophrenia postmortem DLPFC. This combined protocol will be useful not only in the future study of the localizations Na+/H+ exchangers but also more broadly to researchers studying protein trafficking through the Golgi.

Abstract Name: Effects of Singing on Walking in Persons with Parkinson's Disease

Gait and balance impairment are major symptoms of Parkinson's Disease (PD) and can significantly impact functional mobility and quality of life in persons with PD. The benefits of PD medication for gait and balance impairment are in question. As an alternative, external cuing, such as singing, has shown benefits for simple walking tasks in persons with PD. However, complex walking tasks pose the greatest challenge for persons with PD, and there is limited research on how singing affects the performance of complex walking tasks in persons with PD. This study aims to determine the effects of singing on gait spatiotemporal measures during complex walking in persons with PD. Given that singing improved simple walking tasks, we hypothesized that singing would also improve complex walking in persons with PD. Participants performed a series of walking tasks over approximately 30 feet in length:1) over ground walking at their preferred pace, 2) over ground walking while singing, 3) serpentine walking at their preferred pace, and 4) serpentine walking while singing. The song sung was Row, Row, Row Your Boat. APDM Opals (apdm.com) were used to collect spatiotemporal measures; two placed on the top of the feet, two on the wrists, and one on the lumbar spine. The mean will be obtained for each spatiotemporal outcome measure and entered into a 2x3 repeated measures Analysis of Variance to determine differences between conditions (singing vs. no singing) and between groups (healthy young adults, healthy older adults and PD) for over ground and serpentine walking. Posthoc analyses will be completed with Tukey's Honest Significant Difference test. We expect singing to

improve temporal gait measures in both over ground and serpentine walking. This study may provide evidence for an adjuvant therapeutic technique to improve complex walking and mobility in persons with PD.

Abstract Name: Impact of Obesity on Breast Cancer Immune Evasion

As cancer is defined by continual adaptation to its microenvironment, the trajectory of breast cancer growth and its treatment are defined by the coinciding health factors of its patients. We present a novel adaptation of mammalian breast cancer that promotes its evasion of the immune response, particularly within the context of obesity—one of the world's most common chronic diseases and a major risk factor for breast cancer. Obesity triggers systemic inflammation of adipose tissue, and the relationship between this molecular reprogramming and the aggravated growth of breast cancer is poorly understood.This study shows how obesity allows for breast cancer cells to suppress interferon gamma signaling—a hallmark anti-cancer cytokine. To find cancer cells that could adapt to the obese tumor environment, clonal tumor lines generated from a mouse-derived triple-negative breast cancer line (E0771) were transduced with DNA barcodes and pooled into an in-vivo tumor transplant. Competitive growth between different clones was tracked through barcode sequencing, and the most proliferative cell lines were isolated. Transcriptomic analysis of these competitive tumor lines revealed a heightened suppression of the interferon-gamma signaling pathway—in particular, downstream interferon-regulatory factors (IRFs) and guanylate binding proteins (GBPs).Ongoing molecular investigation aims to decipher the underlying mechanisms orchestrating this suppression. Unveiling these interactions promises crucial insights into how obesity-induced changes modulate breast cancer growth. These discoveries hold the potential to illuminate novel pathways for therapeutic interventions in this challenging clinical intersection, offering hope for improved cancer outcomes among obese patients.

Abstract Name: Coping with Creativity: The relationship between Depression/Anxiety and Creative Coping in College-Aged Students

The relationship between creativity and mental illness has been established in the literature. There are multiple possible explanations for how mental illness and creativity are connected, and creativity has shown to be an effective treatment for different mental illnesses (for example, through art therapy). Despite this, there is limited research on how those with mental illnesses use creativity to cope outside of a treatment setting. Information on type of creative coping that the mentally ill naturally gravitate to and find most

effective can further inform possible treatment plans and suggestions. This study aims to address gaps in the literature concerning how college-aged students with the most common mental illnesses, which are depression and anxiety, use creativity to cope. This study will look at how type of mental illness affects the type of creative coping chosen, how severity of mental illness impacts use of creativity, how severity of mental illness impacts frequency of creative coping, and if there is an interaction between multiple mental illnesses present and how that may affect frequency and level of creative coping.

Abstract Name: Structure-Activity Relationship Studies of Human Carboxylesterases Using a Fluorogenic Ester Library

Human carboxylesterases (CESs) are crucial enzymes involved in drug metabolism through the breakdown of ester-containing drugs into active or inactive forms. Although indispensable in pharmacology, knowledge gaps exist regarding the specificity of the predominate forms of CESs, CES1 and CES2, toward different esters. This work seeks to determine the structure-activity relationship (SAR) of CES-substrate esters in vitro by leveraging a library of 96 fluorescein-based AM ester fluorogenic chemical tools. Our work will systematically annotate the substrate preferences of CES1 and CES2, thereby illuminating their distinct or overlapping roles in drug metabolism. Completing these studies will enable fine-tuning of ester-containing drug-candidates in addition to enabling more sensitive tools to study CESs ultimately enhancing the efficacy and cost-effectiveness of drug discovery.

Abstract Name: Correlation of Staffing Turnover for Licensed Nursing Personnel to Quality of Care in Long Term Care Facilities

This research paper addresses the critical issue of substandard care quality in nursing homes, highlighting the significant impact of staffing shortages, inadequate compensation, and insufficient facility education on the well-being of elderly residents and the broader healthcare system. Employing a mixed-methods approach and a comprehensive literature review, the study is anchored in the Donabedian Model of Healthcare Quality, examining structural, process, and outcome aspects of nursing home care. Utilizing a quasi-experimental

design, the research evaluates innovative interventions, including the implementation of a unique digital health information platform and enhanced staff training strategies, aimed at promoting person-centered care and optimizing staffing ratios. This approach takes into account the complexities of nursing home environments, including socioeconomic factors and high staff turnover, especially in economically disadvantaged areas. Ethical considerations are paramount, given the vulnerability of the elderly, ensuring rigorous consent processes and data privacy. The project's success can be evaluated using tools like the modified Person-Centered Care Assessment Tool and the Nursing Home Staff Satisfaction Survey, alongside qualitative feedback. Despite potential limitations like implementation variability and response bias, the findings underscore the effectiveness of combining person-centered practices with technological advancements in improving nursing home care quality. The paper concludes by advocating for comprehensive policy reforms and resource allocations that support the implementation of such interventions, offering a transformative model for nursing home care that integrates both humanistic and technological elements. Moreover, this study underscores the critical role of ongoing education and support for nursing home staff as a cornerstone for sustainable improvements in care quality, addressing both the immediate needs of the elderly and the long-term viability of the healthcare system.Keywords: Nursing Home Care Quality, Staffing Challenges, Person-Centered Care, Health Information Technology, Donabedian Model

Abstract Name: Contribution of RNA Splicing Defects to Joubert Syndrome, a Rare Genetic Condition

Joubert syndrome (JS) is a rare, congenital neurodevelopmental condition diagnosed by the appearance of the “molar tooth sign” on axial brain magnetic imaging (MRI). Patients typically display hypotonia, abnormal eye movements, and ataxia. Substantial progress has been made on identifying the genetic causes of JS, which typically displays recessive inheritance. Nonetheless, the cause still cannot be identified in ~27% of our cohort of JS-affected families and the contribution of causal variants that impact RNA splicing remains unknown. Canonical splice variants impact RNA splicing by disrupting the splice site directly, whereas noncanonical splice variants affect it through alternative mechanisms, which must be validated by RNA analysis. Our goal is to evaluate the role of noncanonical splice variants in the pathogenesis of JS.We previously identified genetic causes in 582 of 714 families with JS. To identify additional causes, we used SpliceAI, a deep learning-based tool to identify variants with predicted splicing effects (SpliceAI score >0.5) for functional validation. We extracted RNA from patient cell lines and reverse transcribed it into complementary DNA (cDNA). Then we used polymerase chain reaction (PCR) to amplify the affected exons with two sets of primers flanking the relevant splice junction. We evaluated PCR products using gel electrophoresis and Sanger sequencing.We found 45 families with ≥1 canonical splice variant and 32 families with ≥1 candidate noncanonical splice variant. We confirmed the pathogenicity of three candidate noncanonical splice variants by demonstrating an abnormal splicing in JS genes, AHI1 and MKS1, in patient samples, bringing the total contribution of aberrant splicing up to 77/714 families. By extrapolation from our data in JS, splice variants may contribute ≥11% to the genetic causes of conditions. A precise genetic diagnosis informs prognosis, avoids unnecessary work-up, guides monitoring for associated complications, and opens the door to gene-specific treatments.

Abstract Name: DBU Catalyzed Nucleophilic Aromatic Substitution: Arylation of Alcohols and Heterocycles

Many drugs are synthesized using nucleophilic aromatic substitution reactions (SNAr), including the antibiotic Linezolid. Etherification is a specific kind of SNAr reaction in which an ether group is created on an aromatic ring. Past methods of carrying out this reaction have significant limitations. For instance, Ullman condensations can only occur with electron-deficient aryl halides and require harsh reaction conditions such as the use of strong bases and high temperatures, which reduce functional group tolerance. For that reason, there has been a movement toward milder conditions made possible by new forms of catalysis, such as Pd-

catalyzed transformations.The organic base, 1,8-Diazabicyclo[5.4.0]undec-7-ene (DBU), in the absence of transition metal catalysts, has been found to increase the rate of SNAr etherification while simultaneously allowing the retention of substituent groups. This reaction has been optimized and tested with a variety of different nucleophiles to evaluate the tolerance to different functional groups. The optimization of the reaction, determination of scope, and chemoselectivity of the reaction will be discussed. With further study, we hope to expand the range of reactants evaluated to further our understanding of the chemoselectivity of the reaction.

Abstract Name: Microbial Diversity in the Soil Surrounding Beech Trees on Bowie State University's Campus

The findings of this research contribute to our understanding of the intricate relationships between trees and their soil micro-biotic environments, emphasizing the importance of micro-biodiversity in sustaining healthy ecosystems. The research furthermore expresses results in a comprehensive analysis of bacterial and fungal communities utilizing samples collected from the soil of targeted trees, lab analysis which was sent for metabarcoding sequencing by NOVOGENE. The objective of this study is to examine the microorganisms in the soil of beech trees to analyze their potential interactions and ecological roles. We found the abundance of various fungi and bacterial groups that contribute to the sustained growth of these trees.

Abstract Name: Antibiotic Resistance of Bacteria Present in Local Water Sites

Resistance to antibiotics has become a major threat to society as a growing rate of bacteria and microbes that cause disease are becoming resistant to normal effective drugs. According to the UN, the rise in antibiotic-resistant bacteria is a global health emergency that could kill 10 million people by 2050. Antibiotic pollution is one way by which bacteria can develop resistance to the antibiotics, rendering them ineffective for human use. Most of the resistance genes we see in human pathogens come from environmental bacteria. The drugs find their way into soil and river via humans, animal waste and leaks from wastewater treatment plants and drug manufacturing facilities. Society must be aware of the spread of antibiotic resistant bacteria and antibiotic resistance genes. If care is not taken, we will head for a post antibiotic era in which common infections and minor injuries, which have been treatable for decades, can once again kill. This research aims to analyze the effects of urbanization along the waterbodies around Bowie State University on antibiotic resistance, comparing upstream (nonurban) and downstream (urban) water samples for colony growth on tetracycline (antibiotic) treated plates and non-tetracycline treated plates. This study may reveal a positive

relationship between urbanization and antibiotic resistance. Water samples were collected from Henry Circle Fountain and Loop Road Lake located on Bowie State University campus, as well as Horsepen Park, outside of the campus grounds. These samples were streaked in plates with antibiotic-treated nutrient agar and plates with no antibiotic treatment as a control, using similar agar preparation and plating techniques as comparable studies. Bacterial growth on plates treated with tetracycline confirmed presence of antibiotic resistant bacteria in the water samples from the three locations. Future research involves performing metagenomic analysis for the bacterial growth from the tetracycline treated plated to determine taxonomy.

Abstract Name: Social Media: Its role in the social relationship among college students (Philippines)

Young people today grow up in a social landscape in which digital technology and social media are ubiquitous in daily life and interpersonal relations, including intimate (romantic and sexual) relationships. This study aimed at identifying why college students engage into a social relationship through different online platforms, it also identified the level of satisfaction on the challenges encountered by college students in staying in social relationships during pandemic towards transitioning to the new normal, and recognized the number of times college students used the coping mechanisms in sustaining a social relationship in the digital realm. The study employed a descriptive method. Seventy college students in the 18 - 21 age range studying at the University of Baguio participated in the study. The appropriate statistical tools for the level of satisfaction of the respondents in response to their online relationship was determined by the Likert-type scale (Dependent Variable). The Independent variables- The Levene's test for equality of variances (homogeneity of variances) and t-test for unequal variances are two statistical tools used to determine the type of social relationship (Platonic vs Romantic). The Burns Relationship Scale was also used to indicate the frequency of usage of the coping mechanisms in staying in social relationships during pandemic towards transitioning to a new normal. The study found out that social media had transformed the manner how college students approached and behaved in intimate relationships. Social media made it easier for college students to engage in social interaction, facilitate rapid relationship progression, and enabled digital togetherness.

Abstract Name: The Issue of Diversity and Multiculturalism in Undergraduate Psychology Curriculum

A continued lack of diversity in psychology curriculum perpetuates the marginalization of minority groups in society and conveys that the field of psychology places secondary importance on diverse perspectives of psychological issues. There has been consensus regarding increased inclusion of diversity in psychology (Boysen, 2011; Dingel & Sage, 2020; Simoni et al., 1999), but efforts to improve psychology curriculum has remained at the graduate level, despite recommendations and support from the APA to feature diversity in undergraduate curriculum (APA, 2022). Effective methods for how to incorporate these elements remain obscure, and there is a lack of studies outlining empirically tested teaching practices and assignments that have resulted in increased multicultural awareness among students. The objective of this study was to explore the current inclusion of minority sociodemographic factors within undergraduate psychology curriculum at a small, private, Central Texas liberal arts university and how students and faculty perceive their integration. A mixed-methods survey approach was used to gather data from faculty and student participants in order to identify gaps in diversity and reveal how minority sociodemographic factors were discussed. Visibility and intersectionality theories were used as frameworks to analyze the survey data collected from participants, as well as syllabi collected from faculty, to reveal where minority sociodemographic factors are salient and where there might be gaps. Differences between student and faculty perceptions in undergraduate psychology curriculum revealed the need for effective strategies for teaching diversity that will guide the field towards best practices for educating future psychologists on the important issues of intersectional diversity.

Abstract Name: Interpolating the 't Hooft Model between instant and light-front forms in the Coulomb gauge.

The 1+1D model of quantum chromodynamics (QCD) in the infinite number of colors, or ‘t Hooft model, is interpolated between the instant form dynamics (IFD) and the light-front dynamics (LFD) using an interpolation parameter δ in the interpolating Coulomb gauge which links the Coulomb gauge ($A^0 = 0$) in IFD and the light-front gauge ($A+ = 0$). While calculations such as these were performed [1] in the interpolating axial gauge which links the the spatial or axial gauge ($A1 = 0$) in IFD and the light-front gauge ($A+ = 0$), there are a number of benefits to the Coulomb gauge that cannot be ignored. All degrees of freedom are physical, making this an ideal choice for finding the bound-state equations and for renormalizability. Using this parameter δ, we find the mass gap equation using both hamiltonian formalism

and feynman diagram analysis, noting that it reproduces both the results for IFD and LFD in the Coulomb gauge and the light-front gauge, respectively. We then derive the quark-antiquark bound-state equation in the interpolating dynamics using the dressed fermion propagator. We also obtain the bound-state wave functions and compare the results between the interpolating coulomb gauge and the interpolating axial gauge. Since QCD respects the gauge symmetry, these results should all be independent of the gauge choice. These wavefunctions are particularly useful in the calculation of quasi-parton distribution functions (quasi-PDFs), in which we can produce an alternative approach to the quasi-PDFs not only with the frame dependence but also with the δ dependence. The interpolation may lead to an alternative quasi-PDF that can be implemented in the lattice QCD without suffering from the large momentum boost. Ma, Bailing, and Chueng-Ryong Ji. "Interpolating 't Hooft Model between Instant and Front Forms." Physical Review D, vol. 104, no. 3, 2021, https://doi.org/10.1103/physrevd.104.036004.

Abstract Name: The Creation of Ubiquitination-Resistant Proteins for Understanding the KSHV Lifecycle

The Kaposi's Sarcoma Herpesvirus, also known as KSHV or HHV8, is the known causative agent of multiple diseases such as Kaposi's Sarcoma (KS), primary effusion lymphoma (PEL), and multicentric Castleman's disease (MCD). KSHV is a human oncovirus with a lifecycle that is divided into two stages, latency, and lytic replication. Genes expressed during the different lifecycle phases are associated with the development of different cancers. The major lytic switch, RTA, is a transcription activator and also has E3 ubiquitin ligase activity. RTA interacts with cellular machinery to hijack the host ubiquitin-proteasome system to evade immune response and modulate cellular processes to promote lytic replication. Previous research conducted in our lab, resulted in the identification of novel substrates that are targeted by RTA. RTA targets proteins for degradation, by utilizing its ubiquitin ligase domain to attach ubiquitin molecules to lysines within target proteins. The goal of the project described here is to identify RTA-resistant mutants. Utilizing site-directed mutagenesis we are mutating each lysine codon to an arginine codon resulting in all lysines being changed to arginine in the resulting protein. Our long-term goal is to determine whether the mutants will be stable in the presence of RTA. RTA resistant mutants will then be expressed in virus-infected cells to evaluate the effects on viral replication, and protein abundance will be analyzed through western blotting.

Abstract Name: Unraveling Rhetorical Landscapes: DemeRx's Communication on Ibogaine for Addiction Recovery

This research seeks to identify rhetorical strategies used to create hype around using psychedelics for addiction recovery. In particular, I present a case study on DemeRx, a self-described "clinical stage drug development company advancing two molecules for the treatment of SUD." Ibogaine is an incredibly promising yet controversial treatment option for addiction. Ibogaine’s safety and efficiency are the subject of ongoing debate. The historical context behind ibogaine's uses will be added from research done in two ibogaine-related collections at Purdue University. By analyzing an archive of communication materials (public statements, patent documents, published website materials, and visual representations), this study aims to decode the rhetorical choices made by DemeRx. The central focus is on understanding how these choices might influence public perception and impact the acceptance of ibogaine as a viable treatment for addiction recovery. Ultimately, this research plans to shed light on how the complex rhetorical landscape of psychedelic rhetoric works to change society's receptiveness to alternative addiction recovery methodologies.

Abstract Name: “No Music on a Dead Planet”: How Indonesian Grassroots Change-Makers Use Music to Declare a Climate Emergency

The escalating threat posed by the rise in greenhouse gas emissions and environmental degradation highlights the urgent need for an immediate governmental response to avert a looming global catastrophe. This research project investigated how Indonesian grassroots change-makers within the Indonesian Knowledge, Climate, Arts & Music Lab (IKLIM) used art to raise awareness about the climate emergency in Bali, Indonesia. The project focused on IKLIM and their Music Declares Emergency Indonesia movement, a local chapter of an international initiative leveraging the cultural and economic influence of the music industry to advocate for systemic changes in addressing climate and ecological challenges. Utilizing a transdisciplinary qualitative approach, this three-month case study in Bali, Indonesia, employed participatory action research methods, including participant observations, archival research, and interviews with musicians and organizers. The findings illuminate music's pivotal role in fostering connections across interconnected issues and facilitating collaborative engagement among organizers, musicians, and audiences in intersectional change-making. Several participants and former activists noted that this collaborative process reignited their spirit to take action. Preliminary results also indicate a transformative journey for individuals within the musical community, transitioning from feelings of loneliness and disconnection to a sense of connection and collaboration. The research underscores the unique manifestations of Indonesian cultural identity within this global movement, offering valuable insights into the local dimensions of this critical issue.

Abstract Name: Early Life Impacts on Beef-Dairy Cross Calves

Feed is the most costly aspect of raising livestock, and proper early life management of any production animal is crucial in maximizing profitability. Beef cattle require an efficient pound of feed to pound of body weight gain to create a viable business for the producer. Furthermore, beef-dairy cross calves are becoming more popular in the dairy industry as a way to increase dairy producer profit. Producers can use sexed beef semen in lower genetic quality dairy cows to produce a profitable dairy-beef steer instead of a lower-producing replacement heifer. Similar to replacement dairy heifers, young beef-dairy cross calves are fed calf-starter in addition to milk during early life to stimulate rumen function and growth. This experiment investigated the effect of a high starch (26%) versus a low starch (16%) Purina calf-starter on the growth of Angus-Holstein cross bull calves. The calves were assigned to the two treatments alternately at enrollment, and the study's trials consisted of 3 groups of 40 bull calves. The calves' body weight, dry matter intake, average daily gain, and body frame measurements were taken over their first four months of life and compared between the two treatments. Experimental results showed that a statistically significant difference occurred only in calf heart girth and dry matter intake ($P \leq 0.05$). Calves on the high starch treatment consumed more grain and had a greater heart girth circumference than calves on the low starch treatment. Body weight, body length, withers height, hip height, and average daily gain did not differ between the two treatments (P > 0.05). Results suggest that calf growers may be able to save money on feed costs by purchasing cheaper, low-starch calf starters with little sacrifice of the size and growth of their animals.

Abstract Name: Effects of Brachial Plexus Birth Injury on the Composition of Biceps, Supraspinatus, and Subscapularis Muscles

Brachial plexus birth injury (BPBI) occurs when the nerve bundle innervating the shoulder is damaged due to excessive stretching of an infant's neck during childbirth. It occurs in about 0.9 of every 1,000 births, with 30-40% of those resulting in lifelong shoulder impairment, including musculoskeletal deformities, reduced range of motion, and muscle paralysis. These deficits vary by injury location (preganglionic vs. postganglionic), but the effect on underlying muscle composition is unknown. We hypothesize diminished muscle growth from BPBI is related to increased collagen content (fibrosis), impairing muscle function. We will examine the effects of altered passive muscle loading and active functional loading on collagen buildup between muscle fibers using four groups.Sprague Dawley rats underwent surgery on one forelimb at postnatal day 3-6: preganglionic or postganglionic neurectomy, forelimb disarticulation (n=8/group/timepoint), or sham surgery (n=6/timepoint). Contralateral limbs served as added controls. Biceps, subscapularis, and supraspinatus muscles were dissected at 2, 3, 4, 8, or 16 weeks post-injury, snap-frozen, cryosectioned longitudinally, and stained using Masson's trichrome. Muscle sections were imaged and analyzed as a ratio of collagen to muscle tissue. Injured-to-uninjured limb ratios were calculated, and groups were compared using the Kruskal-Wallis test with Dunn's correction (GraphPad Prism, $\alpha=0.05$).Preliminary data for the biceps indicate that preganglionic injury has greater fibrosis than sham and disarticulation groups at 3 weeks and only the disarticulation group at 4 weeks. For subscapularis, preganglionic injury has greater fibrosis than postganglionic injury at 4 weeks, and for subscapularis and supraspinatus, postganglionic injury has greater fibrosis at 3 weeks than 4 weeks. This is the first study characterizing fibrosis development and progression in glenohumeral muscles following BPBI. Understanding the progression of altered muscle composition throughout development following BPBI may inform treatment planning.

Abstract Name: Using siHybrids targeting the fnbA mRNA in Staphylococcus aureus to suppress biofilm formation

Staphylococcus aureus is a bacterial species commonly found on the skin but is able to get inside the body and secrete a biofilm that promotes further infection. The biofilm produced by S. aureus acts as a shield to prevent antibiotics or the immune system from affecting cell growth or viability. With the dramatic increase in antibiotic-resistant bacterial pathogens, it is important to find new ways to treat and possibly prevent bacterial infections. The FnBPA protein, encoded by the fnbA gene, is anchored to the surface of S. aureus cells and aids in the formation and development of biofilm. The purpose of this research is to determine if suppression of the fnbA mRNA in S. aureus with siHybrids will reduce the production of biofilm. I predicted that S. aureus cells treated with 5ug and 10ug of siHybrids targeting the fnbA mRNA would cause a significant decrease in biofilm production. After the S. aureus cells had been treated with the siHybrids in a 96-well microtiter plate, the bacteria were stained with 0.4% Crystal Violet, and quantification of biofilm production was determined using a microtiter plate reader. Our results show that treating S. aureus with 10ug of fnbA siHybrids caused a statistically significant decrease in biofilm formation compared to the untreated control.

Abstract Name: Development of Non-opioid Therapeutics to Alleviate Chronic Pain

Chronic pain is pain lasting for more than 12 weeks and impacts people on both physical and mental health. Some medications available including non-steroidal anti-inflammatory drugs (NSAIDs) and opioids. NSAIDs are commonly used for inflammation but long-term usage could lead to serious adverse effects. Opioids have been used for acute pain but are associated with addiction. This leads to a demand for a therapeutics treatment that effectively reduces the pain in a non-addictive manner. Fatty acid amide hydrolase (FAAH) and soluble epoxy hydrolase (sEH) are enzymes responsible for degrading some naturally produced lipids which have anti-inflammatory effects. Thus, the inhibition of these enzymes produces pain alleviation and represents a novel approach for chronic pain treatment. Since the co-administering of drugs could result in serious drug-drug interactions, we decided to design a single drug that will simultaneously inhibit both aforementioned enzymes. This approach is known as polypharmacology and we previously identified several

potent dual FAAH/sEH inhibitors. Herein, the purpose of this study is to explore the structure-activity relationships of isoquinoline and pyridine moieties on FAAH/sEH inhibition. This will be done through a four-step synthesis. With microwave assistance, 2-chlorobenzene sulfonyl chloride and methyl isonipecotate were coupled through a sulfonamide bond. Then, through a saponification reaction, the ester became carboxylic acid intermediate. This underwent EDC coupling with a pinacol ester. With the optimized Suzuki-Miyaura microwave-assisted reaction, this precursor was coupled with different isoquinoline and pyridine moieties to obtain 15 final compounds in moderate yields. Nest, we plan to screen all these products in human FAAH, and human, rat and mouse sEH inhibition assays. In addition, we will perform the molecular modeling studies to better understand the binding modes of this set of analogs. Lastly, the best candidate will be scaled up to 1 gram and tested in chronic pain rat model.

Abstract Name: Hispanic Ethnicity and Access to Healthcare in the US-Mexico Border Region

What is the relationship between Hispanic ethnicity and access to healthcare in the US-Mexico border region? This study examines whether Hispanic ethnicity—and specifically Mexican-American ethnicity—affects one's ability to access healthcare in a predominantly Hispanic community (El Paso, Texas) on the US-Mexico border. The existing literature finds that Mexican-Americans face important barriers to accessing healthcare, such as relatively lower income levels, language difficulties, and immigration status challenges. However, within the US-Mexico border region, Mexican-Americans may have some advantages to accessing healthcare, such as increased capacity and willingness to access care in Mexico. Using original data from a representative survey of El Paso adults in 2022, we run generalized linear regression models to analyze the relationship between Mexican-American ethnicity and access to healthcare. The quantitative analysis helps fill gaps and improves our understanding of ethnic disparities in healthcare access in border regions. The results also have important policy implications for local governments and community organizations that are focused on increasing access to healthcare in predominantly Hispanic communities.

Abstract Name: Exploring The Effectiveness of Podcasts in Health-Related Education Through Service Learning

Health equity strives to eliminate disparities in health outcomes, emphasizing the importance of providing equal opportunities for individuals to attain optimal health. Social determinants, including genetics, behavior, environment, medical care, and education, significantly influence health outcomes. This service-learning project aimed to evaluate the effectiveness of educational podcasts in improving health literacy, specifically focusing on cardiovascular disease, the leading cause of death in the United States. Collaborating with a Professor expert on cardiovascular diseases, a comprehensive podcast script was developed and recorded using high-quality equipment. Participants at the Monte Vista Senior Center were assessed on their knowledge through pre- and post-intervention questionnaires. The modified version of the validated "relationship between cardiovascular risk factors and knowledge of cardiovascular disease", by Adele Burger was used to assess health literacy on cardiovascular disease. The intervention involved presenting an educational podcast, meticulously crafted to enhance participants' knowledge on cardiovascular health. Results from a paired sample t-test on 25 participants demonstrated a statistically significant increase in total scores from pre-intervention (mean score= 2.80) to post-intervention (mean score=3.55), [$t(24) = -2.874$; $p = 0.008$]. Results showed a positive shift in health knowledge following the podcast. These findings suggest that the intervention had a meaningful impact on participants' health literacy, supporting the potential for positive outcomes through targeted educational interventions. This research not only benefits the local community but also contributes to the scientific understanding of effective strategies for community health education.

Abstract Name: Effects of Melatonin on Circumnutation in Arabidopsis thaliana

Melatonin (N-acetyl-5-methoxytryptamine) and auxin (indole-3-acetic acid/IAA) are both tryptophan-derived hormones found in various parts of all plants (Wang et al., 2016). Unlike melatonin, auxin has been extensively studied in plants since its isolation in 1928 (Enders & Strader, 2015), and is known to be involved in regulating circumnutation (Taylor et al., 2021). While recent studies have shed some light on the function of melatonin in plants including abiotic stress responses, root development, light responses, interkingdom communication, and phytohormone and plant signaling (Murch & Erland, 2021), no study has been published solely regarding melatonin's role in circumnutation, even though melatonin is involved with auxin biosynthesis and transport (Wang et al., 2016), which in turn affects circumnutation. This study aims to observe if treatments of melatonin within the range of doses reported to affect gene expression in the model plant organism Arabidopsis thaliana may have visible inhibiting effects on circumnutation due to melatonin's role in regulating auxin biosynthesis and transport. If melatonin is involved in regulating circumnutation in A. thaliana, and A. thaliana plants are grown in soil/medium containing 0–500 μM of melatonin, then I believe the plants grown on a medium with greater melatonin levels will circumnutate at a lesser frequency (displacement/time) than those with a lower melatonin level. Studying these circumnutation patterns will allow us to better understand how and why plants have autonomous, endogenous movements without apparent stimuli (Stolarz, 2009), and studying melatonin's effects on circumnutation in a model plant can shed further light on this hormone's role in the plant kingdom, as well as its relationship with auxin, the 1st phytohormone to be discovered.

Abstract Name: Kinetic Studies of Dimethyldioxirane Epoxidation of Various Alkenes

Epoxy resins have been widely used as resourceful polymers in material applications of coatings, electronic materials, furniture, and adhesives. One of the most important challenges to date is to obtain these epoxy resins without the use of non-renewable resources and cancerogenic/mutagenic and hormone-disrupting detrimental health effects. Dimethyldioxirane is a highly efficient oxidizing agent. Dimethyldioxirane can perform epoxidations under mild conditions and is selective and efficient with the epoxidations. Kinetic studies of dimethyldioxirane epoxidation of vegetable oil will be explored. The kinetic studies will include pseudo-first-order conditions with dried acetone at 23oC. Results will deliver information on the fundamental chemistry that is involved in dimethyldioxirane epoxidations of vegetable oils.

Abstract Name: Young, Black, & Grieved – The Grief Process of Receiving a Mental Illness Diagnosis

Inadequate utilization of mental health services among African American transitional-age adults (aged 18-26) following a mental illness diagnosis is a recognized concern. This qualitative study explores the experiences of transitional-aged adults as they navigate the grief process following such diagnoses. Currently, little research exists regarding the intersection of grief, race, and age in their utilization of mental health resources and the journey toward achieving psychological stability. Through in-depth interviews and thematic analysis, we gained insights into the multifaceted nature of grief in this context, expecting findings that reveal a unique spectrum of emotions and coping mechanisms among African Americans, while also highlighting the distinctive and challenging aspects of this transitional period. Key themes, such as identity disruption, loss of normalcy, and social isolation, were identified. This research study underscores the significance of understanding the grief experiences of transitional-age adults post-diagnosis, enabling targeted interventions and support systems to enhance well-being during the transition to adulthood while managing mental health challenges. The findings emphasize the need for more comprehensive mental health services and the importance of reducing stigma to facilitate a smoother journey through this critical developmental stage. This presentation will humanize the mental health journey of African American young adults and demonstrate that the mental challenges faced by this demographic go beyond the symptoms of their diagnosis.

Abstract Name: Identification and Characterization of a Soil Isolate Utilizing p-hydroxybenzoate as a Sole Carbon Source

The present study is aiming to identify and characterize a strain of soil microbe. The microbe was selected by its ability to utilize p-hydroxybenzoate as a sole carbon source when grown on minimal media. The goal of this study is to identify and characterize the microbe through the microbiologic and genetic analysis. The microbe will also be grown on a larger scale and harvested to begin testing for enzymatic activity of metabolizing the p-hydroxybenzoate carbon source. Since the microbe is grown aerobically, the metabolic pathway is expected to contain a hydroxylase and a dioxygenase. The crude cell extracts generated from the cell paste will be tested for this activity. Results from the continuation of this work, presented last year, will be presented.

Abstract Name: Born in Nation: Protest Music: Impacts on Racial Attitudes, Knowledge, and Emotions

Songs that contain messages of protest or calls to activism frequently appear on Billboard charts. However, little is known about the extent to which listeners process the true meaning of such songs. Occasionally, a specific protest song or music video has spurred significant conversation and debate, but this does not seem to be the case for most of these songs. Previous research has found that protest music can evoke emotions toward in- and out-groups. We conducted a study to determine if the messages conveyed in protest songs could be accurately inferred by participants and sought to evaluate the impact that protest music had on emotions and socio-political attitudes. A between-groups experiment was conducted in which participants were randomly assigned to watch one of two music videos (race vs. war), and then participants completed measures of emotions, moral foundations, and attitudes toward U.S. race relations and foreign and domestic policy issues. Demographic information was also collected. We predict that participants will understand the true meaning of the video and that the video they watch will increase concern for racial vs. foreign/domestic policy issues. We will also explore the impact of participants' identities on the relationship between protest music and socio-political attitudes. Findings from our study will contribute to our understanding of music's impact on society and may provide insight into the relative utility of using music as a form of activism for social change.

Abstract Name: Defining Cell Intrinsic Restriction Factor Activity Detrimental to Tombusviridae Replication

Plant viruses belonging to the Tombusviridae family have relatively small, positive sense (+) RNA genomes. Therefore, the few viral proteins encoded by these genomes must co-opt a variety of host factors to assist in the production of virions. The ongoing evolutionary battle between host organisms and RNA viruses has led to plant antiviral strategies that strive to limit co-opted host factor recruitment and eventual cell exhaustion. Although plants do not have immune responses resembling that of mammalian systems, previous literature has highlighted the presence of innate pathways providing non-specific and immediate responses to pathogens. Plant-infecting tombusviruses serve as excellent models to investigate antiviral activity of cell-intrinsic restriction factors (CIRFs). Recent literature has revealed viral induced gel condensates that are co-localized with viral replication organelles necessary for complete replication and packaging of progeny (+) RNA. Biomolecular condensates are membraneless organelles that are dynamic in nature as a result of liquid-liquid phase separation. The significant role of viral induced replication condensates has led us to question if antiviral proteins are present in the less protected bio-condensates. Therefore, this project will utilize high resolution confocal microscopy fluorescence recovery after photobleaching (FRAP) assays to visualize the ability of fluorescently-tagged antiviral proteins to diffuse into an area of the replication complex subjected to photobleaching. An absence (or very slow) recovery will suggest that antiviral proteins interact with membrane bound components of the VRO. However, medium recovery of fluorescent intensity (approximately 50 % - 60% of the original brightness) within 2 minutes of photobleaching will suggest that antiviral agents are able to disrupt the production of progeny (+) RNA via their presence in the more dynamic gel-like condensate. Understanding how host antiviral agents exploit dynamic, viral induced condensates will provide critical knowledge necessary for the development of more efficient antiviral agents that combat cell exhaustion and plant death.

Abstract Name: Exploring Website Resources Shared Within Online Health Communities (OHCs) In Response To Help-Seeking Posts By Women With Intimate Partner Violence (IPV) Experiences

One in three women worldwide are abused by their intimate partners. Many women with intimate partner violence (IPV) experiences seek help anonymously in online health communities (OHCs) instead of through legal or police services. As OHC members often share websites to answer each other's questions, we investigated the categories and domains of websites shared and how relevant they are to the type(s) of help requested by original posters (OPs). We extracted posts and comments from the r/domesticviolence subreddit on Reddit, including only help-seeking posts written by self-identified adult women with IPV experiences, with at least one website shared in the corresponding comments. Websites were annotated by topic and used

to iteratively develop a codebook. Then, shared websites were categorized as “relevant” or “irrelevant” to the topic(s) of help sought by OPs. Help-seeking posts were annotated for characteristics including post length, mentions of choking, and specific versus general questions. We used a chi-squared test to find that posts with specific questions received more relevant websites (p=0.023), while all other variables were found insignificant (p>0.05). A total of 170 website links were categorized into eight topics: 1) General IPV Resources and Support (34.7%); 2) Understanding IPV (26.5%); 3) Financial, Healthcare, Housing, and Food Support (10%); 4) Miscellaneous (5.9%); 5) Safety Warnings (5.9%); 6) Legal/Government-based Support (5.9%); 7) Escaping an IPV Situation (5.9%); and 8) Emotional Support (3.5%). Approximately 59.4% (n=101) of the shared websites were relevant to the topics of help sought by OPs. This study sheds light on the informational and emotional needs of women with IPV experiences that are currently addressed by website-sharing. These data could be utilized to create a digital tool that automatically suggests relevant and expert-reviewed website resources in IPV OHCs.

Abstract Name: The Effect of Repeated Amphetamine Exposure on Stress Susceptibility in Mice

This project explores the question: how does repeated amphetamine exposure affect vulnerability to stress? Individuals who suffer from a substance use disorder often simultaneously experience a mental disorder, such as generalized anxiety and major depressive disorder. Despite the known high rates of comorbidity between substance abuse and mental illness, the causal relationships underlying these comorbidities remain debated and could go in either, or both, directions. Previous neuroscience research in rodent models has shown that prior exposure to repeated cocaine increases susceptibility to stress in male mice. In this study, we focus on the effect of 3 mg/kg amphetamine pre-exposure on behavioral outcomes in response to a three-day stress paradigm in male (n=33) and female (n=36) mice. Half were exposed to three consecutive days of stress (restraint, fox urine, and tail suspension), and all were subjected to a panel of behavioral tests [light dark emergence (LDE), elevated plus maze (EPM), forced swim (FST), and novelty suppressed feeding (NSF)] to evaluate depressive and anxiety-like behavior.The results from EPM and NSF suggest that stress and amphetamine differentially impact the sexes. In EPM, females demonstrated an increase in anxious behavior following stress, whereas males exhibited a decrease in anxious behavior following stress. Amphetamine contributed to an increase in locomotor activity in females but not males. In NSF, amphetamine-treated females appeared to be more anxious following stress, whereas amphetamine-treated males appeared to be less anxious post stress. A three-way ANOVA revealed a three-way interaction in FST: a history of amphetamine led to anti-depressant-like effects in females only, which were significantly reduced following stress. Future work in Spring 2024 will delve into the expression of FKBP51, a key protein involved in glucocorticoid dynamics along the hypothalamic-pituitary-adrenal axis, to examine the molecular mechanisms that may contribute to the behavioral data.

Abstract Name: "The Effects of Pterostilbene, a Novel Antioxidant, on NADH Oxidase Activity in Human Endothelial Cells Exposed to Hyperglycemic Conditions"

Diabetes is a prevalent chronic health condition associated with significant complications, including diabetic kidney disease. The accumulation of elevated glucose levels in cells triggers an upregulation of NADPH Oxidase (NOX) expression, contributing to diabetic kidney disease. NOX activation results in an increased production of reactive oxygen species (ROS), inducing oxidative stress and cellular proliferation. Pterostilbene, recognized for its natural antioxidant properties, has demonstrated efficacy in reducing oxidative stress across various cell types. This research focuses on elucidating the NOX pathways in endothelial cells exposed to hyperglycemic conditions and assessing the extent of oxidative stress reduction with the introduction of pterostilbene. Human umbilical vein endothelial cells (HUVEC) are cultured at varying timeframes of high glucose media exposure, ranging from 24 to 96 hours, in conjunction with two different concentrations of pterostilbene, 5 μM and 10 μM. To quantify cellular oxidative stress, an Amplex Red assay is employed in addition to a ROS Detection Cell-Based assay to measure superoxide and hydrogen peroxide levels within the cells. Quantitative polymerase chain reaction (qPCR) will also be utilized to assess NOX protein gene expression at the mRNA level. To complement these methods, a western blot analysis is conducted to quantify NOX protein concentrations under distinct environmental conditions. Our research aims to shed light on the potential of pterostilbene as a therapeutic agent in mitigating oxidative stress associated with hyperglycemic conditions in endothelial cells.

Abstract Name: The Astronaut, Man of Today’s Tomorrow: The American Dream in Space

Following the Second World War, a new chapter of scientific discovery and human expansion seemed to open up in front of the American public. Space, the final frontier, offered apparently limitless resources, limitless adventure, and limitless growth to a nation riding a post-war high of technical advancement and industrial might. At the apex of the popular understanding of space was the astronaut—not the engineers, technicians, planners, or laborers who enabled the rocket launches. While the astronaut comfortably took a spot among popular American hero archetypes, the image itself and conceptions related to the astronaut would not remain stagnant: as American culture evolved, so too would the astronaut. Even if popular works about astronauts had no explicit political or social commentary intended, they are irrevocably linked to the time periods from which they originate, and also act as projections of their contemporary creators and audiences for their various insecurities, hopes, fears, and values. My project explores how the popular image of the astronaut has evolved over time through the American popular consciousness. It will address these issues by examining culturally significant popular media, including The Right Stuff, 2001: A Space Odyssey, and Disneyland episodes from the late-1950s, such as “Man in Space”. The evolution of the astronaut through these works can be studied to understand how the American public understood the role of science in society, the truthfulness or inherent failure of the American Dream, and as a case study of general trends throughout American society.

Abstract Name: The impact of book bans on the creation of culturally sustainable classroom libraries and teacher practices.

As restrictive educational legislation increases throughout the country, teachers are facing barriers in the quest to teach in inclusive ways. Such legislation is intended to create more rigorous processes for adapting classroom materials, however, such policies may make it more difficult for teachers to create diverse, welcoming classroom environments. We were interested in studying the impact of such policies in our local and regional school districts. Book banning is not new, but has become increasingly prevalent (Harris & Alter, 2023). Public schools have received unprecedented pressures regarding the materials students can access. Book banning especially targets topics that may be considered controversial. This issue has proven to be highly divisive. On one side of these culture wars are those who seek more restrictive procedures for adapting classroom texts, such as parents' rights groups. On the other are advocates for allowing more freedom in choosing books for student use, especially those who hope to include identity-based texts that directly address race, gender, sexuality, and other issues that may be considered controversial for students (Harris & Alter, 2023).. In the midst of these culture wars, a question emerges: how can teachers include literature that welcomes, and sustains the varied and complex identities of students? Research indicates that classroom literature plays a significant role in student's perceptions of the world (Crocco, 1997), others, and themselves (Whitford, 2023). Thus, the use of Culturally Sustaining Pedagogy (CSP) through a literacy lens becomes vital. CSP amplifies and sustains the experiences of all students (Paris, 2012). In this study, we seek to discover the impact of book banning on teachers' materials and practices. Using survey data and sample books awarded for their portrayal of contemporary concerns and identity-based plots, we will draw conclusions to inform the field in moving forward.

Abstract Name: Do All Georgian Rivers Lead to Europe?: How Foreign and Domestic Actor Interactions Shape Natural Resource Management in the Republic of Georgia

A country bordering Russia in the South Caucasus, Georgia is situated on a geologic plate boundary conducive to a unique geography with mountains serving as headwaters to high velocity rivers. These rivers foster biodiversity and power communities; at the same time, changes in climate threaten to increase glacial melt and heighten risk for natural disaster. Effective natural resource management is key to ensuring a

sustainable future for the country. Environmental NGOs in Georgia receive funding by foreign donors from the US and Europe to manage the country's natural resources. This research seeks to examine how environmental NGOs play a role in the sustainable development regime, mediating to accommodate the demands of Georgian civil society, bilateral agencies, consulting firms, and the domestic government, all within the confines of increasing government ties to Russia and a political pull from European integration. The research is particularly relevant as Georgian civilians seek candidate status in the European Union, causing a conflict of interests among domestic and foreign actors. The purpose of this research is to determine how foreign agencies and donors, Georgian non-governmental organizations, the Georgian government, and Georgian civil society interact with one another to achieve sustainable outcomes in natural resource management. Georgian civic engagement in development is pivotal to ensuring that programs implemented are socially, economically, and environmentally sustainable. The approaches that foreign aid agencies and donors employ affect the extent to which civil society is engaged in the process. The aim is therefore to uncover the interests, priorities, and constraints of each of these actors. To obtain data to understand these interests and constraints, we are conducting interviews with personnel from environmental NGOs in Georgia and their donors, foreign consulting firms, and the Georgian Ministry of Environmental Protection and Agriculture in Georgia.

Abstract Name: The History and Future of Televised Advertising

Many forms of advertising have existed for as long as business has existed. After all, businesses need a way to get word of their goods and services out to potential customers. One of the most impactful and popular forms of advertising in recent history is that of televised advertising. After the first televised advertisement aired in 1941, the business has since taken off, continuing to evolve to fit the advertising climate. Although it is still a popular medium today, it's had some major competition. The internet, with its more interactive approach, has become one of the most popular platforms for consuming media, which in turn attracts advertisers. Media platforms on the internet also make use of algorithms, which select advertisements catered to the individual, which is something that television can't do. People want to watch their shows on demand, which is why many television stations have launched their own streaming platforms. This, however, does not spell the end of television; streaming via the internet is more of an evolution. Although the popularity of television has died down, it is still popular enough to deter advertisers from abandoning the medium.

Abstract Name: Application of Clove Bud Essentials Oil in Reducing Escherichia coli on Pecan Halves

Essential oils (EOs) have been found to be effective in reducing pathogens including Escherichia coli (E. coli) on food surfaces. In this study, we evaluated the efficacy of clove bud EO against E. coli on pecan surface. Pecan halves were first inoculated with ≈ 6.0 log CFU/g of E. coli (ATCC 8739) culture and air dried for 30 min at room temperature in a biosafety cabinet. The samples were then treated with different concentrations of EO (1%, 1.5%, and 2 %, v/w) for 1, 3, and 5 min. Each pecan half was then homogenized in 10 mL of 0.1% sterile peptone water and serial dilutions were spread on Tryptic Soy Agar plates. Plates were incubated at 37 °C for ~18 h and colonies were counted, and log values were calculated. The ANOVA procedures of SAS were used to determine significant differences in the values among treatment times and concentrations. Clove bud EO concentration and treatment time had significant effect on the E. coli reduction (p < 0.05). The log reduction of E. coli increased with the increase in concentration and treatment time. At 5 min of treatment with 2% EO, the populations of E. coli were reduced by 2.93 log10 CFU/g (≈ 99.9%). While the result of this study suggests that EO can be effective in reducing E. coli on pecan halves, further research is required to evaluate the quality characteristics of treated nuts. The use of EOs may contribute to establishing improved practices for enhancing food safety measures in the pecan industry.

Abstract Name: International NGOs Addressing Global South Realities: Hazardous Agricultural Child Labor in Costa Rica

The dominant stance in the international discourse on child labor held by international institutions and non-governmental organizations (NGOs) in the Global North argues for its prevention and eradication due its detrimental impact on children's health and development. In the Global South, there are communities who acknowledge that, while some labor can be hazardous, allowing children to work can also enable wider socialization and a potential to contribute to the family and earn for themselves. Can organizations successfully implement programs in communities with differing perspectives and protect children from tangible harm? Costa Rica is currently leading the charge to get rid of child labor within Latin America; however, there are still 30,000 children in what the government considers to be hazardous labor. This transdisciplinary qualitative case study explores the efforts to combat hazardous child labor within Costa Rica by Defensa de Niños y Niñas Internacional Costa Rica, an international NGO, and how their projects and methodology account for Costa Rican realities despite their Global North roots. Through a three-month internship with the organization from September to November 2023, field research was conducted via participant observation, interviews, surveys, archival research, and arts-based research regarding their work on agricultural child labor, one of the most hazardous and customary forms of child work. The findings highlight a lack of targeted approaches to combat hazardous labor for children in comparison to adolescents. Despite a stated prioritization of community collaboration, community beliefs that contradict the normative international child labor standards guiding the organization and the country's policies are disregarded. In addition, there have been no directed efforts to aid the communities most impacted by hazardous child labor in the country, such as Indigenous and Afro-descendant youth. This research suggests discarding the abolitionist approach for more hazard-focused and community-conscious work to maximize child protection efforts.

Abstract Name: A new technique for measuring the speech-to-song illusion: Timbre priming

The speech-to-song (STS) illusion is a phenomenon where an unchanged spoken phrase is repeated and starts to be perceived as a song by the listener (Deutsch et al., 2011). Although it is still up for debate, researchers theorize the meaning of the spoken words dominates the attention of the listener. After multiple repetitions, the semantics are satiated, leading to increased attentiveness to previously neglected pitch information. Prior research has studied this illusion through the use of self-report Likert scales after multiple repetitions. While this method has worked in the past, there are implicit ways to detect tonal properties, such as timbre priming (Margulis & Levine, 2006). This technique detects musical expectation through reaction times (RTs) to probe notes following a melody. The current study introduces a technique to measure the speech-to-song illusion without self-report. For 80 trials, participants listened to 5 snippets of speech followed by a probe tone that either matched the final phoneme frequency of the speech snippet or not. Participants had to classify the timbre of this probe tone. One of the five speech stimuli is known to elicit the speech-to-song illusion. Data collection is underway, and we expect to be finished with collection by March 2024. We plan to run a multiple regression analysis predicting RT from Trial Number and Speech Type (STS, Control). We expect to find that the STS trials will have a steeper negative slope due to participants hearing the speech more as a song over time. Overall, this study will provide evidence for a new technique to measure the STS illusion through implicit methods.

Abstract Name: Exploring Mites On Lemurs

Mites (class Arachnida) are arthropod ectoparasites living on hosts. Mites have been investigated in mammals regarding their possible role in disease development, and few studies have examined mites on lemurs. Therefore, to study mite presence on lemurs, Duke Lemur Center (DLC) lemur hair samples taken from six facial and eight limb regions were examined under light microscopes. Potential mites were photographed and identified based on their morphology. 30 potential mites were found including some that look like they belong to Demodex, a mite genus commonly found on dogs. In the future, genetic analysis would be needed to identify the specific mite species found. Studying the presence of mites on lemurs will provide insight into the largely unstudied relationship between ectoparasites, mites in particular, and lemurs, and if / how mite proliferation causes illness in lemurs.

Abstract Name: The Cross-Race Effect in Recall on Positive and Negative Feedback

In this experiment, 40 White college-aged students were shown 6 distinct insults (e.g., you are disgusting) and 6 compliments (e.g., you are very sweet) paired with faces from three racial groups (i.e., Asian, Black, and White). Each message was shown three times, once with each face. After studying each message-face pair, the participants' memories of those pairs were tested by presenting each face they had seen with a multiple-choice question. The options were either a compliment, an insult, or "neither message". Lastly, participants took a survey that measured, level of interracial exposure, perception of personal similarity to, and concerns they had with each racial group. A repeated measures ANOVA found an interaction effect between the race of the faces and the type of message. Memory accuracy for White Insults (WI) and Black Compliments (BC) was higher than memory accuracy for White Compliments and Black Insults. Evidence of the CRE is seen in individuals' ability to better recall being insulted by their racial ingroup and complimented by their outgroups. Likely owing to a fear of rejection from desirable groups and a diminished impact of insults from those with whom they are already separated.Moreover, survey questions that asked participants about varying concerns with racial ingroup and outgroup were associated with memory for comments. The strongest correlation was seen between BC and concern about being either stereotyped or misjudged by the outgroup. In contrast, participants who were concerned with being stereotyped by their racial ingroup were more likely to remember WI. A possible result is that they connected unfavorable experiences with this group; hence, they predicted a negative distance.

Abstract Name: Bad Cop Good Cop: The Effects of Fear of Crime and Visibility on Attitudes Towards Law Enforcement

One of the most contentious topics in modern American politics is the role of law enforcement and crime prevention. The recent climate has been increasingly negative due to the highly visible mistreatment of citizens, often racial minorities. Previous studies have found that citizens report a more favorable view of law enforcement when officers limit their use of force and engage with the public respectfully and politely (Avdija, 2010). Research has also demonstrated that these attitudes depend on characteristics like race (Bass, 2001), gender (Hodgson, 2002), and partisanship (Erskine, 1974). However, we know little about the influences of one's hometown and current town on their opinion of the police. This study utilizes an original survey of 350 college students from a regional state university. The survey asked questions about fear of crime and visibility pertaining to students' experiences with law enforcement in their college town and the nearest metropolitan area, and how they affect opinions on law enforcement. The results indicate that students

who have a fear of crime have approximately a 13% decrease in positive attitudes toward police in the college town. Additionally, Democrats were found to have approximately a 24% decrease in positive attitudes toward police as compared to Republicans and Independents. While police visibility broadly was insignificant, whether the interaction was seen as negative or positive was significant. For every additional negative interaction witnessed, the average student reported a 14% decrease in positive attitude toward the police, and for every positive interaction witnessed, a 10% increase in positive attitude toward the police was found. Going forward, if officers want to build a better relationship with the community they serve, we are going to need to see a positive change in their interactions with citizens in the communities they serve.

Abstract Name: DNA Sequencing: Analysis and Authentication of Commercial Gluten-Free Products

Food allergies are a global concern for the health of communities and food safety. In the U.S, Wheat is reported as one of the eight most common IgE-mediated food allergens. The ingestion of wheat has been linked to health-related issues such as allergies such as wheat allergy, non-celiac gluten sensitivity, and various diseases. The most common disease within that group, Celiac disease or “celiac sprue,” is an inherited inflammatory disorder where damage is caused to the small intestine's lining. Sufferers experience symptoms such as skin rash, fatigue and vomiting, to name a few. To protect people with this autoimmune disease, regulatory boards across the globe ask for food products to have mandatory labeling information and declare the use of all ingredients. One tool for the specific identification and discovery of species is DNA barcoding, by analyzing short genetic (DNA) sequences from samples. Using this method, we seek to authenticate food products that are adulterated or misbranded by acts of food fraud.This study's purpose was to determine if gluten-free bread flour contained wheat. The DNA barcoding technique was utilized in this experiment to determine whether any wheat was present in the products. Five distinct types of gluten-free bread flour were tested to see if they would yield the same results. Data and photographs were collected as evidence of the experiment, and all samples were subjected to testing. DNA was extracted from each gluten-free bread flour, and PCR amplification was performed to detect the DNA. The samples were then sent for sequencing, and the results were uploaded to DNA Subway, a system that provides information on the genetic makeup of each sample.

Abstract Name: Evaluating the Impact of Aurora Kinase Inhibition on Immunogenic Cell Death in HPV+ Murine Models.

Human Papillomavirus (HPV) causes over 694,000 cancer cases annually and is the leading cause of cancer

in women in developing countries. HPV-positive (HPV+) models express viral oncoproteins E6 and E7 that bind and degrade tumor suppressor protein p53 and Retinoblastoma (Rb) respectively, leading to abnormal cell growth and division, reduced cell differentiation, and an increased risk of cancer development. Although HPV+ tumors are molecularly distinct from HPV-negative tumors, their treatments are identical. Standard treatments for HPV-driven cancers involve radiotherapy and chemotherapy which have chronic side effects and are not ineffective in 20% of HPV+ cancers. Therefore, there is an urgent need for therapies that are less toxic and more effective. Previously, Johnson Lab conducted a high throughput drug screen (HTDS) evaluating 864 unique compounds. In that HTDS, Aurora kinase inhibitor (Alisertib) was more effective in HPV+ than in HPV- human cancer cells. To investigate the impact of aurora kinase inhibition on immunogenic cell death in HPV+ murine models, I assessed the effect of Aurora Kinase Inhibition on p_AURKA levels in HPV+ murine models, evaluated the impact of AKI on other markers of immunogenic cell death, analyzed the levels of Cytochrome C and HMGB1, and investigated the impact of ABC on p_AURKA levels in HPV+ murine models. The results showed that Aurora Kinase A inhibition leads to immunogenic cell death and apoptosis in murine HPV+ cancer cell lines (C343 and TC1) when treated with 300nM of alisertib. In addition, inhibition of ABC transporters increases alisertib-induced aurora inhibition and apoptosis in TC1. In conclusion, alisertib is more effective at inhibiting aurora kinase A in C343 than in TC-1 cells and drug efflux via ABC transporters may account for drug resistance to alisertib in TC-1.

Abstract Name: Empowering Lives Through a Wellness Center for Parkinson's Disease Patients and Caregivers

Parkinson's Disease (PD) affects millions worldwide, impacting not only individuals but also their families and caregivers. Parkinson's disease is a disorder that gradually affects the nervous system and the associated body. Symptoms start gradually and intensify. Symptoms include tremors, stiffness, altered speech, and loss of balance. This groundbreaking wellness center is designed to support PD sufferers and their support networks. The center aims to empower individuals with PD to maintain independence in daily living.Personal interviews, surveys, and precedent studies were utilized for my research methods. Personal interviews explored the daily struggles of PD patients, and their coping strategies. Survey respondents assessed the difficulty levels of routine tasks, revealing consistent challenges in activities such as cooking, housework, grocery shopping, walking, and writing. Through a range of social, physical, and occupational therapy activities, the center strives to create a supportive community that fosters resilience and a sense of belonging. Precedent studies involved the inclusion of occupational therapy is instrumental in equipping PD patients with practical skills and strategies to navigate daily challenges, promoting autonomy and a higher quality of life. Educational programs within the center further empower individuals with PD to understand and manage the complexities of their condition. Caregivers also benefit from essential tools and counseling services, acknowledging the unique role they play in the journey of their loved ones. This project envisions a holistic wellness center that becomes a beacon of support, education, and empowerment for those affected by Parkinson's Disease, strengthening the possibility of leading fulfilling lives despite its challenges.

Abstract Name: Towards a Method for Characterizing Neural Activity in Response to Magnetic Stimuli

Increasing evidence suggests that some migratory species of birds use the Earth's magnetic field to navigate. To characterize the responses of neurons to magnetic stimuli, a high-density microelectrode array was used to measure the firing patterns of ex vivo avian retinal ganglion cells. To validate the computational methods that were used, data were simulated to emulate neuronal firing patterns. First, stimuli of magnetic orientation were simulated, and linear filters detecting north-south orientation over time were created. After convolving these filters and stimulus and converting the result to spike probabilities, the spike train was simulated as a Poisson process with rate given by the spike probability. Neuron-level estimators were computed from the output to estimate linear filters of stimulus-triggered activity based on the spike-triggered covariance. To measure the accuracy of the findings, the cosine similarity between the estimated and original linear filter was calculated, resulting in a high value of 0.99. A randomization test was used to measure the significance of these results against a neuron that is agnostic to the stimulus, resulting in a significant p-value (< 10-10). This suggests that this method is able to reconstruct the filter of a magnetically-tuned neuron, and in future work we plan to apply these methods to electrophysiological data recorded from living retinas in response to magnetic stimuli to find neurons in the bird retina that encode information about low frequency magnetic field orientation.

Abstract Name: All Poets Dance With Death: A Memoir as an Explication of Biosemiotics and Intersectional History

According to biosemiotics, all living organisms — from the very first cell to all that embody animals and trees and humans — are sign producers. Semiosis permeates our bloodstream and our DNA and extends into the vast and interconnected system of communication. It functions, on certain layers, in tandem with phenomenology: in how subjective contours of the individual experience manifest realities, biosemiotics also ensure the intentionality of symbols, and how symbols compose the meaning of life. My project uses the frame of biosemiotics through the format of a personal memoir: one that will explore the links between biosemiotics and poetry and how it has influenced my personal life. This sign-producing exploration will serve as a platform for intersectionality–attempting to address how poetry impacts personal history–allowing us to define what the "soul" truly is: an expression of inexpressible symbols. Personal journal entries reflecting on life milestones (the death of family members, accounts of my first birthday party), poems, and paintings I have made over the years will be contextualized with biosemiotics research and historical accounts through the multi-dimensional framework of intersectionality. Comparisons drawn from history will focus primarily on deconstructing religious perspectives: the relationship between Calvinism and communism, the semiotic scaffolding of the Protestant Reformation and Creationism, and the

recontextualization of Biblical narratives. The memoir will be used to investigate the profound links between poetry, personal history, and biosemiotics, emphasizing how symbols influence our narratives and lives.

Abstract Name: International Norms, Diffusion, and United Nations Efforts to Promote Judicial Independence

Judicial independence creates a baseline for whether people are treated with dignity and respect by their governments. The lives of people everywhere are influenced by the ability of their country's court system to uphold and protect their rights, and failure to secure this norm leads to grave abuses, especially against the most vulnerable members of a society. Prior research shows that RGOs have limited efficacy in advocating for reform, both for judicial independence and human rights in general. IGOs such as the United Nations also influence the transfer of human rights norms in general, either as a forum of debate or an actor. However, literature on the contributions of IGOs regarding judicial independence reform is entirely focused upon failure or remains lacking. This research answers the question of under what circumstances does the UN succeed. To establish processes by which the United Nations influences domestic judicial reform, I conducted semi-structured interviews and field work with human rights officers based in Geneva who have worked on judicial independence issues. From these interviews, I selected cases in the Democratic Republic of the Congo and Belarus relating to the arbitrary dismissal of judges. Archival work from UN archives, external human rights organizations, and the press, as well as statements from interviewees are then used to illustrate the causal mechanisms within these cases that led to implementation or failure. The research finds that recommendations from UN human rights bodies have higher chances for implementation if influential nations within the international community are applying pressure to adopt and civil society is sufficiently mobilized. UN human rights bodies transmit information on violations to the greater international community and provide legitimacy to civil society groups seeking reform. By creating openness and political will, judicial independence norms diffuse into society and increase overall respect for human rights.

Abstract Name: Skip a Class, Sip a Glass: Unraveling the Teenage Conundrum

Today's literature has primarily examined daily drinking behaviors among teenagers within a sociocultural context. Notably, prior studies have focused on the broader cultural influences on adolescent alcohol consumption. However, the current study stands out as the first to explore the influence of number of class failures and school absences on daily drinking behavior. Leveraging a publicly available dataset from UCI Machine Learning, obtained through a survey of students in language courses in secondary school, our central research question examines the relationship between the number of academic failures and school

absences they experience on the frequency of daily drinking in teens. Addressing a gap in existing literature, this research utilizes a comprehensive dataset to unveil the intricate connections between academic struggles and adolescent alcohol consumption. Methodologically, students were categorized based on the number of academic failures and school absences, which was divided into two categories starting from zero to 5 absences and then 6 absences to beyond. A Two-Way 2x4 ANOVA revealed statistical significance between the number of academic failures and the incidence of daily drinking. Additionally, there is a noteworthy statistical significance between school absences and the frequency of daily drinking among teens. However, the combination of both the number of academic failures and incidence of daily drinking did not reveal any significance. The findings from this study hold significant implications for educators, parents, and policymakers. By identifying the links between academic struggles and daily drinking in teens, targeted interventions within educational settings can be developed to address both academic challenges and potential substance use. This knowledge can inform early detection strategies and tailored support systems for at-risk students, fostering a holistic approach to adolescent well-being.

Abstract Name: Production of Amyloid Precursor Protein is Herpes Simplex Virus 1 Strain-Dependent

Cleavage of amyloid precursor protein (APP) generates the antimicrobial peptide amyloid beta (Aβ), the accumulation of which is linked to the pathogenesis of Alzheimer's Disease (AD). Herpes Simplex Virus Type 1 (HSV-1), a neurotropic DNA virus that establishes lifelong latency, is reportedly associated with AD though this link is controversial. Infection with different strains of HSV-1 lead to a range of presentations, from asymptomatic infection to lethal herpetic encephalitis. We hypothesize that distinct strains of HSV-1 also differentially associate with AD. To begin to address this hypothesis, we tested whether synthesis and proteolytic processing of APP varied following infection with three different HSV-1 strains. Analysis of single-cell RNA sequencing (scRNA-seq) libraries from infected corneas revealed that APP and its key processing components were differentially expressed dependent on HSV-1 strain. A similar result was observed in vitro using an immortalized corneal fibroblast cell line by reverse transcription quantitative polymerase chain reaction (RT-qPCR). Furthermore, APP and Aβ levels differed dependent on HSV-1 strain as measured by western blot. Clinically, these findings may contribute to resolving the controversy regarding HSV-1 association with AD.

Abstract Name: Evidence of predation in vertebrate fossils from the Late Devonian (Famennian) Catskill Formation of Pennsylvania: further insight into the ecological context of the fin-to-limb transition

Trophic interactions among the vertebrate taxa of the Late Devonian Period (383–359 Ma) can illuminate the ecological context of the vertebrate fin-to-limb transition. However, the ecology of these Late Devonian environments has thus far been an understudied topic. The Catskill Formation of northcentral Pennsylvania, USA, has provided some of the best insights into the freshwater environments that played host to this transition. Fossils collected from many different sites across the region have produced a diverse assemblage of gnathostomes (jawed vertebrates) including 'placoderms,' 'acanthodians,' chondrichthyans, actinopterygians, and a variety of sarcopterygians including multiple distinct tristichopterid species and fragmentary remains of early limbed forms. To understand paleo-trophic interactions in the Catskill Formation, we looked at direct evidence in the form of bite traces. Here we analyze twenty-eight bone deformations in various types of vertebrate skeletal remains that fit the criteria we used to identify direct evidence of predation. Bite traces were primarily found in the head and trunk shields of smaller species of 'placoderm', with other osteichthyan skull material and additional postcranial elements also present. The small-bodied 'placoderms' studied here are inferred to sit at a lower trophic level in these paleoecosystems than their larger osteichthyan counterparts. With this new information, we can confidently establish that the small-bodied 'placoderm' species were prey items for larger sarcopterygians. Additionally, these bite traces confirm that tristichopterid species primarily represent the apex-predator roles in their respective paleoecosystems once they reach full ontogenetic development and that they engage in cannibalistic behavior. As they develop, our evidence also shows that niche partitioning occurs in sarcopterygians of the Catskill Formation, most notably amongst the representative tristichopterid species. All of this new information offers additional ecological context to the Late Devonian freshwater ecosystems of Pennsylvania, and thus to our understanding of the fin-to-limb transition.

Abstract Name: Accessing my Autistic Self: Reflections from Autistic Adults on the Benefits of Program Engagement with the Autism Society of Central Virginia in Richmond, Virginia

Autism, a neurological and developmental disability that impacts interaction, communication, and behavior, has historically been situated as a disorder that needs to be cured, fostering ableist stigma and social exclusion to the detriment of the well-being of the autistic community. Given prior literature's disproportionate attention to youth and males as well as its exclusion of autistic voices in a participatory manner and its operationalization of a medical model, I sought to identify the personal realities of autistic adults in the context of their engagement with a local non-profit support service that offers social, recreational, and educational programming. Drawing from critical disability theory, feminist methodology, and a transformative paradigm, this autoethnographic qualitative case study explores my own experiences as a recently diagnosed, autistic adult female as I navigate a new identity in community through a three-month internship with the Autism Society of Central Virginia from September to November 2023. In consideration of the diverse realities and support needs of individuals on the autism spectrum, which remain misunderstood and underrepresented, I supplement my personal reflections with archival research, participant observations, and five semi-structured interviews with autistic female and/or non-binary adults. Findings indicate participants are able to better embrace their autistic self and construct a positive strength-based identity as they gain access to affirmation and acknowledgement, education and empowerment, and inclusion and connection in a space of shared understanding and intersectionality through their engagement with the Autism Society of Central Virginia. I also conclude that professional skill-building opportunities in neuroinclusive environments should be expanded to reflect participants' challenges in the transition-to-adulthood process.

Abstract Name: Improving Social Interactions by Reducing Screen Time and Promoting Physical Activity

Over time Americans have been spending more time looking at a screen which has created a sense of division in society. This division has taken a toll on mental illness, with over 50 million (20%) Americans being affected. Society is also seeing a drastic rise in obesity and other health-related problems due to the time spent looking at screens. It is shown that diet, exercise, and mental stimulation can help solve these issues. The purpose of this study is to explore how to create an engaging environment that encourages people to connect with others through board games and lawn games. An online survey was conducted using random and convenient samples to gain insight, knowledge, and data on how people spend their time and interact with different activities. Responses indicated that 32.7% of participants preferred lawn games, and 67.3% preferred board games. The overall space planning reflects this data by having a larger board game area and a smaller lawn game area for users. Studies also indicated that board games have been shown to increase brain function by stimulating parts of the brain that are responsible for memory formation and complex thought processes for all ages. Similarly, lawn games have several benefits, such as fostering relationships with friends and family, creating memories, and having fun in a social setting. These games can help promote physical activity by having individuals retrieve game equipment and physically participate in the games, therefore, increasing the heart rate and improving cardiovascular health. In conclusion, mental and physical well-being has been a concern in America, and this activity café can provide an environment that allows people to grow and improve their well-being.

Abstract Name: Shifting Trends: An Analysis of Post-Cold War Military Expenditures (1992-2020)

Since the fall of the Soviet Union, military expenditures globally have seen major changes, from the status of the U.S. as the sole dominant power to the rise of China more recently. Previous research on the topic of military expenditure has looked at the significance of specific variables such as GDP and conflict on military expenditure or the effect of military expenditure on another variable such as economic growth. In this project, I look at shifts in military expenditure from 1992-2020 and the causes of military expenditure for specific countries during this time. I find that global military expenditure has shifted from primarily Western nations in Europe and the United States to Asian nations such as China and India. This is primarily due to stagnation in European military expenditure and a steady and continued rise in spending in Asia. In addition, I analyze military expenditure for specific nations including the United States, where I develop regression models that predict factors that shape military expenditures in these nations.

Abstract Name: Assessing Racialized Sexual Violent Experiences and Stress Biomarkers in Black Transwomen

An estimated 1.5 million individuals in the United States are transgenders, and 40% belong to a minority racial or ethnic group. Members of minority and marginalized demographic groups experience sexual victimization more than twice the rate of majority or dominant demographic group members. One's hypothesis is that race and gender uniquely intersect to influence the victim's experiences, attitudes, perceptions, and resilience. Sexual violence against African American transwomen, for example, is intersectional because it includes both the racial and gender identity of the victims. The hypothesis underpinning this study is that race and gender uniquely intersect, shaping the experiences, attitudes, perceptions, and resilience of victims. Due to the scarcity of instruments that account for intersectional identities, the researcher proposes to develop and validate a novel questionnaire for uncovering factors related to the intersectionality of race, gender, and related trauma due to sexual victimization. Many studies account for race-based and gender-based victimization as distinct constructs, but specific demographic groups, such as Black transwomen are understudied. The methodologies are often insufficient due to sampling bias or lack of adequate survey instruments. This double victimization, in turn, might increase the physiological and psychological stress burdens for this marginalized population.Furthermore, perceptions about victimization might also influence stress hormones like cortisol or immune reactivity.However, these conjectures require further study.

Abstract Name: Behind the Wave: Conservative Advocacy Groups and the Diffusion of State-Level Anti-LGBTQ+ Legislation

Between January and May 2023, conservative lawmakers introduced more than 500 anti-LGBTQ+ bills in state legislatures. Public support for LGBTQ+ individuals rose consistently through the first part of the 21st century until a national coalition of conservative organizations launched a campaign in 2015 for state "bathroom bills" that sought to prevent transgender students from using bathrooms that align with their gender identities. After this campaign largely failed, there was less anti-LGBTQ+ action in state legislatures, until 2020. The rapid passage of anti-LGBTQ+ laws since 2020, and the similarities between the bills, cannot be explained by a traditional policy diffusion framework. Instead, I argue that the spread of these laws follows the pattern of anti-trans bathroom laws and same-sex marriage bans. That is, the expeditious adoption

of recent anti-LGBTQ+ legislation is the result of a coordinated campaign by conservative advocacy groups. In this paper, I show that these groups have launched concerted lobbying and organizing efforts. Through quantitative textual analysis, I show that the text of most anti-LGBTQ+ laws passed by state legislatures is closely related. I argue that this is because of the advocacy movement—and that state legislators may have copied text provided by conservative organizations or other states. Specifically, I use network software to spatially map bill text similarity, analyzing clusters of high correlation and connecting them to concrete advocate action. Further, applying event history analysis, I demonstrate that the passage of anti-LGBTQ+ laws over time is associated with the rise in advocacy by a coalition of conservative groups at statistically significant levels. This paper departs from traditional explanations of policy diffusion, adding evidence to recent work by other researchers showing a growing trend where state lawmakers pass bills because of national advocacy campaigns rather than broad public support.

Abstract Name: Factors Affecting the Resilience of Unhealthy Relationship Dynamics From Childhood into Adulthood

AbstractThis study aims to investigate the effects of parental abuse and self-verification on the levels of emotional abuse in intimate relationships in adulthood within an Egyptian context. The study includes a total of 40 students from Egyptian private universities ages 18 to 24. Participants completed a self-report questionnaire via Qualtrics which explores three primary subtopics; namely, parental abuse, self-verification and emotional abuse in intimate relationships. Linear regression models are utilized for data analysis to explore correlations between study variables. Results indicate that there is a significant positive correlation between parental abuse in childhood and adult emotional abuse from a significant other. Meanwhile, there is no significant relationship between self-verification and emotional abuse in adulthood. Limitations and implications of the findings are discussed.

Abstract Name: Interspecific Venom Variation Between Two Shades of Aphonopelma Tarantulas

Interspecific phenotypic variation is a common occurrence throughout the animal kingdom and evolves in response to differential selection pressures between species. Species-based differences occur frequently in venomous species including arachnids, and is often due to differences in gene presence/absence. These differences tend to be dramatic in closely related species. The North American tarantulas (Theraphosidae: Aphonopelma), have undergone recent taxonomic changes which identified several lineages of previously undescribed species. To test for interspecific venom variation in two species, we converted mRNA to cDNA from the venom gland and sequenced the RNA-seq libraries on an Illumina NovaSeq 6000. Using our data, we generated the first venom gland transcriptome for A. hentzi (Texas Brown Tarantula) and A. anax (Texas Tan Tarantula). By comparing annotated transcriptomes between species we found evidence of interspecific differences. Specifically, we found similar protein families between the species but differences in expression and sequence that may be leading to the overall differences in their venom transcriptome profiles. Examining interspecific venom variation offers a window into the evolution and ecology of both species, and provides data for a poorly studied family of organisms.

Abstract Name: Beyond Simple: Exploring Intricate Jewelry Techniques

Seemingly simple yet intricate jewelry pieces were what sparked my research passion. However, my love for delicate and detailed jewelry collided with the realization that crafting such elegance posed challenges. Undeterred, I embarked on the journey to explore and answer how simple and complex can be merged into one entity. This project aimed to explore and create intricate jewelry using diverse techniques. My journey began with wax casting, where I refined my wax carving skills by meticulously crafting fine, detailed rings. Upon completing the casting process, I started learning more about filigree, what it was, and its techniques. Simultaneously, I forged jump rings and chains to attach them to my filigree and casting creations. Expanding further, I ventured into designing various chain types, bringing beautiful bracelets and necklaces to life. Toward the conclusion of my summer-long project, I ended up creating thirteen rings, two pendants, five earrings, three bracelets, and a complete jewelry set. These outcomes stimulated me to bring life into more creations as my journey advances. I am currently working on an honors thesis project, delving into the intricacies of gold plating. I aim to apply the skills acquired from this research to yet another honors thesis project. Throughout this journey, I faced notable challenges, particularly in mastering filigree and fine-chain building techniques. However, these challenges inspired me to craft jewelry pieces that are a reflection of my hard work. This experience has not only unlocked new skills in precision and patience but also advanced my existing ones in creativity and handcraftsmanship.

Abstract Name: Utilizing Optical Character Recognition for Handwritten Arabic Alphabet Learning

The emergence of interactive language learning tools like Duolingo or Rosetta Stone has revolutionized the process of learning new languages, making it easier than ever before. While these tools excel in teaching spoken and basic written language skills, they face limitations when it comes to recognizing and deciphering handwritten texts. This challenge creates a divide between people's willingness to engage in handwritten language learning, particularly in alphabets like Arabic. The different styles of handwriting, strokes, and character shapes pose difficulties for language learners, often discouraging them from continued learning. To address this gap, this project is underway to develop a program utilizing optical character recognition (OCR) techniques to assist language learners in deciphering and distinguishing letters from photos of handwritten texts, specifically focusing on the Arabic language. Utilizing OCR unconventionally and breaking away from traditional translation applications, this project breaks down individual characters from handwritten Arabic

texts, enhancing readability for users. To train the application on handwritten Arabic characters, the Arabic Handwritten Characters Dataset (AHCD) and the Hijja dataset were employed. The chosen approach involves exploring various convolutional neural network (CNN) training models, assessing dataset compatibility, and optimizing accuracy. TensorFlow was selected as the preferred model for its accuracy and effectiveness in recognizing individual characters as separate entities. Future steps involve implementing TensorFlow training into an accessible OCR learning tool, offering a dynamic style of learning for recognizing individual letters from word compositions. Beyond language learning, the tool's capabilities can extend to diverse applications. For instance, it could be employed in product design to automatically break down 3D objects into exploded 2D views, potentially streamlining the design process, offering benefits to design professionals and contributing to broader educational initiatives. The project signifies a step towards unlocking the versatile potential of OCR beyond its traditional applications.

Abstract Name: Navigating High-Dimensional Data for Stable Cognitive State Modeling in Human-Autonomy Teams

Developing autonomous systems that can predict the cognitive state of their human ‘teammate(s)’ is important for facilitating effective human-autonomy teaming in many settings, such as on deep space missions. Predictive models can use physiological features derived from electrocardiogram, respiration, electrodermal activity, and eye-tracking data to predict an individual’s trust, workload, and situation awareness (TWSA). A core challenge of using physiological signals to monitor cognitive states is that the large number of candidate features able to be derived from these signals results in high-dimensional data. Current methods of down-selecting features often result in overfit models or unstable feature sets. Alternative dimensionality reduction methods must be analyzed to define physiological-based model-building processes that achieve both stability and high predictive performance. This research compares a variety of dimensionality reduction approaches, including both supervised and unsupervised methods, which include or exclude the desired TWSA variable in their reduction processes. Physiological data was collected from 10 participants while they completed a habitat monitoring task. Each participant completed 15 trials, yielding a total of 150 observations. Physiological features were extracted from the data collected during the task. Comparisons are made regarding the predictive accuracy and stability of the feature sets selected by stepwise, principal component analysis, partial least squares, and LASSO methods. Strong internal validation is performed through bootstrapping. Identifying dimensionality reduction methods that are both stable and yield predictive accuracy is critical to providing consistent, useful solutions when working with high-dimensional data. This work can also be expanded to analyze different types of datasets across other fields, as different combinations of dimensionality reduction algorithms may achieve better performance for other datasets.

Abstract Name: Is Stout A Food Desert?

This study examines the connection between food accessibility, transportation, and student perceptions at the University of Wisconsin-Stout to determine if it qualifies as a food desert. Using a mixed-methods approach, including a survey and an interview with a local food pantry manager, the study explores housing arrangements and transportation modes as independent variables and perceived abundance of food deserts, food pricing, and student satisfaction with fruits and vegetables as dependent variables. The hypothesis is the belief of Stout is a food desert because of the on-campus stores selection of food is moderately nutritious is severely lacking in options. Contrary to the initial hypothesis, the results reveal no statistically significant evidence supporting the anticipated links. The findings underscore the complexity of factors influencing food accessibility, pricing, and satisfaction, challenging the simplicity of the basic hypothesis. While the study does not provide evidence to classify Stout as a food desert based on on-campus food options, it emphasizes the need for continued research and refined methodologies to understand students' nutritional landscapes and suggests exploring interventions and policies to address the identified complexities.

Abstract Name: Biological Evaluation of Novel Tubulin Inhibitors for Treatment of Cancer

Cancer is a leading cause of death worldwide. Cancer cells are defined by uncontrolled and abnormal cell division. Therefore, inhibiting cancer cell division is a validated anti-cancer approach clinically. Both cell structure and cell division depend on active microtubule dynamics, which is a process in which alpha and beta subunits of tubulin polymerize and depolymerize. Small molecule tubulin inhibitors are used in chemotherapy cocktails to treat various cancers, however current tubulin inhibitors are toxic and cancer cell resistance can occur. To overcome these issues, we have been part of a research project to discover novel tubulin inhibitors that target the colchicine binding site on the beta subunit. Paneling of these novel small molecules that are potential tubulin inhibitors reveals that out of those tested, two compounds show the potential to inhibit tubulin polymerization directly and cause effects consistent with tubulin inhibition in cancer cell lines. The data from this research will help to understand which chemical structures function best to impair microtubule dynamics. Design and testing tubulin inhibitors like these may be able to overcome issues with those currently in the clinic and ultimately could be developed to aid patients in their fight against cancer.

Abstract Name: Three-State Donor-Acceptor Biaryl Lactone Molecular Switches with Enhanced Solubility

Our research is focused on the synthesis of a bridged biphenyl molecule with an amino donor and tetraethylene glycol solubilizing groups (TEG). This three-state biphenyl molecule, due to its chemical properties, will find applications as nanoscale fluorescent sensors and molecular mechanical devices. Biphenyl molecules have known dihedral angles, leading to differing optical and conducting properties when manipulated. Utilizing a lactone-bridge, we can force the molecule into and out of planarity. At low pH, the molecule takes a planar conformation (“ON”), while at high pH it's non-planar (“OFF”). Previous research has shown similar two-state molecules’ effectiveness at readily switching conformations when exposed to different chemical environments. Prior research combined cyano and nitro acceptors with differing amino donors within biphenyl molecules to enhance optical properties and pH sensitivity. This pH sensitivity will be more precise with the addition of a third “OFF” state. At low pH, the amino group should become protonated, leading to the second “OFF” state and giving a narrow “ON” state. The “ON” state results in visible color differences from the “OFF” states of the molecule. These characteristics improve the usefulness of these molecules as pH sensors. Our research aims to synthesize a biphenyl molecule with a cyano acceptor, and TEGs. Prior research shows nitrile fluoresces better than its nitro counterpart. Long TEGs will increase the solubility of the molecule, enhancing the practicality of the planar biphenyl molecule as a dye. We have successfully synthesized one of our target molecules, a benzene ring with an iodine and a para-TEG group. We will be continuing our work to synthesize a three-state donor-acceptor biaryl lactone molecular switch with a cyano acceptor and TEGs, enhancing solubility and fluorescence.

Abstract Name: Impact of Personal Narrative on Victim Empathy

Throughout the United States, Asian Americans face many struggles, including discrimination, stereotypes, and violence. The current study was conducted to assess the impact of hearing a personal narrative on readers’ empathy for hate crimes against Asian Americans. Previous literature does not address how responses to hearing stories may differ based on gender. Thus, 27 Asian Americans were studied through a convenience sample, 12 of which were men and 15 of which were women, to see if gender also played a role in empathy. Random assignment was used to expose half of the participants to a personal narrative. The personal narrative described each researcher’s empathy for the hate crime victims. Data analysis revealed no interaction between gender and personal narrative. Asian American women exposed to the personal narrative did not have different empathy ratings compared to the women who were not exposed to the narrative. Asian American men had decreased empathy scores when exposed to the personal narrative versus those not exposed. However, women reported statistically higher empathy than men in the study for both experimental and control conditions.

Abstract Name: Digital Display and the Evolution of the Icon

The personal computer has changed the way that we live our daily lives, though it is an invention we have come to take for granted. This paper explores the way that the personal computer came to be something that is accessible to people from all walks of life and intuitive enough that people can instantly navigate and decipher tools from each other. The design of the interface of the personal computer is intentional down to each and every pixel. People like Susan Kare played a massive role in converting what we knew about icons into their digital equivalent, forging a new way to interact with the digital interface. The adaptation of icons into the digital world has played a pivotal role in creating an inclusive and cohesive space stitched together with intentional design. Icons now play a massive role in our understanding of user interface and experience design, connecting people around the world by limiting language barriers.

Abstract Name: Disconnection of Hindu Symbology & Culture From Its Origin Due to Cultural Appropriation

Due to the vast amount of information at the fingertips of the world the responsibility to do research and use cultures iconography respectfully grows. We know there have been cases of cultural appropriation leading to defamation of certain people and symbols in the past, but it goes much deeper than just those that make it to the news over lawsuits. The world is slowly becoming desensitized to its rich history of culture and storytelling as ancient symbols become nothing more than marketing material and product branding. The people (art directors, designers, business owners, etc.) in charge of these situations whether that be in marketing, movie-making, graphic design, book-writing, or otherwise, now have to be conscious of the pains they inflict on cultures when they use imagery that has such deep roots. While Coca-Cola using the swastika lovingly in an ad campaign may not have directly led to the Nazi Regime picking it up as their emblem, the actions that we take as a world culture have consequences, unseen, that may ripple throughout the foreseeable future. While the swastika may already be banned in many countries, we have a duty to do due diligence to make sure that this doesn't continue to disconnect ancient cultures any further from their origins than they already have been.

Abstract Name: The CIA's Dark Arts: The Strategy of Tension and Stay-Behind Units

The United States has a long and storied history of cooperation with bad actors with the goal of "sowing Democracy," "protecting national security interests," and "thwarting the rise of authoritarian governments." Through the recruitment of Nazi veterans, the Italian Mafia (La Cosa Nostra), neo-fascists, and the Roman Catholic Church, the CIA has been able to orchestrate key events globally in the war against communism launched just after World War II. Due to the threat of its Communist Party and its strategic location adjacent to the Iron Curtain, Italy was ground zero for the collaboration of all these forces, through the creation of stay-behind units, rampant rigging of elections, and a number of false flag operations all meant to keep the Italian Communist Party from ever taking power. Major funding for these endeavors came from the smuggling of heroin into American jazz clubs, a practice that became a primary funding blueprint for future CIA-trained "freedom fighters" supporting American national interests.

Abstract Name: Evaluating the Impacts of 6-gingerol on the Metabolic Activity of HCT-116 and DLD-1 Colon Cancer Cell Lines

About one third of Americans are diagnosed with some type of cancer in their lifetime. Numerous studies are looking into anti-inflammatory natural therapies that inhibit the growth of different cancers to make treatments affordable, safer, and more accessible. The purpose of this study is to see if ginger can be used as a natural therapy in colon cancer treatment and how different concentrations of ginger affect the metabolic activity of colon cancer cells. In this study, I investigated the effects of 6-gingerol, a pungent compound in ginger, on the HCT-116 and DLD-1 colon cancer cell lines. Previous scholarship has looked into the relationship between 6-gingerol and colon cancer cell lines using different compounds for testing cell activity. These studies have also looked more specifically into the mechanisms involved in the inhibition of cancer cell growth. In this study, the cancer cell lines were treated in vitro with differing concentrations of 6-gingerol to examine if there is a connection between 6-gingerol concentration and the inhibition of cancer cell metabolic function using an MTT assay. Healthy cells metabolize MTT, a yellow compound, to formazan, a purple compound. The light absorbance of these colored compounds can be measured spectrophotometrically which can then be interpreted to see the change in metabolic activity of the cancer cells. In this in vitro study, we found that 6-gingerol inhibits most of the metabolic activity of both HCT-116 cell lines and DLD-1 cell lines at concentrations of 600μM to 800μM of 6-gingerol. These findings show that 6-gingerol has an impact in decreasing the activity of colon cancer cells.

Abstract Name: The Role of pH Preference in Shaping Soil Microbial Communities: A Study on an Abundant Soil Bacteria

Microorganisms are fundamental for ecosystem processes like carbon and nutrient cycling in soil. Environmental changes affect the composition of soil microbial communities and thereby, their contributions to ecosystem processes. However, it still remains difficult to predict which soil microorganisms will respond to environmental changes. A plausible solution is to understand how traits contribute to their community composition and functioning. By analyzing the traits and phylogeny of Curtobacterium strains, an abundant soil bacterium, we can gain insight into how environmental change affects soil microbial composition. It has been shown that soil pH is a main driver of community composition, therefore pH preference is a relevant trait to understand community responses. We isolated 271 Curtobacterium strains by collecting grass or dominant flora litter at 24 different locations managed by the University of California Natural Reserve System. We identified Curtobacterium strains by genomic sequencing and classified them into clades and subclades on a phylogenetic tree. To test for pH preference, we performed growth curves with selected strains representing all the clades in the phylogeny. Strains were grown in minimal media with pH ranges from 3.2 to 10.1 in 0.3 increments. We calculated the maximum growth rate at each pH level to obtain a pH performance curve. We then performed mantel correlation tests between phenotypic distance (pH performance) and genetic distance to assess whether phylogenetic similarity can predict the pH performance of the strains. Our results show an overall correlation of ($r = 0.24$,$p < 0.05$) and this correlation is higher when comparing very closely related strains ($r = 0.44$, $p < 0.05$). Overall our results suggest that pH performance is a trait that is conserved at the clade level.

Abstract Name: Intertidal Temperature Variation and Mussel Physiology

Mussels of the genus Mytilus are biological engineers, creating mussel beds in intertidal habitats that increase biodiversity. Mussels experience daily tidal fluctuations that expose them to abiotic stressors (heat, changes in salinity) and their tolerance to stress can inform us regarding ecosystem health. However, climate change (CC) is predicted to increase seawater temperature and decrease salinity, which may have detrimental effects on coastal marine animals, like mussels. Therefore, the goal of our study was to determine field thermal and salinity conditions experienced by mussels at various sites and use these data to collaboratively develop a laboratory heat ramping device that exposes mussels to simulated stress allowing us to study the effect of CC on mussel physiology. We deployed temperature and conductivity loggers at four sites (Ballona Creek, Marina del Rey, Pacific Palisades, Malibu) in Los Angeles County at three intertidal heights (high, mid, low) and within tide pools in August 2023. Loggers continuously collected data every 15-30 min and logger data was offloaded every few weeks. We found that minimum and mean seawater temperatures were similar across all sites but maximum temperature and standard deviation varied by site. The highest temperature

recorded (32.15ºC) was measured during a mid-day low tide. Salinity within Ballona Creek had the greatest variation compared to Marina del Rey, with the lowest salinity recorded being 0 ppt and the highest at 37 ppt. Thus, our study shows that there are microhabitat variations in abiotic conditions within the sites we surveyed. Our study identified changes in environmental conditions experienced by mussels at various sites that we will use as experimental parameters in the development of our mussel heat ramping device.

Abstract Name: Exploration of Reluctance to Speak about Controversial Topics on a Small College Campus

Controversial topics are important parts of discussion in many college classrooms, and due to the nature of these topics, students may feel reluctant to speak freely about them. Today, students feel polarized as a reflection of the world outside academic settings. This study aims to explore whether students at a small college follow the national trend of being reluctant to speak about controversial topics and, if so, what factors may influence their reluctance. The Campus Expression Survey is a nationally distributed survey that asks students if they are reluctant to speak about five controversial topics. The sample consists of 233 UMR undergraduate students. We hypothesize that students who are reluctant to speak about controversial topics are more concerned that peers will criticize their views as offensive than they are that their professors will criticize them. A McNemar's Chi-Square test was used to analyze the results of the survey to determine if students were more concerned about criticisms from their peers or criticisms from their professors. The results indicate that students were more concerned about their peers than about their professors. This may be due to the likelihood that peers influence behavior more than professors and how social media affects in-person behaviors. We also used a t-test to examine whether the amount of topics students are reluctant to speak about affects their GPA, and found that the average GPA of students who are reluctant about a moderate number of topics is higher than those reluctant about an extreme number. These results may highlight areas in classroom structure that may be targets for attempting to decrease reluctance to speak.

Abstract Name: Generation and characterization of feline macrophage cell lines to identify host factors that promote lethal outcomes from feline coronavirus.

Feline Coronavirus infects epithelial cells of the intestine as feline enteric coronavirus (FECV), leading to mild symptoms. During infection the virus can switch target cells and infect macrophages as feline infectious peritonitis virus (FIPV), causing a systemic and often lethal disease. The factors responsible for conversion from FECV to FIPV are not well understood. In domestic cats the switch from FECV to FIPV occurs in 5-10% of cases, whereas exposure of cheetahs to FCoV at U.S. Zoos resulted in 90% exhibiting symptoms of FIPV. While domestic cats are genetically diverse, cheetahs lack genetic diversity. We aim to investigate the increased rate of FECV to FIPV conversion in cheetahs compared to domestic cats. However, tools to study FCoV infection in vitro are lacking, with just one feline macrophage cell line available from the American Tissue Culture Collection (ATCC). We generated a new domestic feline macrophage cell line, termed FMAC, using single integration lentivirus to integrate an immortalizing gene into isolated primary macrophages. Here we show this cell line is easy to propagate, displays macrophage characteristics, and is susceptible to infection with FIPV isolate of FCoV. While infection of FMAC with FIPV results in little cytopathic effect, infectious virus is produced. We are currently analyzing infection of FMAC with FECV isolate of FCoV. Next we intend to isolate RNA for RNA-seq transcriptome analysis to compare host antiviral gene expression in response to FIPV and FECV in FMAC and a feline kidney epithelial cell line, CRFK (from ATCC). Our laboratory aims to generate additional domestic feline macrophage cell lines and at least one cheetah macrophage cell line to identify host genetic factors that correlate with differences in FCoV replication. We will deposit FMAC and any additional cell lines generated with ATCC to allow researchers access and advance studies of feline pathogens.

Abstract Name: Queer Gender and Sexuality Versus Traditional Systems of Power in Popular Anime Series

How does fluid gender and sexuality in Ouran High School Host Club challenge or affirm traditional power structures? Since its emergence in the late 20th century, anime, or Japanese animation, has grown in increasing global popularity, with strong ties to consumerism and fan culture. Our work integrates television studies, animation studies, anime studies, and queer studies to examine the popular television series, Ouran High School Host Club. Using existing literature on Japanese culture, particularly the club and educational system, as well as queer concepts such as Camp and queer temporality, we offer a close textual analysis of several episodes of Ouran High School Host Club. In our work, we evaluate the formal elements of animation as well as common anime motifs in order to highlight genre and medium specific conventions. Our paper examines how the host club space constructs queerness by obscuring heterosexuality and gender conformance through costume and a play with sensuality and eroticism. We focus on sequences where outside characters, who conform to the traditional power structures, interact with the queer space of the host club. Through this assessment, we observe how the club either transforms or defeats its critics. We also note how the characters use the host club space to help others, and themselves. Through the adaptive functionality of the club space, the club members resist the pressures to grow up and integrate into more rigid cultural structures. Through our examination of the conflict between queerness and the systems of power in Ouran High School Host Club, we indicate further questions for analyzing other anime works.

Abstract Name: Role of L-2-hydroxyglutarate (L-2HG) in t(4;14) positive myeloma

Although an oncometabolite D-2-hydroxyglutarate (D-2HG) produced by isocitrate dehydrogenase (IDH) mutants has been extensively studied in cancer, the role of its enantiomer L-2HG remains elusive. Our previous untargeted metabolomics study of bone marrow supernatants from patients with monoclonal gammopathy of undetermined significance (MGUS), which is a pre-malignant condition, and multiple myeloma (MM) identified 2HG as a biomarker of myeloma disease progression. However, it remains unclear how 2HG contributes to myeloma progression. Here we show that oncogenic constitutively active fibroblast growth factor receptor 3 (FGFR3) directly phosphorylates LDHA at Y10, which activates its non-canonical activity to produce L-2HG. We also found that the FGFR kinase inhibitor TKI258 (Dovitinib) decreased LDHA Y 10 phosphorylation, LDHA levels, L-2HG levels, and proliferation of t(4;14) positive myeloma (t(4;14)+) cells, in which FGFR3 is overactivated. Interestingly, TKI258-induced defects in myeloma cell proliferation were rescued by octyl-L-2HG and LDHA knockout decreased L-2HG levels and proliferation of t(4;14)+ cells. Thus, our data strongly supports a model in which increased L-2HG production from LDHA might increase myeloma growth in the presence of overactivated FGFR3 signaling. I recently found a novel LDHA mutant that selectively inhibits the canonical LDHA activity while activating the non-canonical activity. By using this mutant, we will address the hypothesis that LDHA Y10 phosphorylation coordinates the canonical and non-canonical activity of LDHA, thereby regulating t(4;14)+ myeloma growth.

Abstract Name: Practitioners' Experiences Delivering Social Services for Latinx Families

Introduction. Children grow and develop, with people, and communities being their most significant influences (Hayes et al., 2023). Studies show that responsibility for the care and education of children are divided between family and early childhood education settings (Sadownik and Jevtić, 2023). However, there is limited research on practitioners' experiences serving Latinx families. Using Bronfenbrenner's Ecological Model, this study explores: 1) What supports practitioners need to better address Latinx parents' concerns and challenges through programs and services? 2) What are practitioners doing to culturally align services for Latinx families? Participants & Methods. 37 interviews were conducted in English & Spanish with practitioners. Practitioners included teachers, administrators, community liaisons,program coordinators, and community-based organizations. The interviews lasted 30 minutes to an hour. Audio recordings of the interviews were transcribed in their original language and will be coded in Nvivo. Findings. Preliminary findings indicate that practitioners thought multiple programs were working well for families. For practitioners to be able to effectively provide these services, they needed resources such as additional staff, funding, space, and more outreach events to connect with the community. Additionally, practitioners attempted to culturally align social services with Latinx families by offering English learning classes for

parents to facilitate navigating services, and surveys to understand parents' cultural background. Discussion. Findings suggest that to provide adequate support for Latinx families, we need to explore further how to best support that practitioners for them to effectively guide Latinx families in accessing resources to support their children's learning.

Abstract Name: Assessing the Sublethal Impact of Glyphosate on Culex quinquefasciatus: Insights into Larval Development, Adult Emergence, and Oviposition Behavior

Glyphosate, a widely used herbicide, has been a subject of increasing concern due to its potential environmental impact. This study investigated the effects of glyphosate exposure on the developmental stages of Culex quinquefasciatus, a mosquito species of public health significance. Two distinct larval groups were employed, with one serving as the control exposed to tap water and the other as the treatment group, exposed to glyphosate solutions at concentrations of 0.1 and 1 mg/l. Daily data collection commenced from hatching to adult emergence, with a focus on larval and pupal development, adult emergence rate, adult morphometrics, e.g., wingspan and body length, oviposition rate and the egg viability. Statistical analyses revealed significant differences in larval and pupal counts between treatment and control groups, particularly on days 8 and 9, suggesting a critical impact of glyphosate on larval development during this period. Adult emergence showed no significant differences, but morphometric analysis indicated a reduction in adult size with an increase in glyphosate concentration. Oviposition and egg viability experiments displayed no significant differences. The triple-choice assay demonstrated no preference in oviposition medium selection. Overall, this study provides valuable insights into the sublethal effects of glyphosate on Culex quinquefasciatus, contributing to our understanding of the potential ecological consequences of glyphosate exposure on mosquito populations.

Abstract Name: Social Life Cycle Assessment of Strawberry Production in California

California is the leading state of strawberry production, producing 90% of the U.S. strawberries. Harvesting

and processing of strawberries is highly labor intensive. With the ongoing effects of climate change in California, strawberry production will be more challenging. In order to keep up with strawberry demand, there has been the development of agriculture technology implementation. The primary goal of this research is to assess the social, positive and negative, impacts of strawberry production in California. California produces a diverse set of crops, making up a large percentage of the nation's food supply. Many underserved communities and laborers also reside and work in California's agricultural areas. We will utilize the Social Life Cycle Assessment methodology for workers and the three sub-categories of: Health and Safety, Fair Salary, and Working Hours. Under health and safety, we investigated the possible chemical exposures, such as Azoxystrobin and 1,3-Dichloropropene, and required personal protective equipment to assess health impacts. Further, we used CalOSHA and Workers' Compensation Insurance Rating Bureau data to evaluate the reported injuries. Workers' Compensation Insurance Rating Bureau was also specifically used to extract compensation rates. Higher impacts for health and safety were found in the planting and harvesting stages compared to packaging. Not all data was available by stage of strawberry production, and a more in-depth survey needs to be conducted. We have conducted two field visits to five strawberry producers to collect more information for the re-planting and harvest stages. Assessing strawberry production from cradle to gate, will allow us to thoroughly evaluate the social impacts to create collaborative solutions and sustainable practices such as mechanization.

Abstract Name: QUdar The Future Of Baseball Analytics

Baseball is one of the most popular sports across the entire world, with this being the case there are many different forms of analytics that are involved to constantly evolve the game. One of these metrics is velocity or how hard a player is throwing. This is currently measured by a device called a radar gun that is pointed at the ball to read the velocity. These guns are often very expensive and fragile and have little to no other reliable options. This is why we created QUdar, an application for iPhone that can read the velocity of a ball just by using the camera of the phone in order to fill this void. We used Unity in order to accomplish this task by making a program that breaks down a video frame by frame and uses Artificial Intelligence (AI) Technology in order to read the velocity of the ball. Along with making the program to read the velocity we have also made the application user-friendly and displayed the results in a way that would be helpful for a coach or a player. Our poster shows some of the process of application and also shows why our application is more feasible than using and buying an actual radar gun.

Abstract Name: Investigating colorectal cancer tumor heterogeneity and crosstalk within a vascularized niche

Colorectal cancer (CRC) is one of the most common and aggressive gastrointestinal tract malignancies and has the second-highest mortality rate across all cancers. Understanding tumor and microenvironment cell-cell communication is pivotal to comprehending tumor progression. Previously, the Hughes Lab developed a three-dimensional vascularized micro-tumor (VMT) recapitulating the complex human tumor microenvironment by including perfused vasculature, cancer cell lines, and stroma within a transparent organ-on-a-chip microfluidic device. By conducting scRNA sequencing on control microfluidic devices and two CRC VMTs using the TP53 and KRAS mutant SW480 and the KRAS mutant metastatic HCT116, we hypothesized that tumor heterogeneity alters cell-cell communication, driving tumor progression. We robustly integrated the dataset through numerous techniques, such as scMC, Seurat V3, and Harmony, to confirm changes in cell populations induced by the tumor and to characterize tumor heterogeneity. In doing so, we identified a unique tumor population. To identify specific ligand-receptor interactions unique to the VMTs, cell-cell communication was performed. Analysis revealed signaling from the tumor to the fibroblasts via receptors CD44/CD74. Additionally, intratumor signaling showed upregulation of Wnt and FGF signaling pathways through FGF2/18-FGFR1/4. Importantly, these pathways aid in cancer metastasis, immune evasion and growth. As 90% of the anticancer drugs developed fail to get FDA approval despite showcasing promising preclinical results, this data may bring light to understanding cancer heterogeneity in-depth and aid with the future development of immunotherapies and drug screening to reduce mortality rate.

Abstract Name: It’s Not All in Your Head: The Autonomic Nervous System’s Effect on Dance Performance

The autonomic nervous system is a section of the peripheral nervous system that controls the internal organs and involuntary bodily functions. The autonomic nervous system activates the “fight or flight” response within the body which can have adverse effects on performance and works to return the body to a state of homeostasis after responding to stressful stimuli. Any stressful situation that the body detects as a threat can trigger the autonomic nervous system, including fears surrounding embarrassment, social rejection, or occupational failure. This fear is often enough to trigger the autonomic nervous system and negatively affect performance, especially in dancers. The autonomic nervous system can drastically affect dancers on performance day through a multitude of physical symptoms due to the immense amount of stress and pressure dancers place on themselves during performances. While the autonomic nervous system can present symptoms that make performance difficult, with the right tools and techniques, dancers can view performances in a positive manner to lessen their symptoms on performance day. This research was supported by articles surrounding behavioral neuroscience, sports psychology, and dance science with sources including An Introduction to Brain and Behavior by Bryan Kolb and Ian Q. Whishaw.

Abstract Name: “The Real Dorian”: Oscar Wilde’s The Picture of Dorian Gray and Social Networking Culture Today

Social networking sites (SNS) today allow people to suspend and edit their world at the click of a finger. The images we create and alter become a form of autobiography—a life story in which we aim to present ourselves in a particular light that eventually becomes our identity within society. Every period in history has certain physical characteristics that are mutually understood to signify specific personality traits. In the Victorian period, this was true in life as well as in literature. The line between life and literature is a border that Oscar Wilde masterfully blurs in his timeless depiction of human behavior in The Picture of Dorian Gray as he creates the world of Dorian Gray—a world of influencers and the influenced. My project is a literary analysis in which I juxtapose Wilde’s novel The Picture of Dorian Gray with today’s social networking culture through a contemporary lens of social comparison theory and cognitive dissonance to demonstrate the Victorian novel’s timeless themes of influence, image, and perception. In my project, I engage with previous scholarship addressing the Victorian Era, the history of portraiture, doubles in literature, life writing on SNS, and recent studies on social comparison and cognitive dissonance as they relate to SNS. I conclude that Wilde’s novel is still relevant today because his attention to human behavior correlates with the danger of losing oneself in our culture of fast-changing trends and glorified, manipulated life images.

Abstract Name: Setting Up and Using Electroporation to Knock Out Genes to Investigate Neural Crest Cell Migration

Neural crest cells are an embryonic stem cell population in vertebrates. They form in the neural tube but migrate during early stages of development and differentiate to form several different parts of the organism. Some of the derivatives of neural crest cells include skin pigment cells, craniofacial bone and cartilage, and the vast majority of the peripheral nervous system. Disruptions in neural crest development can result in birth defects like cleft lip and palate, neurofibromatosis, and familial dysautonomia. However, the mechanisms of neural crest formation and migration have not been fully described. In previous research, Dr. Jacques-Fricke identified 674 genes that could be potential regulators of neural crest cell development. Previous student researchers have described the expression patterns of candidate genes across neural crest development, however, this analysis has not determined functional relevance. My research was to establish a functioning electroporation system that allows us to knock out genes to examine their function in neural crest cell migration. Electroporation works by injecting a chemical underneath an embryo and then using electricity to drive the chemical into the embryo. In our lab, we inject morpholinos, which are an antisense method of blocking specific gene expression. Unilateral injection of a morpholino, followed by reincubation, allows for a side by side comparison of neural crest development between control and knockdown conditions. The morpholinos that we use have a FITC tag, which allows visualization of morpholino targeting with fluorescence microscopy. I was able to detect effective electroporation, with FITC fluorescence appearing in the electroporated embryos. Future work will optimize targeting of morpholinos to areas of interest within the embryos. Because we can now electroporate and examine gene function in neural crest development, this

could lead to the identification of new targets for preventative measures for developmental disorders caused by aberrant neural crest cell migration.

Abstract Name: Using Natural Observation to Indicate Generalization of Social Skills in Children with Autism Through a Web Program

Developing social skills in school-aged children with cognitive disabilities is critical to classroom learning, forming peer relationships, and independence in adolescence and adulthood. This study is a continuation of research examining the efficiency of We Are Friends, an app designed to increase social skills in children who struggle behaviorally and emotionally. Results from the previous study showed that skills were greatly improved in participants when the program was used in conjunction with ongoing classroom instruction as opposed to the control group that received no intervention. However, the original results did not reflect whether targeted social skills were generalized outside contrived settings. The current study aims to expound on this to determine whether skill acquisition from the use of the program will generalize to unstructured settings, as well as if peer socialization will positively affect social skills in non-participant groups. Participants are 1st to 4th-grade students with cognitive disabilities. Natural observations of participants were conducted at outdoor recess to gather frequency data on specific social skills. This data is composited to determine whether participants improved socially after intervention compared to baseline. Results show that We Are Friends is effective in social skill acquisition and generalization among participants. These findings suggest that state educational systems should support and implement the program as an aid for teachers for the lasting impact it has on children who experience social impairments. Future research should be conducted to determine whether the program will generalize these skills outside of school to home and community settings.

Abstract Name: Examining America's Socio-Spatial Problem by Comparing Oakland County with North Holland

This paper argues that America’s reliance on automobiles hinders mobility for all Americans. Census data from 2013 stated that 76.4% of Americans commuted to work alone by car. Aside from select metropolitan cities where public transit has long been established, Americans need a car to get around their environment. Sociological research details the distinct way that cars have implemented themselves into American society. Unlike countries that embrace public transportation, America’s system of car dependency isolates individuals,

convincing them that privacy outweighs the drawbacks that cars have to societal arrangement. Furthermore, it decreases social acceptance and physical space for transportation alternatives, like bicycles. This paper will compare Oakland County, Michigan to the Dutch province of North Holland. The two regions are similar in their geographic size and population but have contrasting perspectives of how mobility functions in society. Oakland County plays a vital role in the Detroit auto industry, while North Holland and its largest city, Amsterdam, are beacons of bicycle accessibility. This paper will assess how the two regions utilize space, specifically space for mobility, and how it impacts their respective social environments. Expected results from this investigation will show that the Dutch system allows more space for society to thrive and humans to interact, while the American system spreads individuals from their desired destinations and limits interactions. Although many Americans need their car to get around, an analysis into Dutch mobility will highlight that individuals do not need a car, if space for bicycles are provided. If bicycles are viable in a region like Oakland County, they are also viable in other regions across the United States. where they are currently not prevalent.

Abstract Name: Using Surfactants on Microbially Induced Calcium Carbonate Precipitation to Promote Uniform Precipitation in Shale Fractures

Hydraulic fracturing is commonly used to crack impermeable shale reservoirs hundreds of meters below the ground to extract natural gas. Once the commercial gas production ends, the cracks in the subsurface may start to leak remaining greenhouse gases into the atmosphere. Microbially induced calcium carbonate precipitation (MICP) can be applied in this situation as a biological cement and is preferred over cement due to its low initial viscosity and ability to penetrate small cracks. Hydrocarbons trapped within the shale matrix is hydrophobic and may inhibit attachment of microbes to the shale during the MICP process. Sporocarcina pasteurii is commonly used for MICP, due to its ability to produce urease, a catalyst for urea hydrolysis. Using this process in the presence of urea and calcium, calcium carbonate precipitates. Addition of surfactants in shale microbe injection have previously been found to decrease the wettability contact angle of the shale, which also reduces the hydrophobicity. This study aims to use surfactants in the MICP process to promote uniform precipitation of calcium carbonate in shale fractures. Kinetic growth studies have been performed with S. pasteurii in the presence of surfactants including Tween-80, Cocamidopropyl betaine, Sodium dodecyl sulfate, Triton x-100 and Rhamnolipid. These studies revealed that all surfactants tested except Tween-80 and Rhamnolipid inhibit the growth of S. pasteurii. A flow through experiment in three shale columns will be performed next. In each column, S. pasteurii with either Tween-80, Rhamnolipid or no surfactant will be injected into the column at 1 mL/min along with urea and calcium. NMR imaging will be used periodically during the flow-through experiment to measure the total pore space in each of the columns. It is expected that cores in the presence of surfactant will seal both faster and more uniformly than the core without surfactants.

Abstract Name: Econ vs Eco - Analyzing Public Perspectives on the Interplay Between Economic Development and Environmental Protection

Over the past decade, there has been a noteworthy shift in the landscape of discussions surrounding climate change and pollution. A growing number of Americans are expressing heightened concern about the potential repercussions of human activities on the Earth's ecosystems, particularly in the context of economic pursuits. Interested by the work conducted by Dr. Gene M. Grossman and Dr. Alan B. Krueger in their studies focusing on the environmental impacts of the North American Trade Agreement (NAFTA), and curious about public opinions on the delicate balance between economic development and environmental protection, I conducted a sixteen-question survey created on survey monkey and published on Amazon Mechanical Turk, targeting a broad spectrum of the American populace. Analyzing the data from 200 survey participants using SPSS Statistics cross tabulations unveiled statistically significant correlations between demographics and their responses. Notably, female respondents demonstrated a heightened awareness of their individual impact in the larger-scale economy compared to their male counterparts. Overall, men leaned more towards favoring economic development, seemingly downplaying their individual role in the economy and worrying a lot less about its environmental effects. Turning to age, intriguing generational "gaps" surfaced in favor of environmentally conscious initiatives. Individuals aged 65 and over emerged as the most pro-environment group, standing in sharp contrast to the 18 to 29 and specially the 30 to 64 age groups, who leaned heavily towards favoring economic development. These findings paint a nuanced picture of how personal values, national interests, and societal priorities interact within the American landscape. Such insights prove invaluable for understanding perspectives on macroscale projects and guiding government entities on what the general population considers essential for modern societal progress.

Abstract Name: A Mixed Methods Exploration of the Relationship between Fathers' Physical Play and Infant Motor Skill Development

Recently, fathers have become increasingly involved in parenting decisions and behaviors. These changes have led to extensive research on the importance of fathers in child development, demonstrating that compared to mothers, fathers engage in more hands-on, physically stimulating play with their children, and encourage exploration of the environment. However, it remains unclear when these behaviors begin, and whether fathers shape infant motor development specifically. The current study aims to examine specific beliefs fathers have about infant development with a focus on physical play and stimulation of motor skills.For Study 1, 259 American first-time parents (170 mothers) of infants 1-7 months completed the Parental Beliefs about Motor Development and Infant Motor Habits Questionnaires online (PD-MD and MOHAB). Results revealed many similar parenting beliefs across mothers and fathers, but fathers emphasized stimulating infant’s motor development significantly more than mothers (p=.021), and this was associated with infants spending more time in stimulating positions such as prone (p=.026).To further

investigate fathers' beliefs, Study 2 involved 12 additional first-time fathers of infants 1-10 months who participated in online interviews and completed the PB-MD and MOHAB surveys. Interview questions asked how fathers engaged in physical play and whether they presented motor challenges to their infants. Though the study is ongoing, many fathers described making use of objects or modifying the infant's environment during times of play to induce engagement of specific muscles or body parts (n = 10), as well as fathers using their own body to stimulate infants' grasping, crawling, and more (n = 7). Responses demonstrate that fathers show intentional engagement of even young infants in ways that stimulate motor skill development, but they gauge their interactions based on their child's ability status and around advice they receive from external sources and role models.

Abstract Name: Stefan Sagmeister; Transcending Conventional Boundaries

This paper delves into the creative world and mind of Stefan Sagmeister. Sagmeister has altered the graphic design industry through his work as an influential figure in the realm of visual communication. Stefan Sagmester, a well known Austrian graphic designer, has influenced the creative world with his work for the last 50 years; his intentional decisions, sabbaticals, and attitude towards his work are displayed through the thoughtful process he has explained in many interviews, as well as his own books. Sagmeister's practices set him apart from other designers due to his intentionality in his work. Through a meticulous review of Sagmeister's notable projects, creative processes, and philosophical pinnings, this research aims to unravel the intricacies of his design thought process, as well as the effects his upbringing and personal experiences have on his mindset. The paper starts with a provision of a brief history of Stefan Sagmeister's background, then later elaborates key milestones in his career and the evolution of his distinctive style. Primary sources such as interviews, articles, and Sagmeister's own writings demonstrate his influences and his unique approach to graphic design. Additionally the paper sheds light on how he transcends conventional boundaries to create visually compelling and thought-provoking designs.

Abstract Name: Policing the Campus: University of Utah Student and Faculty Satisfaction with Campus Police

The continuous discourse revolving around policing in America has two sides, one suggesting police do not serve to stop gender-based violence, and another side that argues policing is the only way to adequately address gender-based violence. Using the situation of gender-based violence as either a defense or rejection of police. With the events that have occurred on the University of Utah campus in regard to Lauren

McCluskey, a student who was murdered by her male partner after reporting to campus police, policing on the University of Utah's campus has found "itself in the center of such national debate, amongst a population (college students) that faces high levels of gender-based violence. In this research, we analyze current scholarship on police satisfaction, campus gender-based violence, and police perception differences among racially oppressed people. We created a survey with a line of questioning that allows us insight into the current satisfaction of students and faculty at the University of Utah with their campus police department's handling of violence and crises. We utilized recruitment methods that involved outreach initiatives on the part of administrators from all different departments on campus to collect adequately representative data. Analysis of the survey data will be completed a couple of months following the NCUR 2024 Conference and will use a combination of bivariate and multivariate statistical analysis.

Abstract Name: Investigating the neuronal identity of the preoptic area neurons projecting to the ventral tegmental area affected during the development of depressive-like behaviors

Depression is a common but serious mood disorder that can lead to severe symptoms which influence how a person feels, thinks, and handles daily activities. Recent research has theorized that depression is primarily associated with more complex neuroregulatory systems and neural circuits, which then cause secondary disturbances of neurotransmitter systems. Notably, GABA, an inhibitory neurotransmitter, and glutamate, an excitatory neurotransmitter, have been identified to play a role in the etiology of depression. An imbalance in GABA and glutamate levels have been implicated in depression, where impairments in the GABAergic and glutamatergic systems have played significant roles in depression pathophysiology. Our lab has collected preliminary data on the impact of the preoptic area to ventral tegmental area (POA → VTA) circuit on the development of depressive-like behaviors. We have found that when depressive-like conditions were induced in mice through the social defeat stress (SDS) protocol described by Golden et al., the RABV-labeled POA neurons projecting to the VTA decreased compared to the control and were reversed following a ketamine injection. Now, the question is which POA neurons projecting to the VTA are affected by SDS: excitatory, inhibitory, or both. This project's aim is to determine the neuronal identity of the POA neurons projecting to VTA as GABAergic or glutamatergic using in situ hybridization. Comparison of the percentage of GABAergic and glutamatergic POA neurons between the control and SDS groups will allow us to identify the predominant POA neuronal subtype, which is expected to be glutamatergic, aligning with the excitatory synapse hypothesis of depression from Thompson, et al. Identifying the predominant POA neuronal subtype projecting to the VTA affected during SDS enables targeted modifications of its activity. This, in turn, facilitates a better understanding of its involvement in the onset of depressive-like behaviors and contributes toward potential therapeutic interventions for depression.

Abstract Name: DO BLACK WOMEN DESIRE PREGNANCY?: GENDER RACIAL SOCIALIZATION ON THE RELATIONSHIP BETWEEN STEREOTYPE-CONFIRMATION CONCERN AND PREGNANCY DESIRE AMONG COLLEGE-AGED BLACK WOMEN

Although research concerning racial differences in pregnancy attitudes has concluded that Black women are less positive than White women toward childbearing, few studies have examined possible predictors for why this difference in pregnancy desire exists. Young adult Black women's pregnancy attitudes may be influenced by the gendered-racial stressors Black women encounter in healthcare during pregnancy. Previous literature suggests that when Black women are aware of racial stereotypes prior to interacting with a healthcare official, they experience symptoms related to depression and low self-esteem due to the fear of confirming preconceived stereotypes, known as stereotype confirmation concern. Also, due to gendered racism, Black adolescent girls are socialized in particular ways by their guardians, influencing how they understand their racial and gender identities. Therefore, the current study aims to examine Black women's desire to get pregnant by investigating whether the relationship between stereotype confirmation concern and pregnancy desire is moderated by the gendered racial socialization messages received among young Black women. This research is informed by the reproductive justice framework, which places importance on the sexual and reproductive health and rights of women with marginalized identities. Data will be collected from Black women currently serving as undergraduate students at Spelman College. Participants will complete an online Qualtrics survey after randomly viewing one of three flyers with statistics regarding pregnant Black women. It is hypothesized that there will be a negative relationship between stereotype confirmation concern in healthcare and pregnancy desire, in which more stereotype confirmation concern will lead to the desire to avoid pregnancy. The researcher also hypothesized that gendered-racial socialized messages about sexual behaviors will moderate the relationship between stereotype confirmation concern and pregnancy desire, which will strengthen the relationship. This research may assist in the development of healthcare policies that ensure the proper care of Black women.

Abstract Name: Effects of Brachial Plexus Birth Injury on Muscle Spindle Morphology of Biceps, Supraspinatus, and Subscapularis Muscles

Brachial plexus birth injury (BPBI) is a neuromuscular injury that occurs in 1 out of every 1,000 live births, often causing lifelong shoulder muscle paralysis, reduced range of motion, and musculoskeletal deformities. Deficits depend on severity and location of injury (preganglionic vs. postganglionic), resulting in different effects on functional mobility and neuromusculoskeletal signaling that disrupt muscle and bone development. Muscle spindles are stretch sensory organs located within skeletal muscle responsible for afferent signaling pathways and can be denervated following injury. We hypothesize muscle spindle quantity will be lower in injured limbs and higher in uninjured limbs to overcome limitations in injured-limb muscle function.Sprague Dawley rats underwent surgery on one forelimb at 3-6 days postnatally: preganglionic neurectomy (n=4), postganglionic neurectomy (n=5), forelimb disarticulation (n=7), or sham (n=6). Biceps, supraspinatus, and subscapularis muscles were dissected for injured and uninjured limbs at 2, 3, 4, or 16 weeks post-injury,

snap-frozen, cryosectioned, and stained using hematoxylin and eosin. Muscle sections were imaged, and muscle spindles were counted. Limb comparisons were made using paired t-tests, and group comparisons were performed with Kruskal-Wallis tests (GraphPad Prism, α=0.05).Analyses are ongoing to understand the progression of altered muscle composition following BPBI. Preliminary results at 3 and 4 weeks indicate that muscle spindle quantity tended to decrease over time in the injured biceps and supraspinatus muscles for the postganglionic group (p<0.1). While no significant differences were observed, this could be attributed to the current small sample size. This study is the first to characterize progressive changes to muscle spindles after BPBI injury, which may inform optimal timing for treatments.

Abstract Name: Leveraging Encapsulated Nanoparticle DNA to Advance Tracing Technology

Nanoparticle DNA tracers are a new technology that we are working to characterize as a useful tool designed to replace the use of chemical tracers in the oil and gas industries. The current chemical tracers, fluorobenzoic acids (FBAs), demonstrate many limitations that reduce the accuracy of data obtained from fields while also bringing into question their cost-effectiveness and impact on the environment. These new tracers are composed of several DNA strands bound to an iron oxide bead within a silica capsule. The iron bead allows the tracer to be removed from the environment with a powerful magnet, and the silica capsule enables the tracer to withstand high temperatures and pressures and prevents the DNA from interacting with underground rock formations. After the tracer is recovered, quantitative polymerase chain reaction (qPCR) is utilized to determine the identity of the tracer. Unlike FBAs, the tracers can be designed as either hydrophilic or hydrophobic, allowing them to trace either oil or water. Also, the base pairs in the DNA strand can be rearranged to create an essentially unlimited number of unique tracers. These factors increase the accuracy of data obtained from the field, which provides insight into the location of underground resources and the productivity of current wells. This data can prevent unnecessary drilling and lead to the closure of unproductive wells, saving vast amounts of water and electricity. In addition, DNA tracers are more cost-effective than FBAs since they can be synthesized rapidly. Current efforts are focusing on ensuring the accuracy of tracer detection and synthesizing new tracers. Overall, nanoparticle DNA tracing technology is an efficient, reliable, and environmentally friendly alternative to the traditional tracers used in the oil and gas industries, and it has a wide variety of potential applications including tracing microbes for infectious diseases, environmental tracing, and leak tracing.

Abstract Name: Localizing the neurons that regulate sleep-deficiencies in Angelman Syndrome mouse brains

Sleep is regulated by both homeostatic and circadian mechanisms. The neuronal mechanisms responsible for sleep homeostasis have yet to be identified. Previously, we demonstrated that removing the maternal Ube3a allele alters sleep homeostasis. The maternal deletion of Ube3a causes Angelman Syndrome phenotypes in mice. To determine the neuronal population responsible for Ube3a action, we conducted genetic screening using conditional knockout of Ube3a and identified neuronal subtypes within the mouse brain that appear to be responsible for sleep homeostasis. Through this screen, we identified a neuronal subtype that expresses the vesicular inhibitory amino acid transporter (VIAAT), a protein that is commonly used to identify GABAergic neurons. Additionally, this neuronal subtype does not express GABA-synthesizing enzymes GAD65/67 and does not uptake glutamate (GABA precursor) or glycine. Thus, Ube3a functions in a small subset of potentially GABAergic neurons to regulate sleep homeostasis. The location of this neuronal subtype is not known, and the goal of the present study is to locate this population. We are implementing transgenic mouse models that expressed GFP in VIAAT-expressing cells and mCherry in GAD2-expressing cells to locate the cells of interest via two-photon serial tomography. We have identified the striatum, superior colliculus, inferior colliculus, subiculum, post subiculum, hypothalamus, and hippocampus as potential locations for VIAAT-expressing cells that do not express GAD65/67. Currently, we are investigating the localization of these neurons within the identified brain regions, and we plan to characterize this neuronal population in the Ube3a knockout. Determining the location of these VIAAT-expressing cells has the potential to reveal a brain center responsible for sleep homeostasis and provide insight into mechanisms that underlie sleep regulation.

Abstract Name: Nano-intercalated Bioactive Molecules Modulate Colorectal Cancer Stem Cells- HCT-116

Bioactive molecules derived from plants have the potential to modulate the proliferation of cancer cells. Previous research in our laboratory has shown that curcumin, lutein, capsaicin, and lycopene are effective at modulating the growth of certain cancer cell lines; viz. breast cancer cells (MCF-7), colorectal cancer cells (HCT-116), and prostate cancer cells (PC3 and LnCap) by apoptosis. We hypothesize that phytochemicals intercalated in montmorillonite (MMT) nanoclay will be a more effective nano-delivery system that targets cancer cells and reduce effects on healthy cells. Characterization studies were conducted on curcumin and MMT alone and then intercalted MMT and curcumin, using thin-layer chromatography and fourier transform infrared spectroscopy to confirm intercalation. A release study of the curcumin was performed under different

pH conditions over 24 hours to determine the quantity of the phytochemical released at specific times. The shortest time was observed at pH 3 with a concentration of 14.17 µg/ml after 3 hours for curcumin and the highest was at 6 hours, with a concentration of 17.89 µg/ml. The starting materials alone and the intercalated phytochemicals were then used as a treatment for colorectal cancer cells for 48 or 96 hours, and cell proliferation was assayed using a crystal violet assay. After 96 hours of treatment, a biphasic cancer cell modulatory inhibition effect was observed in the HCT116 cell line by curcumin alone and MMT intercalated curcumin. These findings confirm that edible MMT nanoclay intercalated phytochemicals could be a potential cancer therapy in the field of nanomedicine.

Abstract Name: Identifying Critical Memory-Related Genes through Single-Cell Genomics and Deep Learning Analysis

Immediate-early genes (IEGs) are swiftly transcribed in response to stimuli, crucial for stress responses and gene regulation. Among these, Jun, part of the AP-1 transcription factor with Fos, is linked to memory and plasticity. Jun expression is heterogeneous at a single-cell level in response to stimuli, a phenomenon influenced by gene expression and suppression pre-stimulation. Identifying key genes driving Jun upregulation at the single-cell level can unveil memory formation mechanisms. Single-cell RNA sequencing (scRNA-seq) was employed for its precision in gene expression analysis at the cellular level, in contrast to bulk RNA sequencing.ScRNA-seq data from the mouse hippocampus pre- and post-stimulation with brain-derived neurotrophic factor (BDNF) were collected. Deep learning was applied to unravel complex relationships in high-dimensional data, and gradient class activation mapping (Grad-CAM) helped identify key genes.A deep, fully connected neural network was built, trained to predict changes in Jun expression post-stimulation using the expression of 5000 highly variable genes measured at the single-cell level pre-stimulation. The model achieved ~65 percent accuracy in predicting Jun regulation. Grad-CAM revealed the top 150 key genes governing Jun's heterogeneous expression in response to stimuli. The findings suggest that genes related to neurite growth and neuron morphogenesis are vital for memory formation.

Abstract Name: Electrochemical Desulfurization Of Cysteine Containing Peptides

An electrochemical desulfurization method for cysteine-containing peptides has been established, employing a phosphine reagent. The preliminary investigation of this method was conducted using the Ikea ELectraSyn system. A protected dipeptide was employed as a screening tool to assess the optimal conditions for

electrochemical desulfurization. This protocol necessitates a methodical exploration of alternative phosphine reagents, electrode potentials, and solvents. Additionally, the method versatility will be examined by attempting the desulfurization of various peptide substrates, encompassing both protected and unprotected functional groups

Abstract Name: Insights into the Dynamics of Climate-Induced Heat Wave Events in the United States

Anthropogenic emissions have caused wide-ranging effects on our planet and its inhabitants. It is important to understand the changes our climate will undergo at a local scale so communities can plan and adapt for future impacts as emissions cause warming to become more prevalent around the world. Our study classified heat waves as two or more consecutive days where the average daily temperature reached the 95th percentile of a 30-year historical period. Analyzing the changes in the intensity, duration, and frequency of heat waves across the continental United States under a climate change mitigation scenario (e.g., SSP2-4.5) and assessing corresponding changes in the population exposed to heat waves can significantly deepen our societal understanding of climate change effects within different regions of the country. Our results show that the frequency of heat waves is expected to increase while the intensity and duration of heat waves vary regionally. Regional differences within “Building America Climate Zones” showed duration and intensity increasing in the Cold, Hot-Humid, Marine, Mixed-Humid, and Very Cold zones while staying approximately constant in Hot Dry and Mixed Dry zones, showing that moisture of the zone could impact heat wave trends over time. We investigated the population impacted by heatwaves within the US throughout the 21st century (every decade from 2010 to 2090). An overall increase in the population affected by heatwaves through the first half of the twenty-first century is anticipated. The peak is predicted to occur in 2060 with 112 million people, 27% of the population, experiencing at least one heat wave event during the year. From 2060 to 2090, a plateau in the population affected by heatwaves is observed. As the number of people impacted by heat waves increases, a rise in the health impacts and costs associated with heat events may follow.

Abstract Name: Investigating Persistent Increases in Anxiety and Insular Cortex Response to Stress Following Recovery from Activity-Based Anorexia in Adolescent Female Rats

Anorexia Nervosa (AN) is a common neuropsychiatric illness that primarily affects adolescent females. AN has the highest mortality rate among all neuropsychiatric disorders due to severe weight loss from caloric restriction and increased activity. The causes of AN are complex and multifaceted but often include anxiety, which is comorbid with AN, commonly persists following recovery, and may contribute to high relapse rates; thus, it is imperative to understand long-lasting neural alterations that contribute to anxiety and relapse. The

insula - a cortical brain region - mediates feelings of bodily state including satiety and disgust, and changes in insular structure/function remain after AN recovery. Increased caloric intake during recovery may increase feelings of disgust, triggering heightened anxiety responses and relapse. To assess this, we used activity-based anorexia (ABA) to model AN in rats. Adolescent female rats were assigned to 4 treatment groups: Sedentary (SED): ad libitum food + no running wheel; Exercise (EX): ad libitum food + running wheel; Chronically-Food Restricted (CFR): restricted food + no running wheel; Activity-Based Anorexia (ABA): restricted food + running wheel. This treatment caused precipitous weight loss in ABA rats, and food restriction and wheel access were halted when ABA rats lost 20-25% BW, at which point ABA/CFR rats were allowed to recover their body weight. Following recovery, rats were assessed for anxiety on the elevated plus maze (EPMZ) and open-field test (OFT) and then either exposed to restraint stress or left undisturbed and sacrificed, after which brains were processed for cFos using immunohistochemistry. We observed increased anxiety in ABA rats following recovery, and we are currently assessing whether persistent changes in insular activation also occur following stress exposure. Our results will provide important information regarding the role of insula in long-lasting neural changes and anxiety following recovery from AN.

Abstract Name: Recommendations for Federal Regulations of Third-Party Litigation Funding in the United States

Past research on third-party litigation funding (TPLF) has established that while the industry is attracting attention from investors, it needs to be regulated to some extent. Additionally, professionals agree there are both societal benefits and risks stemming from this type of money lending. TPLF describes a situation in which a plaintiff pursuing a lawsuit cannot cover their legal expenses and accepts a loan from an investor or company in exchange for a portion of the settlement or interest payments. This can help provide legal access to people who cannot financially afford it independently, but there are potential issues with bringing a third party into the relationship between a lawyer and their client. While authors have conducted research exploring some of these perspectives, they have yet to focus on how lawsuits have responded to regulations placed on the industry in other countries. Nations with more developed TPLF markets, such as Canada, the United Kingdom, and Australia, are examples that the United States should look to before taking its next steps in writing legislation. This research aims to analyze historical trends and patterned responses that lawsuits have had to the regulations that the three countries, Canada, the U.K., and Australia, have implemented and recommend if and how the United States should federally restrict the unregulated TPLF industry. This study combines looking at the current legislation from these nations and comparing that with any reported data available. In addition to this, individual cases were used to provide context to how these laws play out in real claims. This year, there is a bill circulating in the U.S. Congress to impose restrictions on TPLF at the federal level. Using conclusions drawn from the case studies of the three aforementioned countries, I will proceed to determine if the currently proposed bill is sufficient.

Abstract Name: Living Like a Ghost: Iraqi Refugee Women and the Social Relocation Gap in Feminist Identity Theory

Social relocation, marked by sudden shifts in geography, culture, and societal expectations, disrupts an individual's equilibrium and her understanding of her community. The Iraqi-American refugee woman, torn from her homeland and thrown suddenly into a foreign culture, is forced into what feminist theorists call “the borderlands experience” – the experience of navigating between two cultures at odds with each other. This experience is both damaging to their sense of identity, and undertheorized in feminist literature. That this experience is undertheorized is surprising, given the inclusive aims and ideals of feminist philosophy. At present, my sisters and I continue to exist on its outskirts. Women like me have yet to feel included or represented in the literature or broader community discourse. The focus of this research paper is twofold: first, I aim to investigate the experiences of Iraqi refugee women in the United States, what they go through, and how they live out their identity. I will explore their experience by conducting a series of interviews, including the voices of my family and the elders in my community. I will include their narratives in my paper and make space for their voices in my theoretical analysis. Second, I will extend two dominant intersectional feminisms, multiplicity theory (Fujiwara 2018) and borderlands identity theory (Anzaldúa 1999) into a new domain: the experience of Iraqi refugee women. I will argue that forced social relocation is detrimental to the Iraqi-American woman’s experience in ways not yet captured by the feminist literature on complex immigrant identity.

Abstract Name: Quantifying Water Uptake on Atmospheric Particulate Matter (PM) under various Relative Humidity levels Analyzed with Diffuse Reflectance Infrared Fourier Transform Spectroscopy (DRIFTS) Technique.

Clouds are a critical component of the atmosphere, which predominantly cools the planet by scattering solar radiation back to space. Particulate matter (PM) are small solids suspended in the air that can initiate the seeding process for cloud formation. This process is directly related to the relative humidity (RH) above the PM surface and how much water it absorbs/uptakes. In the initial stages of this process, PM collects sparingly small layers of water, otherwise known as monolayers. Details of water uptake at this level are still lacking in the literature and we desire to quantify water uptake on atmospheric PM to enhance literature values. Two types of PM (Fe_2O_3, TiO_2) are investigated in these studies using the Diffuse Reflectance Infrared Fourier Transform Spectroscopy (DRIFTS) technique. Spectra are recorded using two modes, absorbance, and Kubelka-Munk (KM) as a function of relative humidity (RH), to assess which is more reliable. Integrated absorbance and KM data can be used with the Brunauer-Emmett-Teller (BET) equation to determine the number of monolayers created with increasing relative humidity levels. The data shows that the maximum amount of monolayers formed from 5% to 84% humidity was 2.5 for TiO_2, which is smaller than reported in the literature and indicates differences between the absorbance mode and KM mode in quantitative DRIFTS studies.

Abstract Name: The Impact of Sodium Bicarbonate on Alkenone Production in Haptohyte Algae

Alkenones are unique very long chain fatty acids, spanning from 35 to 41 carbons long with 1 to 5 trans double bonds and are produced by only five known species—all of which are haptophytes, a phylum of unicellular algae. Although the biological significance of alkenones remains largely unknown, a couple hypotheses have proposed roles as energy storage molecules or membrane fluidity modulators. A variety of potential commercial applications for alkenones as anti-fungal and antibacterial compounds, biofuels, and UV protective products have also been explored, but further research requires the identification of the genes and proteins involved in alkenone synthesis, which are currently unknown. By identifying compounds that disrupt or upregulate the production of alkenones in the cell, we can identify the genes and proteins involved. The goal of this project was to quantify the effect of sodium bicarbonate, a source of carbon, on the alkenone production of three species of haptophytes: Isochrysis galbana, Emiliania huxleyi, and Gephyrocapsa oceanica. This was achieved by growing cultures of each species for 11 days total, adding 25mM sodium bicarbonate on the 10th day. After growth, cells were lysed through liquid nitrogen grinding and lipids were isolated using solvent extraction, being later identified and quantified through GC-MS. We found that, in G. oceanica, carbon supplementation doubled alkenone production while decreasing it in E. huxleyi by about 78%. Alkenone extraction in I. galbana proved difficult, indicating a need for further study and possible alterations in the extraction method.

Abstract Name: Feminism for the Descamisadas: a Rhetorical Analysis of Eva Perón’s Speeches

Eva Perón’s “moral reform” feminism inspired the beginnings of feminist expansion in Argentina by praising tradition and promoting gender equality. Peronism, a populist movement, mobilized the Argentine working-class after decades of socioeconomic oppression. Eva Perón empowered Argentine working-class women, her descamisadas (“shirtless ones”), in fiery speeches. Eva Perón’s feminism was exceptional for a first-wave feminist context:: working as a female politician in a traditionalistic nation. Though scholars have labeled Eva Perón a “non-feminist,” I contend that her approach to feminism was extraordinary because of her ability to craft rhetorical appeals to working-class women. I analyzed Eva Perón’s speechwriting during her political career (1946-1952), determining how her visions for feminism and social welfare changed over time and by location. I utilized the rhetorical framework, starting with the historical and rhetorical situation and then finishing my analysis by examining how Eva Perón’s rhetorical choices appealed to messages of respect, loyalty, and love.

Abstract Name: Defining the Role of Focal Adhesion Kinase in Melanoma

The propensity of melanoma to metastasize to distant sites, including the brain, makes it the deadliest form of skin cancer. Despite the success of new FDA-approved therapies, resulting in a decline in melanoma mortality rates over the past six years, the development of brain metastases is one of the primary causes of treatment failure. Understanding the mechanism of melanoma metastasis development will allow for novel therapeutic strategies to improve the overall survival of afflicted individuals, specifically in the case of brain metastases. Concurrent interplay signaling between the mitogen-activated protein kinase (MAPK) and the phosphatidylinositol 3'- kinase/protein kinase B (PI3K/AKT) pathways has been demonstrated to lead to metastasis of melanoma. However, the use of pharmacological AKT inhibitors in melanoma clinical trials has either had limited efficacy or exhibited significant toxicity. To identify alternative targets, we used a proteomic analysis of non-metastatic and metastatic melanoma tumors and discovered that focal adhesion kinase (FAK), a non-receptor tyrosine kinase, is a specific effector of AKT1. Therefore, we hypothesized that FAK may be sufficient to promote melanoma metastasis and may be an alternative therapeutic target. To test this hypothesis, we utilized an established autochthonous mouse model of melanoma to evaluate the effect of FAK on tumor progression and metastasis. Tumors were induced in mice through expression of activated FAK in cooperation with mutant BRAF, a gene altered in over 50% of all human melanomas, as well as loss of the tumor suppressors Cdkn2a and Pten, which are commonly silenced in melanoma. Expression of activated FAK phenocopied the expression of activated AKT1 as assessed by tumor penetrance, latency, and metastasis thereby validating our proteomic data. These results enhance our mechanistic understanding of melanoma brain metastases and suggest that FAK may be a viable therapeutic target to improve the survival of patients with metastatic melanoma.

Abstract Name: Determining the Structure(s) of the CYRANO long noncoding RNA

MicroRNAs (miRNAs) guide Argonaute (AGO) proteins to bind and repress target RNAs. However, some targets, referred to as trigger RNAs, direct miRNA degradation instead. Trigger RNAs base-pair extensively with the miRNA, which induces a conformational change in the miRNA–AGO complex and recruits the ZSWIM8 E3 ubiquitin ligase, resulting in destruction of both AGO and miRNA. The CYRANO long noncoding RNA is a potenttrigger, reducing miR-7 levels up to 50-fold and the CYRANO miR-7 binding site is required but not sufficient for this activity. Preliminary studies in the Kleaveland lab have identified at least three accessory regions of CYRANO that enhance miR-7 degradation, however, the mechanistic basis for this enhancement is not known. Our hypothesis is that RNA structure affects CYRANO-directed miR-7 degradation. To begin to test this hypothesis, we will determine the 2D structure of the CYRANO miR-7 binding site in vivo in control cells and miR-7-deficient cells using chemical probing with dimethyl sulfate (DMS) followed by high-throughput sequencing. DMS methylates accessible nitrogenous bases in RNA, which can be detected as mutations after reverse-transcription. As the same RNA sequence may exist in multiple structures, we will use deconvolution and annotation of ribonucleic conformational ensembles (DANCE-MaP) to identify the number of unique structures in the ensemble and characterize each of their features. Follow-up studies will determine how loss of CYRANO accessory regions affects structure of the miR-7 binding site and how loss of miR-7 binding affects the structure(s) of these accessory regions. By identifying structural characteristics of CYRANO, we can better understand how CYRANO and perhaps other triggers work.

Abstract Name: Barney Bubbles Known to Few, an Inspiration to Many

The designer, Barney Bubbles, was an influential figure during the 60s psychedelic art movement, mostly known for his album cover works. Despite his short career he still had a noticeable impact on graphic design due to his bold, experimental ideas, that pushed boundaries and expectations while still managing to be a designer who makes appealing works. Bubbles is a lesser-known designer, who despite this has still managed to have a good sense of quiet influence on graphic design today. Even still, Barney Bubbles' album covers and other works on magazines, and even music videos should be studied by designers of today, as they can take mass inspiration from Bubbles' work and add more creativity and variety within the field.

Abstract Name: Can Plant Growth Hormones Minimize the Effects of Salinity Stress on Brachypodium distachyon?

Soil salinization is a process of excessive buildup of various soluble salts in soil that can negatively impacts plant growth and overall health. With the increase in droughts due to climate change, salinity stress is one of the most detrimental problems faced in agriculture that will lead to a reduction in overall quality and quantity of crops, especially in areas where there is already limited access to food. Thus, these prior studies indicate that finding ways to mitigate salinity stress in plants is important. Interestingly, plant hormones, besides regulating plant growth and development in normal conditions, may also be able to mitigate these effects and help plants adapt to environmental stressors such as salt stress. We hypothesized that gibberellic acid (GA3), a plant growth hormone, could mitigate the effects of salinity stress by up-regulating physiological activities. To test our hypothesis, we cultured Brachypodium distachyon, a small grass plant used as a model to study biomass and biofuels, in mini-fabricated ecosystems (EcoFABs) in different conditions: No salinity stress, salinity stress, and salinity stress with the addition of GA3. Each week plant root and shoots were measured and analyzed using Image J, an image processing program. We found that the increase of salinity stress negatively affected B. distachyon growth of roots and shoots when compared to the control (roots were 10% shorter and shoots 17.8% shorter). With the addition of GA3, the negative effects of increased salinity were reduced by 10%. These data show that GA3 mitigates the effect of increased salt salinity in plants. Additional studies are needed and with more replicates per group to strengthen these conclusions and to determine the dose-response effect of GA3 on mitigation of salinity stress.

Abstract Name: Investigating calf satiety after a meal of whole milk or electrolytes using taste aversion

Satiety in dairy calves can be experienced in varying degrees based on the environment they are put in. Transported calves typically experience more hunger than those on commercial farms or other places due to restricted or no feed given. Dairy calves can be transported for up to 28 hours with no access to feed or water causing hunger and greater body weight loss to be experienced. Previous research shows that transported electrolyte-fed calves had a greater body weight loss than milk-fed calves. It is proven that while electrolytes provide immediate hydration, providing milk as a pre-transport meal instead has a longer-lasting effect and reduces the need for glucose to be utilized as a primary source for energy. Although studies have been done to show the effects of both meals, the impact of feeding electrolytes vs milk on calf hunger is unknown. In

this study, 100 study calves were given a meal of whole milk or electrolytes in the morning and performed a taste aversion test in the afternoon with regular or bitter milk. The treatments given to the calves were determined using a Latin square design to investigate the varying degrees of calf satiety experienced. A randomized selection of calves were also given activity monitors to determine the effect of the meals given on their activity. Looking at some data, it was seen that dairy-fed calves drink <10% of the bitter milk 41% of the time while electrolyte-fed calves drink <10% of the bitter milk 28% of the time. Dairy-fed calves who consumed >90% of the bitter milk did so 33% of the time while electrolyte-fed calves consumed <90% of the bitter milk 48% of the time. We can also see that electrolyte-fed calves consumed more grain than those fed milk showing the unsatisafcation of electrolytes to their hunger.

Abstract Name: Building a Research Symposium from the Ground Up

Undergraduate research experiences increase students' understanding of the research process and confidence in their research skills as well as develop transferable skills such as thinking critically, communicating research findings and experiences to both general and practitioner audiences, and working independently and/or in small groups. In our department, we encourage undergraduate and graduate research experiences both in and out of the classroom. Each semester, our department hosts a student symposium giving students the opportunity to present their undergraduate and graduate research and capstone experiences. The purpose of this session is to share the evolving story of our departmental symposium with specific emphasis on "nuts and bolts" guidance on how the symposium is organized each semester. Now in its 16th year, our symposium has transformed over time to meet the changing needs of our students and in consideration of sustainability efforts. Currently, each semester nearly 100 students submit abstracts to present poster presentations, class projects, oral presentations, and round table discussions. Students report feeling empowered and excited after having the opportunity to share their research in a public setting with a departmental and community audience. Departmental faculty mentor students, create the program, identify and invite outside community members, evaluate presentations, moderate sessions, and coordinate administrative tasks while creating a conference-like experience for our student body. We have learned many tips and tricks over the years that help the symposium run smoothly and support student learning. In this session, we will not only share our own plan for hosting a student symposium, but also limitations that we have found and potential solutions for future symposiums.

Abstract Name: Causes, Consequences, and Correlates of Intimate Partner Violence among College Students

Intimate partner violence (IPV) is a prevalent issue, defined as any form of violence inflicted by a current or former intimate partner, including psychological, physical, sexual, and economic abuse. This deeply concerning problem not only jeopardizes the well-being of victims but also has a global reach, affecting millions. College students, however, are uniquely vulnerable to IPV due to a combination of factors in relations to their life stage, social environment, and stressors they encounter. This research aims to investigate the causes, consequences, and correlates of intimate partner violence among college students. Utilizing the American College Health Association's 2022 National College Health Assessment III (ACHA-NCHA III) data, this study incorporates an array of variables, encompassing risky behaviors, mental health indicators, substance misuse (including alcohol and drug abuse), personal experiences of intimate partner violence, general violence encounters, and demographic characteristics such as academic year, age, gender, and race. This research will be using IBM's Statistical Package for the Social Sciences (SPSS), this research endeavors to unravel the intricate web of factors contributing to IPV among college students. By shedding light on problems, we can advance our understanding of this issue and work towards more effective prevention and intervention strategies, ultimately striving for safer and healthier relationships within the college community and beyond.

Abstract Name: Exploring the Economic Implications of Subscription-Based Services on Low-Income Households

The subscription-based business model has emerged as a dominant force across diverse industries, offering convenience and flexibility to consumers. However, its impact on low-income families and individuals remains largely unexplored. This research proposal aims to delve into the economic ramifications of subscription-based services on households with limited financial resources. By scrutinizing its effects on purchasing power, investment capabilities, retirement prospects, and other opportunities for this demographic, this study seeks to uncover potential challenges faced by low-income groups trapped in this modern age business model.The significance of this research lies in its potential to offer practical insights to subscription service providers, policymakers, and consumer advocacy groups. Understanding the nuanced impact of this business model on low-income households is pivotal in fostering inclusivity and equity within the market landscape. By shedding light on the implications for this demographic, this study aspires to contribute to a more comprehensive understanding of the subscription-driven business model.

Abstract Name: Corporate Governance Factors and Financial Performance of Public U.S. Restaurant Companies

The sales of the restaurant industry in the United States are expected to reach $997 billion by the end of 2023. The industry is characterized by many minority managers and owners, a substantial percentage of single-unit businesses, and numerous chains. For publicly listed restaurant companies, strong corporate governance is a critical determinant of firm success. This study aims to investigate the relationship between corporate governance characteristics and company financial performance. The sample of this study consists of public restaurant companies in Security Industry Codes (SICs) 5810 and 5812. The observation period will be between 2010 and 2022. The total sample will include approximately 55 restaurant firms. Data on corporate governance characteristics will be manually obtained from Def 14A (Proxy statements) and SEC annual filings (10-Ks) by a team of researchers. The dependent variable in this study is firm financial performance, measured by Return on Assets and Stock Returns. This study uses control variables such as company size (number of restaurant stores), liquidity, debt to equity, and more. Data for the dependent and control variables will be obtained from the Center for Research in Security Prices (CRSP) and Compustat. Potential independent variables are corporate governance measures such as board diversity (inclusion of individuals from various backgrounds), franchising proportion (number of franchised stores to total stores), shareholder rights (the legal privileges of owners for a corporation), etc. The variance in firm financial performance will be captured through multiple regression analysis. This research study expects the board of director's independence and CEO duality to harm firm financial performance. On the other hand, franchising proportion and stronger shareholder rights are hypothesized to have a positive relationship with company performance. The results of this study will provide implications for company executives about how to achieve better corporate governance that leads to firm success.

Abstract Name: The COVID-19 Pandemic in Spanish and Portuguese-Speaking Countries: An In-Depth Spatial-Temporal Analysis in Latin America, and Spain and Portugal in Europe

I plan on pursuing a public health project utilizing GIS and spatial data science, specifically investigating the spatial-temporal analysis of COVID-19 in Latin America and Spain and Portugal in Europe located at country level. This will be achieved by using daily and cumulative case data from the WHO (World Health Organization) and air quality data from the World Air Quality Index Project 2020 data. The COVID-19 pandemic has become one of the most major public health concerns in over 100 years. Since late 2019, there have been over 700 million cases and almost 7 million deaths. Every country has handled the pandemic differently. Some have had the ability to remain stable, while others have struggled to return to normalcy. Latin America and Europe have had very different experiences regarding the pandemic. Due to cultural similarities, this study involves the comparison of Latin America and European countries such as Spain and Portugal during the time period of March 2020 through July 2021. This time period was chosen because there was a lot of uncertainty during this time with a lot of new patterns emerging regarding how to deal with the pandemic. This study is solely focused on the spatial-temporal patterns of COVID-19 infections among the select countries, correlation between lockdowns, vaccination, infections, and correlation between infection and air quality. This in-depth analysis will directly benefit a deeper understanding of the dynamic nature of this ongoing pandemic and inform more effective and efficient public health policies and actions at varying

spatial scales. A better understanding will allow society as a whole to learn from their mistakes and be better prepared for another possible public health crisis in the future.

Abstract Name: Human Entanglement and Jeff VanderMeer's Southern Reach Trilogy

In this environmental humanities project, I look at The Southern Reach Trilogy by Jeff VanderMeer and its themes of human transformation and entanglement in the environment. My work connects with Dr. Heather Sullivan's book project, The Dark Green: Plants, People, Power, but focuses on the multi-species relationships and human entanglement in VanderMeer's novels–Annihilation, Authority, and Acceptance. I argue that the total physical transformations of human characters by nonhuman organisms in novels illustrate human entanglement in the environment; VanderMeer makes our connections to and dependency on nonhuman species visually blatant in the novels through the transformation of human bodies into wild hybrids of altered forms. Current concepts of bodily entanglements arise from contemporary science, new environmental thought, and ancient and indigenous cultures that point towards the interconnectedness of organisms. This understanding is in contrast to the prevailing idea of separation in industrialized cultures, that somehow humans are outside of the environment that they inhabit. The living world is built upon the connections between different organisms. Plants and fungi form and rely on relationships with each other to exchange energy and nutrients. Other fungal species infect insects so that they are able to disperse their spores. Our own bodies are supported by a multitude of microbes that help us break down food and protect us from illnesses that enter our bodies. Without these connections and relationships, there would be no multicellular life on Earth. VanderMeer's Southern Reach Trilogy acts as a thought experiment about such entanglements by pushing human-nonhuman relationships into extreme new form and making visible the very ecological interactions we often overlook.

Abstract Name: Even Silent Women Seldom Survive: Disobedience, Silence, and Audre Lorde in Shakespeare's King Lear and Measure for Measure

Shakespearean heroines, too, "have been taught that silence would save [them], but it won't" (Lorde 41). Examined through a feminist lens of Audre Lorde's beliefs on the power of speech, this paper investigates how King Lear's Cordelia and Measure for Measure's Isabella wrestle with gendered power dynamics within their plays. Both heroines pointedly wield speech and silence both, struggling against the environments within which they exist. Cordelia and Isabella are each heavily scrutinized for their actions within Shakespeare's worlds; Cordelia, for her stubbornness, and Isabella, for her internal turmoil. Each woman has moments of bold silence and intrepid speech. By viewing these women's actions as results of the anti-

feminism landscape in which they function, we can revisit what it means to be a woman, and to choose silence over speech, or vice versa. Using a lens of Lorde's work relating to female power through speech demonstrates how gendered environments transgress both literature and reality. Lorde's work becomes especially poignant once we realize the oppression of Cordelia and Isabella within the environments of their plays. Whilst both challenge the gender norms of Shakespeare's time, and do so for the benefit of King Lear and Measure for Measure's plots, neither are liberated from gender oppression. This paper challenges research that frames Shakespeare's plots as revolutionary for gender stereotyping, because, while these scholars are certainly correct, they overlook the underlying power dynamics that disallow Cordelia and Isabella from surviving their stances against symbols of power. While the choice may be between speech or silence for both heroines, Lorde's words ring true, and the weight of anti-feminism forces them each to sink.

Abstract Name: Comparative analysis of the novel singleton phage Magritte and other Microbacterium phages.

Bacteriophages (phages) are genetically highly diverse viruses that specifically infect bacterial cells in order to survive and reproduce. The taxonomy for the majority of phages is based on their grouping into clusters and subclusters according to their shared genomic characteristics. Alongside known clustered phages, unique phages called singletons also exist that lack genomic similarity with one other and other clustered phages. The presence of unique genomic characteristics makes it more difficult to annotate them, even if they were to be isolated on the same bacterial host. Our goal in this study was to comparatively analyze genomic relationships between our novel singleton phage Magritte with other singletons and clustered phages, and to establish the possible evolutionally associations between them. Phage Magritte is a lysogenic phage isolated on the Microbacterium foliorum host. Electron microscopy analysis revealed that Magritte exhibits the Siphoviridae morphotype and has a long flexible tail. In comparison with other singletons, Magritte has a large genome of 133,228 bp, while the average singleton genome size is 60,866 bp. It also contains numerous tRNA genes. Three unique genes are also present within the genome with a length of 5975, 4697 and 4358 bp which do not belong to any known phage phams and do not have any known functions at present. Using the gene content similarity (GCS) analysis tool and Phamerator maps, we identified specific phams that make Magritte a unique and complex phage. These phams were not concentrated along a single point in the genome. The analysis of the enormous diversity and evolutionary relationships of bacteriophages is a big task, and studying the unusual genomic characteristics of singleton phages like Magritte can shed light into understanding bacteriophage biology and evolution.

Abstract Name: Design and Synthesis of Peroxisome Targeted Fluorophores

Peroxisomes are organelles that house multiple key metabolic pathways often mirroring the mitochondria in processes like beta-oxidation. The single membrane of the peroxisome isolates their oxidative metabolic processes from the rest of the cell and results in import processes being required to deliver biomolecules to the peroxisomal matrix. Despite their known role in these important pathways, the peroxisomes remain understudied. We believe that the dearth of methods to target small molecules to the peroxisomes is a major factor preventing a better understanding of peroxisomal biochemistry. To address this need, our group is interested in delivering a wider range of fluorophore classes to the peroxisomes to be able to expand the color pallet of peroxisome fluorescent dyes. To achieve this, we are designing molecules that utilize the Pex5-dependant peroxisomal import pathway to target their import to the peroxisomes. Here, we report our efforts to date to design, synthesize, and evaluate these new peroxisome targeted fluorophores.

Abstract Name: The Places In Between

According to the 2020 Census, Milwaukee is the second most black-white segregated area in the United States. It’s been this way for the last 10 years. In Milwaukee, there are 191 neighborhoods. There are six neighborhoods where 9 of 10 residents are black. In contrast, there are five neighborhoods where 8 of 10 residents are non-Hispanic white. In between these eleven neighborhoods are the neighborhoods of Harambee and Riverwest. Both neighborhoods tell the same story about fighting off gentrification, but on two different sides of the coin. One neighborhood, Harambee, has been a cultural hub for people of color for almost 100 years, and is slowly beginning gentrification. The other, Riverwest, has lost its cultural significance as the shadow of gentrification casts over. The project allows viewers travel to these neighborhoods and get to know the places that existand the stories of the people that survive in these areas. It showcases the real life stories of people who have spent their lives in the places in between gentrification and segregation. These people are often forgotten, but deserve to have their stories heard, remembered, and memorialized. This is my city, and this is my project.

Abstract Name: Isolation and characterization of potential antimicrobial producing microorganisms from wetlands of Minnesota in a general microbiology laboratory

The need for new antibiotics is becoming critical worldwide as more antibiotic resistance is revealed. To this end, we used the Tiny Earth model to identify, isolate, and identify potentially new sources of antibiotics from soil samples from the wetlands of Minnesota. The Tiny Earth project is a student-sourcing antibiotic discovery community dedicated to discovering potential new antimicrobials. This project was made possible through funding provided by the Legislative-Citizen Commission on Minnesota Resources (LCCMR). The current research project compares the results from three successive semesters of general microbiology (Fall 2021, 2022, and 2023). The media used were the following: nutrient, 10% tryptic soy, actinomyces, and glycerol yeast extract (gyea). The following were used as ESKAPE safe relative pathogens: Enterococcus raffinosus, Staphylococcus aureus, Escherichia coli, Acinetobacter baylyi, Pseudomonas putida, and Klebsiella aerogenes. Chemical extraction involved growing the isolate on agar plates and using ethyl acetate to extract substances to be tested against the ESKAPE safe relative pathogens. This process produced 58 isolates recovered from Fall 2021, 43 isolates were found to be pure and 13 of them showed continued inhibition against the ESKAPE pathogens. From the Fall 2022 samples there were 34 isolates demonstrating continued inhibition with ongoing effort to isolate pure cultures. And finally, there were 75 isolates initially recovered that demonstrated inhibition against the safe relative pathogens in this current fall semester. Ongoing research to isolate pure cultures and characterize the chemicals associated with the observed inhibition will be presented. Lessons learned over the course of this project will also be presented as well as future drug discovery opportunities related to the wetland environment.

Abstract Name: Disabilities Represented in Theater

In the summer of 2023, research was conducted on how disabilities are portrayed in theater. This research is specified in the literature part, for example: how the character is written, how people treat them, how the disability is portrayed, and the overall emotion towards the disability/disabled character. Within this conduction, fourteen plays were used. Out of these plays: Forty-three percent (43%) beastify the disabled character. Fifty percent (50%) infantilize the disabled character. Twenty-nine percent (29%) objectify the disabled character. Fifty percent (50%) of the plays were overall negative in regards to the character with a disability. Fifty percent (50%) of the plays resulted in the disabled characters' death. Seventy-one percent (71%) used slurs and derogatory names against the character with a disability. In conclusion, disabilities are portrayed in a negative manner. This typically results in some form of discrimination, violence, and or death. The reason why this research is important is to bring light on this situation, the situation being that the theater world has a tendency to depict those with disabilities in a negative way and very little story’s show disabilities being a positive thing. This can be impressionable to audiences as they only typically see disabilities being portrayed in a negative light rather than a positive one. If left unchecked it could allow

people to feel as though disabilities are only these negative things that cause problems and nothing else. Not only damaging those who have disabilities, but also potentially subjecting them to unfair biases.

Abstract Name: An Examination of Emotion Perception Mediated by The CRE

The Cross Race Effect (CRE) is a sociocultural phenomenon that affects the ability to perceive and remember the faces of individuals based on race. Understanding the differences in emotional perception based solely on race may be a key factor in terms of understanding dangerous perceptions in racist/prejudiced encounters. These underlying, potentially incorrect, differences in emotional perception are key factors in carving systems of racial disparity that rely upon face-to-face screening and communication: including healthcare, job opportunities, education, and more. The present study expanded upon prior literature on emotion perception mediated by the CRE while controlling for common limitations. Utilizing a free-choice, untimed, and continuous exposure emotional perception task, it was postulated that 1.) participants would be able to more accurately recognize the facial expressions of own-race faces and 2.) participants would have a wider variety of emotional perceptions for own-races faces. A total of N = 19 participants were selected through a non-probability convenience sampling technique from an HBCU in Atlanta, GA. A demographics survey was provided to the participants to assess the perceived interaction with Black and Caucasian Americans. Afterward, participants met with the researcher to complete one of two versions of a self-made emotion recognition instrument. Emotion expressions for the instrument were obtained from the Chicago Face DatabaseTM and contained Happy, Neutral, Fearful, and Anger expressions. Participants were tasked with identifying any number of facial expressions perceived on all 32 faces. A dependent T-test shows that participants were able to correctly identify significantly more emotions on Black American faces opposed to Caucasian American faces (t(18) = 1.938, p<.05). This indicates strong support for emotion perception being mediated by the CRE and interracial contact. Further research includes a more diverse sample, investigation of the role of racial implicit bias, and systematic definition of success criteria.

Abstract Name: Medium spiny neuron excitability is greater during early development in rats

The striatal brain regions are key for important processes like premotor function, habituation, and motivated behaviors. When these regions are disrupted, disorders such as Parkinson’s Disease and drug addiction can result. The medium spiny neuron (MSN) is a key neuron type that serves as the output neuron of the striatal brain regions. Though the MSN is present in striatal regions such as the caudate putamen (CP) and the nucleus accumbens core (AcbC), it is unclear whether the physiological properties of the MSN differ between

each of those regions. Many computational models assume identical MSN properties across regions by default, despite these regions mediating different behavior properties. Very few neuroscience studies differentiate between sex and developmental period even though there are known sex and developmental differences in the functional output of the striatal regions. Thus, we tested if MSN electrophysiological properties differ by striatal brain region, sex and developmental period. Meta-analysis included four previously collected datasets, each capturing whole-cell patch clamp recordings in tissue from females and males in one region (i.e., CP or AcbC) and during one developmental period. Excitability was assessed via a battery of biophysical attributes describing the input-output properties of the MSN. We found that MSN excitability differed by all three variable groups, though developmental period exerted the most influence. For example, rheobase, the amount of current needed to elicit an action potential, differed significantly in the CP between prepubertal and adult male rats. Overall, we found an age-linked difference in neuronal excitability wherein prepubertal rat MSNs were more excitable than those of adult rats. These findings indicate that MSN electrophysiological properties, particularly those implicated in excitability, exhibit complex regional, developmental, and sex-based specificity not accounted for by existing models.

Abstract Name: A Genetics Course-based Undergraduate Research Experience (CURE) Designed to Improve Transfer Student Success in STEM: Lessons Learned from Multiple Implementations.

The University of New Mexico-Valencia Campus is a two-year branch of the University of New Mexico serving mainly first-generation and low-income students. Recent internal university data measured low levels of retention, graduation, participation and feeling of belonging in STEM students, particularly of transfer students, at UNM. STEM students that participate in research as undergraduates have been shown to have increased retention and graduation rates of students that do not. I designed this CURE to address these issues by providing future STEM transfer students with experience using modern genetics laboratory, field, and data analysis techniques. In this project, under predefined parameters, students design, propose and carryout a 16s metagenomics survey of a habitat of their choosing. The course in which the students are enrolled is the second semester in the biology majors' introductory series, typically taken by students in their second year as an undergraduate. Working in self-selected groups, students propose a research site and collection protocol, supported by research literature. They then collect and preserve their samples appropriately before extracting DNA, preparing the 16s libraries and sequencing. Finally, using Mothur on the Galaxy platform, students analyze their sequence data to present their research at the campus' year-end STEM research symposium. Lessons learned through the years of implementing this course as well as ideas for future refinement of this course will be presented.

Abstract Name: Rapid and Tunable Self-assembly of Microscopic Particles using Light

Self-assembly is an autonomous process in which small components organize into large structures. Self-assembly of micro- and nanoscale colloidal particles has gained attention recently as an accessible, bottom-up method of fabricating functional materials. We developed a light-driven mechanism to engineer the self-assembly of microscopic particles into ordered structures within the timescale of 1-10 minutes. We prepared a binary mixture of gold nanoparticles (d = 15 nm) and microscopic colloidal polystyrene particles (D = 0.7 μm-10 μm), and illuminated the suspension with high-intensity green LED light (power = 14 mW). The photothermal heating of the gold nanoparticles generates a temperature gradient which causes a convection flow. We observe the large polystyrene particles form a crystalline monolayer under the convective flow. We achieved large-scale, rapid crystallization for 10 μm particles within 10 minutes and 1 μm particles within a few seconds. We found that the crystalline order of the assembled monolayer can be tuned by using gold nanoparticles with different surface functionalizations. We observed more crystalline structures formed when using CTAB (Cetyltrimethylammonium bromide) coated gold nanoparticles compared to citrate-functionalized gold nanoparticles. We attribute this effect to the screening of the repulsive interaction between negatively charged polystyrene particles in the presence of the positively charged CTAB-coated nanoparticles. Finally, we experimentally measured the temperature increase of the suspension caused by the gold nanoparticles to be in the range of 5℃ to 10℃ by performing a melting experiment of CTAB crystals under light. Our simple experimental system using gold nanoparticles and LED light is a significant step towards achieving rapid, light-driven self-assembly of colloidal particles.

Abstract Name: The Unspoken Reality of Our Communities: How We Are Conditioned to Build Better Communities for All Those Except Us

My research focuses on Black and Latino communities and how their social and natural environments impact them. It examines how social structures lay the groundwork for how communities function, as well as understanding the structure's overall functionality. I will not only write about this issue but I want my writing and research to be used as a resource to help improve any difficulties experienced in my community, modeling methods that can be used in other communities, as Karenga touches on in his paper "The Crisis of Black Middle Class Leadership: A Critical Analysis". My project focuses on the Bronx, since it has numerous cultures in each neighborhood but is still segregated based on culture, racial and ethnic background. Additionally, I am from The Bronx so I have seen how these structures have changed. However, I want to make sure that I incorporate and highlight the lived experiences of my fellow community members, as I do not know everything about my community, to shape the improvement that is needed. In discussing the background and technicalities of how these communities function, I use findings from interviews with former teachers and classmates of mine and participant observation to propose realistic solutions that use already existing resources in these communities (e.g. contacting the only bookstore in the Bronx, contacting our mobile book stores, make better use of recreational and college help centers, and contact NYC schools about accurately and effectively providing a Culturally Responsive Sustaining Education and Teaching (CRSE/CRT)). It takes a lot of strength to get out of the vicious cycle of a lifestyle of just settling, though it may be comforting, the younger generations need to see how they can make use of their resources and education. That encouragement and representation starts in the community they live in.

Abstract Name: Purloined Poe: Borges's Art of Translation

While Saussure argued that a translation can never be true to an unattainable 'original', Borges responded with the opposite - "the original is not true to the translation" (Krystal 2002). My research will explore the theory of translation at work in one of Borges's renderings of an English language text. Borges translated dozens of works in various languages from different genres, from Sturluson's 'Prose Edda' to one of the founders of detective fiction, 'The Purloined Letter' by Edgar Allan Poe. Many scholars in both English and Spanishhave argued that Borges in his translations has created a 'Poe' that is uniquely his. It isn't a matter of translating Poe into Spanish, or even into Borges, but Borges's act of translating the 'idea' of Poe into Latin American thought and cultural perspective. The pillars of Latinoamerican literature that rose from the literary boom in the 1960s were made possible by a surge of translation of literature of many languages into Spanish, transforming the cultural and linguistic perspective of these works. While a certain level of creativity is necessary for a successful translation, Borges approaches translation as the creation of something new. To translate Poe is not to translate the words themselves, but to create a 'Poe' specific to the cultural and linguistic framework of Argentine Spanish. With these ideas in mind, I will explore what W.V.O. Quine calls 'linguistic understanding' and 'linguistic being' of Borges's Poe in his translation of 'The Purloined Letter'.

Abstract Name: The Relationship Between Age and Gender on Dream Recall Frequency

Sleep and dreams have always been a topic of interest for many psychologists and neuroscientists. Dreaming occurs in everyone each night and is speculated to benefit the human body in information processing and memory. However, dream experience varies with each individual. Previous studies suggest that dream recall frequency (DRF) is linked to age and gender; specifically, DRF declines with increasing age, and women are more likely to recall more dreams compared to other genders. This study aims to determine whether there is a correlation between age and DRF as well as gender and DRF. A 17-question survey was sent out in Laredo, Texas by means of social media to gather information about individuals' dreams and factors that may affect their DRF. 62.3% of participants (48 responses) reported sometimes recalling their dreams upon awakening. 18.2% (14 responses) always remember their dreams, 16.9% (13 responses) rarely recall their dreams, and 2.6% (2 responses) never remember their dreams. The average score on dream recall was 1.96 out of a 3.0 scale. A slight incline with a correlation coefficient of 0.0095 in dream recall frequency with increasing age was noted. However, the change was not significant enough to accurately identify a relationship between age and dream recall. Findings suggest that more data needs to be collected before reaching any conclusions about the relationship between DRF and 1) age and 2) gender due to small sample size in this study.

Abstract Name: Repurposing FDA-approved drugs to sensitize TP53 Mutant Diffuse Intrinsic Pontine Glioma to radiation therapy

Diffuse Intrinsic Pontine Glioma (DIPG) is a form of pediatric brain cancer that originates in the brainstem, mainly affecting children aged 4-11. The survival of children with DIPG has not changed in more than 50 years, and remains <1% with a prognosis of 8-11 months. The standard of care, radiation therapy, will shrink the tumor in most patients and provide symptomatic relief. However, all DIPG will become resistant to radiation therapy. Almost all DIPG have mutations in the p53 pathway. TP53 plays an important role in regulating apoptosis, cell cycle arrest, and metabolism. A common phenotype that is associated with TP53-inactivating mutation is resistance to radiotherapy. To find drugs that could sensitize DIPG cells to radiation, we utilized a TP53 mutant zebrafish line for an in vivo screen of 1,400 FDA-approved compounds to find radiosensitizers that did not rely on an active TP53 pathway. TP53 mutant zebrafish embryos are insensitive to radiation, while radiation halts development in wild-type zebrafish embryos. Drugs were considered hits if they induced apoptosis in the TP53 mutant zebrafish embryos in combination with radiation, but had no adverse effect on embryos that were not irradiated. The top nine hits from this drug screen were further screened against human DIPG cells that had a mutation in TP53 and were radiation resistant. We found that 3 of the nine hits from the zebrafish screen significantly sensitized the human DIPG cells to radiation both in vitro and in an in vivo zebrafish xenograft model (p<0.01). These drugs will next be tested in other DIPG cell lines to confirm their effectiveness as radiosensitizers and characterized for their mechanism of action, particularly related to response to DNA damage staining and metabolism after irradiation.

Abstract Name: Identification of Novel Inhibitors Against Alzheimer’s Disease Using Multi-Task Neural Networks-Based QSAR

Alzheimer's disease (AD) is an irreversible, multifactorial neurological disorder with a complex and not fully understood pathophysiology. Numerous protein targets that contribute to the disease's progression have been identified. Recent research has focused on the discovery and development of multitarget-directed ligands

(MTDLs), which are capable of inhibiting multiple targets simultaneously. Traditional Quantitative Structure-Activity Relationship (QSAR) methods, based on Single-Task Learning (STL), often struggle due to insufficient compound activity data. In contrast, Multi-Task Learning (MTL)-based QSAR models overcome this limitation by simultaneously considering multiple similar biological targets, thus enhancing prediction accuracy through the shared information transfer across tasks. Particularly, the Instance-based MTL formulation utilizes a quantitative similarity measure between task pairs at the variable level. This is achieved by adding n extra attributes that represent similarity values to other targets, with n being the number of targets. In this study, our aim is to learn embedded vector representations of target protein sequences, leveraging the extensive amount of available unlabeled protein sequence data. We trained unsupervised doc2vec embedding models on 524,529 protein sequences from UniProt. These models were then used to infer encodings of target sequences for generating the n target similarity attributes. Our study utilized datasets from ChEMBL, which include annotations of bioactivity on 29 AD-related targets, encompassing a total of 48,322 molecules. We compared STL and MTL strategies, incorporating both Random Forest and Deep Neural Networks, to screen for effective MTDLs for AD.

Abstract Name: 'Things Just Got Spicy' -- Podcasting, Political Engagement, and Gen Z

The growing popularity of podcasts among Gen Z prosumers (consumers + producers) has been exponential, even in the academic context, since the platform took off in 2004 (Rosell-Aguilar 2007; Seemiller and Grace 2017; McMahon 2021; Bratcher 2022). As a producer of my own political poetry-based Gen-Z podcast “Things Just Got Spicy,” I explore Gen Z’s media habits, particularly as they pertain to their political cynicism about failed institutions and the efforts by previous generations to resolve global problems. The question I ask is: How is Gen Z using political podcasting as both a pedagogical and activism tool, and how does this matter in our contemporary political culture, especially with upcoming elections? I argue that political fatigue has prompted Gen Z prosumers to create their own participatory cultures, selecting peer-curated sources of authentic and trustworthy information, seeking autonomy in learning and advocacy efforts, and using digital platforms for self-expression that are diverse and inclusive. As Gen-Z continues to move away from traditional media sources, research indicates they prefer environments that are more horizontally structured. This creates spaces where Gen Z-ers are not afraid to participate, and their participation is valued by their peers. I explore how podcasting can be used as a creative activism and pedagogical tool by and for Gen Z prosumers; who are more politically engaged than is the popular belief. Adapting the A.I.D.A (attention-interest-desire-action) consumer purchase model and using an auto-ethnographic approach, I address how, in the case of my own podcast by using student voices and experiences to discuss under-the-radar political, social and economic global issues, I have been able to move students from awareness to participatory action and active knowledge-seeking. As this podcast and other similar projects demonstrate, Gen Z participants show a nuanced understanding that political engagement encompasses a multitude of pathways.

Abstract Name: Ice boots without water drainage support optimal hoof temperatures for the prevention and treatment of laminitis

Cryotherapy is often used to reduce inflammation in acute equine laminitis cases. Certain hoof temperatures have been suggested as effective in minimizing the inflammatory process; however, there is limited evidence on which methods commonly used in veterinary hospitals are best at achieving these temperatures. The objective is to determine how different methods of cryotherapy influence the rate and extent of cooling for the equine hoof wall. Clinically sound horses (n = 4) were exposed to three hoof cooling treatments and a control (no treatment application). Treatments included (1) ice surrounding the hoof in a 5 L fluid bag with water drainage holes, (2) ice surrounding the hoof in a bag without drainage holes, and (3) ice in a commercial wader-style boot. Hoof wall temperatures were collected via thermal imaging every 2 hours for 12 hours after treatment applications. Thermally imaged body temperatures and thermometer-based rectal temperatures, heat index, relative humidity, and ambient temperature were also recorded. Hoof temperatures responded to treatment and were also impacted by time, with hoof temperatures declining and remaining lower than when not exposed to treatment. The fluid bag without water drainage demonstrated the greatest rate and extent of cooling over a 12-hour period. Medial, dorsal, and lateral hoof wall surface temperature responses were similar to each other, reflecting consistent measurements across different aspects of the hoof. The wader boot showed similar trends to (1) the bag without drainage holes; however, it was not well tolerated by the horses, leading to early termination of data collection. This study demonstrates cryotherapy treatments that maintain an ice-water slurry around the hoof result in more optimal hoof temperatures for the prevention and treatment of laminitis. Further research is needed to uniformly evaluate other cryotherapy applications and determine increased specificity of temperature in which the application of cryotherapy is effective.

Abstract Name: Aerospace Engineering Systems Perspective Through Case Studies

Failure case studies are an excellent teaching tool for engineering students. Eight NASA failure investigation reports were analyzed for root cause and recommendations for improvements so that similar failures would not occur in the future. The recommendations call attention to the need for better informal and formal communication to create informed decision making and uncover errors in a timely manner. Analysis of the collection of historical real-world scenarios highlights a need for practical knowledge within a systems perspective. The use of case studies in engineering classes is a simple and practical way to bring the theme of failure into the discussion and learning environment. Research showed that case studies are a useful learning mechanism for studying real world failures. Failure case studies get students to think about the system from different perspectives. The NASA failure reports, in particular, are nicely laid out and useful for familiarizing students with engineering problem solving and solution approaches. Professors can present the particular case studies in class that come from NASA reports. By putting students into problem solving mode with a big

picture perspective, they figure out what solutions are possible. Although students might not understand the significance of a systems perspective from these failure reports, these skills will be appreciated over time. Students read and analyze the failure investigation board recommendations and then compare their own solutions to outcomes from the report. Incorporating case studies into projects has students putting their new systems skills to use with each other in the classroom before they enter the workforce. Early exposure to these reports makes students comfortable with failure. Getting engineers to think about recommendations from failure case studies can be achieved within the structure of the existing engineering education with a systems focus embedded in the coursework.

Abstract Name: How Disgust Response Predicts Aversion to Precision Fermentation

Precision fermentation is the process of using microbial hosts as “factories” to produce specific functional ingredients which are then used to create food that would typically require some level of input from an animal. This can create more sustainable means to harvest food that wouldn’t have a significant impact on the environment. However, the impact of a disgust response to this process needed to be studied to understand what can be done to make it more appealing. The present study tested the hypothesis that foods produced by precision fermentation would elicit an increased disgust response from participants. A survey was sent out using MTurk that consisted of several questionnaires and demographic questions to determine how likely people are to have an aversion to precision fermentation. The participants were then randomly assigned to a control group in which they were presented with a picture of a cheese pizza, were told that the cheese was made from cow’s milk, and were provided an explanation of the process of how cheese is produced. The experimental group was presented with the same picture but were told the cheese was created from precision fermentation and were presented with a description of the process. While participants seemed hesitant to try food made through precision fermentation, they ultimately appeared open to trying it at least once due to their curiosity. The average rating given by people to the precision fermentation option and the process that people are more familiar with was very similar with just a difference of a few points. If the benefits are emphasized while making it clear that this process won’t leave the consumer ill, people will want to learn more about the process and this beneficial method could become more widespread.

Abstract Name: Syllabus Features and Students’ Perception of the Course and the Instructor

Classroom first impressions are important to students, and they should also be important to professors. In academia, these impressions are not just made on the first class day but also through the syllabi teachers present before lectures begin. Elements in the syllabus that may influence these impressions include tone/warmth and graphics. Some syllabus elements may determine whether students are even willing to remain enrolled in the course. Professors may motivate students by including syllabus and instructor snapshots with their syllabus. These snapshots are graphic-heavy, 1-page overviews that provide students with highlights about the course content and professor teaching the course. We investigated the effects these snapshots had on students' perception of the course and instructor. Study participants were representative of their Primarily White Institution (PWI); the majority of the individuals in this study were White, heterosexual, women from a large campus. The study measures included questions about students' perceptions of the course and instructor, how thoroughly they read the syllabus, the teacher's perceived care and competence, and demographics. Using an experimental design, randomly assigned participants viewed one of four versions of a psychology statistics syllabus with or without snapshots and completed a web-based survey. An instructor snapshot had a small, positive effect on students' overall perception of the perceived care and competence of the instructor. A syllabus snapshot had a small, positive effect on students' willingness to take the course. Additionally, White students and women had more positive perceptions of the instructor than students of color or men.

Abstract Name: Exposure to 5 kHz and 10 kHz Ultrasound Disrupts Nuclear Transport of HeLa Cells

Ultrasound is a medical imaging technique that uses sound waves to create images of soft tissues and internal organs. Ultrasound used at low frequencies has beneficial effects on cells including increased proliferation and differentiation rates due to an increase in growth-factor-related-gene expression. However, exposure to ultrasound stimulation can have adverse effects on cells creating deformities in the Nuclear Pore Complex (NPC), rupturing of the Nuclear Envelope (NE), and triggering apoptosis. The NPC is vital for proliferation and survival, as it is the selective gateway by which molecules transit the NE. Transport proteins importin alpha and importin beta used for import, and exportin for export, must be in the right place to interact with the NPC and perform nuclear transport. Because ultrasound disturbs the NPC and NE, we asked if nuclear transport is also disturbed at the frequencies 2.5, 5.5, 10, and 20 kHz in HeLa cells. Cell viability was observed via MTT assays followed by immunofluorescence and image j software to visualize transporter localization. 2.5 kHz did not affect cell viability, whereas 5 kHz lowered cell viability by 25%, 10 kHz by 19%, and 20 kHz by 22%, therefore we focused on 5 and 10kHz. Exposure to 5 kHz had no impact on importin alpha and exportin expression in the nucleus, yet increased importin beta in the cytoplasm, which may indicate a decrease in nuclear transport. Conversely, 10 kHz caused a decrease in exportin expression in the nucleus, while causing an increase of importin alpha and beta in the nucleus, which reflects an upregulation of nuclear transport. These results may indicate why 5kHz had a greater impact than 10 kHz on cell viability. Our next steps are to investigate the NPC and NE to see if changes in these organelles after exposure to ultrasound are the cause of altered transport.

Abstract Name: An Exploration of Land-Based Wellness Practices in Recovery from Addiction: Learnings from Indigenous People on Vancouver Island

In 2016 addiction was declared a public health emergency, with British Columbia at the forefront of the crisis. In 2022, it was reported that fatal overdose was the leading cause of death for those ages 10 - 18 (BC Coroners Service, 2022). As Indigenous communities are experiencing disproportionately higher effects of this emergency, the need for culturally appropriate solutions is urgent (Norton et al., 2022). This has led to a growing interest in identifying and promoting practices that promote recovery and support Indigenous youth. Despite the immense need, Vancouver Island does not have many in-patient facilities for youth. This will change in the coming year, as a youth wellness center is planned as part of an initiative to expand services for Indigenous youth with a particular focus on land-based wellness. This research focused on identifying land-based practices that have helped in the recovery of Indigenous individuals with the belief that their experiences can provide valuable insight for new program development. Through a lens of appreciative inquiry, semi-structured interviews were conducted with Indigenous individuals in recovery from addiction on Vancouver Island about the land-based practices and services they found most helpful in maintaining their recovery and fostering holistic wellness. From these interviews, themes emerged that may inform the development of culturally appropriate recovery and wellness programming for Indigenous youth exploring recovery and sobriety. The results of this study show that Indigenous individuals' lived experience and knowledges provides valuable insights toward improving and enhancing the lives of those who follow. Their perspectives can inform community responses to the challenges of addiction that are grounded in local culture and knowledge.

Abstract Name: Perception vs. Reality: How NFL Scouts, Fantasy Football Experts, and College Students Value NFL Players

Fantasy football, a virtual game tied to real players' performance, has become a significant influence in modern sports culture. It not only shapes fan engagement with the National Football League (NFL) but also affects player evaluations and league marketing strategies. Notably, the NFL, a multi-billion-dollar industry, and its revenue streams are now partially dependent on public perceptions of a player's fantasy value, which may differ greatly from their actual on-field value to a team. NFL players undergo evaluation by two distinct groups: fantasy football experts and NFL scouts and managers. Each has contrasting criteria for what makes a 'good' player. Fantasy football experts prioritize statistics, consistency, and maximizing fantasy points in the short run, emphasizing opportunities and touchdowns. In contrast, NFL scouts and managers heavily consider a player's physical attributes and long-term potential to contribute to a team's success. This study aims to fill a gap in previous research by comparing these distinct evaluation styles and analyzing the best NFL wide

receivers and running backs for each group over the past five seasons. The lists of players will be determined by a variety of advanced metrics closely aligned with each evaluation style. College-aged students familiar with the NFL and fantasy football will then rank these players in a focus group, helping determine if public perception aligns more with fantasy experts or NFL scouts. Previous research suggests participants will lean towards the former, offering valuable insights into the game's real-world impact. The results of this study can further influence the NFL's marketing strategies, player endorsements, and player acquisition processes. Additionally, this research can lay the groundwork for further exploration of how fan perceptions of players in different sports leagues contrast with their actual value to a team.

Abstract Name: Microbiome Derived Metabolites and Their Potential Protective Benefits During Sepsis and Immobilization Induced Muscle Dysfunction

Background: The Covid-19 epidemic has uncovered major limitations in healthcare practices and presented major challenges to clinical nutrition support in the intensive care unit (ICU). Patients suffer from increased muscle breakdown, which exacerbates the body's ability to recover from the viral infection. The impact of the microbiome on enteral nutrition support for critically ill patients is not well understood. Research has focused on the pre-biotics (i.e. dietary fibers, simple/complex sugars, and amino acids/peptides/proteins) and pro-biotics (i.e. bacterial species of interest) improves patient outcomes, but other studies fail to find such benefits. Many bacterial derived metabolites (post-biotics) are absorbed into systemic circulation and taken up by peripheral tissue. Thus, the impact of the post-biotics are equally, if not more, important for the host compared to pre- and pro-biotics. We hypothesize that post-biotics, such as short chain fatty acids (SCFAs) and succinate, will contribute to attenuating the catabolic effects of sepsis and immobilization on peripheral tissue such as skeletal muscle.Methods & Results: Sepsis was induced in mice through intraperitoneal injection of anerobic bacteria mixture. Antibiotics and fluids began 12 hours post sepsis induction and continued BID for 3 days. Immobilization was achieved using 3D printed casts and taped onto the mouse hindlimb unilaterally. Muscle function was assessed on day 4 post sepsis or immobilization by measuring plantarflexion in vivo using isometric force measurements. Mitochondrial function was assessed using high resolution respirometry and reactive oxygen species production was measured using AmplexRed fluorescence. Short chain fatty acids and succinate are either provided with the fluids during resuscitation post sepsis or through drinking water ad lib.Conclusions: SFCAs and succinate may be required for protecting peripheral tissue during ICU-like conditions. Although more studies are required to confirm these findings in human patients, changing standard enteral and/or parenteral nutrition may help reduce ICU mortality.

Abstract Name: Sleep Quality in Relation to Time Spent Outdoors Versus Time Spent on Screens Daily

Prior research has shown a strong correlation between exposure to blue light and a decrease in sleep quality. Exposure to ultraviolet light has been shown to decrease the effects of environmental stressors, which could increase sleep quality. The current study explores the effect of natural light versus artificial light in relation to sleep quality among college students. The researcher hypothesized that there would be a positive correlation between outdoor exposure and better sleep quality and an inverse association between blue light exposure and sleep quality. This study used the Questionnaire of Sleep and Psychological Functioning at Work (Zupanic et al., 2021) to examine sleep quality. The Screen Time Behavior Questionnaire was used to measure device utilization (Banderia et al., 2020). Outdoor exposure and recreational habits were measured with the Outdoor Play Questionnaire (Mullenbach et al., 2019). The sample included 104 full-time college students from a Christian university. A correlation and simple regression analysis were conducted to analyze the data. The findings revealed that hours of watching television significantly predicted poor sleep quality (b1 = .094, p =< .05. There was no relationship between outdoor exposure and recreational habits and sleep quality. These findings demonstrate a need for a decrease in screen usage. Further research must address the ways that outdoor activity may increase sleep quality among college students.

Abstract Name: Air Pollutant Spatial Analysis and Interpretation of Oil Field Emission Data within South LA County

Petroleum oil drilling started in the 1890s within LA County. Many original well sites have continued into the modern day, but regulations for oil drilling have not been meaningly updated since the 1950s. As such, oil fields can be in proximity with vulnerable communities. Minimal research has been completed into the air quality impacts of oil drilling within urban environments in lower-income, BIPOC communities. The Los Angeles Voices on Oil, Community, and Environment Study (LAS VOCES) is a project aimed at this gap in research; the analysis of air quality data in comparison to general community health.Air quality information in the community is recorded using HAQ-Pods; these packages incorporate low-cost sensors to quantify various pollutants, including VOCs, ozone, CO, and NOX. The package's low cost and maneuverability allow for the deployment of a large network of pods to gather high spatial resolution data around four main areas in the community: an active oil well, an idle well, a deconstructed well, and a highway away from any oil site. Calibration of the low-cost sensor data is done through a "one hop" calibration method; each individual pod is calibrated to a "secondary standard" pod. The secondary standard pod is then deployed next to a reference instrument that is less susceptible to humidity and temperature changes. Calibration models are fit based on RMSE and R2. This allows for our low-cost sensor data to be comparable to reference-grade data.After calibration, variation in pollutant field concentrations across different areas in the community will be determined. The proposed poster will show different calibration model fits for the CO and ozone data and visual graphics to communicate the differences in air pollution across an urban oil extraction environment. This project shows the value in low-cost sensors for data gathering and pollutant spatial analysis.

Abstract Name: Age differences in reactivation of neural representations in learning and retrieval of modified associations

Older adults have a specific deficit in forming associations which includes difficulty modifying existing associations. This may be due to age differences in reactivation of neural representations. Specifically, we hypothesize older adults do not effectively reinstate patterns of neural activity representing previously-encoded associations when encoding and retrieving new or updated associations. We tested this hypothesis in an fMRI experiment in which young and older adults memorized and recalled pairings of low-imageability words with pictures of faces, scenes, and objects. Each of the five scanner runs included three phases: 1) initial learning of pairs; 2) cued recall of initial pictures and learning of new pictures; and 3) cued recall of new pictures. Outside the scanner at post-test, participants identified the “new” picture for each word from a set of three, including the new picture for that word, the initial picture for that word, and an unstudied picture. Algorithms were trained to classify picture type from each trial using fMRI patterns collected during the initial encoding phase, and then tested on the patterns obtained during subsequent phases. For both age groups, the algorithm successfully classified neural patterns by picture type during the learning phases. For neural patterns collected during recall, classification was better for young than older adults, consistent with better reactivation of encoded information during recall. At post-test, older adults were significantly more likely than young adults to mis-identify the initial picture for each word. Critically, post-test performance was linked to reactivation of neural representations in the scanner. For both age groups, correctly identified “new” pictures at post-test were associated with greater reactivation of neural patterns for initial pictures during encoding of the new picture. The findings support the hypothesis that older adult memory may be improved by encouraging reactivation of prior associations when learning new or modified associations.

Abstract Name: Paraben Exposure Results in Developmental Abnormalities in Zebrafish

Parabens are chemicals commonly found in mascaras, lip glosses, lotion, scrubs, and other cosmetics as a preservative. They enter the body through skin, and esterases are unable to break them down. Parabens have been found in fetal blood, indicating their ability to cross the uteroplacental barrier. They act as an endocrine disruptor, interfering with the nuclear receptors for androgens, estrogens, progesterone, and influencing enzymes that metabolize natural hormones. Using zebrafish (Danio rerio) embryos as my model organism, I sought to find if parabens influence fetal development. At 24 hpf, dechorionated embryos were exposed to different concentrations of butylparaben [6.25 μM, 12.5 μM. 25 μM], and propylparaben [6.25 μM, 12.5 μM, 25 μM, 50 μM.] Zebrafish were also placed into two controls, the E3 solution and E3 with 0.1% DMSO. The fish were observed 48, 72, and 96 hpf for developmental defects and measurements of the yolk sac, pericardial sac, total length, eye diameter, and heart rate were taken. They were removed from the solution and placed into E3 medium at 72 hpf. A significant enlargement of the pericardial sac and yolk sac, a spine curvature, and a decreased eye diameter was observed upon treatment, particularly in the higher concentrations of both chemicals. Heart visualization of the high concentration treatment groups revealed a stretching of the heart resulting from the pericardial edema. The survival rate was decreased among the higher treatment groups of both propyl and butylparaben solutions. By 5 dpf, all zebrafish from the highest concentrations of paraben solution in both chemicals died, and the fish in the 12.5 μM butylparaben group and 25 μM propylparaben group exhibited extreme edema throughout their body, indicating a disfunction of osmotic balance causing them to retain fluids due to a developmental defect caused by their previous paraben exposure.

Abstract Name: Comparing Views of Classroom Expression Between Majority and Minority Demographic Groups on a Small College Campus

Controversial conversations can be intellectually beneficial to students. However, instead of taking part in such conversations, college students are choosing to avoid these topics altogether. It is worth exploring the prevalence of this avoidance on small college campuses, and how it may look different for majority student groups versus minority student groups. This study specifically looked at students at the University of Minnesota Rochester campus where we compared the majority group, white females, to the minority group, all others. In particular, we are looking at student views related to a learning environment where students are exposed to all types of speech and viewpoints, even if it means allowing speech that is offensive or biased. To explore this topic, we examined student responses on the campus expression survey provided by Heterodox Academy. The majority student group reported preferring a learning environment with less limited classroom expression in comparison to all other demographic groups combined. Excerpts from qualitative student interviews offer support for these findings. These results might reflect an attitude that the majority group has in regards to less limited classroom expression. Our results suggest that classroom leaders and instructors may benefit from considering the differences in the majority and minority status of students when facilitating student discussion.

Abstract Name: The Effects of Dance Composition on Mental Health

While dance is shown to be a way of expression and an alternative physical activity, there is considerable evidence that suggests the “double play” of musical stimulation in the reward centers of the brain and the excitement of the somatosensory cortex from dance decrease cortisol and increase dopamine levels, therefore decreasing stress and depression related symptoms. In the study, a student was chosen to participate in a project that consisted of learning a dance every other week throughout a fourteen-week semester—a total of seven dances—and then perform and record the video to be sent in as proof of compliance. The student was asked to keep a journal throughout the project and write about how the choreography and musical duo made them feel at three separate points: when they first watched the dance, during the learning process, and after the final performance. The dances consisted of a variety of choreographers and alternated in overarching themes of joy and maladaptive emotions. The journal entries of the student showed a positive correlation between the emotional style of the choreography and internal emotion felt during and post-performance; a more joyful style dance or musical composition generated more joyous emotions throughout the process and post-performance. However, when performing compositions of emotional themes, the entries reinforced a more emotional mood from the performer, but in correlation to times of stress or more depressive states, the emotional connection to the movements and song choice had the opposite effect: a release of built-up stress and anxiety. These results demonstrate the effect that the style and musical composition of the dance can have on the mental state of the student, suggesting a possible use as a non-pharmacological treatment for neuropsychological disorders such as anxiety, depression, and other mood disorders experienced by students in high stress environments.

Abstract Name: Investigating the effects of urban noise on communication in birds: an experimental approach

Birds that are successful colonizers of urban areas exhibit increased tolerance to human disturbance. Disturbance from anthropogenic noise may be difficult to overcome because it includes frequencies that overlap with the frequency of birds’ acoustic signals in ways that impact communication. Populations of birds that live in noisy urban areas sing using higher minimum frequencies than those living in quieter areas. Higher minimum frequency may make songs more detectable in urban noise because they escape masking frequencies of urban noise. In this study, we experimentally test whether masking noise (frequencies that overlapped with song) had more impact on detection than non-masking noise (frequencies that did not overlap with song) in song sparrows (Melospiza melodia), a species that has been shown to use songs with higher minimum frequencies in response to urban noise. We played song embedded in masking noise and song embedded in non-masking noise to 25 territorial males and measured behavioral response of males. If

masking noise impacts detection, we should find that males will differ in their response to song played in masking versus non-masking noise. We found that males responded similarly to playbacks. Our results suggest that song played in masking versus non-masking noise were equally detectable. One possible explanation for our findings is that frequency shifting in song sparrows does not function to increase detection in urban noise, but instead functions to maintain the ability of conspecifics to discriminate between males based on song. Or if discrimination is less possible in masking noise, then frequency shifting may function to decrease the costs of singing in noise. Future studies should investigate the ability of receivers to discriminate among acoustic signals in urban noise.

Abstract Name: Differences in sedentary behavior by shift type in female nurses engaged in rotating shifts: An exploratory, with-in person analysis

Purpose: To explore the associations between physical activity and sedentary behaviors in nurses working rotating shifts. Context: Lack of physical activity and increased sedentary time are primary concerns to health, causing issues like diabetes and cardiovascular disease. Previous research in this area has relied on between person comparisons. This study explored the with-in person differences, which controls for the variation among people, to elucidate further the role of shift type on health behaviors. Methods: This is a secondary, exploratory analysis of data from a larger study. Nurses engaged in rotating shifts (i.e., worked both day and night shifts) were recruited. Sociodemographic data and participants' work schedule (e.g., day shift, night shift, or day off) were collected. Participants wore a triaxial accelerometer on their left hip to objectively measure physical activity and sedentary behavior for 24 days. Paired T-tests were used to examine the within-person differences in mean moderate to vigorous physical active (MVPA) and sedentary time between day shift, night shift, and days off. Results: Participants (N = 10) were all white and female with a mean age of 31.6 years old (standard deviation [SD] 6.2, range 23-42). There was no statistical significance between shift types and MVPA. However, sedentary time was greater on night shift compared to day shift (687.2 [95.9] vs. 602.7 [39.4], P = .029) and on night shift compared to days off (678.5 [93.5] vs. 491.2 [153.2], P = .004). Additionally, sedentary time was greater on day shift compared to days off (597.1 [105.5] vs. 470 [144.6], P = .035). Conclusion: Nurses rotating shifts spent more time in sedentary behaviors on night shift than both day shift and days off. Interventions to reduce sedentary behavior and mitigate its negative health consequences, should be developed and tested.

Abstract Name: Distribution of Sediment Containing Zinc, Copper, and Lead Trace Metals in the Lower

Susquehanna River

The nation's largest estuary, the Chesapeake Bay, is highly influenced by the Bay's largest sediment depositor: the Susquehanna River. The 444 mile river drains 27,500 square miles from land in New York, Pennsylvania, and Maryland. Due to the size of the watershed, land use, and regulations, the Susquehanna River ends up transporting much of the sediment that empties into the Chesapeake Bay. Within the sediment are often anthropogenic pollutants including trace metals such as zinc, copper, and lead. The Conowingo Dam was built in the lower Susquehanna River during the 1920's as a hydroelectric dam, but subsequently acted as a means to catch sediment. Given this, how does the dam impact the distribution of trace metals in sediments? Two sites upstream from the dam and four sites downstream were sampled in triplicate, sieved into three fractions, and digested using a 5:1 mix of nitric acid to 30% hydrogen peroxide. The concentration of the trace metals was evaluated using an atomic absorption spectrophotometer. In general, the base of the Conowingo Dam had the highest concentrations with the largest range of variability of trace metals found. There was variability in the trends seen between metals within the same site as well. Sites such as Havre de Grace contained concentrations of lead as high as 48.38 ppm, compared to the highest concentration of copper, 9.546 ppm. The results from the sieved fractions suggest that particle size has some influence on trace metal concentration. It was found that the highest concentration of metals was in the fractions containing sediment larger than 250 micrometers and the fraction containing sediment smaller than 63 micrometers.

Lily Franklin

Abstract Name: Jacqueline Casey in Design - Bleu Franklin

Jacqueline Casey has a simple yet familiar start to the art world as many other artists do. She parents wanting her to have a more stable job while she only wanted to make art. When she finally has the chance and freedom, she sets off to an art college in the hopes of becoming a fashion designer. She meets the person that will introduce her to her future job, Muriel Cooper, in college. They were the best of friends and ended up working at the Massachusetts Institute for Technology together for many years. She meets and marries her husband, Billy Casey, before Muriel takes off to learn more about design and art elsewhere. Ten years of work pays off when Jacqueline Casey gets the promotion to Design and media Director. This position enabled Casey to hired Ralph Coburn. They will work together during a five-month trip to Europe where they will intake other culture's designs and incorporate them into MIT designs. They learn from a Swiss girl and adopt the "Swiss" style. The style that they brought to MIT helped Casey and Coburn revolutionize their work and improve their designs. It is shown through Casey's work how she had improved through the years and became this pinacol of a modern, clean, straight to the point kind of design that many take inspiration from. She had set that path ablaze for many people to use and draw from in their own ways, making an art revolution.

Abstract Name: Identity Races, Game Faces, and Mental Spaces: An In-Depth Exploration of Intersectional Identities and Their Impact on the Mental Well-being of Black and African American Women in Athletics

The nationwide effort to prioritize mental health in college athletics must include a deeper understanding of how background, culture, and intersectionality predict and affect mental health outcomes. Research highlights significant mental health disparities between Black and non-black individuals. Mental Health America (2022) reported adult Black and African American Americans are more likely to have feelings of sadness, hopelessness, and worthlessness than adult whites and are more likely to attempt suicide. Alarmingly, while overall suicide rates decreased in 2019 and 2020, rates increased among Black Americans, particularly those aged 10 to 24, where suicide ranked as the third leading cause of death in 2020 (WISQARS, 2023).Given the alarming statistical data and predictive variables, indicating a greater susceptibility to mental health challenges in this demographic, it is crucial to prioritize the well-being of Black and African-American female collegiate athletes. Black women face unique challenges related to their identity and often adopt the "strong black woman" stereotype, which can have positive and negative effects. Student-athletes, are also grappling with rising mental health issues, making suicide attempts more likely, especially among women and student-athletes of color (NCAA, 2022, p. 9).This study explores the mental health experiences of six Black and African-American female athletes in the NCAA through an intersectional lens, considering the historical and contemporary impacts of systemic oppression. Collecting data will involve an IRB-approved comprehensive literature review, surveys, and interviews. Various mediums will present and showcase the real experiences of these athletes and highlight systemic oppression's generational impact.The anticipated contribution is to raise awareness of the multifaceted adversity Black and African-American female athletes face. By shedding light on their challenges, it aims to inspire collective efforts to remove barriers and create a more inclusive and supportive environment for all athletes, particularly those with diverse identities who have historically been marginalized.

Abstract Name: Green Card, Greener Pastures: How a New Pathway to Citizenship Will Affect Undocumented Immigrants

Illegal immigration and the process of obtaining citizenship have been popular and contentious areas of discussion for many years. Many have attempted to rectify the system by proposing programs such as the DREAM Act and DACA, yet little has been accomplished in terms of how undocumented immigrants can obtain citizenship. The FRAIT Initiative aims to improve the immigration system by forgiving those who have paid taxes, approving more visas, adding more security checkpoints to the southern border, and quickening the process of obtaining residence status and citizenship as a whole. This paper will draw information from sources such as the American Immigration Council, the Institute of Taxation and Economic Policy, and the Migrant Policy Institute in order to explain the need for radical changes to the United States' immigration system. Keywords: immigration; immigration reform; undocumented immigrants; illegal immigration; FRAIT Act; DACA; DREAM Act; border control; ITIN

Abstract Name: Exploring the Structural Root Causes of Food Insecurity Before, During, and After the COVID-19 Public Health Emergency Order

Background: Food insecurity rates skyrocketed during the COVID-19 pandemic, particularly affecting low-income, and communities of color. In response to the heightened food insecurity rates, the U.S. expanded various food assistance programs, however, these expansions ended in early 2023 with the lifting of the public health emergency order. We consider how the health inequities embedded within structural root causes may have shifted public discourse and policy response. Purpose: The aim of this study was to explore whether articles in the New York Times (NYT) discussed root causes of food insecurity and to describe the type of root causes discussed before, during, and after the COVID-19 pandemic emergency. Methods: We used the ProQuest U.S. Major Dailies database to identify articles covering food insecurity in the NYT, before (P1; February 2019-2020), during (P2; March 2020-December 2022), and after the ending of the pandemic emergency which officially ended in May 2023 (P3; January-September 2023). From the resulting N=8,171 articles (P1: 1,772; P2: 5,277; and P3: 1,122), we used a constructed week design and randomly selected N=1,354 articles for a final analytic sample representing 10 weeks in P1 (N=291), 27 in P2 (N=872), and 7 in P3 (N=191). We coded each article for the major causes of food insecurity; specific federal/state programs mentioned; and mention of special populations. Preliminary Findings: Few articles discussed that food insecurity stemmed from structural root causes. The most common types of root causes mentioned were past polices, systemic racism, and societal structures. In contrast, most articles mentioned that food insecurity was a result of inflation, budget cuts to food programs, and supply chain interruptions. Conclusion: The root causes of food insecurity were less commonly discussed in the media. We discuss implications of using news media to expand the understanding of the root causes of food insecurity.

Abstract Name: The Interplay of Various Transcription-Related Proteins on Cell Identity

Proteins play a vital role in comprising our physical characteristics as well as maintaining bodily processes and other functions. They are constructed from the nucleic acid known as messenger RNA (mRNA), which in turn is constructed from DNA, the genetic information in each of our cells. This mRNA-from-DNA relationship is known as transcription. Cellular regulation of transcription, controlling the when and where of mRNA production, plays a critical role in differentiation, a dynamic process in which a cell with generic features develops specialized functions, such as immune cell functions. However, the exact relationship between transcription regulation and cellular differentiation is unknown. Histone chaperones are a diverse class of proteins that help regulate all DNA-mediated processes and are a good subject for study into this relationship. By targeting the DNA replication-associated histone chaperone CAF-1 and the transcription-associated SPT6, we used loss-of-function assays to investigate the relationship of these molecular processes

in maintaining the identity of granulocyte-macrophage progenitor cells (GMPs). GMPs are niched in the bone marrow and have the potential to differentiate into white blood cells, such as neutrophils. We report that depletion of histone chaperones SPT6 and CAF-1 alters the progenitor identity by allowing different transcription-related factors, such as the AP-1 transcription factor family, to drive alternative gene programs. To validate these findings, we are establishing a CRISPRi system in GMPs to transcriptionally silence these genes, which will allow us to confirm the functional importance of our transcription factor candidates. These findings could improve the understanding of hematopoiesis at large, as well as certain blood diseases like acute myeloid leukemia, where the diagnosis is based off of an abnormal accumulation of myeloid progenitors and harbors an exceptionally lethal prognosis.

Abstract Name: The Effectiveness of Vinegar as a Natural Household Antimicrobial

A growing number of people view commercial cleaning products as detrimental to the health of humans and pets because of the volatile organic compounds (VOCs) released during use, and the potential they have to worsen health conditions. Natural cleaning products, such as vinegar and baking soda, do not release VOCs. Whether those natural cleaning products can effectively remove microorganisms and if the quality of cleaning is lost when switching from harsh chemical disinfectant cleaning products to more natural products is explored in this study. This study was performed as an At-Home experiment and aimed to evaluate the effectiveness of a natural cleaner in removing microorganisms from a washcloth contaminated with mold. Three cotton washcloths were dampened with hot water and placed into a plastic container to develop mold for 7 days in a warm humid environment (garage). To test the cleansing properties of a natural cleanser, each washcloth was soaked for one hour in a solution of either household chlorine, vinegar, or water in a ratio of 1/4 cup cleaner to eight cups of water. Microbial growth characteristics from each solution were determined on TSA plates. The highest microbial reduction was achieved using the household chlorine solution in comparison to vinegar and water. The water solution without cleanser contained the most diverse microbial growth in color, form, elevation, and margin. Treatment with vinegar reduced the diversity of microbial growth but was less effective than using a household chlorine solution. Further analysis using various concentrations of “safer” natural cleansing products will be explored. Our findings from this research could provide further implications for using natural cleansers to reduce potential pathogenic microbes from sensitive items in the common household including foods, pet areas, and infant toys.

Abstract Name: Handshake #1

(3d Visual Arts Display)Welded steel, cast aluminum, gun parts The weaponization of a deal; a cast aluminum handshake replaces the firing mechanisms of a shotgun. It explores the handshake as an inciting incident, a symbol of money, power, and the enforcement of peace. This work was produced with the tools and facilities of the Michigan State Sculpture Department, under the support and supervision of Jacqueline Sullivan-gould, Laura Cloud, and Walter Peebles. Some artists that both inspired me and provided context for this work are Nemo Gould, and Hugh Haydens work as Both artists use firearms in combination with other materials to make comentary about different societal trends.Handshake #1 responds to situations where a relationship or union between two parties becomes violent for another, a situation modeled tragically by the United States involvment in the distribution of arms to the Gaza Strip. the work responds to high dollar buisiness deals that often make money at the expence of third world countries, and the environment. handshake #1 points viewers towards the conclusion that mankind is complicit in a violent system.to make this work, a handshake was molded on two people, and then used to pour wax into. this wax was converted into aluminum using lost wax casting . Once aluminum, it was shaped to fit the profile of the firing portion of a shotgun, a barrel welded out of mild steel pipe was fitted, as well as the wood from a shotgun.In working on this piece I learned how to cast, drill, grind, weld, and fabricate with casted aluminum in combination with other found materials. this piece fits into my body of work as I often use my practice to question the violence I see in every day life, and aim to make my audience question it as well.

Abstract Name: Distance as a Barrier: A Statistical Analysis of Health Impacts from a Clinic Closure in Rural Wisconsin

Rural areas face unique healthcare challenges impacting their patients. One major driver of the disparity between urban and rural patient health outcomes is distance. This research seeks to answer how the closure of a clinic in rural Wisconsin affects nearby patients and how significant of a role distance plays. An abundance of research exists on the greater overall adversity and distinctive obstacles that rural healthcare faces. Rural patients have lower incomes, higher risk of chronic illnesses, more difficult access to healthcare, and are less likely to be insured. Internally, rural healthcare struggles to recruit and retain its workforce, accrues lower revenues, and receives fewer inpatients. Market factors are only worsening these trends with rural hospitals closing regularly. A defining aspect of rural healthcare and the more remote locations is increased distance. Findings of the impact of distance on healthcare outcomes differ greatly. Although literature is extensive on the topic of rural hospital closures, research on rural clinic closures is absent. This study seeks to fill that gap. The impact of a clinic closure on the patient population was evaluated on an observational study of 589 patients that were originally paneled to the closed clinic prior to the closure on December 31st, 2021. Data for those patients was also captured through the following year of 2022. Five health indicators were assessed based on patients' drive time before and after closure through paired samples Wilcoxon signed rank tests, ordinal logistic regression, and paired Mann Whitney U-tests dependent on data distribution and data type. Although the drive time median from 2021 to 2022 increased 135.30%, there were no significant effects found in health outcomes. With a temporally short dataset, this could change in the future. As such, this study or a similar study should be continued or revisited in the future.

Abstract Name: Integrated Design and Development of a Sub-Orbital Launch and Recovery System

Orbital Labs aims to design and develop the Sub-Orbital Launch and Recovery (S.O.L.A.R.) system, a high-

altitude balloon mission with the intersection of three disciplines: firmware, electrical, and mechanical. Firmware topics focus on the Orbital Avionics Controller (OAC) firmware which is an embedded system adopting FreeRTOS for task-based architecture with Python scripts and git version control for development. Electrical topics focus on the development of a robust avionics hardware, integrating sensing capabilities, telemetry and power management solutions. Mechanical coverage invokes a lightweight aluminum chassis design with intricate trussing for rigidity and flexibility, a payload bay with elastic tethers for mechanical and electrical control of experiments, and a recovery system with parachute deployment mechanisms. The successful implementation of these technical components is essential for the mission's success in acquiring critical high altitude balloon research data.

Abstract Name: A modern CURE for a long-standing undergraduate neuroscience methods course

Our Neuroscience Methods course has long been the most anticipated and loved course in the Neuroscience major at Regis University, but the format was quickly becoming outdated and stale; a change was needed. We found ourselves facing two challenges: 1) our faculty and students were no longer fulfilled by conducting replication studies in this course, and 2) the number of students declaring the neuroscience major – and consequently, student interest in independent research – was outpacing capacity in faculty research labs. Our students desired more authentic research experiences and our faculty wanted to combine their teaching and research efforts more efficiently. We needed a CURE! Course-based undergraduate research experiences (CUREs) have been gaining popularity as a way to integrate research experiences into the undergraduate curriculum. In contrast to independent research in a faculty mentor's lab, CUREs provide a means to scale the experience of engaging in authentic research to a broader population of students. This increased accessibility was attractive to us as faculty because it allows us to provide a higher-quality educational experience to a wider swath of students, while also increasing our scholarly productivity. CUREs allow students to move away from traditional "cookbook" lab activities – or in our case, forgo replication experiments – and work on novel questions instead. This invigorates the course experience for students and provides "real world" research experience that better prepares students for graduate school and careers in the sciences. CUREs have been demonstrated to benefit both the students and the instructors and it's easy to see why they are growing in popularity; however, this transition was not without significant challenges. Here we discuss the hurdles we faced in reimagining this course as a CURE, share some of the solutions we developed, and invite conversation around ways to further improve this course moving forward.

Abstract Name: Abolitionist Rhetoric and the Campaign Song in 1860

Music has played a significant role in presidential politicking since the 1840 campaign of William Henry Harrison (Scott, 2017). This music was circulated in small, printed booklets called “songsters.” In the 19th century, campaign songs typically praised one candidate, or denigrated others, but sometimes lyrics expressed specific viewpoints or outlined aspects of the candidates’ policy platforms (Miles, 1990). The campaign of 1860 was no exception. There were four major candidates for this election: Abraham Lincoln (Republican party), John Breckinridge (Southern Democratic party), John Bell (Constitutional Union), and Stephen Douglas (Democratic Party). The candidates debated many topics, but the main issue at this time was slavery, and candidates turned to the power of song to sway public opinion. Songs for the Great Campaign of 1860 is a collection compiled for the campaign of Abraham Lincoln and his running mate, Hannibal Hamlin. This collection includes “Help! O Help!,” an abolitionist song composed during the period. Unlike the traditional campaign song, “Help! O Help” makes an emotional appeal by offering a poignant narrative of an enslaved mother. “Help! O Help!” tugs at the heartstrings of those who listen to it and exposes them to the grief and loss that enslaved individuals faced on a daily basis. While several scholars have turned a critical lens to campaign music, few have analyzed how songs in campaign songsters dialogue with other abolitionist texts. Drawing on anti-slavery rhetoric in newspapers, pamphlets, and personal narratives, this paper analyzes “Help! O Help!” against the backdrop of these texts, illustrating the vital role music played in the circulation of ideas in the campaign of 1860.

Abstract Name: Integrating Undergraduate Research into Field-Based Science Courses

Communication, teamwork, and problem-solving skills are among the top five cognitive competencies sought after by employers. Participation in mentored undergraduate research can help students develop those three skills as they progress from structured, prescribed research projects to autonomous, independent ones. However, most mentored undergraduate research involves one faculty working with 2-3 students addressing research questions in the mentor’s field of expertise. This model only allows for a limited number of students who are not constrained by financial and/or family obligations to engage in extracurricular research. It also does not provide opportunities for cross-disciplinary communication and/or collaboration with students and mentors from unrelated disciplines to address real-world problems.In the Geography, Geology, and Environmental Science department at UW-Whitewater, we strive to broaden undergraduate research participation in several ways. Besides following the traditional model of mentored research, we infuse research components in our field-based courses to expose larger groups of students with a range of academic preparation to place-based research in context of a course. We have also developed a learning ecosystem model where students and mentors from unrelated disciplines work collaboratively with stakeholders from indigenous communities to address issues faced by those communities. Both of these approaches have successfully engaged students from diverse backgrounds in this high-impact educational practice.In this presentation we will share case studies of mentored research conducted in context of field-based courses and collaborative transdisciplinary research with indigenous communities, and discuss strategies for creating such undergraduate research models on other campuses.

Abstract Name: Family Clinical Healthcare Experience, Familial Support, and Coping Mechanisms Among Nursing Students: A Mixed Methods Study

Background: Nursing students report high levels of stress, and poor stress management can affect academic success. Families are a well-known source of social support among students. Shared experience may enhance social support, but it is unknown whether families with clinical healthcare experience provide stronger support and how this difference impacts perceived stress and coping mechanisms. Objectives: The objective of this work is to understand the role of family clinical healthcare experience in the stress and stress management of nursing students. Methods: This is a mixed methods study. We conducted a scoping review of the literature concerning stress and coping mechanisms among nursing students, searching PubMed for “nursing students”, “stress”, “social support”, “coping mechanisms”, and related terms. Next, we will survey and interview nursing students about stressors, coping mechanisms, and family work history. Results: Of 302 results, 19 articles met our inclusion criteria. These indicated that nursing students experience high stress, which is associated with maladaptive coping mechanisms. Students reporting poor social and faculty support tend to report more stress and maladaptive coping behaviors. Experiencing burnout while in school later increases turnover and intent to leave among new nurses. Whether or not students from families with clinical healthcare experience report less stress and less maladaptive behavior has not been studied. Discussion: Increasing the supply and retention of nurses is critical to overcoming staffing shortages. Our literature review indicates that stress is particularly high among nursing students and is an important factor in supply and retention. Stress, particularly poorly managed stress, increases attrition among nursing students and new-to-practice nurses, as this stress continues into their careers. Our next steps will explore whether or not shared clinical healthcare experience between students and their families changes the students’ experience of stress and stress management.

Abstract Name: On Narrative as Epistemological Tool

The central focus of my research is the defense of narrative as an epistemological tool to be considered alongside rationality. I begin by defining my terms: by “rationality,” I mean the mental process by which conceptual and observational data are related to one another according to observable and demonstrable connections. By “narrative,” I mean the cognitive and linguistic process by which events, people, emotional content, and concepts are cohesively related. The two definitions are remarkably similar, although my definition of narrative deals with a broader, more encompassing process. In this respect, they are, as I put it, “epistemological siblings." Next, I contextualize my thesis within broader historical understandings of epistemology from various traditions: Greek conceptions provided by Aristotle, theological perspectives by St. Thomas Aquinas, the early modern philosophy of Immanuel Kant, and Zen Buddhist traditions. I then move on to contemporary work by literary critic Jonathan Gottschall, neuroscientist Michael Gazzaniga, philosopher M. Giulia Napolitano, and psychologist Jerome Bruner. Through their work, I defend my central

argument, showing that ways of knowing come just as much from the human brain's innate processes of narrative construction to create an understanding of the world around us, other people, and ourselves and that this method of knowledge-making is what is more commonly employed by most people. I conclude the paper by illustrating, through the work of Gottschall, as well as a brief look at the potential effects of artificial intelligence upon mass media, that this narrative epistemology has dangerous implications, as narratives can be misused in the hands of bad actors who wish to sway public opinion, political affairs, and social movements, thus necessitating a vigilance on the part of all citizens to engage with both epistemological tools, rationality and narrative, very wisely.

Abstract Name: Versatile Lower Limb Prosthesis for Dynamic Mobility

Most prosthetics on the market focus on either the biomechanics of walking or running. In comparison to walking, running involves greater speed, force, and range of motion. Overloading the musculoskeletal system can lead to injury, so it is important to accommodate the forces involved in different movements. Our goal is to develop a prosthetic that accommodates both walking and running. We began by researching walking and running leg prosthetics comparing their differences. This led us to design a prototype utilizing a collapsible pylon with a hinged ball joint knee and a pivoting foot blade that will be adjusted based on the activity. The hinged ball joint knee design allows for internal and external rotation. The pivoting foot blade connects the pylon through an adaptable ankle, and its design incorporates characteristics of the blades used for walking and running for heightened performance. Utilizing the iterative design process, we have developed a dynamic leg prosthetic and identified areas for future research on the pylon and the joints have dual purposes of connection and user functionality. Test results measuring the gait discrepancies caused by the prosthesis using motion capture, yield testing of prototypes, finite element simulation, and fit verification with commercial shoes will be presented. The effectiveness of the angle adjustment of the foot blade to increase functionality based on the activity, and the efficacy of the knee in conjunction with the adjustable pylon will also be demonstrated. Furthermore, we are creating a prosthetic that allows a user to carry out more exercises and standard activities more efficiently. Accomplished by designing an adjustable knee and ankle supported by a pylon that conforms based on the desired activity. Applying the biomechanics found in running and walking the prosthetic can increase access to healthier lifestyles by emulating the actions of a biological leg.

Abstract Name: Microbiome of PCB Contaminated Sediments

Polychlorinated Biphenyls (PCBs) are toxic chemicals which were popularly used in electrical manufacturing companies from the 1930s - 1970s and are known to cause significant health concerns for humans even today. These have also been termed “forever chemicals” due to their ability to bind to sediments and soils, which results in difficulties with removal or degradation in contaminated environments. One site of widespread PCB contamination is Pittsfield, Massachusetts, where improper disposal of industrial waste by a General Electric plant has led to chronically contaminated rivers and ponds, even decades later. The aim of this research project is to learn more about the microbial communities that coexist with these toxic forever chemicals, hoping to find evidence that they can degrade PCBs through metabolism. This specific study within the project focuses on microbial diversity of sediment samples collected from the contaminated Woods Pond, located downstream of the Pittsfield General Electric plant. Procedures performed were DNA extractions, PCR amplification, and 16S rRNA amplicon sequencing on an Oxford Nanopore MinION DNA Sequencer. Preliminary data suggest that the samples contain genera known to be associated with PCB degradation, such as Paenibacillus, Clostridium, Rhizobium, Sphingobacteria and Methyloversatilis. With this understanding, future efforts aim to evaluate the ability of these environmental bacteria to degrade PCBs.

Abstract Name: Domesticating Ayahuasca: Ethnobotany and Phylogeography of Psychotria viridis

Belonging to the angiosperm family Rubiaceae, Psychotria viridis is a shrub traditionally used as a primary component of the hallucinogenic brew ayahuasca due to its high concentration of the compound N-N, dimethyltryptamine (DMT). Production of ayahuasca requires P. viridis to be brewed in conjunction with an additional plant, often the vine Banisteriopsis caapi, containing monoamine oxidase inhibitors (MAOIs) that allow for the absorption of DMT when taken orally. The hallucinogenic properties of DMT are essential to the wide variety of functions of ayahuasca in its use by various Indigenous groups in parts of Latin America. Despite its significance, however, little is known of the genetic structure and diversity within P. viridis, its geographic origin(s), or the extent of its relationship with humans. This project intends to provide a comprehensive review of the botanical and cultural significance of this plant, and to subsequently gain insight into the species' genotypic variation and spatial distribution as they relate to human activity and ayahuasca use. To this end, genomic DNA was extracted from herbarium specimens of P. viridis sourced from across the range of past and present ayahuasca usage and sequenced via target sequence capture. These resulting data will be used for phylogenetic analysis to assess evolutionary relationships and genetic clustering within P. viridis, and the integration of geographic data will allow for phylogeographic analysis for the determination of potential geographic origins, dispersal patterns, and domestication events of this culturally important species.

Abstract Name: Evaluating the Effectiveness of Social-Norm Based Messaging and Dynamic Feedback on Reducing Food Waste in University Dining Halls

Around one-third of all food produced in America is wasted, creating environmental, economic, and social ramifications. We seek to measure and reduce food waste and food waste behaviors in two all-you-can-eat dining halls at a large, public, Western university. Leveraging the potential for behavioral change in university populations, especially among young adults, we focus on all-you-can-eat dining halls, known for their higher propensity for generating food waste compared to a la carte dining facilities. Prior studies on social norm-based messaging in the context of food waste have often been limited by short sampling periods and failure to account for natural time variations in food waste levels. This study attempts to improve upon these limitations by performing a difference-in-difference analysis between two dining halls and sampling daily over a three-month period. This field study and survey model will implement a two week pre-intervention survey, six week intervention period, and four week post-intervention survey period (n=500). Our primary objective is to assess whether social norm-based posters displayed during the intervention period can effectively reduce food waste and influence self-reported food waste attitudes and behaviors among diners. The surveys will also utilize the Social Norm Espousal Scale (SNES) to explore whether social norm espousal moderates the effect of social norm displays on changes in food waste attitudes and self-reported behaviors.We anticipate a significant reduction in average food waste weights in the treatment dining hall compared to the control during the intervention period. This study contributes to the growing literature on food waste and hopes to advance the field's understanding of social-norm based messaging in the broader context of waste reduction. Furthermore, our findings will help advance the university towards campus-wide and state-wide sustainability goals.

Abstract Name: Time Devoted to Grooming in Response to Varroa Mites Within a Honeybee Hive Population

Grooming behavior is an important practice exercised by the honey bee (Apis mellifera) against varroa mites (Varroa destructor), one of the most destructive pests of the honey bee. Since time and energy devoted to grooming are unavailable for other essential tasks, it is predicted that the relationship between mite level and proportion of groomed mites will not be linear. At some level of mites, honey bees will not be able to further increase the proportion groomed and a quadradic model will be a better fit to the data. There is a significant relationship between the total number of mites in the colony and the proportion of mature daughter mites groomed (p=0.003) and adding a squared term improves the model as indicated by a higher r2 value. There is also a significant relationship between the total number of mites in the colony and the proportion of founder mother mites (p=0.034) but a linear model is the best fit to the data. It is predicted that the amount of time

spent grooming will increase with a higher count in varroa mite and although honeybees have a high plasticity for switching from task to task, there would be a clustered population of specialized allogrooming bees in the sample. Methods include using Dadant mite traps to conduct a monthly mite count and a stereomicroscope to count the number of trapped mites with body damage consistent with honeybee grooming and identify the lifestage of varroa mite. For behavioral observation, we established an ethogram of grooming behaviors and other hygienic behaviors to: a) evaluate if the time devoted to grooming increases with increasing infestation levels and b) determine if grooming time is spread across individuals or clustered to a subset of individuals.

Abstract Name: Developing a Passive CO2 Capture Device Utilizing Photothermal Heating Effect

Current aqueous-amine carbon capture methods suffer from a limited efficiency due to the energy-intensive process of separating CO2 from capture solutions. This process requires substantial energy inputs to heat the solution and regenerate the solvent. Previous research has demonstrated that photothermal excitation of nanoparticles can initiate CO2 release without the typical energy requirements for heating the bulk solution. This phenomenon has the potential to significantly reduce the overall energy cost of carbon capture methods by increasing CO2 release efficiency using localized photothermal heating and solar energy. We propose utilizing this photothermal effect in a device capable of passively extracting CO2 from point sources and continuously regenerating the solvent through solar energy. We have demonstrated the efficacy of this system at a bench-scale by suspending carbon-black nanoparticles in capture solution and layering the suspension between a CO2 membrane a window. The efficiency of this process is strongly influenced by the composition and thickness of the membranes, the surface area to volume ratio (A/V) of the solvent-air interface, and solvent composition. While the device can run continuously, we suggest that day to night cycling of the light source can optimize CO2 loading and release. By utilizing localized photothermal heating and solar energy, this device has the potential to enhance CO2 release efficiency and reduce energy costs for carbon capture.

Abstract Name: Assessing gill pigmentation over time in Atlantic sturgeon and paddlefish

Paddlefish and Atlantic sturgeon are part of the order Acipenseriformes which includes all sturgeon species,

the American paddlefish, and the now-extinct Chinese paddlefish; all of which are basal ray-finned fish. Both species live in rivers in the eastern United States, but can survive in salt or brackish water as well. Gill pigmentation in paddlefish and Atlantic sturgeon is a topic that has not been looked at much in previous studies and it is unknown whether or not it serves a purpose in these fish species. However, it has been looked at in freshwater and marine stickleback species which show that salinity might be a factor influencing gill pigmentation of certain fish species. The primary aim of this study was to quantify gill pigmentation during the early development of paddlefish and Atlantic sturgeon using the bullhead catfish as a control. Based on unpublished results from student studies, it was expected that gill pigmentation in the two primary organisms will increase over time. This study involved sampling juvenile paddlefish and Atlantic sturgeon from various facilities across the United States and euthanizing them with a lethal dose of anesthetic. The gill arches were removed with scissors high-definition images were taken of the gill arches and were uploaded to two online programs (Image Color Summarizer and ImageJ) which quantified the amount of pigmentation in each gill arch and the results were organized into bar graphs. The gill arches were also viewed under a light microscope where the localization of pigment cells was determined. Gill pigmentation in both of the primary organisms did increase over time but it was not significant. This study will hopefully lead to other studies that determine whether or not gill pigmentation serves a purpose in Acipenseriformes or studies that look at other species of sturgeon.

Abstract Name: Effect of Hypoxia on the Structure of HIF1A mRNA 5′ Untranslated Region

The HIF1A gene is a transcriptional activator that regulates cellular responses to hypoxia by inducing transcription in many other genes, and plays an essential role in embryonic vascularization, tumor angiogenesis, and ischemic diseases. Overexpressed HIF1A gene has been found to be linked to many forms of carcinoma, breast, ovarian, and lung cancer. The gene is reported to exhibit internal ribosome entry site (IRES) activity. IRES activity uses regulatory structures located in the 5′ untranslated region of the mRNA allowing cap-independent translation. In the case of the HIF1A mRNA, IRES activity must be specifically activated under hypoxic stress. The mechanism of this process is unclear. To address this, we are interested in measuring changes in the structure and interactions of the regulatory region subjected to chemically-induced hypoxia. We have applied SHAPE-MaP to investigate the secondary structure of the regulatory region of the HIF1A mRNA in human cell lines to better understand the mechanisms of stress-induced initiation. We compare SHAPE data collected using gene-specific targeting of the HIF1A mRNA under (a) cell-free, (b) in-cell normoxic, and (c) in-cell hypoxic conditions. Our cell-free structure model reveals a highly structured 5′ UTR with multiple short hairpins motifs. Next, we closely compare live cell SHAPE data identifying regions that are affected by hypoxia. In addition to changes in SHAPE reactivity, we have detected changing patterns of protein interactions within the 5′ UTR under the varying conditions. Future directions include utilizing RNP-MaP, a UV-crosslinking strategy to examine specific protein-motif interactions affecting hypoxic translation, along with DMS-MaP to directly evaluate base-pairing with more specificity. Lastly, we identify orthogonal strategies to validate the HIF1A mRNA structure and interactions.

Abstract Name: Quantum Uncertainty: Surprising Implications for Ethics

The idea that matter may not exist without observation (or that matter may come into existence at the time of observation) has puzzled physicists since the theoretical foundations of modern quantum theory were first established in the 1920s. These developments have led to an incipient “turn” in these sciences toward alternative non-materialist explanations of reality -- many of which bear some striking resemblances to Platonist and/or Neoplatonist “idealist” theories.Such hypotheses, though controversial, have entered into the “mainstream” of discourse. Considerable variety of views that have developed. Some physicists and mathematicians have adopted “hard” idealist views. Other physicists and mathematicians have adopted what might be classified as “soft” idealist views which posit that ideal entities exist and may coexist with some sort of physical entities, even if humans are incapable of precisely apprehending the physical.In this paper, I do not take any position in the mathematical and scientific debates between materialists and idealists. What I do is explore some of the implications of this movement toward idealism (in mathematics and science) for the philosophical study of ethics. Specifically, I focus on the potential implications to the following three schools of ethical thought: moral relativism, error theory and ethical realism. I will argue that the problems that are posed by quantum theory to the “objectivity” of certain types of scientific claims within the physical sciences (e.g. the measurement and observer problems) have implications for philosophical ethics that are quite the opposite of what many may initially suspect. I argue that certain idealistic implications that can be inferred from quantum theory would be fatal for nihilistic ethical theories such as moral relativism and error theory. Furthermore, I argue that certain idealistic implications that can potentially be inferred from quantum theory could lend support for “realist” conceptions of ethics.

Abstract Name: Disparities in Access to Home Air Conditioning in the Greater Los Angeles Region

Background: The greater Los Angeles region comprises a wide range of demographics and has a hot climate. In this study, we sought to examine how access to home air conditioning (AC) is distributed across census tracts within the California Energy Commission’s Climate Zone 8 region and whether there are demographic-related disparities in AC penetration. We hope that a better understanding of this distribution may give guidance to policy makers. Methods: Demographic data and AC penetration data of residents from census tracts in Climate Zone 8 were gathered from the American Community Survey 2013-2017 five-year estimates and an AC classification model (Chen et al. 2020), respectively. The demographic variables include race/ethnicity, income, immigration status, occupation, age, and number of persons per household. Using generalized linear models, the association between demographics and census tracts with high AC penetration (above population mean) was assessed. Results: The prevalence ratio (PR) of census tracts having higher AC penetration was 0.005 times [95% CI: 0.0004-0.052] lower for each additional percent of non-Hispanic, Black residents and 0.236 times [95% CI: 0.126-0.441] lower for each additional percent of Hispanic residents. The percentage of census tracts with a median household income in the third quartile (PR: 1.819 [95% CI: 1.182-2.799]) were associated with higher AC penetration. Conclusion: The key takeaway is that race/ethnicity and income are the only statistically significant predictors of AC penetration. Census tracts in

the Greater Los Angeles region with more Black or Hispanic residents and lower household income were less likely to be air-conditioned.

Abstract Name: Implementation and validation of a semi-automated workflow for body composition measurement in a clinical image viewing platform

Quantification of muscle mass and adipose tissue can inform prognosis and aid treatment planning for cancer patients. Important barriers to routine measurement of body composition includes the need for specialized software and limited implementation in FDA-cleared platforms used for routine clinical imaging review and reporting. To address this need, we have developed and validated a semi-automated workflow in a commercially available, FDA-cleared multimodal image viewing and analysis platform. We developed a 2D segmentation for body composition (2D-SBC) workflow using MIM Encore to define and display regions of interests (ROIs) on a single axial slice at the L3 level for subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT), and skeletal muscle (SM). These data points are used to calculate a skeletal muscle index (SMI) based on previously established methods. The user draws the appropriate ROIs with workflow-defined constraints and refinement steps to improve speed and accuracy. Results were compared with the established software package Slice-O-Matic in a total of 100 patients who underwent CT of the abdomen and pelvis for oncologic indications. The time required to analyze each study was similar with our workflow and with Slice-O-Matic. There was strong agreement for SM, VAT, and SAT areas and for classification of sarcopenia based on an established SMI cutoff (Kappa statistic 0.88). Of the 100 patients, only 6 had discrepant sarcopenia classification with SMIs close to the cutoff value, averaging less than 1.0 cm2/m2 above or below the cutoff. Our workflow has comparable accuracy and efficiency compared to a well-established method used routinely for research. This workflow is implemented in a clinical image viewing system, is easily shared between users across institutions, does not require specialized training, and can be readily modified for specific applications, making this technique available to a wider range of users.

Abstract Name: Synthesis of Magnetic Particles and Investigating its Toxicity in Breast Cancer Cells

Students were given demonstrations and hands-on experience with multiple techniques in the nanomedicine lab at the University of North Texas. This included printing with two different bio-printers: the Lumen X, which uses digital light processing (DSP), and INKREDIBLE+, which uses extrusion printing, and students learned about the different advantages of each. Some potential uses of bioprinters can be used for the artificial restoration of tissues or scaffolds for cell culture. Students also observed and assisted with creating polymer nanofibers using electrospinning, and multi-layered iron oxide magnetic nanoparticles using a wet chemical approach, and were able to observe their results during a live demonstration of scanning electron microscopy (SEM) using their created samples. Electrospinning generates scaffolds using desired solutions that serve purposes including wound healing or tissue engineering. Magnetic nanoparticles provide a less invasive drug delivery method. Students also performed multiple steps of the cell culturing process, including cell thawing, passaging, and freezing, and also learned about the importance and reasoning behind all these to produce healthy, viable cell lines for experimentation. They also helped to prepare 96-well plates to perform multiple cell assays including MTT assay, LIVE/DEAD assay, and F-actin/DAPI staining, and then observed the results of these using fluorescence microscopy and cell counting.

Abstract Name: Character Strengths In Children's Literature: Narrative Theme Versus Vocabulary

Positive psychologists have identified 24 character strengths that every human posseses to a certain degree. Each of the character strengths falls within one of six broad virtue categories: wisdom, courage, humanity, justice, temperance, and transcendence. Research on positive psychology intervention has suggested that people who are aware of their strengths, regularly use their strengths, and engage in gratitude and reflection of their strengths have increased happiness and overall well-being, compared to those who do not. Recent studies that have examined the impact of character strengths and individual wellbeing have focused primarily on adult and adolescent populations, not children. Some studies have examined various techniques for developing strengths in adolescents through positive education programs or through scholarly meetings, courses, and intervention exercises. Although these studies provide valuable insight, they lack information on how to appropriately assess or develop character strengths in children. UNO's Positive Psychology, Arts, and Humanities (PPAH) Lab is investigating whether reading literature that embodies the 24 strengths increases children’s knowledge and use of strengths and their overall well-being. This study aims to investigate what criteria is needed to establish the validity of character strengths in children’s books, before the literature can be used as a tool to enhance character strengths in children. For this study, undergraduate and graduate student participants read six children’s book scripts (one book per virtue) from one of the following two conditions: narrative theme or vocabulary. Participants then answer comprehension questions and categorize each book into 1 of the 24 character strengths. Based on findings from the PPAH Lab's preliminary studies, I hypothesize that participants in the vocabulary condition will categorize more books in the correct character strength than the narrative theme condition. Findings from this study will inform future research and provide a framework for selecting literature to enhance character strengths in children.

Abstract Name: Financial Inclusion in Latin America: Factors for Continuing Development

Over 50% of the Latin American population is unbanked, making financial inclusion a key factor for society's development. Since 2017, the financial system has been growing, including an additional 11% of the population annually. Therefore, this research will be focused on: What are the most critical factors that have helped financial inclusion increase in Latin American adults in the past five years? To answer this question this study analyzed the key factors that have contributed to the increase in financial inclusion among Latinos adults over the past five years. For this mixed-methods study, I interviewed 10 participants in Latin America. Qualitative data was gathered from the interview transcripts and analyzed thematically. Four World Bank data sets - internet access/bank account holders, GDP per capita/ bank account holders, GDP per capita/ ebanking, Covid-19 / digital payment - were analyzed using exponential regression modeling in python. Findings revealed that technological and social factors have had a significant impact. The preference of Latinos for food delivery services has motivated them to use fintech services. Blockchain has enabled financial inclusion in rural areas by allowing people to access banking services through their mobiles. Key factors include the transparency of fintech over traditional banks, financial products such as checking and saving accounts in the bank account, and fewer annual/transaction fees. Technology is critical to bring people into the financial system having outcomes such as access to education, housing, and transportation.Key Words: Financial Inclusion, Fintech, Latin America, Inequality

Abstract Name: Unveiling Spatial Patterns: Data Mining Insights from Enhanced 3D Building Datasets for Informed Urban Planning

Large-scale urban building data, such as OSM Buildings, have practical significance for urban planning strategies, architectural design, and environmental impact assessments. A holistic perspective on the built environment enables data-informed decision-making, laying the groundwork for improved urban development, risk management, and resource allocation. However, to truly benefit from big urban building data, it is critically important to develop scalable algorithms that can reveal insightful patterns of building infrastructure at a regional scale and provide summarized building information for city planners and operators.This research aims to mine the spatial distribution of buildings with similar building information, establishing a robust foundation for data-informed urban planning and risk management. The objectives of this research are threefold: 1) to enhance the completeness and accuracy of 3D building representations, 2) to identify latent patterns within the dataset, and 3) to contribute valuable insights to the field of spatial data analysis. This research addresses the intricate challenges posed by fragmented polygons within 3D building datasets, recognizing their impediment to precise data pattern mining. The necessity for cohesive and accurate building representations is particularly pronounced in domains where spatial information is pivotal for decision-making.Our methodology includes a multi-step process, initiating with the merging of intersecting polygons and defining new attributes. These additional attributes enrich the dataset, providing a

comprehensive representation of buildings. Subsequently, k-means clustering analysis is applied to the building attributes our algorithm generated and finds hidden spatial patterns of building data. Rigorous data cleaning and normalization procedures are performed to enhance the reliability of the clustering outcomes. The clustering analysis results unveil distinct patterns within the dataset, shedding light on inherent structures and variations. Visual representations through geospatial mapping offer a clear and intuitive presentation of identified patterns. Specific clusters and trends are found and provide valuable insights for further interpretation and application.

Abstract Name: The Relationship Between Companion Animals and Emotional Regulation

In recent years, there has been an increase in companion animals (trained ESAs and pets) in higher education settings (Foster, 2022). Universities are implementing group animal therapy before exams with the goal of helping lower students' stress (Kivlen, 2022). Although there are many benefits to companion animals in university settings, there are minimal studies to help defend the emotional and physical benefits of college students owning a companion animal. The present study aims to determine the relationship between owning a companion animal (a pet, emotional support animal, or a trained service animal) and one's ability to regulate their emotions. The researcher hypothesized that having a companion animal would increase one's emotional regulation. In this study, pet attachment was measured with the Pet Attachment Questionnaire (Staats et al., 1996). Emotional Regulation of Sadness and Worry was measured with the Positive Emotional Self-regulation Questionnaire (López-Valle et al., 2018). The sample included 136 full-time college students from a Christian university. A t-test and a simple regression analysis were conducted to analyze the data. The findings in this research revealed that perceived pet attachment predicted emotional regulation of sadness (b1 = 0.237, p < .05). The more reported pet attachment was associated with higher levels of emotional regulation of sadness in college students. In addition, there was a statistically significant difference in emotional regulation between males and females (t = -2.61, p < .05). Female students (M = 3.44, SD = 0.41) showed higher levels of pet attachment than male college students (M = 3.08, SD = 0.67). The findings emphasize the need for society and university institutions to recognize that emotional regulation in college students is impacted by pet attachment.

Abstract Name: Germany Versus the United States: Comparative Analysis of the Allocation Strategies and Leveraging of Foreign Financial Assistance

This study analyzes how donor governments, such as the United States and Germany, have historically leveraged foreign financial assistance by strategically allocating foreign aid. Foreign aid has a track record of

having been praised for lending a helping hand to underdeveloped countries and their citizens. However, various international aid case studies demonstrate how, historically and currently, foreign aid has been detrimental to the development and growth of foreign governments. Notably, this research focused directly on a case study comparison between how military aid and developmental aid are leveraged and/or allocated in the United States and Germany. Using a cross-analysis strategy between academic literature and quantitative data from NATO, the Organization of Economic Cooperation Development (OECD), and Foreign Assistance.gov, this research analyzed the underlying intentions of foreign aid donations. As a result, it was concluded that the United States allocates aid with national security interests in mind; however, Germany does not. In fact, the United States in 2022 solely accounted for almost 70% of the total NATO fund, funding more than NATO Europe and Canada combined, while Germany only made up 5.27%. Germany has traditionally only allocated development aid due to its collectivist culture and has typically restrained from donating military aid. Nevertheless, given the current Russian attack, Germany has recently made history by reversing an old foreign aid policy and granting military aid to Ukraine.

Abstract Name: Ethnicity and Income Effects on Change Over Time in Primary Exceptionality for Elementary-School Students

An accurate “primary exceptionality” to drive IEPs is critical for students to receive appropriate special-education services in schools. Change over time in a student’s primary exceptionality/disability category (i.e., mobility) suggests that a student may have initially received a misdiagnosis. Although prior studies show race and income disparities in disability status (disproportionality for certain groups/categories at one time-point), few studies have examined mobility in exceptionality category over time, and none have examined how race or income impact longitudinal mobility of disability categories. My psychology honor’s thesis examines how ethnicity and poverty-status impact mobility in student primary exceptionality status from Kindergarten through 5th grade, using existing longitudinal data from a large (n ~ 38,000), ethnically diverse sample (~58% Latine, 30% Black, 12% White/Other).I use data from the Miami School Readiness Project, which followed predominantly low-income children in various pre-K programs throughout elementary school. I focus on the ~7,000 students identified with a disability during elementary school. Ethnicity (Latine, Black, White/other), poverty-status (free/reduced-price lunch receipt), and primary exceptionality status, each grade, were gathered through de-identified school records. My questions are: 1) What is the overall mobility rate in primary exceptionality from kindergarten through 5th grade? 2) How does mobility vary by initial category (i.e., ASD, LD etc…), 3) Does mobility vary as a function of ethnicity or poverty-status?Based on prior research, I expect there to be considerable mobility over time across disability categories, with higher mobility in more subjective initial categories, such as emotional disability. I expect minoritized students and those in poverty to show more mobility in categories over time, which, if found, would have equity and policy implications. I am currently cleaning the data and finalizing variables. The Chi-square, ANOVA, and multiple regression analyses in SPSS will be complete in time for the conference.

Abstract Name: Quilting as a Means of Fostering Political Communication

There are many ways in which people politically communicate. Conventional ways have been public speaking, collecting petitions, or attending public meetings; however, more direct approaches have included rallies, protests, and strikes. Before women were legally allowed to participate in U.S. politics, many communicated their political views and opinions through quilting – an unconventional yet indirect approach. Today, all genders – though the majority continue to be women – use quilts as a method of expressing their thoughts about political and social issues. Furthermore, these quilts can now reach a larger audience through social media. The goal of our research was to answer the question: How do political messaging quilts posted on social media platforms contribute to understanding or engaging people in politics and social issues? The purpose of this study is to recognize quilts as political messages and as effective forms of promoting activism on social media. This research examined 48 political quilts on TikTok, Instagram, Twitter, and Reddit over the span of three weeks. Results indicated that the majority of quilters were female, there was a wider interest in LGBTQIA+ issues, and that these posts promoted various forms of activism from its audience; hence, dictating that political quilts posted on social media were catalysts for activism. The attention the political quilts received on social media platforms was significant because it is a form of political communication that has not previously received much recognition by other activists. Regardless, quilting should be acknowledged as a form of activism. The textile medium is not as direct as a protest, but the passion it manifests is as deep as any activist's.

Abstract Name: Examining the Efficacy of Music Therapy on the Upper Extremity of Post-stroke Patients: A Systematic Review and Meta-analysis

Stroke is the second most common cause of death worldwide, caused by an interruption of blood flow to the brain, which results in necrotic cell death. This pathological cascade has ramifications in neurological motor, sensory, and behavior deficits. There has been some recent research using a therapeutic application of music as a vehicle to improve motor function of the upper extremity of post-stroke patients. Music-supported therapy is a newer class of music therapy that works to improve motor function through a standardized program of keyboard and drum exercises, and it is continuing to be integrated into the field of rehabilitation. This study aims to search three areas of music therapy, such as music-supported therapy, technological applications, and musical sonification, to examine a positive effect of music therapy on the upper extremity, thus supporting its use for the treatment of stroke-induced motor dysfunction. To conduct a meta-analysis of trials examining the effect of music therapy to rehabilitate the upper extremity of post-stroke patients, comprehensive literature searches of PubMed, CINAHL, MEDLINE, Music Index, Cochrane, and Web of Science from their inception to November 2023 were performed. Instruments, such as the 9 Hole Peg Test (9HPT), the Box and Block Test (BBT), and the Wolf Motor Function Test (WMFT), were used to evaluate the results of the intervention, and the studies classified in each category were investigated and underwent sub-analyses using a standard mean difference in the change from baseline and the 95% confidence interval

(CI) for analysis. This study also aims to advocate for the further research and integration of integrative therapies in medicine.

Abstract Name: Validation of a bone-on-chip microdevice to mimic the bone-vascular microenvironment.

Bone-on-chip devices enable controlled study of the cellular microenvironment in response to various stimuli. Previous systems did not incorporate both vasculature and mineralized bone, which are necessary to mimic bone-vascular interactions important for bone metabolism. Our bone-on-chip platform addresses this gap. We previously used computational fluid dynamics in COMSOL Multiphysics® to optimize chamber heights and flow rates for device functionality. The objective of this study was to validate these computational results in physical devices. Devices were fabricated by shaping polydimethylsiloxane (PDMS) in 3D-printed resin molds for bone and endothelial cell chambers, layering and separating them with a polycarbonate membrane, and manually bonding using plasma treatment. To validate flow characteristics, 10-μm fluorescent beads were perfused through the assembled device chambers, and using fluorescence imaging, bead velocity was calculated as the bead trail length divided by exposure time. Shear stress along the walls of the device chambers were derived using true device geometry and pipe flow equations. Results were compared with predicted values from computational models for varying flow rates of 100-1200 μL/min. Predicted average velocities ranged from 0.011965 to 0.14337 m/s, and shear stresses ranged from 0.785 to 9.524 dynes/cm2. Across this same flow rate range, experimental average velocities ranged from 0.010526 to 0.116005 m/s, and shear stresses ranged from 0.75 to 9.07 dynes/cm2. Compared to predicted values, these preliminary device testing data were within 19% error for average velocity and 5% error for shear stress for all tested flow rates. Experimental discrepancies likely resulted primarily from limitations in fabrication of exact chamber heights and measurement of velocity in a single plane. These data show that our device functions within reasonable expectation and support the accuracy of our COMSOL model. Next steps include further device validation using dextran diffusion and inclusion of endothelial cells in the device.

Abstract Name: Data Goggles: A Research and Development Tool

A collaborative project with SAS’s Research and Development (R&D) department aimed to tackle the challenge posed by the absence of an internal tool for streamlined data access and analysis. This deficiency significantly impacted team productivity and hindered the efficient utilization of datasets. The project adopted a methodical approach, delving into a comprehensive examination of data-related issues and

formulating targeted solutions. Specific programs were implemented to optimize software performance across various computing environments, ensuring a smooth and efficient deployment process. The development of Data Goggles, a specialized tool, entailed carefully aligning its features, interface, and functionality with the intricacies of the R&D workflow.To enhance usability, an interface was crafted via the JavaScript library, React. Leveraging Docker Hub, a repository of pre-built software components, played a crucial role in simplifying the setup and usage of Data Goggles. The integration of Kubernetes as a data manager for the website ensured scalability and operational efficiency across diverse computing infrastructures. The methodological framework incorporated rigorous testing and continuous refinement to guarantee precision in addressing the identified challenges. The project's successful conclusion involved the automation of the entire process through Jenkins, an open source automation server, thereby enhancing accessibility for all SAS employees. This research-focused initiative made a substantial contribution, providing R&D teams with a robust resource to expedite data retrieval and analysis processes.In summary, this project not only demonstrated the impact of innovative methodologies in addressing real-world challenges, but also emphasized the critical role of methodological rigor in developing technology solutions within the organizational context of SAS. The integration of established tools, frameworks, and a research-oriented approach collectively underscored the project's commitment to delivering tangible improvements in data management for SAS's R&D department and holds potential for broader applications in similar contexts.

Abstract Name: The Origins of Southern Appalachian Folk Medicine and Its Survival In The Post-World War II Cultural And Religious Climate

The purpose of this research is to track the development of Southern Appalachian Folk Medicine (SAFM) from the colonization of the Southeastern United States into the modern day by analyzing the interactions between the three major contributors to the Southern Folk medicinal system which include European, African, and Indigenous cultures and practices. To better understand how and why the SAFM system came to be, this research looked at the materia medica (the materials used for medical treatments) as well as the beliefs that informed people's use of the materia medica. It also looks at the effects of the Christian Church on folk medicinal systems on European practices and on African and Indigenous practices as they were combined to form SAFM. The final piece of this research looked for evidence of the survival of Folk medicine systems after World War II. Original interviews were conducted with a family from Appalachia to understand what kinds of Folk Medicine are still used. The findings of these interviews corroborated trends present in research conducted from 1970 to 1990. They demonstrated a steady decrease in the use of Appalachian Folk medicine. Folk medicine is defined as the “vernacular knowledge about the cause, prevention, and treatment of illness used by a particular social group.” In Southern Appalachia, this vernacular knowledge is the offspring of centuries of cultural syncretism between European, African, and Indigenous traditions. By examining the influence of European, African, and Indigenous Folk practices on the Southern Appalachian region, it is evident that the magico-religious and naturalistic beliefs that informed the Southern Appalachian experience are a complex web of borrowed, bought, and stolen practices that, over time, built the Folk materia medica and Folk astrological system, which culminated into SAFM and which survived the United States’ major cultural and religious shifts post-World War II.

Abstract Name: Alternative Ways of Being; Music, Disability, and Adaptive Technology

Disability is a part of the everyday for many of us, and our rights should be considered with regards to research and the innovations and inventions that involve us. Human rights include disability rights, and we have a right to accommodations that allow us the same freedoms as abled individuals. For instance, the right to create - inclusive of the right to make music - is a human right. Thus, the advent of new technologies that allow us to make music is a necessary development. Individuals with mobility disabilities now have the capacity to be involved in the music-making process, rendering them more publicly autonomous. This visibility undermines the stigma that disabled individuals are unable to make their own decisions. To illustrate the promise of adaptive music technology and the obstacles that still remain, I study Pauline Oliveros, a musician and humanitarian, and the Adaptive Use Musical Instrument, which she helped to create in 2006. I situate the AUMI within the broader history of adaptive technologies in music, supplemented by conventional research as well as interviews with people close to the creation of AUMI. This research demonstrates the capacity of adaptive music technology, along with the open-mindedness of its users, to transform a space into a creative community in which those of us with disabilities can have equity, where we can receive the accommodations we need and want, and to compose music - as is our right.

Abstract Name: Integrating Socio-Behavioral Factors into Monkeypox Modeling: A Novel Framework for Informed Disease Mitigation

Monkeypox (MPX), a zoonotic ailment similar to smallpox that originates from Central and West Africa, is a global health threat of growing concern. The increased incidence of MPX in recent years, instigated by a halt in smallpox immunizations and an upsurge in vulnerable host populations, necessitates a nuanced understanding of its transmission dynamics to create proactive measures for averting the ominous trajectory many countries are currently navigating. Current Susceptible-Vaccinated-Exposed-Infectious-Recovered (SVEIR) models, a mathematical means to address public health crises, often overlook critical socio-behavioral factors such as the impact of misinformation on vaccination rates. To address said gap, this research aims to introduce a comprehensive array of novel features that will enhance the representational capacity of epidemiological simulations and provide a more holistic perspective on MPX propagation within a population. An advanced iteration of the SVEIR model captures the multi-faceted relationships between parameters governing perceived infection risk, misinformation factors, behavioral changes, disease-induced mortality, immunity waning, and the effectiveness of educational campaigns. This model further integrates categories for mild and asymptomatic cases, seasonal variation of disease spread, and vaccine efficacy awareness. Crucially, the model also utilizes game theory by establishing a Nash equilibrium to distinguish between informed and uninformed individuals, offering a strategic dimension to vaccination decision-making processes. The inclusion of these components in the extended system of ordinary differential equations

(ODEs) allows for a broader range of real-world scenarios, potentially allowing the developed framework to become a versatile template for addressing other infectious diseases. Via parameter adjustments, the model can be applied to diseases such as influenza, measles, and Ebola. Overall, the refined model could serve as a valuable tool for researchers and policymakers to gain insights into and design targeted strategies for disease mitigation and control.

Abstract Name: A Content Analysis of How Immigration is Framed and Discussed in Media

This research is a content analysis of media portrayal of immigrants through an examination of news articles discussing the Biden Administration's Temporary Protected Status (TPS) policy for Venezuelans. The study addresses two primary questions: 1) What different categories are highlighted in media outlets in response to President Biden's TPS policy for 472,000 Venezuelans? 2) How are immigrants being framed, and what negative issues arise from poor coverage?Analyzing thirty news articles from diverse sources, the study reveals major takeaways. Limited comprehensive reporting emerges as a significant concern, with only 10% of articles fully covering the immigration policy, leaving substantial information gaps. Incomplete coverage of reasons for migration is noted, with only around half of the articles providing insights into the motivations behind Venezuelans leaving their home country. Diverse perspectives on the bill's passage and an underreported extension of TPS for Venezuelans further characterize the media landscape.The conclusions underscore the omission of humanity in articles discussing immigration, contributing to a skewed perception. Comprehensive reporting is found to be insufficient, and as consumers of news, there is a rightful expectation for a complete view of events. The dangerous consequence of omitting vital information is the creation and perpetuation of negative stereotypes toward immigrants.

Abstract Name: Is Mexican Art Mexican?

Discovering the origins of Mexican art can be difficult as not all Mexican art is directly derived from Mexico. The Spanish conquest resulted in a genocide of Mesoamericans who were forced to comply to the Spanish religion and customs. The Spanish burned their belongings and made Mesoamerican art extremely difficult to find. Today the impact of the Spanish conquest continues to linger throughout Mexico, it is present in architecture, the iconography of the Lady of Guadalupe, and the incorporation of Spanish tile in design.

Abstract Name: Developing a 3D collagen model of cardiac fibrosis

According to the CDC, every 34 seconds someone dies from a cardiovascular-related disease, making it the number one cause of death in the country. Cardiac fibrosis, which typically appears after heart injury, is characterized by the stiffening of contractile fibroblast tissues caused by the excessive production of extracellular matrix. The purpose of this project is to create a 3D model of cardiac fibrosis that can be used to study the progression and its characteristics. With the use of collagen type VI (Col VI) and CCN1, proteins that play a key role in wound healing, and a mixture of both, we investigated whether the results would differ from the control group. Our 3D model consists of seeding 3T3 fibroblast cells within our collagen type I hydrogel, in a 96-well plate that is cultured for 5 days in the incubator. On day 5, we start our immunostaining process where the samples were stained with Alexa-phalloidin for F- actin, α-SMA for alpha-smooth muscle, and DAPI for nuclei. Finally, we use a fluorescent microscope for our imaging analysis. According to our data, the 3D model containing collagen type VI increased fibroblast proliferation. On the other hand, the model containing CCN1 showed a decreased fibroblast proliferation. With the data, we hope to develop an ideal 3D model of cardiac fibrosis that can be used to test scaffolds and other therapeutic drugs with the purpose of improving cardiac functionality and regenerate tissue.

Abstract Name: CHEMICAL VS. GENOMIC: DOES TAXONOMY REALLY TELL ALL?

Fungi are naturally found in all environments with over 600 species interacting daily with humans (Casadevall, American Society for Microbiology, 2017). Fungal natural products are a rich source of antimicrobial anticancer drugs (Jakubczyk, Molecules, 2020). The Carlson Library has isolated 108 unique aquatic fungal species based on observations on collection location, morphology, growth rate, and areas of spore coverage used to distinguish strains. We aim to characterize fungal species based on chemical identity and 18s rRNA sequencing to build a phylogenetic tree to understand the diversity captured by current isolation and culturing methods. Fungi are initially plated on Potato Dextrose Agarose (PDA) media plates and grown until they sporulate 7-10 days (Ezeonuegbu, Sci Rep, 2022). They are then cultured into liquid media and grown on a rotary shaker 110 rpm. Fungi were pelleted, DNA WAS extracted for PCR, and submitted for Sanger sequencing of the 18s rRNA region using standard primers ITS1 and ITS4. Representative strains from each phylogenetic branch will be grown for chemical characterization. Ethyl acetate is added to the flask to cover the media and hyphae. The ethyl acetate is then filtered and dried in vacuuo. All extracts will be profiled by High Performance Liquid Chromatography (HPLC) and Liquid Chromatography Mass Spectroscopy (LCMS). The chemical fingerprints will be analyzed using the mPACT metabolomics platform to identify “chemical families” (Samples, 2023). Previously unknown metabolites, as identified by comparing to databases, will be prioritized for further characterization. This will determine if genetic or chemical families will be more robust for strain prioritization.

Abstract Name: Investigating U-to-C RNA editing by synthetic DTW:KP3 designer protein in vitro conditions

RNA editing is a post-transcriptional process that can convert, insert, or delete nucleotides. C-to-U and A-to-I base editing is utilized by most eukaryotes to alter DNA and RNA sequences. Recent developments have applied base editing as a tool to correct DNA gene mutations that have been linked to genetic diseases. Unlike the well-characterized irreversible C-to-U base editing mechanisms, U-to-C base editing lacks an established biochemical mechanism for the proposed animation of uracil and a simple reverse of the C-to-U mechanism would be disfavored. Recently, researchers have reported U-to-C base editing of RNA from three synthetic proteins expressed in bacteria. These proteins utilize a synthetic PPR tract that provides specificity for a C-terminal domain called DYW:KP based on consensus sequences originating from the nuclear genome of ferns and hornworts. One of these proteins DYW:KP3 was selected for examining catalysis in vitro. DYW:KP3 was expressed in bacteria, purified, and mixed with putative substrate RNA to determine the presence of C-to-U or U-to-C activity. Sanger sequencing of RT-PCR products revealed DYW:KP3 did not exhibit any base editing activity in vitro when given C templates or U templates. No activity was observed in these reactions, which leads us to conclude the protein may not have folded in a conformation conducive to catalyzing base editing.

Abstract Name: Exploring Honey's Antimicrobial Efficacy as a Therapeutic Approach to Inhibit Cutibacterium acnes Growth

Honey has been shown to treat skin wounds and infections due to its antimicrobial and antioxidant properties. The bioactivity potential of honey helps regulate the growth of bacteria and aid in skin homeostasis due to its antimicrobial effects attributed to high sugar content, low pH, and hydrogen peroxide. Honey has shown no microbial resistance and is a promising solution for maintaining a healthy skin microbiome because it can inhibit bacterial growth of S.aureus, stimulate collagen production, exfoliate, hydrate, and cleanse the skin. In a previous study, we examined more than 100 local Texas honey samples for their antimicrobial and antioxidant properties by the well-diffusion method, XTT, hydrogen peroxide activity, total phenolic and flavonoid contents, and DPPH. We identified some honeys with greater antioxidant potential, presented greater antimicrobial capacity comparable with current medical-grade honeys. Although several studies have analyzed honey's antimicrobial efficiency against numerous gram-positive and gram-negative bacteria, the effect on Cutibacterium acnes remains unknown. C. acnes is an anaerobic gram-positive bacterial strain that invades the sebaceous follicles of the skin microbe and creates acne. This study analyzed the antimicrobial capacity of local Texas honey against C. acnes in terms of bactericidal and bacteriostatic activity. We classified honey color according to the Pfund scale using a Spectrophotometer and then used the Well Diffusion method to determine the zone of inhibition of the honey samples with greater antioxidant potential. Results indicated darker honey (amber, dark amber) had the largest zone of inhibition and, therefore, greater antimicrobial capacity than lighter honey. The results indicate that honey can be used as a medical-grade therapeutic approach to treat acne. The honey samples identified as having superior antimicrobial capacity against C. acnes can be further studied to determine their application in human clinical trials and expand the chemistry of honey by formulating creams, ointments, and gels

Abstract Name: Analysis of Amino Acid Content in Nutritional Supplements

When looking to increase muscle mass through strength training, one of the main recommendations is to begin taking protein supplements. Protein helps muscles torn during exercise to recover faster, leading to an increase in lean muscle mass. There are few previous studies on the content of protein powder supplements as

they are not regulated by the Food and Drug Administration (FDA). This study was conducted to identify and quantify amino acids in three different protein powders. To quantify the amount of protein in each supplement, the powders were digested into their individual amino acids. After digestion, amino acids were analyzed by using High Performance Liquid Chromatography (HPLC). Online derivatization using phthaldialdehyde (OPA) was performed on an Agilent 1100 HPLC and gradient separation was performed using phosphate buffer and acetonitrile. Emission data was collected at 450 nm with excitation at 338 nm. From the data collected, it was shown that the Body Fortress brand had 6.3g of amino acids, Shaklee had 0.49g and Vega had 2.14g. There could be limitations in the data due to the hydrolysis method. For future work, alternative methods for protein hydrolysis could be explored.

Abstract Name: Leveraging Interdisciplinary Nutritional Knowledge (LINK) Scholars Program: Preparing Underrepresented Students for the Food and Human Sciences Workforce

Addressing the high rates of chronic disease among Hispanics/Latinos requires effective, culturally tailored programming and staff who practice cultural humility. The current profiles of public health professionals and registered dietitians point to the need to increase the number of underrepresented students trained to serve the growing Latino population. The Leveraging Interdisciplinary Nutritional Knowledge (LINK) Program is a collaboration among five Hispanic-Serving Institutions to establish an academic pipeline linking three community college partners to California State University (CSU) Fullerton and CSU Long Beach. The LINK Scholars Program is one component whose purpose is to promote the first-year success of 26 underrepresented students in food and human sciences by providing them with a 12-month fellowship to better prepare them to enter the workforce and/or pursue advanced degrees. At the CSUs, undergraduate transfer and first-year graduate students are screened and selected as LINK Scholars. LINK Scholars participate in: 1) a one-week summer orientation and training on Latino chronic disease prevention; 2) bimonthly learning communities focused on nutrition-related research and professional development; 3) a series focused on leadership skills development; 4) one semester of faculty-mentored research; and 5) a summer externship for experiential learning in a professional setting. Student academic performance and training outcomes were assessed using baseline and post-program surveys. A total of six undergraduates and eight graduates have completed the program, and eight undergraduates and eight graduates are currently enrolled. Among those who completed baseline and post-program surveys, all LINK Scholars were in good academic standing and self-reported increased knowledge in research skills and ability (87%), culturally and linguistically relevant interventions (80%), and chronic diseases among Latinos (70%). All LINK Scholars plan to pursue graduate school. Interdisciplinary training, mentorship, and financial support programs show promise in preparing the future food and human sciences workforce. Student success stories will be presented.

Abstract Name: Wild Fire Detection System

Wildfires are catastrophic events that have become increasingly frequent destroying property and lives. Wildfire detection at its simplest is forest rangers watching the landscape from observation towers. However, modern detection techniques include satellite imaging, infrared (IR) imaging, and electronic sensor networks. Ongoing research has shown, that by incorporating a hybrid system of both sensor networking and IR imaging, a cost-effective model for wildfire detection can be produced. Previous work has shown that an embedded system built on this technology results in detection of thermal signatures between 40-50 feet with datalogging and transmittance of humidity, temperature, and gas/smoke detection via radio frequency [1]. The work presented here, is an extension of the technology used in transmitting the data from sensor to sensor. The initial system used the ARM Cortex-A72 processor found on inexpensive development boards such as the Raspberry Pi microprocessor. The work presented here is based on a smaller, more power efficient, RP2040 processor based on the ARM Cortex-M0+ core found on the Raspberry Pi Pico microcontroller and the LoRa RYLR896 Antenna Transceiver Module from REYAX

Abstract Name: A Comparison Of Nutritional Analysis Of Different Generations

Many think that obesity is a recent issue due to increased rates being reported in the US but obesity has been a prevalent issue for a long time and has even been declared an epidemic in the United States in 1999. Every person’s body is different and each individual may have some underlying health disease that requires them to be on a specific diet or a “personalized nutrition” plan. In this research, we hope to better understand the nutrition needed by an individual to remain healthy and not be considered under or overweight. A daily food log was completed by the participants (generations x and generations z) for a week in which they wrote down everything they consumed in as much detail as possible. Once data was collected it was analyzed using the Diet Analysis Plus Software to get an estimate of participants' daily food intake and break it down into nutritional information. However there was no difference in our data, this could be due to many factors such as sample size response bias and limitation with the software used. Overall, it was noted that generation Z did consume more protein compared to generation X. This could be because of the new diets that generation Z are following or the traditional eating habits of generation X. In general more research should be done with a bigger sample size to determine if there really is a difference in eating habits.

Abstract Name: How Immigration Status and Skin Tone Effects Perceived Leadership

This study aimed to investigate the effects of perceived leadership styles based on immigration status, skin tone, and gender. A diverse sample of 66 participants, aged 18-22, were recruited from Albright College. Participants were exposed to manipulated images of faces representing immigrants and non-immigrants with varying skin tones. They rated the leadership styles of the individuals shown in the images using a Likert scale. Results indicated that immigration status influenced the perception of leadership styles, with immigrants being perceived as having a higher leadership style compared to non-immigrants. However, skin tone did not have a significant main effect on perceived leadership styles. Additionally, gender of the image shown interacted with immigration status, with female non-immigrants being perceived as having a higher leadership style. The results indicated significant biases in perceived leadership. Non-immigrants (M= 150.48, SD= 28.04) scored higher than immigrants (M=118.60, SD= 24.40), F(1, 65)= 248.67, p<.001, η= 0.793. While there was no main effect for skin tone, a significant interaction between skin tone and immigration status was observed, F(1,65)= 5.20, p = .026, η= 0.074. In terms of gender, females (M=138.30, SD= 24.52) scored slightly higher than males (M=132.93, SD= 27.97), F(1,65)= 6.30, p=0.014, η= 0.089. A significant interaction between immigration status and gender was also noted, F(1, 60)= 296.62, p<.001, η= 0.832.These findings reveal a notable bias against immigrants in leadership perception, aligning with existing literature on workplace stereotypes. The lack of significant differences based on skin tone was unexpected, considering the prevalent issues of colorism and racism, and might be attributed to the methodology. These implications are significant for organizational diversity and inclusion, highlighting the need to address biases, particularly concerning immigration status.

Abstract Name: Exploring Cultural Variations in Emotion and Neurocognitive Processes among Dark Personalities

The dark personalities consist of socially aversive traits of Machiavellianism, narcissism, and psychopathy. These traits have been found to aid in career success and handling crisis, but they are also linked to impaired emotional awareness and a lack of empathy. Additionally, Machiavellianism and psychopathy are associated with poorer self-control, whereas narcissism and psychopathy are linked to impulsivity. Little is known about the relationships between dark personality traits and culture identification. This study compares 54 (31Hispanic/Latino and 23 Caucasian) university students with traits of psychopathy and Machiavellianism

(P/M) versus 42 (24 Hispanic/Latino and 18 Caucasian) students with traits of Narcissism (Narc) on aspects of emotional processes (emotional awareness and empathy) and neurocognition (self-control and inhibition). Participants' personality traits were assessed using the Short Dark Triad questionnaire. Additionally, participants' emotional awareness was assessed using the Toronto Alexithymia Scale, whereas empathy was measured using the Empathy Quotient. Neurocognitive functioning was measured using the Tangney Self-Control Scale and Stop-it Inhibition Test. A series of 2 (Culture Group) x 2 (Dark Personalities) Analyses of Variance revealed a trend-level significant Group by Personalities interaction in emotional awareness, ($F(1, 48)=3.921$, $p=.054$ $\eta^2=0.08$). Hispanic/Latino students tended to exhibit lower levels of emotional awareness compared to their Caucasian counterparts with P/M traits, while Caucasian students tended to exhibit lower levels of emotional awareness compared to their Hispanic/Latino counterparts with Narc traits. No significant Group by Personalities interactions were found for empathy ($F(1, 48)=2.012$ p=n.s., $\eta^2=0.039$), self-control ($F=(1, 48)=0.270$, p=n.s., $\eta^2=0.003$), or response inhibition ($F(1, 48)=2.398$, p=n.s., $\eta^2=0.025$). These preliminary findings could potentially expand our understanding of the specific roles of emotional processing and neurocognition in individuals with dark personality traits of different cultural backgrounds.

Abstract Name: The Fight for Housing, Transportation, and Climate Change: CEQA and CALGreen Report

California Green Building Standards Code (CALGreen), the nation's first set of green housing codes, and the California Environmental Quality Act (CEQA) have been cited as possible impediments to the development of housing and transportation due their implementation of additional regulations that could slow development. Thus, this paper aims to explore how green regulations affect the development of public transit and housing in California. Through a comparative, large n-study, this paper investigates the impacts of 1) 2010 CALGreen on the state's housing development, and 2) CEQA and its SB 743 expansion, on the development of public transportation. I study the relationship of housing, CALGreen, transportation and CEQA/SB 743 by comparing the change rate of housing/change rate of population & change rate rideship/change rate of population between California and Texas and two time intervals. I extracted data from the US Census and the American Community Survey (ACS). Through a comparative, large n-study, results showed a tentative conclusion that neither policy has an effect on the change rate of Housing Units/Change Rate per capita. This is one of the first studies that explores the relationship between CEQA/CALGreen and public transportation/housing and hopefully invites further research and educate policymakers in the state.

Abstract Name: Isolation and Characterization of Guanide Degrading Bacteria from Municipal Wastewater

Biguanides are important compounds because they are widely used in agriculture and medicine. Metformin (1,1-dimethylbiguanide) is the most prescribed Type II Diabetes drug worldwide. The widespread use of biguanides has led to detection of these compounds at high levels in rivers and coastal waters. Many of these chemicals, including metformin and guanylurea, are considered emerging water pollutants. The goal of the research was to investigate the microbial degradation of two compounds structurally similar to metformin: biguanide and cyanoguanidine. We hypothesized that because biguanides and similar chemicals are abundant in wastewater, sludge-derived microbial cultures can serve as a source to isolate microorganisms capable of metabolizing these pollutants. The experimental approach consisted of establishing enrichment cultures using three separate kinds of sludge (RAS, TAS, and PAS) and microbial media with biguanide or cyanoguanidine as the sole nitrogen source for growth. Aliquots of enrichment culture were taken after 72 hours of incubation, serially diluted, and plated on minimum media containing biguanide or cyanoguanidine to isolate bacteria that utilized these chemicals as a nitrogen source. HPLC analysis was used to monitor and quantify the disappearance of these compounds in response to microbial growth. The HPLC analysis results revealed degradation of biguanide and cyanoguanidine by activated sludge consortia. Four bacteria strains capable of utilizing biguanide and cyanoguanidine as sole nitrogen sources for growth, were isolated characterized by Gram staining and 16S rRNA PCR. The results showed these organisms were Gram negative and closely related to strains belonging to the genus Klebsiella. Future work will focus on genome analysis to identify candidate genes encoding biguanide and cyanoguanidine degrading enzymes

Abstract Name: Mental health among service members who experienced military sexual trauma: Exploring the roles of individual characteristics and social supports

Military sexual trauma (MST) refers to sexual assault or harassment that occurs during one's military service and can threaten service member well-being and readiness. Though MST may be underreported due to fears of retaliation, prevalence estimates suggest that 15-40% of women and 1-4% of men have experienced MST on post-9/11 deployments and that women and racial minorities are at a greater risk of MST than men or white Service members. Using a social-ecological lens, data from the Army STARRS All Army Study were used to conduct within group analyses of 114 service members who had experienced sexual assault on deployment to understand how individual factors (sex and race) and social factors (mental health support and unit cohesion) contribute to current mental health symptoms (anxiety and depression). Analyses of variance (ANOVAs) results suggest that there were no differences in depressive or anxiety symptoms among MST survivors based on their sex or race (individual factors), but those with greater mental health support and unit cohesion reported fewer depressive and anxiety symptoms compared to those who reported less mental health support and less unit cohesion (social factors). Using multiple linear regression, this study also explored additive associations between mental health support and unit cohesion, two malleable and protective factors, on mental health symptoms. Having received greater mental health support and higher unit cohesion were both uniquely linked to lower depressive and anxiety symptoms. Overall, results suggest that protective, social factors may be more salient in understanding the current mental health symptoms of service members who experienced sexual assault while deployed compared to individual level factors. In addition to MST prevention efforts, stakeholders may consider implementing policies and interventions focused on promoting mental health help-seeking and unit cohesion to mitigate risks to mental health due to deployment MST.

Abstract Name: Boundaries for Beyond Abuse: Utilizing Intimacy Choreography Practices to Support & Fill Gaps in VIRTUS Training

Intimacy Choreography supports the aims of one of the Catholic Church's sexual abuse prevention programs: VIRTUS. The tools of intimacy choreography education company Theatrical Intimacy Education and VIRTUS both aim to establish and uphold boundaries - but in different capacities. Intimacy Choreography provides boundary-setting tools to help performers in scenarios of low stakes (defined as legally acceptable) risk such as exploring creative options in the rehearsal space, while VIRTUS provides tools to prevent and respond to high stakes (defined as legally unacceptable) risk. This presentation compares the tools of each area, and posits how Intimacy Choreography's consent-based practices are a good fit for Catholic diocesan schools' theatre programs that utilize VIRTUS training.

Abstract Name: The Effects of Implicit Sequence Learning on Cognitive and Sensorimotor Function in Older Adults

As we age, cognitive sequencing faces changes with degeneration of neurotransmitter systems and brain matter atrophy. Systems including visual perception, working memory, complex learning, learning rate, learning magnitude, and serial reaction time face degeneration. Purpose: To investigate motor based versus judgment based tasks and the cognitive and sensorimotor relationship for older adults to implicitly chain together events. Methods: Community dwelling older adults (N=20; aged 64.9 ± 6.8) were recruited to participate in neuromuscular and cognitive testing. Participants completed eight perturbation treadmill sessions incorporating various stability challenges consisting of trunk stability, step stability, and continuous slip and trip simulations. Testers distract the participant with conversation adding the element of dual tasking during testing. Additionally, the first and last sessions included a balance and functional assessments. Prior to cognitive testing, participants filled out baseline assessments: Initial Screening and Standard neuropsychological assessments. Following the pre-assessments, participants were given a series of visual and auditory stimulus events through a computer screen to assess implicit sequence learning. Subjects were cued to respond to the events using computer keys, mouse and buttons and their reaction time was recorded. Results: It is hypothesized that perturbation training revealed neuromuscular adaptations to tripping and slipping, improving reactive control of stability and a faster ability to react to sudden pushes off balance.

Cognitive testing revealed a shorter response time and faster rate of pattern recognition as the trials continued indicating implicit learning. Discussion: The results of this study indicate that there is decreased reaction and response time that contributes to the decreased fall risk. Our findings contribute to the growing body of knowledge on healthy aging, showing age preservation in learning deterministic sequences. This leaves open the possibility that motor and judgment based tasks are supported by independent mechanisms.

Abstract Name: The Cross Race-Effect and Political Messages Affecting Memory Accuracy

The cross-race effect (CRE) is an individual's tendency to recognize faces within their own race more accurately than faces outside of their race. Sporer (2001) suggests that the CRE is caused by an ingroup and outgroup effect, such that we process ingroup faces better. However, this is not true for some ingroups such as university affiliation but may occur for ingroups that are more contentious at times such as political groups. The emotional enhancement of memory effect (Kensinger, 2009) states that an emotional stimulus is more likely to be recalled. In this study, we expect the CRE to be stronger as participants recall faces associated with their own political ingroup and outgroups that may illicit an emotional response. Sixty-four college-aged White participants (Female = 54, Male = 10) were grouped by political ideology based on their ratings of left leaning and right leaning messages. They were shown 36 faces, 12 from each race (Asian, Black, and White). Faces were paired with left, right, or neutral leaning political messages. Participants' memory was tested by showing the 36 studied faces intermixed with 36 new faces in a standard recognition accuracy test. A repeated-measures ANOVA revealed significant interaction between the race of faces studied, political leaning of the message, and the participant's political affiliation. The size of the CRE differed based on race of face, such that the CRE was largest between White and Asian faces. More interestingly, the CRE was smallest, and essentially mitigated, when right leaning messages were paired with Black faces, but largest when paired with Asian faces. Moreover, participants who leaned left remembered Black faces better than those who leaned right, possibly due to how similar they thought their social and political concerns were to Black-Americans.

Abstract Name: Research Training and Mentoring to Cultivate the Next Generation of Public Health Professionals to Address Latino Health Disparities

Background: With Hispanics/Latinos soon to be the majority in California, there is a need for specialized training among public health professionals to serve Latinos impacted by the alarming rates of chronic conditions. To mitigate this gap in expertise, a 10-week training and mentorship program was developed to expand knowledge, provide professional development, and hands-on research experience. Methods: The 10-week ANDALE Latino Research Training Program aimed to recruit 50 underrepresented undergraduate students from various health-related disciplines. Four cohorts of scholars of received specialized research training in Latino-specific nutrition and health promotion, community based participatory research, intervention development, and culturally and linguistically effective strategies for sustained and positive health outcomes through a one-week training followed by nine weeks of hands-on research with a faculty mentor. Scholars also received faculty mentorship and professional development opportunities. Participants

completed a baseline survey, a post-survey at the end of the 10-week program, a one-semester post-survey after participation, and a one-year post participation survey to assess changes in knowledge, skills, abilities, sense of belonging, and preparedness to enter the workforce or graduate studies. Paired t-test and ANOVA test were used to assess changes over time. Results: Fifty-three undergraduate students participated in the ANDALE Program with the last cohort completing the program October 2023. The presentation will expand on the program training topics, student/faculty matching process, and lessons learned from the last 3 years. Student success outcomes such as overall GPA, academic standing, and graduation will be discussed, in addition to changes in research knowledge, skills, abilities, sense of belonging, and preparedness to enter the workforce or graduate studies. Conclusion: Short-term research programs that provide experiential learning through hands-on research and faculty mentorship positively impacted students' cognitive, personal, and professional development and preparation to enter the workforce or apply and succeed in graduate or professional school.

Abstract Name: Annexin A2 Expression in Prostate Cancer Cells

Metastasis is a major cause of morbidity in prostate cancer patients; the primary mortality is metastasis of bone tissue. Despite substantial efforts to understand prostate cancer metastasis, the mechanisms involved in preparing the metastatic niche for colonizing the prostate cancer cells are still unknown. Therefore, there is an urgency to identify essential regulators of bone metastasis in prostate cancer for therapeutic targets. Annexin A2 is a calcium-dependent phospholipid-binding protein overexpressed in prostate cancer's poorly differentiated high-grade adenocarcinomas. Phosphorylation of AnxA2 at tyrosine-23 creates an important event for the localization of AnxA2 to the cell surface. It provides a binding site for tissue plasminogen activators at the cell surface and converts plasminogen into plasmin, which plays an essential role in the invasion and metastasis of cancer. However, the cell surface expression of AnxA2 in prostate cancer is unknown. Therefore, in the present study, we demonstrated the cell surface expression of AnxA2 in prostate cancer cells to delineate the mechanism of bone metastasis. Prostate cancer cell lines, PC3, and DU145 were grown. Immunoblotting was used to detect the expression of pAnxA2-Y23 and AnxA2 proteins in cells. Our results demonstrated that the expression of pAnxA2-Y23 is very high in prostate cancer cells (PC3 and DU145 cells) compared to normal prostate epithelial cells. However, the expression of total AnxA2 in both prostate normal and cancer cell lines is comparable. Results suggest that the cell surface expression of AnxA2 is high in prostate cancer cells due to increased phosphorylation of AnxA2 at tyrosine 23.

Abstract Name: Sewershed Surveillance of ARGs in Central Appalachia: Building a Monitoring Framework for Rural Systems

Unregulated antibiotic use and resulting antibiotic waste streams can lead to the dissemination of antibiotic resistant bacteria (ARB) and antibiotic resistance (ARGs) into the environment, especially where wastewater treatment infrastructure is not present and/or underdeveloped. However, wastewater-based surveillance (WBS) is a promising methodology for monitoring health outcomes and mitigating negative impacts from potential future, novel epidemics. The difference in regional trends in measured antibiotic concentrations compared to public sales data indicates that WBS can be useful in detecting ARGs and antibiotic resistant-bacteria that can't be diagnosed as effectively and promptly with clinical surveillance. For this study, phenotypic and genotypic analysis of ARGs and ARB was conducted in a rural sewershed with a population size of ~2,500. Samples were collected at regular intervals at five wastewater sampling points (WWTP influent, WWTP effluent, a manhole downstream of a residential living facility, a manhole downstream of septic effluent, and a manhole downstream of a veterinary hospital) and two surface water sampling points (one downstream and one downstream of the WWTP effluent discharge). We cultured for total and cefotaxime-resistant E.coli and quantified concentrations of two ARGs (intl1 and blaCTX-M-1) using ddPCR. Preliminary results show the percentage of cefotaxime-resistant E.coli compared to total culturable E.coli was highest at WWTP effluent (at 4.97%) compared to 0%-0.9% across other sites. However, concentrations of blaCTX-M-1 in log (gene copies per mil) were highest at the WWTP influent (at 3.38 Log (CFU/100mL)).

Abstract Name: Dracula: Adaptations and Modern Perceptions

Dracula is a 1897 novel written by Bram Stoker, and it has become ubiquitous in modern culture. Dracula is a story with interesting characters, a sense of urgency that drives the plot forward, and more comedy than one would expect. There are so many adaptations of this classic novel that little emphasis is placed on the original. Many people who have not read Dracula, but have seen an adaptation seem to believe they understand the plot of the book, or that there is no need to read the novel. This will be an examination of several adaptations of Dracula, a study of how Dracula is perceived in the modern day, and an attempt to unite different adaptations with modern perceptions of the novel. Survey results will be used to gauge modern perceptions of Dracula, and different film and book analysis techniques will be used to understand Dracula and its adaptations. Most literature on Dracula focuses on one particular adaptation, but this will focus on the core elements of the original novel. This will then focus on which of those elements have been carried over to contemporary perceptions of Dracula. Instead of examining one particular story this is an examination of how being adapted dozens of times has changed the core of what Dracula is. Dracula is a novel that has been drastically changed from its original context through over a century of adaptations. It is important to examine where these changes came from, and how drastically these changes affect modern perceptions of the novel.

Abstract Name: Using Prompt Engineering in Generative AI to Improve Database Design

Prompt engineering is crucial for maximizing the potential of generative AI in complex technical tasks such as database design. Various prompt formats and structures can lead to differing effectiveness for specific tasks. This research aims to refine prompt design and evaluation methods, exploring and comparing strategies to improve AI-generated output quality. Furthermore, this study investigates the versatility of prompt engineering in tailoring outputs for schema coherence, data model accuracy, and adaptability to various database requirements. By analyzing case studies and experiments, the study demonstrates how well-crafted prompts shape database structure generation, highlighting the critical role of tailored prompt design in producing high-quality, domain-specific outputs. The research advances generative AI technologies by examining various prompt formulation approaches and assessing their impact on output quality.

Abstract Name: Student Definitions of College Student Success

Understanding students' definitions of success in college is just as important as understanding institutional perspectives about student success in college. Most colleges and universities measure student success via variables such as GPA, retention, and persistence to graduation. Students, however, might have a more personal definition of success in college, such as the development of social networks or the ability to enact social justice. The purpose of this research is to gauge how students define success in college. Students were surveyed about their definition of success in college and were asked to identify which potential success indicators were important to them. As a partial replication and extension of the work of Langout et al. (2022), some survey items were drawn from the Borderlands survey. To further understand student definitions of success in college, focus groups were conducted. While data are still being collected, results will indicate how well student definitions of success in college correspond with institutional definitions of student success. This research can help colleges and universities develop a more holistic definition of student success that better reflects needs and goals of different college student populations.

Abstract Name: Impact of Liming on Denitrifying Genes in Soil Microbial Communities

This study aims to understand some of the dynamics surrounding the denitrifying soil microbial community in a truffle orchard. Burwell Farms in North Carolina cultivates Tuber borchii and has orchards at multiple stages of development: 1.5 years old (Young), 3.5 years old (Middle), and 7.5 years old (Old). Part of their cultivation process involves the application of liming to raise the soil pH - steps that benefit the target fungus. Past research in soil systems supports the idea that liming builds the denitrifying bacterial community over time. This study took advantage of the multiple stages of orchard age to run a chrono-sequence study to see how the denitrifying capabilities of the bacterial community changed as the orchard ages and soil pH increases.Soil samples were collected from plots of different ages: Young, Middle and Old. The sample's DNA was subjected to quantitative- PCR focusing on the nitrite reductase gene nirK to assess denitrifying gene abundance. While the trend showed a decrease in denitrifying organisms as the orchard ages, results reveal that liming has not significantly impacted denitrifying genes in this time span. Subsequent experiments via cloning and capillary DNA sequencing confirm that the nirK gene being analyzed is of bacterial origin. These findings provide insights into the role of microorganisms in shaping the nitrogen cycle and contribute essential knowledge for the success of the farm by understanding the intricate relationship between soil pH and denitrifying microbial populations.

Abstract Name: The Role of Source Credibility on Persuasion Towards Conservation Farming

One source of pollution in the Red Cedar Watershed is runoff from surrounding agricultural land. Implementation of best management practices (BMPs) would promote soil integrity and decrease the runoff polluting the watershed. Encouraging the adoption of BMPs is challenging since factors outside of the argument itself can affect persuasiveness. One such factor is source credibility. Understanding who local farmers find most credible can aid in crafting the most persuasive arguments about adopting BMPs. A survey was mailed to a random sample of 300 farmers in Dunn and Barron County. Additionally, a digital version of the survey was distributed at a local farmer's market. The survey assessed the perceived familiarity, trustworthiness, knowledge, and persuasiveness of various groups that might approach farmers about adopting BMPs. Survey results found that respondents rated groups more closely linked to the local community more favorably. Within those local groups, neighbors/other farmers and county conservation services were rated as the most credible. Additionally, there was a statistically significant relationship between respondents who rated farmer-led councils as trustworthy and knowledgeable and reporting using more BMPs. This may suggest that farmer-led councils are another influential local group. This information indicates that persuasive arguments in favor of BMPs should focus on ties to the local community and groups like peer farmers, farmer-led councils, and county conservation services are integral in opening these dialogues.

Abstract Name: Determining the Expression Pattern of BRINP2 during Migratory Neural Crest Cell Development in Chicken Embryos

Neural crest cells (NCCs) are unique stem cell types found only in vertebrate embryos. NCCs migrate and differentiate into different cell types to form structures such as craniofacial bones, the peripheral nervous system, and more. Genetic regulatory networks control the migration, differentiation, and formation of NCCs. Dr. Bridget Jacques-Fricke and colleagues identified 674 genes that are potential regulators of NCC development. My research focuses on one of these candidate regulators:Bone morphogenetic protein/retinoic acid-inducible neural-specific proteins (BRINP2). BRINP2 is a part of the Membrane Attack Complex/Perforin (MACPF) superfamily. While the MACPF domain is traditionally associated with immune function, some MACPF family members have a role in forming adhesions in migrating cells. Although BRINP2 is part of the MACPF superfamily, its specific role in adhesion and molecular function in cell migration is unknown. To determine which genes are potential regulators of NCC development, we must understand the expression pattern of our targeted genes. By performing in situ hybridization, we found BRINP2 to be expressed in premigratory and a subset of migratory NCCs in chick embryos. Future research could focus on molecular functional analysis of BRINP2 by performing a loss of function analysis in premigratory and migratory NCCs to determine the effect of BRINP2 on NCCs development. Abnormalities in NCC development can lead to various congenital disorders such as cleft lip and palate, neuroblastoma, and more. Understanding the mechanisms underlying NCC development is crucial for gaining insights into developmental disorders and exploring potential therapies.

Abstract Name: Engineering Fluorescent Reporter Strains To Generate High-Throughput Detection of White-Opaque Switching in Candida albicans

Candida albicans, a diploid polymorphic fungus, has evolved a unique heritable epigenetic program that enables reversible phenotypic switching between two cell types, referred to as “white” and “opaque”. These cell types are established and maintained by distinct transcriptional programs that lead to differences in metabolic preferences, mating competencies, cellular morphologies, responses to environmental signals, interactions with the host’s innate immune system, and expression of approximately 20% of genes in the genome. Traditionally, these programs are studied by generating gene knockouts and assessing their effects on phenotypic switching. These switch analyses measure the percentage of cells within individual white or opaque colonies that have switched phenotypes relative to the original progenitor cell. However, this classic assay is laborious, inefficient, susceptible to “jackpot” effects and user-user variability, and has a limited dynamic range. We will use CRISPR to engineer a fluorescence-based cell-type reporter strain that will enable discrimination between white and opaque phenotypes using flow cytometry. The reporter strain will undergo two different transcriptional fusions of fluorescent reporters, mScarlett and mNeonGreen, placed

under the control of highly expressed white and opaque specific promoters respectively. Once developed each colony will be passed through an automated flow cytometer for determination of cell-type identity with populations of cells recovered from single white and opaque colonies. Effective reporter strains will subsequently be subjected to traditional colony counting-based white-to-opaque and opaque-to-white switching assays to confirm that the wild-type switching frequencies are unaffected by our reporter constructs. The resulting switch reporter strain will be used to develop a high-throughput assay that will enable accurate quantitation of switching frequencies with individual colonies grown on agar medium.

Abstract Name: Investigating the Physical and Psychological Effects of Learning Piano in Arthritis and Attention Deficit Hyperactivity Disorder Populations

The purpose of this study is to understand if a piano-playing intervention may result in positive psychological experiences or improved physical function in an arthritic or ADHD population, potentially leading to new treatment techniques for other physical and neurodiverse populations. The first part of the study is complete and includes participants with arthritis. With an age range of 20 to 87, five participants had limited previous piano experience and an average self-rating piano skill of less than one out of ten. They engaged in one-on-one piano lessons three times a week, for six weeks. Their psychological well-being was assessed through quality of life questionnaires, while their physical ability was measured through range of motion, grip strength, and pinch strength. Findings did not suggest any significant improvements after the piano sessions ended, but various flexion, extension, and perceived skill measurements neared statistical significance. Further research is encouraged with larger sample sizes. The second part of the study is ongoing and includes individuals with attention deficit hyperactivity disorder (ADHD). Because ADHD exhibits a different manifestation of physical and mental abilities, pre- and post-intervention assessments of this population include gait and postural control using a dual-task paradigm. The Stroop (matching colors and words) and Serial Seven Test (counting backward by seven) were used to increase the cognitive demands during balance (both tests) and gait (Serial Seven only). For balance, ellipse area (overall sway), sample entropy (sway regularity), and DFA alpha (sway randomness) will be calculated from 30 seconds of quiet stance on a Bertec force plate using custom Matlab scripts. Gait, velocity, step length, stride length, and cadence are calculated using a GaitRITE overground walkway. Following piano instruction, assessments will be analyzed for any physical or psychological improvements. Results from both parts of the study will be presented at the conference.

Abstract Name: Adjustments for Kurtosis and Continuity on the Prentice Test

The test of Prentice is a non-parametric statistical test for the two-way analysis of variance using ranks. The null distribution of this test is typically approximated using the Chi-square distribution. However, the exact null distribution deviates from the Chi-square approximation in certain cases commonly found in applications of the test concerning the tail probabilities of the distribution, motivating adjustments to the approximation. This work presents adjustments to this null distribution correcting for continuity, multivariate skewness, and multivariate kurtosis with improvements on previous approximations for the majority of cases. The effects of alternative scoring methods as non-polynomial functions of rank sums are also presented as a broader application of the approximation.

Abstract Name: The Effects of Singing on Gait Variability during Complex Walking in Persons with Parkinson's Disease

Gait and balance impairment are major symptoms of Parkinson’s Disease (PD) and can significantly impact functional mobility and quality of life in persons with PD. The benefits of PD medication for gait and balance impairment are in question. As an alternative, external cuing, such as singing, has shown benefits for simple walking tasks in persons with PD. However, complex walking tasks pose the greatest challenge for persons with PD, and there is limited research on how singing affects the performance of complex walking tasks in persons with PD. This study aims to determine the effects of singing on gait variability during complex walking in persons with PD. Given that singing improved simple walking tasks, we hypothesized that singing would also improve complex walking in persons with PD. Participants performed a series of walking tasks over approximately 30 feet in length: 1) over ground walking at their preferred pace, 2) over ground walking while singing, 3) serpentine walking at their preferred pace, and 4) serpentine walking while singing. The song sung was Row, Row, Row Your Boat. APDM Opals (apdm.com) were used to collect spatiotemporal measures; two placed on the top of the feet, two on the wrists, and one on the lumbar spine. The coefficient of variation will be obtained for each spatiotemporal outcome measure and entered into a 2x3 repeated measures Analysis of Variance to determine differences between conditions (singing vs. no singing) and between groups (healthy young adults, healthy older adults and PD) for over ground and serpentine walking. Posthoc analyses will be completed with Tukey’s Honest Significant Difference test. We expect singing to improve gait variability in both over ground and serpentine walking. This study may provide evidence for an adjuvant therapeutic technique to improve complex walking and mobility in persons with PD.

Abstract Name: Characterization of MDH1/2/3 Protein Regulation Using Phosphomimetics

The Malate Dehydrogenase (MDH) gene is responsible for catalyzing the oxidation of oxaloacetate and malate. The reaction is important in cellular metabolism; more specifically, it is significant in the Citric Acid cycle to produce NADH molecules for the Electron Transport Chain. The budding yeast Saccharomyces cerevisiae encodes three isozymes of the yeast MDH protein, which differ according to their location in a cell: Cytosolic (MDH1), Mitochondrial (MDH2), and Peroxisomal (MDH3). These isozymes are components of the malate–aspartate NADH shuttle, which are novel metabolic longevity-regulators. Overexpression of the malate–aspartate NADH shuttle components may initiate calorie-restricted life-span extension due to a cell's increased metabolic fitness. The S. cerevisiae MDH proteins were used since their key sites and cellular metabolism are strongly conserved to that of human MDH proteins. By understanding the characterization of the S. cerevisiae MDH proteins in calorie-restricted life-span extension, it might be possible to induce life-span extension using human MDH proteins. The MDH protein regulation mechanisms were analyzed using phosphorylation to substitute an amino acid with a negatively-charged amino acid called a phospho-mimic. We performed site-directed mutagenesis to generate the putative phosphorylation sites. Current work focuses on these mutants and their effect on isozyme function.

Abstract Name: Defining the Preferred Substrates of Louisiana Freshwater Sponge Species

The Louisiana Freshwater Sponge Project investigates what substrates contribute to the growth and development of different freshwater sponge species. Freshwater sponges are understudied, environmental health indicators. These organisms are filter feeds that assist in cleaning freshwater ecosystems. To further understand the driving factors of freshwater sponges, the Louisiana Freshwater Sponge Project has prioritized the identification and tracking the species richness of these organisms. Previous studies show that freshwater sponge survival is dependent on water quality and availability of substrates. However, the literature provides little research on the preferred substrates that contribute to sponge growth and development. This study analyzed the substrate specificity of 1106 collected sponge samples from 232 water systems in Louisiana. During sampling, sponges were photographed attached to their substrates. In the lab, the sponges were identified using sponge morphology and/or DNA sequencing of COX-1 gene. Substrates were classified as logs, rocks, tree roots, trash, plant roots, bricks. Using Excel, substrates were documented for fourteen species in Louisiana. The analysis of this collection of data has found rocks and logs being the most abundant substrate. However, some species are limited to root systems and logs. This information contributes to the environmental parameters that support sponge growth.

Abstract Name: The Effect of Contrast on Motion Induced Blindness and Perceptual Filling-In

In visual perception research, two phenomena are of great interest. Motion induced blindness (MIB) is the phenomenon where a motion mask causes a distinct target in the visual field to perceptively disappear, and perceptual filling-in (PFI) is where the visual stimulus of a target doesn't match the area surrounding it, and surrounding movement causes the target to disappear into its surround. The common mechanism hypothesis is the widely theorized idea that the neural mechanisms causal to these two phenomena are the same. Contradictory conclusions in literature regarding the effects of low contrast luminance between the target and its background in MIB and PFI stimuli has left room for clarification on whether effects of contrast support the common mechanism hypothesis (Bonneh et al., 2001; Hsu et al., 2004). In this study, the impact of contrast luminance between a target and its background, with four contrast levels (two low-contrast and two high-contrast levels), is examined using software-based stimulus. Three variables were measured: fading duration, time to the first disappearance, and total number of disappearances. Results thus far, based on five sets of trials for each contrast level from individual participants, show that the number of times a participant indicates a target appears and disappears is significantly different between low-contrast luminance values (-40% and 40% contrast) for MIB. PFI shows no significant differences between any of the variables, which contrasts with results from MIB; differences between results for MIB and PFI do not support the common mechanism hypothesis. Further data collection and analysis is actively being conducted and shows promising results, which may or may not reflect the similarity in the pattern of effect seen thus far between the two phenomena and will be able to shed light on the validity of the common mechanism hypothesis.

Abstract Name: Adolescent Parental, Peer, and Romantic Relationships as a Predictor of Romantic Identity Development

In the field of study regarding adolescent development Erik Erikson proposed the importance of developing identity through social relationships. The process for developing identity in this stage has received a great deal of theoretical and empirical attention since Erikson first proposed his ideas. However, the field still lacks a deeper understanding of what patterns across relationships with parents, peers, and romantic partners affect the development of romantic identity in adolescence. The goal of this study is to gain a better understanding of how supportive relationships with parents, peers, and romantic partners in adolescence affect that development. We will review existing knowledge on the influence of relationships on adolescent development. Then will perform a latent profile analysis on extant data gathered from high school students in Utah to correlate perceived support and disclosure in parental, peer, and romantic relationships of adolescents with their current engagement in romantic experiences. This will aim to answer the question "how does the pattern across parental, peer, and romantic relationships affect the development of romantic identity in

adolescence?". We will measure the effect from interest in, effort towards, and confidence in romantic relationships. We will be able to analyze the results to better understand the influence of various patterns across these relationships on an adolescent's development of romantic identity.

Abstract Name: The Intersection of Race, Mental Health, and Incarceration Among Black Americans

Research has indicated that being a member of a racial minority group with mental health challenges is associated with disproportionate experiences with the criminal justice system, especially for Black individuals compared to White individuals (Flores et al., 2023). Moreover, research indicates that experiences with the criminal justice system, including incarceration, can significantly increase the risk for mental health challenges for both Black men (Assari et al., 2018; Turney et al., 2013) and women (Kilpatrick et al., 2021). This paper will explore four pivotal topics related to race, mental health, and incarceration, with a specific emphasis on the experiences of Black individuals. The first issue delves into how an individual's race/ethnicity and other interpersonal factors impact the early life patterns of adolescents' involvement with the criminal legal system (Boen et al., 2022), as well as the interaction between race/ethnicity and mental illness concerning the incarceration of youth and their likelihood of confinement (White, 2016). The second issue explores how mental health affects the experiences faced by Black inmates during their incarceration, including disparities in mental health referrals and diagnosis (Fatos et al., 2015) and instances of correctional staff-involved violence (Grosholz et al., 2023). The third issue examines potential mental health outcomes associated with incarceration for Black individuals. Specifically, this section focuses on research identifying factors that explain the increased mental health consequences experienced by both Black men (Addison et al., 2022; Assari et al., 2018; Turney et al., 2013) and women (Kilpatrick et al., 2021). Finally, alternative solutions are explored to encourage therapeutic justice within the Juvenile and Criminal Justice Systems (Cusack et al., 2013) and to implement improved mental health programs to address the needs of Black individuals and other racial minority groups (Vinson et al., 2021).

Abstract Name: Stress and Mental Health

Stressful Life Events (SLEs) are defined as undesirable and/or unplanned events that generally induce a sense of anxiety and/or have other negative mental health consequences. Research that was previously done on the topic investigated Adverse Childhood Experiences (ACEs) and how they affected behavior in adulthood. However, not only did these studies utilize questionnaires that contained vulgar and extreme scenarios of child abuse, they also failed to account for the affect that current stressors may have on an individual, which have the potential to alter the results of the study. The results could be mistaken as a product of child abuse

when they could instead be caused by stressors in the present. The purpose of the following study was to assess how both self-rated stress levels and SLEs are associated with the current mental health status of emerging adults (aged 18-29), and to examine whether coping styles and resiliency may moderate these associations. It is hypothesized that stressful life experiences have the potential to build resiliency and improve the ability to cope with nerve-wracking experiences. The surveys were distributed to 18-29 year olds on Adelphi University's campus, a sample that consisted of both students and staff members. The survey items tested whether SLEs moderate the association between current stress levels and mental health. The predicted outcome of the study was that participants who report a higher frequency in experienced stress will also report being more prepared to cope with current or future stressful life experiences. These results would suggest that resilience to mental health issues and coping ability are moderated by the frequency and severity of SLEs.

Abstract Name: Statistical Analyses of Student Responses to Current Geoscience Research

This project aims to showcase geoscience career attainability by exposing students to present-day geoscientists, the least diverse field in the STEM discipline. To address this gap statistically, students will be exposed to these scientists' research revealing students' degree of relatability to more diversely identifiable scientists in the context of the classroom. Future curriculum can then cater to those preferences by centering curriculum around more applicable research for the classroom setting.Students in Dr. Juk Bhattacharyya's Geology 100 course were prompted with questions regarding minority scientists' research: (1) how the research benefits society through its communication; (2) what students found most interesting about the research; and (3) how the research can be applied to the student's personal life and career.Previously, student responses were analyzed by separating each of the responses into categories. This allowed calculation of how many students preferred specific elements of the research. Responses to Dr. Karin Goldberg's research which were collected from students enrolled in Geology 100, were analyzed differently by sorting each response into multiple categories to more comprehensively reflect the student's entire response to Goldberg's research. This prohibits portraying the data as a percentage of exactly how many students prefer each specific aspect of the scientist's research but allows a more comprehensive analysis of trends between responses. For example, possible consistency in responses falling into several of the same categories can be seen. Furthermore, the categories have been grouped into like topics such as those containing specific scientific language, those pertaining to the interest level/entertainment quality of the research, those pertaining to the presentation of the research across different mediums, et cetera. By grouping responses into several categories within these topics, data can be drawn about whether responses applied to the same topic multiple times or included elements from many different topics.

Abstract Name: Creating a questionnaire to account for contextual differences in replication

Research into solutions to the replication problems in psychology has been primarily focused on perfecting direct replications (Brandt et al., 2014) or proposing possible changes within the scientific research culture (Klein, 2022). While some research addresses the influence of the broader sociocultural context on replication (Ramscar et al., 2015; Van Bavel et al., 2016; Greenfield, 2017), little research looks into how to take contexts in account when conducting replications. In order to account for the difference in contexts from the original and the replication, I propose creating a voluntary questionnaire to be administered to participants concurrently with all psychological studies. This questionnaire will attempt to identify contextual variables that might influence the results of the study—for example, differences in culture from the original sample or linguistic shifts. Furthermore, I propose that all replications include a direct replication and that all participants fill out the same questionnaire as the participants in the original. Regardless of whether the results of the replication match those of the original, responses from the questionnaire ought to be analyzed for discrepancies between the original and the replication. In the event that the results do not replicate, researchers ought to conduct conceptual replications that take into account the discrepancies. Finally, I propose that responses from the questionnaire ought to be compiled to develop a model that predicts when, due to contextual factors, a study could be expected to fail to replicate.

Abstract Name: Isolation and characterization of potential antimicrobial pigment from a wetland microorganism with unique properties

Antibiotic resistance is a growing worldwide crisis with the need to develop new antibiotics. To this end, we used the Tiny Earth model to identify, isolate, and identify potentially new sources of antibiotics from soil samples from the wetlands of Minnesota. The Tiny Earth project is a student-sourcing antibiotic discovery community dedicated to discovering potential new antimicrobials. This project was made possible through funding provided by the Legislative-Citizen Commission on Minnesota Resources (LCCMR). In Fall 2021, University of Minnesota crookston students collected a sample from wetlands of northern minnesota. The soil samples were further analyzed using standard techniques to identify the presence of potential antibiotic producing microorganisms. The following were used as ESKAPE safe relative pathogens: Enterococcus raffinosus, Staphylococcus aureus, Escherichia coli, Acinetobacter baylyi, Pseudomonas putida, and Klebsiella aerogenes. The streak plate method and Gram staining were used to obtain pure cultures. The pure isolates were then again tested against the same pathogen for antimicrobial activity. Chemical extraction involved growing the isolate on agar plates and using ethyl acetate to extract substances to be tested against the ESKAPE safe relative pathogens. Through this process, we identified a bacterial strain that exhibited development of a red color/pigment only after storage in the refrigerator, accompanied by an observed increase in inhibitory activity against the safe relative pathogen. This phenomenon has not been reported in the literature. Further characterization of this strain and the pigment will be presented.

Abstract Name: Sickle cell disease severity and outcomes in Anuak patients: A scoping review

Southeast Minnesota is home to a significant population of Anuak individuals who seek care within the Mayo Clinic Health Systems. The city of Austin, MN, is home to a population numbering around 450 Anuak individuals who are seen at the Mayo Clinic Austin location as well as the Rochester main campus of Mayo Clinic. In total, more than 3000 Anuak individuals live in Minnesota in what is considered to be the largest Anuak population outside of East Africa. For pediatric patients with Sickle Cell disease (SCD), 75% are Anuak. The majority of these patients have severe sickle cell disease with chronic anemia, frequent pain crises, cardiac ventricular enlargement, acute chest pain, and multiple hospital admissions. A scoping review utilizing the following databases was conducted: Ovid MEDLINE(R) and Epub Ahead of Print, In-Process & Other Non-Indexed Citations, and Daily, Ovid EMBASE, Ovid Cochrane Central Register of Controlled Trials, Ovid Cochrane Database of Systematic Reviews, and Scopus. Only two studies met established criteria. Unfortunately, both sources of literature were dated and not consistent with current trends. Despite communicating with colleagues in Ethiopia, there is no accurate or robust data about the incidence or prevalence of SCD among the Anuak people. The local Anuak diaspora in Southeast Minnesota likely represents the best current data in this patient population. There is a need for further research and data on SCD outcomes in this special population.

Abstract Name: Sickle Cell Patient Education Materials

Sickle cell disease (SCD) is a genetic disorder that affects the shape and function of red blood cells. People with SCD may experience various complications, such as anemia, jaundice, splenomegaly, and stroke. These complications can affect their physical, mental, and social well-being. Therefore, patients and families need to understand the causes, symptoms, and treatments of SCD and how to prevent and manage crises. This patient education resource aims to help patients and families learn about SCD using plain language, visual aids, and analogous. It covers the following topics: problems, solutions, 3D sickle cell model, understanding SCD, Sickle Cell Trait (SCT), blood flow blockage, and genetic patterns. The resource offers strategies and tools to enhance the quality of life for SCD patients. This resource provides a solution in the form of a 3D Sickle Cell Patient Education Model. This model is a tangible and detailed representation of how SCD affects the blood vessels and red blood cells in various body parts. The model compares normal and sickled red blood cells and demonstrates how they can cause blockage, inflammation, and reduced oxygen and nutrient delivery. The model explains the role of hemoglobin and the genetic inheritance of SCD. It can assist patients

and their families comprehend the disease process and the significance of adhering to the treatment plan. Moreover, the model can aid the SCD communities and healthcare industries in raising awareness and advocating for better education about the disease. By utilizing these resources, patients, families, healthcare providers, and the sickle cell community can better manage and support the impact of SCD on patients' health and lives.

Abstract Name: Quantifying tumor microenvironment changes following HER2 inhibition with tucatinib IHC in HER2+ breast cancer

Human epidermal growth receptor 2 (HER2) is a membrane-bound protein that is overexpressed in 25 percent of breast cancer. Tumor microenvironment changes can be imaged through positron emission tomography (PET) imaging, which uses radiotracers to visualize molecular processes. Immunohistochemistry (IHC) is the clinical gold standard for validating biological alterations in tumor. IHC of biological markers like hypoxia, proliferation, and HER2 proteins can be used to verify imaging. The goal is to use PET imaging and IHC to visualize and quantify the effects of tucatinib within the HER2+ breast cancer tumor microenvironment. HER2+ BCM-3472 (PDX) and BT474 (cell line) were engrafted 3 weeks and 4-6 weeks prior to treatment in NSG and nude mice, respectively. Tucatinib therapy began on day 0. For [18F]-FLT and [18F]-FMISO PET imaging, imaging was conducted on days 0, 3, and 7. For [89Zr]-Pertuzumab PET imaging, imaging was conducted on days 0, 7, and 14. On the final day, tumors were excised for IHC, which used HIF-1a, Ki-67, HER2 and phospho-HER2 antibodies. Nonparametric T test was used for statistical analysis. For FLT-PET, control BT474 tumors had an SUV of 0.55, and tucatinib treated BT474 tumors had one of .288 (p<0.05). For FMISO-PET, control BT474 tumors had an SUV of 1.4, and tucatinib treated BT474 tumors had one of 1.1 (p<0.05). For [89Zr]-Pertuzumab-PET, control BT474 tumors had an SUV of 19.1, and tucatinib treated BT474 tumors had one of 11.9 (p<0.05). Qualitative analysis showed differences in IHC staining; quantitative analysis is ongoing. The PET imaging and IHC show that tucatinib can modify hypoxia, proliferation, and HER2 expression in HER2+ tumors. Tucatinib’s ability to pass though the blood-brain-barrier and modify the tumor microenvironment makes it a candidate for combinatorial therapy.

Abstract Name: Exploring Coffee Silverskin Extract's Effects on Age-Related Gene DVE-1/SATB1 During UV- Induced Oxidative Stress

Aging is the gradual and progressive loss of function in the majority of living organisms, ultimately resulting in death. While many aging models have been proposed, no single model can explain aging fully, as both genes and the environment play roles. C. elegans, the small nematode, is a model organism often used in studying lifespan and aging. Based on an earlier study that used a RNAi screen to identify C. elegans genes affecting lifespan and were implicated in human aging, DVE-1 repression decreased lifespan. In addition to genes, such as DVE-1, environmental stressors such as oxidative stress accelerate aging. When there is an imbalance of reactive oxygen species (ROS) and antioxidants, the excess ROS chemically attacks cellular molecules causing dysfunction. Antioxidants chemically interact with ROS, making them inert. Increased ROS can be produced through exposure to ultraviolet (UV) radiation. Since increased ROS can lead to diseases such as cancer, dermatitis, and psoriasis, antioxidants increase health benefits and decrease age-related risks. A natural product that contains antioxidant compounds is coffee silverskin (CS), the outer layer of coffee beans that comes off when roasted. Its high antioxidant capacity, which is of unknown character, has the potential to preserve health and increase longevity. The purpose of this study is to investigate the molecular effects of CS treatment, alone and after UV-induced oxidative stress, on the levels and alternative splicing of age-related gene, DVE-1. We expect that CS treatment will increase levels of DVE-1 RNA and/or alternative splicing, as measured by quantitative reverse transcription polymerase chain reaction (qRT-PCR) and endpoint PCR, to produce functional proteins compared to untreated and UV-treated nematodes. This study is significant in the context of averting age-related diseases and extending a healthy lifespan, utilizing nematodes as a model for human research.

Abstract Name: Exploring the Mechanisms of Action of MW151, a Novel Anti- Inflammatory Drug Candidate for Alzheimer's Disease

The dysregulation of inflammation within the brain, known as neuroinflammation, plays a pivotal role in the development and progression of various neurodegenerative disorders, notably Alzheimer's Disease (AD). A promising avenue in combating this inflammation lies in MW151, a small molecule drug designed to selectively suppress abnormal inflammatory responses. Despite its potential, the precise molecular mechanisms through which MW151 operates remain elusive. In the context of AD, microglia cells serve as the central immune players within the brain and represent the epicenter of dysregulated inflammation. Recent studies have hinted at a fascinating prospect: the potential involvement of cellular metabolism modulation in reigning in these inflammatory responses. While the interplay between cellular metabolism and immune response has been extensively studied in cancer biology and immunology, its exploration within the realm of dementia research is still in its nascent stages. Our current project delves into this intriguing possibility by investigating the hypothesis that MW151 exercises its anti-inflammatory effects by hindering induced glycolysis, a phenomenon observed in myeloid cells as a response to inflammatory activation. This exploration of the connection between cellular metabolic pathways and neuroinflammatory responses could shed light on novel therapeutic strategies for AD and related neurodegenerative conditions. To unravel the biological targets and mechanisms underlying the action of MW151, our research employs a comprehensive approach encompassing cell culture techniques and multi-omic analyses. These assays aim to uncover the intricate network of biological interactions affected by MW151, offering crucial insights into its mechanism of action and potential targets for therapeutic intervention.

Abstract Name: Role of Cholecystokinin in Regulating the Motivational Properties of Nicotine

Nicotine addiction through habitual tobacco use is a leading cause of premature death in the United States. Circulating cholecystokinin (CCK) levels are elevated in tobacco smokers relative to non-smokers, particularly after food consumption, yet the consequences of this effect on nicotine intake are unknown. Recent data generated in our lab suggest that circulating CCK levels are similarly elevated in mice injected with nicotine. CCK is known to act on vagal sensory neurons that express CCK receptors (CCKR+ neurons) to modulate food consumption. Here, we report an important role for vagal CCKR+ neurons in regulating the motivational properties of nicotine. First, we injected a toxin (CCK-saporin) that selectively lesions CCKR+ neurons into the vagus nerve (nodose ganglia) of mice. The lesioned and intact control mice were prepared with chronic indwelling jugular catheters and permitted to self-administer nicotine. We found that CCKR+-lesioned mice self-administered greater quantities of nicotine compared to control mice. This effect was most apparent when higher (aversive) doses of nicotine were available for consumption, suggesting that CCKR+ neurons regulate aversive sensory responses to nicotine that limit its consumption. Next, we investigated the mechanism by which nicotine elevated circulating CCK levels. Since previous experiments from our lab have shown that nicotine activates bitter taste receptors (T2R), and T2R-expressing enteroendocrine cells in the gut release CCK, we injected T2R-knockout mice with nicotine and assayed CCK plasma concentrations using an enzyme immunoassay. T2R-knockout mice showed similarly elevated nicotine-induced postprandial CCK plasma levels as wildtype controls, suggesting that this effect is not mediated by direct activation of T2R+ enteroendocrine cells by nicotine. These studies show that peripheral CCKRs regulate nicotine intake due in part to actions on vagal sensory afferents. This novel “bottom-up” regulation of nicotine intake by the nodose ganglia may prove useful for the development of novel addiction therapies.

Abstract Name: Characterizing Parent Perceptions of Indiana-based Pediatric Mental Health Services for Autism Spectrum Disorder

For parents, local Community Mental Health Centers (CMHC) provide a low-cost, easy to access option

where their child can receive high-quality outpatient, school-based, and family-based therapeutic services to improve their functioning and reduce mental health symptom severity. CMHC's therapists are skilled at implementing time-limited standard pediatric therapeutic protocols yet struggle to care for children with more complex symptom presentations where advanced training in and use of diagnosis-specific therapeutic techniques are a necessity. Autism Spectrum Disorder (ASD) is one complex behavioral health condition CMHC therapists report feeling less competent caring for, citing limited financial resources and lack of specialized training. CMHC therapist perceptions on caring ASD children has been investigated; however, less is known as to how parents whose ASD child receives CMHC services perceives care. To characterize parent satisfaction, a quantitative online Qualtrics survey will be disseminated to Indiana-based online parent communities. Fifty parents whose ASD child has received therapeutic care at an Indiana-based CMHC will provide anonymous feedback on services. Parents will provide information on their ASD child's symptoms or concerns for which they sought care for at their local CMHC, and type of services received. Parents will answer questions on perceived effectiveness of the services and the therapist(s), perceived overall satisfaction, and perceived drawbacks or barriers. Descriptive analyses will categorize parent perceptions, and the three most common parent concerns for the CMHC care their child received will be identified. Outcomes of this study will inform future research to improve the quality of community-based care ASD children receive at Indiana-based CMHCs.

Abstract Name: Hey Look Ma, I Made It! College, Emerging Adulthood Development, & Quality Of Parental Relationships.

Emerging Adulthood (EA) is a distinct life stage typically spanning ages 18 to 29 and is characterized by identity exploration, self-focus, instability, a sense of possibilities, and feeling in-between. During this critical period, parent-child relationships assume a pivotal role in shaping the identity and providing guidance and support to emerging adults. The warmth within the familial unit serves as a secure foundation for exploration and personal growth, while an individual's self-concept plays a crucial role in decision-making and psychological well-being. In this study, we aimed to investigate the connections between familial warmth, the development of emerging adults, and their self-concept. Additionally, we explored how the physical distance between emerging adults and their parental home influences the quality of family relationships. Our study involved 192 emerging adults, aged 18 to 22, enrolled in a mid-sized Southeastern college. The participants completed an online questionnaire consisting of four key instruments: The Inventory of Parent and Peer Attachment, The Inventory of the Dimensions of Emerging Adulthood, The Self-Concept Self Report Scale, and The Family Warmth and Supportiveness Measure. These instruments collectively assessed their relationships with parents, various dimensions of EA, self-concept, and perceptions of familial warmth and supportiveness. Our findings revealed that emerging adults who reported stronger trust, communication, and familial warmth also exhibited healthier self-concepts. Conversely, lower levels of alienation from parental support were associated with more positive self-concept development. Trust and communication with parents had a positive influence on multiple dimensions of emerging adulthood. Warm and supportive families fostered identity exploration, experimentation, self-focus, other-focus, and the feeling of being in-between among emerging adults. Notably, the proximity of emerging adults to their parental home was found to potentially influence trust and communication, with possible implications for self-concept development and the dimensions of Emerging Adulthood.

Abstract Name: PCR Analysis for Detection of Tetracycline Resistance Genes in Gram-Negative Soil Bacteria

Since the development of the first antibiotic in the early 20th century, antibiotic resistance has become one of the greatest challenges faced by clinicians and public health experts in modern history. Demand for antibiotics in treating bacterial infections has severely outpaced new drug development, making it harder to combat the same pathogens year after year. Previous research has shown a cyclical relationship of gene transfer between human and environmental microbiomes. Several clinically significant antibiotic resistance genes (ARGs) are believed to have originated from soil bacteria, and the presence of livestock in an environment is associated with higher levels of resistance in local soil bacteria. Further investigation into

these dynamics will be a critical step in finding solutions to this crisis. This study is focused on resistance to the antibiotic tetracycline in Gram-negative bacteria from 37 soil samples taken from the Sangre de Cristo Mountains of New Mexico. Tetracycline is a broad-spectrum antibiotic with well documented resistance mechanisms in both clinical and environmental bacteria, making it ideal for use as a model for studying resistome interactions between human and soil microbiomes. Past work on these samples has shown a positive correlation between the amount of human foot traffic and levels of tetracycline resistance in soil bacteria from the sampled areas. This study is focused on using polymerase chain reaction (PCR) and gel electrophoresis to determine the presence (or lack thereof) of five key tetracycline resistance genes (tet(A), tet(B), tet(D), tet(E), tet(G)) in the soil microbiome. Bacteria will be cultured from each sample, and DNA will be extracted. DNA samples will be incubated alongside primers specific to each of the five genes, and amplified samples will undergo gel electrophoresis for comparison with positive controls to determine whether the genes are present in each sample.

Abstract Name: Characterization of dissolved organic matter of Disposable Face Masks during photochemical weathering in Freshwater environments

The astounding surge in the use of disposable face masks has exacerbated the adverse consequences associated with their improper disposal, posting a significant threat to the environment. Despite growing concerns, there remains a lack of comprehensive understanding of the biological and chemical reactivities of disposable face masks (FMs) and their ultimate fate in aquatic ecosystems. In this study, we investigated the photochemical reactivity of KN95 FMs (5-ply) and their degradation products. The FMs were split into five layers, consisting of outer and inner layers of non-woven fabric (1st and 5th, hydrophobic), a layer of hot air cotton (2nd, hydrophilic) and two layers of melt-blown fabric (3rd and 4th, hydrophobic), for photochemical degradation. Time-series samples were collected for optical and chemical characterization of dissolved organic matter (DOM), including dissolved organic carbon (DOC), chromophoric and fluorescence DOM (CDOM and FDOM), and surface properties. All layers show significant extent of degradation, with DOC exhibiting exponentially increase following UV-irradiation exposure, and notably the 2nd layer released the highest DOC. Similarly, the 2nd layer released more CDOM during photodegradation, with the sequence 2nd ly>1st ly>5th ly>4th ly≥3rd ly. The fluorescence intensities of FMs-released DOM consistently increased during the photochemical degradation of KN95, demonstrating a continuous DOM production from each layer. The results from fluorescence EEMs are consistent with those observed for both DOC and CDOM. In terms of the quality of FMs-released DOM, there was a concurrent decrease in both aromaticity (SUVA254) and apparent DOM-molecular weight (based on S275-295) under UV-irradiation, suggesting simultaneous DOM production and degradation. Disposable face masks are a fundamental part of the collaborative effort to safeguard public health, particularly during pandemics. Further studies are needed to quantify the environmental impacts of degradation products of FMs.

Abstract Name: Images of the Second World War: Themes of Frugality Within the Home Front War Poster

This presentation explores the impactful role of war posters during World War II, specifically those directed toward the home front with a focus in themes of frugality. Recognizing the unprecedented scale of the war, the governments on both sides of the conflict employed visual propaganda to influence public behavior and opinion. The home front posters targeted civilians with a crucial message: the need for frugality to conserve resources for the war effort. As the massive war effort strained essential resources, promoting the conservation of materials became integral components of the government's strategy. The presentation analyzes posters illustrating concepts of reducing, reusing, and recycling, victory gardens and canning, and purchasing war bonds, all of which portray civilian contributions as vital to the broader war strategy. The presentation also highlights the uniqueness of home front poster design, contrasting them with posters aimed at the war front and posters released during World War I, and explores the impact of the home front poster. While the poster's direct effects were transient, the poster provides valuable insights into government influence, consumer behavior, and the powerful nature art.

Abstract Name: Picturing a Geologist: Accessibility and Inclusivity in the Geosciences at Northern Arizona University

Geoscience remains one of the least diverse fields in STEM, and there has been an increase in research documenting hostile working environments reported by many scholars, including academics with disabilities, BIPOC, LGBTQ+ individuals, and those in religious minorities (Berhe et al., 2022). There are several accessibility issues with field-based learning at my university. For individuals with disabilities or injuries, barriers to field-based learning include inaccessible and uneven terrain to outcrops of rock. Other barriers present themselves in the form of expensive gear necessary for a field trip, and time commitment away from work, family, and friends. In addition, a sense of belonging is necessary for effective field-based work, and it is not common for all students to be respected, feel safe, or relevant. The issue includes the larger narrative that "Myths are stories that have taken on historical and cultural dimensions; they are narratives that have become part of the fabric of our lives" (Smith 2017). The image, or myth, of a geologist that many people hold in their mind, is narrow: often a male in outdoor clothes, who is able-bodied. My project is an audio piece disseminating information about the barriers that NAU students and faculty face in geoscience and about the work currently being done to remediate these barriers. The audio piece will be a compilation of interviews with faculty, staff, and students of the geosciences while also including relevant storytelling of what field-based learning is like for students. A written storytelling piece will also accompany the audio piece so different audiences can interact with the information. There are implications and consequences of following the status quo without engaging in conversation, and therefore starting a conversation about accessibility in the geosciences at my university can be a catalyst for change.

Abstract Name: Bauhaus Maestro: Herbert Bayer’s Global Design Impact

Herbert Bayer, a Bauhaus master, left an indelible mark on modernist design spanning Germany and America. His multidisciplinary, stripped-down work epitomizes the Bauhaus philosophies of form follows function. Bayer’s pivotal time as a Bauhaus student, under masters such as Wassily Kandinsky and László Moholy-Nagy, led to his creation of the Universal typeface. His role as the first master of a typographic workshop at the Bauhaus accelerated his career as a designer. He emphasized functionality and simplicity in his work. Controversially, Bayer worked with the Third Reich, which he calls his advertising purgatory. After Emigrating to the United States, he largely worked with the Museum of Modern Art, and the Container Corporation of America. Through his work with the Museum of Modern Art, he created dynamic exhibitions. His most important work with the Container Corporation of America was the World Geo-Graphic Atlas: A Composite of Man’s Environment. This work exemplifies his commitment to merging art, technology, and information. It also showcased his belief in designs' ability to be educational and allow complex information to be accessible to the average person. He then worked with the Aspen Institute with his former employer at the CCA. There, he designed an environment that showcased his commitment to Bauhaus principles of total design. He created a unified experience through architecture, murals, and sculptures. His late-life work continued to explore a harmonious fusion of geometric form, function, and nature through softer lines. Bayer’s life has left an enduring impact on the evolution of graphic design. His legacy extends beyond graphic design prowess. His ability to blend form, function, and aesthetics continues to inspire designers today.

Abstract Name: The Effect of Pollinator-Plant-Pollinator Interactions on the Gut Microbiomes of Pollinators

Pollinators are an essential component in natural systems and impact public health and nutrition. We are interested in how the pollinator gut microbiome is affected by location and landscape biodiversity in the Northern Great Plains. Specifically, we seek to find how gut microbiota are shared and connected via their interactions with host plants by analyzing how the microbiomes of these species overlap with one another. We predict that pollinators that interact with the same host plants will have similar gut microbiomes. We also predict that pollinators with many host plant associations will have more indirect interactions with other pollinator species, leading them to have more overlapping microbiota associations and an overall more diverse microbiome. Using Illumina sequencing, we compared the bacterial and floral composition of hymenopteran and dipteran guts and bee pollen baskets. Our results indicate that these species share selected bacterial strains that are likely encountered on shared host plants in natural habitats.These results will shed light into the interactions and associations of pollinators in the Northern Great Plains region and how these interactions have the potential to spread bacteria among pollinator communities. Understanding these associations within the microbiome of pollinators and their host plants will allow understanding of links between plant and pollinator health. Information about indirect pollinator interactions has the potential to manage the spread of harmful bacterial species and disease. With this knowledge, managers can take steps to protect the involved pollinators in natural and agricultural habitats. Areas of future research include exploring pollinator plant preferences based on bacterial communities.

Abstract Name: Fostering Student Empowerment and Community Engagement: The Impact of Student-Led SWAP Programs on Underrepresented College Student Success

This research project investigated the transformative potential of interdisciplinary, student-led Students With A Purpose (SWAP) programs in higher education. The central research question revolves around understanding the impact of SWAP programs on underrepresented college students. The study explored their effectiveness in fostering social consciousness, leadership, and entrepreneurship skills among participants. The research addressed a critical aspect of student engagement and empowerment. By focusing on SWAP programs, the study makes a contribution to the area of inquiry by shedding light on SWAP's role in

empowering underrepresented students. The research methodology involved a comparative study between Valdosta State University and Central Washington University SWAP chapters. A comprehensive literature review was conducted, emphasizing the SWAP model, and employed surveys, interviews, and document analysis to evaluate the achievements and strategies of these chapters. The outcomes showcase the substantial social, personal, and academic benefits experienced by SWAP program participants, which enhanced their critical thinking abilities and community engagement. These findings provide effective strategies that can serve as models for other universities interested in similar initiatives. Real success stories and insights into the impact of SWAP programs on underrepresented student retention will be presented. Given the decline in undergraduate student retention due to socioeconomic, cultural, and systemic barriers, this study underscores the necessity of engaging underrepresented student populations in higher education. It highlights the significant role of extracurricular experiential learning projects, like the SWAP programs, in bolstering student commitment to their campuses and local communities. The research illuminates how SWAP programs serve not only as a catalyst for academic engagement but also as a critical tool in empowering underrepresented students, thereby enhancing their retention and success in higher education. The research aligns with the conference theme by exemplifying how student-led initiatives can actively engage minds and empower students to become socially conscious leaders.

Abstract Name: The Inclusivity of Transgender and Gender Non-Conforming Students in North Carolina Universities' Sexual Assault Resources

Sexual assault (SA) is a significant problem on college campuses with 2.2 to 14.8 percent of college students reporting experiences of SA. The rates of SA are highest among those who identify as transgender (20.9%), even when compared to other sexual and gender minorities (6.4%-15.7%). There is a gap in the SA care of the transgender and gender non-conforming (TGNC) population, and little research has looked at the inclusivity of TGNC students within university resources. This study focuses on the level of inclusiveness portrayed in North Carolina universities' online SA resources. A random sample of 50 different North Carolina universities was selected using the Integrated Postsecondary Education Data System (IPEDS) 2020-2021 data. Each school's publicly available website content pertaining to SA was analyzed for gender inclusivity by giving each website a score based on various inclusivity indicators, including on SA definitions, TGNC-specific resources, gender neutrality, nondiscrimination, understanding of gender/gender identity, and accessibility. Each university received an inclusivity score (IS) out of 32 to allow comparison across institutions (M=16.7; SD=7.8). The three lowest-scoring schools (IS=2) were all religiously affiliated, suggesting that religious affiliation could be associated with inclusivity. Whether a school is an HBCU was not statistically significant (P=0.8122), but school size (P=0.0209), private/public status (P=0.0030), and religious affiliation (P=0.0003) were found to be statistically significant in predicting total inclusivity score, suggesting that large, public, nonreligious schools are more likely to be inclusive. This study will prove useful for research into the development of an interconnected TGNC-affirming community support system on college campuses by identifying common gaps in inclusivity and characteristics of inclusive schools.

Abstract Name: Rapid Isolation of Protein Complexes from Cellular Lysates

One of the most important requirements in many protein biochemistry experiments is the ability to isolate and purify proteins of interest. Traditional methods typically aim to generate large quantities of proteins; however, such methods typically rely on long, multi-day experiments and are only effective for well-behaved proteins. Co-immunoprecipitation (co-IP) is one common tool to purify protein samples and can give insight into protein-protein interactions. Co-IPs performed from cell lysates can also recover native post-translational modifications and binding partners compared to traditional methods. However, current co-IP methods are time-consuming, require extensive amounts of starting material, and may contain significant amounts of non-specific contamination. I have refined a novel approach termed “micro-IP” that enables micro-scale purifications of native protein complexes from cell lysates that require less than one gram of starting material. Micro-IP utilizes neodymium magnets to immobilize magnetic resin beads coated with specific antibodies. The beads are flowed through thin tubing and become clustered by the neodymium trap. Cell lysate is then flowed through the tubing and over the resin, which captures target proteins through interactions with the antibodies coated on the resin. This results in a 4-fold decrease in time, and a 5-fold decrease in the amount of sample needed, and yields are purer than standard co-IP methods. These improvements can therefore pave the way for faster, cheaper, and cleaner protein purification. This method may be used to discover new biochemical interactions, mechanisms, and pathways.

Abstract Name: Inhibiting the growth of a human pathogenic fungus Cryptococcus neoformans via genetic alteration

Cryptococcus neoformans is a yeast fungus that is found throughout the globe. C. neoformans poses little threat to healthy humans, however, it is an opportunistic pathogen for immunocompromised people. The immunocompromised population in underdeveloped countries is susceptible to cryptococcosis caused by the fungus, which can lead to cryptococcal meningitis. Calcineurin, an enzyme, plays an essential role in thermo-tolerance and virulence in C. neoformans, and it negatively regulates the expression of the BYC1 and BYC4 genes. Our goal was to elucidate how the BYC1 and BYC4 genes of calcineurin are involved in the growth of C. neoformans at the human body temperature (37oC). We hypothesized that the yeast would become hypersensitive to the overexpression of these genes and show low growth at 37oC due to decreased thermo-tolerance, mimicking the thermos-sensitivity caused by calcineurin inhibitors. Methods included insertions of BYC1 and BYC4 overexpression constructs into the genome of wildtype C. neoformans strain via electroporation. Resulting strains were screened using spot-assays to visualize growth at 30oC (control) and 37oC, then images were taken. Any mutant(s) expressing thermos-sensitivity was then tested in an intranasal-infected murine animal study to determine survival and colony forming units (CFUs) in the brain and lungs. In conclusion, four BYC1 transformed strains exhibited reduced growth at 37oC compared to the wildtype strain, confirming four BYC1 overexpression mutants. The mutant exhibiting the most thermos-sensitivity was used for murine study along with the wildtype. The mice infected with the mutant had a significant

increase in survival compared to the wildtype. There was a significant decrease in the CFUs of mice lungs infected with the mutant compared to those infected with the wildtype. This project can lead to the research of potential antifungal treatments that overexpress the BYC1 gene, negatively impacting C. neoformans cells and not patients' cells.

Samantha Giordano-Mooga

Abstract Name: A Research Mentor Is NOT your Friend—But Your Lab Group Can Become Your Chosen Family

Many undergraduate students (UGs) choose to conduct research, not due to a genuine love of research, but because they have heard it is one of the check boxes needed for the professional school of their choice. While these students still contribute to the productivity of the research team, motivating them to become invested in the research process can be challenging. As an UG research mentor in the School of Health Professions Biomedical Sciences Program, my goal is for students to develop true research inquiry and critical thinking, which is essential for future evidence-based practitioners. Motivating students through exciting research findings, or the idea of publishing a paper or presenting at a conference is not always effective in creating dedicated pre-health researchers. Unconventional methods, which have little to do with research have been the most effective way of engaging students in research and having lasting impacts on their futures. As the principal investigator of the G-Moo (Giordano-Mooga) Research Group, an entirely undergraduate research group, I prioritize community building as much as writing my next paper. As a G-Moo researcher, UGs have UG research mentors, monthly birthday celebrations at lab meeting, a mentor with a student-first mentality, career counseling, and a listening ear. Throughout my seven years as a UG research mentor, I have mentored 51 UGs, have had five "legacies" (younger siblings) join my lab, attended 3 weddings, had students visit me after my children were born, and keep in contact with countless students. As a researcher, I have had 7 students attend graduate school, published 6 papers with UG authors, and 15 students present at national meetings. While we often say your mentor isn't your friend—I want to change the narrative—your research group can be a part of your chosen family and create successful dedicated UG researchers.

Abstract Name: Elucidating the Effect TFE3 Modulation has on Microglia

The median age is increasingly rising within our world and, as a result, so are age-related diseases, like neurodegenerative diseases. Some of the prevalent neurodegenerative diseases can have neuroinflammation

caused by activation of local glial populations such as microglia, the resident macrophages of the brain. TFE3 is a transcription factor which regulates lysosomal gene transcription in response to inflammation in cell culture models; however, the effects of TFE3 modulation on microglia have not yet been elucidated in vivo.Using Tfe3 wildtype (WT) and Tfe3 knockout (KO) mice models, RNA sequencing was performed to obtain the differential expression of genes in the Hippocampal region. Interestingly, the sequencing data showed alterations in oligodendrocyte and microglia genes. We then used DropViz to show the expression profiles of Tfe3 in microglia and neurons in the hippocampal and frontal cortex regions. The profiles show that Tfe3 is more highly expressed in microglia when compared to neurons. To study the effect Tfe3 alteration has on microglia numbers and morphology, we are using Tfe3 WT and KO mice models and extracting their brains around 4–5 weeks of age. To mark microglia for quantification, we will perform immunofluorescence on Tfe3 WT and KO mice models using the microglial marker Iba-1. A confocal microscope will be used to collect z-stack images of the mouse cortex and midbrain, and the number of microglia and their morphological characteristics will be assessed using Imaris software.These results will test whether TFE3 is required for the normal maintenance of microglial number and structure in the brain. Future experiments will explore how TFE3 is required for the brain's responses to inflammation, with relevance for neurodegeneration.

Abstract Name: The Effect Injuries Have on Team Performance in the NFL

This research investigates the relationship between injuries and win probability in the National Football League (NFL) using regression analysis. The study employs panel data covering game results and injuries for 32 NFL teams across all seasons from 2016 to 2019. The primary independent variable measure the amount of injuries listed by a team before their weekly match. The regression models, both with and without controls, consistently show a negative association between injuries and win probability, signifying that teams with more injuries are on an average less likely to win a game. The modest magnitudes of the coefficients and the limited explanatory power of the models caution against definitive causal interpretations. Our findings align with existing literature emphasizing the adverse impact of injuries on team success but reveal nuances that warrant further exploration. The policy implications suggest a need for investment in injury prevention strategies, and future research could delve into qualitative aspects of injuries and team-specific management strategies to deepen our understanding of the complexities shaping NFL outcomes.

Abstract Name: The Evolution of Street Art: From Rebellion to Cultural Expression

Delve into the profound evolution of street art, shifting from an act of rebellion to a legitimate and celebrated

art form that mirrors cultural shifts and societal values, historical development of graffiti and street art, emphasizing their emergence in the 20th century, the transition from vandalism to urban art, the role of graffiti as a form of urban resistance, and the controversies surrounding these art forms. Urban art, including graffiti, murals, and installations, explored as a dynamic and inclusive medium breaking down barriers between traditional art spaces and the public sphere. Unfold the emergence of graffiti in 20th-century New York City, its evolution within the hip-hop movement, and the subsequent convergence with countercultural movements like punk and feminist art. The 21st century witnessed a transformation in public perception, with renowned artists like Banksy blurring the lines between street and mainstream art. The essay touches upon street art's controversy, addressing legal and ethical dilemmas, property values, and neighborhood aesthetics. Public art initiatives and mural programs are highlighted for their role in mitigating controversies and promoting street art, providing legal outlets and fostering community engagement. The impact of technology, including digital tools, social media, and augmented reality, on street art is discussed, illustrating their influence on artists' creative process and global reach. The essay concludes by emphasizing the enduring significance of street art, calling for a balanced approach to regulation that allows the coexistence of artistic freedom and public responsibility. Street art is portrayed as a testament to the evolution of art, culture, and society, constantly pushing boundaries and challenging norms.

Abstract Name: Feeling vs Thinking: Stout Student’s Conspiratorial Attitudes and Trust in Government

The prevalence of political conspiracy theories has been growing in the American political sphere in the past century. From the belief in the government having covert roles in tragedies like the assassination of John F. Kennedy and the terrorist attacks on September 11th, 2001, to Democrats putting microchips in the Covid-19 vaccine, conspiracy theories that are linked to politics and the government are increasing in visibility. These beliefs encourage extremist beliefs and anti-democratic behavior, the opposite of what a country like the United States is built on. Previous research has also shown that when institutions lack trust, this can do more than just weaken the citizens’ relationship with these institutions, but it also weakens the citizens’ trust in their friends, family, and strangers. Thus, the relationship between trust in institutions and political conspiracy theories is an important topic of study. In this project, I ask how prevalent are beliefs in political conspiracies among college students, and how does the number of conspiracy theories they believe in affect their trust in government at all levels? Leveraging a unique survey of 1400 students at the University of Wisconsin-Stout and six in-depth interviews, answers as to why and how these beliefs come about, where they come from, and how they affect trust and faith in government were sought. Results indicate that the average student believes in 2 conspiracy theories, and that there is a negative relationship between the number of conspiracy theories believed in and trust in government, with consistent results across all levels of government bodies and agencies. These results were robust, with extensive controls for the effects of partisanship, mental stress, and number of years at the university. These findings highlight the potential need to address the spread of misinformation and conspiracy theories since trust in democratic institutions is so important.

Abstract Name: Investigating Mossy Fiber Bouton Alterations after Traumatic Brain Injury

Traumatic brain injury (TBI) is a significant public health concern, often resulting in long-term cognitive and motor impairments. Synaptic connections of granule cell neurons within the hippocampal dentate gyrus after TBI is poorly understood. The mossy fiber pathway plays a crucial role in the hippocampal circuitry, serving as a connection between the granule cell neurons (GCNs) in the dentate gyrus (DG) and the CA3 pyramidal neurons. This pathway has long been recognized for its significance in memory formation and information processing within the hippocampus. To evaluate how TBI alters mossy fiber bouton (MFB) numbers and surface volume in the CA3 region of the hippocampus, reporter mice were used to label granule cell neurons and their presynaptic connections. 8-week old mice were injected with tamoxifen and naïve (n=7 females, n=8 males) mice were euthanized 6-weeks post tamoxifen injections. Injured (n=3 females, n=2 males) mice received a controlled cortical impact (CCI) 6-weeks after tamoxifen injection and euthanized 3 days postinjury. Images of tdTomato+ pre-synaptic terminals in CA3 region of the hippocampus were acquired at 40x magnification using a Nikon confocal microscope. Image stacks from each animal were imported into Imaris for 3D visualization and reconstruction. Individual MFB have numerous synaptic release sites and a reduction in bouton density can be offset by a compensatory increase in the number of release sites that can be measured indirectly by examining its surface volume. Significantly fewer MFB were observed in the CA3 region of the hippocampus ipsilateral to impact compared to contralateral CA3 region (p=0.039). However, the surface volume of the MFB did not change 3 days post injury. Surviving mature granule cell neurons have significant alterations to MFB numbers 3 days post injury suggesting impaired connectivity acutely after TBI.

Abstract Name: Applications and Limitations of LLM Use in The High School Education System

As the world rapidly digitizes, students and teachers rely increasingly on technology to help them in the classroom. Recent advances with Large Language Models (LLMs) allow teachers and students to use AI to help themselves do work in the classroom. In this study, I explore the perspectives of students and teachers to understand their opinions about teachers using LLMs to generate learning resources and students using LLMs to help them with classwork and homework. To do this, I conduct open-ended interviews and surveys. I discovered that teachers and students support themselves using ChatGPT more than the other group. However, this is not always the case; many other factors must be considered. This paper will answer questions related to how LLMs should effectively be used in the classroom, as well as proper limitations that should be put in place to guarantee the best classroom environment.

Abstract Name: Design hero Abstract

This paper focuses on a design hero and their history and influence within design. For this research paper, Alvin Lustig who has made major contributions to American design with hundreds of book cover designs will be discussed. The paper contains his initial work with interior design with examples shown and even some of his accolades. From there he dabbles in cover design transitioning into his work under New Directions Publishing and an example of his past work. His own process is talked about with how he gets to the final product and also how he experimented with different techniques for his book cover designs. After that, Lustig discusses his views and ideas about designers and what differentiates a traditional and Contemporary designer. He gets into the logistics of the design process He discusses his thoughts on how they differ and that they go through different processes. There is also a section that highlights his time as an educator and inserts his pearls of wisdom that young designers can keep with them when faced with design obstacles. As well as talk a little about his final years dealing with diabetes and how he was able to work with his clients while losing his vision. Closing off with some final remarks and how American design would be forever changed by his passion and experimentation.

Abstract Name: The Impact of Technology on Graphic Design

This comprehensive research paper explores how technology has influenced graphic design throughout history. From the Industrial Revolution to present day, each era has experienced significant breakthroughs that have revolutionized the way we create, visualize, and experience graphic design. These advancements have had varying degrees of impact on every aspect of design, including production techniques, audience reach, and overall visual aesthetics. For instance, the Victorian era's invention of the printing press resulted in a significant increase in production capabilities while simultaneously leading to a counter-production movement, and moveable type during the Renaissance allowed for more efficient and varied printing of type. In addition, the introduction of computer technology and digital design in the late 20th century enabled anyone to create and share designs worldwide, influencing both visual styles and engagement levels. However, it also introduced the challenge of a new medium. Today, the rapid emergence of AI in the industry has given rise to both skepticism and immense possibilities. All of these technological advancements have had applicable and measurable impacts in the field of graphic design. Through analyzing the effects of these technological advancements, we can gain valuable insights into the future of graphic design. This enables industry professionals to remain informed and current in an ever-changing visual landscape.

Abstract Name: Early stage lineage tracing via mid-late stage neural lineage reconstruction in Drosophila

Neural lineages are defined as groupings of neurons formed by individual, genetically specified neuroblasts. These lineages are distinguishable due to their axon tracts that are recognizable at later developmental stages, which progress towards the neuropil, which is a network at the center of the embryonic brain. We speculate that lineages interact with other lineages in a preferential and predictable manner, and vary in factors such as axon length and growth cone size. Growth cones exist at the tip of the developing axon tract, and are used to guide its growth. We aim to distinguish between lineages, specifically at earlier developmental stages, and gain a better understanding of lineage phenotype and interaction. We used transmission electron microscopy to generate 3D reconstructions of neural lineages in mid-late stage Drosophila embryos; specifically, lineages that are thought to belong to the antennal lobe and the mushroom body and lineages that have yet to be traced in the posteromedial region. We confirmed that lineage phenotype varies most notably in length and growth cone size, and we speculate that neurons of different lineages interact in a stereotyped manner already at this early stage in their development. Our findings will provide insight into the problem of the development of circuitry: we want to evaluate how the association of neurons with specific lineages shape the neural circuits of the differentiated brain.

Abstract Name: Sensorially Accessible Design for Neurodivergence

The built world was made for a very select few. While most people run into issues with the systems and environment around them, Neurodivergent individuals are much more likely to have frustrating and even debilitating interactions with systems, places, and things. This population is often overlooked in design, even though it accounts for an estimated 15-20% of the world. As we begin to become more accepting of neurodiversity in our society, our designed environment should better reflect that. While design guidelines and considerations exist for many disciplines (architecture, interior design and UX/UI), we're still lacking a proper framework on how to address neurodiversity in Product Design. As Product designers may have a hand in designing most of the objects you interact with everyday, we should constantly be looking for ways to design more accessibly. In order to establish these suggestions, research needs to be done in collaboration with the neurodivergent community around their perceptions of the products in their life. Currently the research focus is how products are interacted with through sight, sound, and touch, and subsequently how sensory sensitivities affect these perceptions. Through collaborative design workshops, the researcher intends to establish some correlation between the vast individuality of the spectrum. These workshops focus on introducing participants to materials and samples and learning more about the individuals' perceptions. The intended output of these workshops and subsequent guidelines is a tool that designers can use and reference

when designing for neurodivergent individuals. Establishing some baseline of knowledge will help elevate everyone's work, and be another step towards properly considering the communities we design for.

Abstract Name: The Effects of Spiraling Propellant Exhausts on Rockets and Its Possible Applications on Liquid Propellent Engines

The thrust that rockets rely on for flight is the reaction force of its propellant being shot at hypersonic speeds out of the rear of the vessel. The force produced is dependent on the amount of propellant being pushed out, the velocity of the propellant, and the pressure difference between the propellant and the external environment; the third factor is unimportant to this research, but the former two factors are integral to it. It is known that spinning projectiles travel farther and straighter due to spin stabilization; this is why gun barrels are made with spiraled grooves inside them. Such ideas have precedent in the Aerospace industry as a study by the American Institute of Physics has used this method to improve the efficiency of thermal rockets. It allowed their low power electric thrusters to achieve thrust similar to that of higher power electric systems by using propellent spin stabilization to produce high propellent density while maintaining lower propellent speed and power. The purpose of my research is to use these principles to improve the efficiency of higher power chemical engines. While working at a scale of 10-20 times smaller than an actual thruster, we'll test out different ways of creating spiraling motion in our model, including but not limited to adding rifling in the rocket nozzle as well as injecting the propellent at an angle. We'll also preemptively account for the torque to be produced by these methods and find ways to counteract it. The goal of this stage of research is to simply to confirm the underlying logic and identify useful applications for it in the field. I expect the experiments to be substantial in their results, even if not drastically significant, as it will be a starting point for other research efforts into spiraling propellant exhaust vortexes.

Abstract Name: The Impact that school shootings have on children in the United States and the support they are given as a result of the trauma

School shootings in the United States have nearly tripled in the past twenty-five years, exposing over 338,000 children to the trauma of mass shootings (Sandy Hook Promise, 2013). The purpose of this research is to highlight the impact that school shootings have on children and identify ways to support children as a result of the trauma they endure. Through a systematic review of literature on school shootings in the U.S., my thesis examines the limited research on school and community support for students given to them directly in the wake of such events. Next, I examine possible avenues for support to bridge the gap between the initial response to school shootings and the long-term support that communities can provide to these children. I find

that trauma-informed teaching along with understanding adverse childhood experiences are two critical ways that teachers as well as the community can further support children who face a traumatic experience, like a school shooting. By showing the impact that school shootings have on children's lives both emotionally and physically, my thesis explores the importance of what happens once the media attention wanes. I aim to contribute to a critical discussion of how to better support children and communities affected by mass shootings over the long-term.

Abstract Name: Identification of an Unknown Fungus That is Lethal to Sand Fly Colonies

Colonies of sand fly larvae (vectors of the parasite that causes leishmaniasis) in a research lab at the Walter Reid Army Research Institute of Research were being killed by an unknown “blue” mold that was contaminating their food (rabbit dung). This research was conducted to determine the identity of the unknown fungus and its potential impacts to sand flies. To identify the fungus, DNA extraction, PCR, and sequencing analysis were conducted. In addition, we performed an experiment to determine if the fungus was phototropic (grows toward the light), a characteristic of dung fungi. Results confirmed that the fungus is phototropic and was identified as Aspergillus giganteus. This research has implications not only to care for sand flies, but also in potential fungal chemicals that may have insecticidal properties.

Abstract Name: Effects of Slow-Paced Breathing on Rumination and HRV

The neurovisceral integration model highlights the intricate process of self regulation and dysregulation, which can be understood through a functional and structural network. Self-regulation involves not only emotion regulation but also attention regulation. Difficulty in self-regulating cognitions and behaviors leads to rumination and worry, which are often seen in various psychological disorders. Vagal tone is an indicator of autonomic nervous system regulation, which has been found to be related to attention and emotion regulation. A high vagal tone reflects parasympathetic nervous system activity and is linked to better attention, emotion regulation, and behavioral flexibility. Prior studies have found that breathing at a slow

pace can increase vagal tone, resulting in higher heart rate variability and improved decision-making. Past studies have also shown that executive functioning of the prefrontal cortex and heart rate variability (HRV) are connected and that HRV is an indicator of vagal tone. This study aimed to look at the effects of a slow-paced breathing task on participants' cognitive function and HRV and assess whether slow-paced breathing was beneficial. A slow-paced breathing technique was used to examine the effects of stress levels when completing the Wisconsin Card Sorting Task (WCST), a measure of cognitive flexibility. Specifically, this study examined the effect of slow-paced breathing on state rumination and stress levels by looking at participants' individual self-control, rumination and HRV scores. Participants were California State University Channel Islands undergraduate students. Physiological data from approximately 70 participants has been included and more data will be collected. Participants were randomly assigned to either a control (nature video) or experimental (slow-paced breathing) condition. We hypothesized that slow-paced breathing would reduce state rumination in those with higher self-control scores and increase HRV in all participants. The preliminary results show a decrease in state rumination.

Abstract Name: The Changing Understanding of Mental Health: Exploring Generational Differences

Mental Illness has been around since the beginning of time. However, our understanding of the causes, treatment, and long-term impacts of mental illness changes over time. In fact, the evolution of mental illness has not been linear or progressive but rather cyclical. Whether or not a behavior is considered “normal” or “abnormal” depends on the context surrounding the behavior and thus changes as a function of a particular time and culture. This study looks at three distinct generational cohorts: those born in the 1940s/1950s (Baby Boomer); those born in the 1970s/1980s (Gen X); and those born in the 2000s (Millennial/Gen Z). First, I thoroughly describe historical and contextual information, especially in terms of major sociocultural, political, environmental, and economic events during these time periods. Next, a content analysis was conducted looking at auto-biographies written by individuals living with mental health issues across the three aforementioned generations. Through coding and constant comparison, this content analysis determined the presence of certain words, themes, and concepts within the text that describes the understanding and lived experiences of someone with mental illness. The content was then compared, assessing generational differences. Results showed that our understanding and experiences with mental health issues are heavily influenced by time and culture. Specifically, issues related to stigma, health literacy, loneliness, internet usage, coping mechanisms, and seeking help varied across generations. Although some issues (such as stigmatization of mental health) have improved across generations, other challenges have emerged (such as too much information). Additionally, intersectionality with race, ethnicity, gender, sexuality, and religion were considered. Finally, trends in mental health diagnoses and treatment are highlighted over this time period using data from the Centers for Disease Control and Prevention and the National Institutes on Health. In conclusion, this study provides recommendations for more individualized mental health care.

Abstract Name: Building Citizens in Classrooms: Examining the Impact of Developmentally-Appropriate Civic Discourse Curriculum

Civic discourse is a crucial element of democracy that seems to have disappeared in America's polarized political climate, replaced with baseless claims & tenuous arguments. Lost in such debates are the abilities to compromise and find common ground, the cornerstones of democracy. To ensure the health of our democracy, researchers argue we must develop civic discourse skills in children and adolescents rather than waiting until adulthood (Byrd, 2012). Social domain theory (SDT) asserts that children and adolescents understand issues of fairness, social norms, and human welfare (key elements of citizenship & democracy) differently at various stages of development (Nucci, 2008). Deepening students' understanding of these politically-relevant issues is most effectively through peer-to-peer discourse. There has been limited application of SDT in K-12 classrooms, which greatly inhibits students' potential moral and civic discourse development. The Educating For Democracy initiative (EFD) addresses these gaps by providing K-12 students developmentally-appropriate opportunities to exercise empathetic thinking regarding historical inequities through civic discourse with peers and synthesize their collective positions into writing. Given the lack of research into developmentally-appropriate civic discourse activities for K-12 students, this current study examined students' thoughts about engagement with EFD materials. Through the use of focus groups, the exploratory qualitative study examined fifty 3rd-8th grade students' experiences with EFD curriculum (i.e. units, lesson plans, writing prompts). Using the constant comparative method (Kolb, 2012), thematic changes were identified across focus groups (Braun & Clark, 2006). Three themes emerged in preliminary data: that participants valued engaging with peer-to-peer civic discourse around issues of race and justice, participants appreciated conversations around racial implications and racism, and that participants enjoyed learning about topics typically prohibited in schools (e.g. confederate monument debates). This suggests that students not only understood developmentally-appropriate curriculum, but, through interaction with EFD materials, felt empowered to become justice-oriented, cooperation-focused citizens of democracy.

Abstract Name: Hippocampal Subregions and their Relationship to News Events Memory in Older Adults with Normal Cognition or Mild Cognitive Impairment

Individuals with Mild Cognitive Impairment (MCI) are at risk for developing Alzheimer's disease (AD). According to existing tests, MCI patients exhibit extensive impairment in remembering the past (retrograde memory, RM) concurrent with only mild impairment in new learning. This finding suggests that more sensitive RM tests could identify MCI closer to when subtle neural and cognitive changes begin, therefore improving earlier diagnosis and access to interventions. In older adults with either MCI (N=33) or normal cognition (NC) (N=34), we examined if a novel RM news events test (RM-NET) can significantly predict brain volumes of hippocampal subregions known to decline in AD (i.e., CA1 and subiculum). RM-NET scores significantly predicted the volumes of the whole hippocampus, subiculum, CA1, and dentate gyrus in the MCI group. No significant relationships were identified in the NC group for the RM-NET scores. The RM-NET holds promise for tapping into the brain structures that are known to decline early in AD.

Abstract Name: Interactive Spanish Teaching Resources

This project helped students learn basic Spanish concepts, continue to develop their language skills, and critically think in a foreign language through a variety of didactic material and activities that covered personal, cultural, political, and social aspects. Further, the core concepts of culturally responsive pedagogy helped students reach academic success, be culturally competent, and develop critical consciousness. Although the research project focused on all three, it is important to note that the development of critical consciousness with the purpose of students being able to look at social injustices, identify them, and come up with a solution is what various activities emphasized. The material also focused on helping students be culturally competent by providing numerous situations and scenarios that happen all over the world in different countries. This allowed them to understand other cultures' values and social issues. This research also focused on one concept from the theory of multiple intelligences. It is important to recognize that students have different ways of learning. That is why educators were presented with diverse activities at all Spanish levels that encompassed linguistic, visual, and intrapersonal intelligence. Equally important, this empirical research focused on the use of different teaching resources for students to acquire a higher level of learning in the Spanish language, and teachers assessed the students to see results. Finally, one conclusion that is drawn from the research is that the use of interactive activities derived from short films and podcasts enhanced learning to the fullest in the Spanish language. Results included students being able to complete all activities designed for their level of Spanish and recording better academic results in the classrooms.

Abstract Name: History Of Package Design

Within the history of packaging, it was important to reflect on how packaging was first made and how important design would eventually evolve. Typography and information graphics in design today have a communicative and proper effect on branding. Package design has also created many evolutions, such as internet packaging, which is known today. Overall, packaging has affected the way consumers see products. Such as how color, design, and typography can behaviorally affect the consumer. Typography on package containers was influenced by trends and fashion throughout the years, such as from Chicago and its design communities. These types of influences not only influenced designers but also influenced the growth of package design. Influences of typefaces from the Swiss movement affect the way packaging looks. Packing within typography influenced movements such as optimism and idealism. These movements would help change the way typography should look on packaging. From idealism and optimism, throughout the 1990s, a lot of packaging would be redesigned, such as when Campbell's red-signed their label. In the 2000s, the

internet became bigger, creating websites such as SAP. Designed by Frog Designs, it would help create the beginning and growth of package design. meaning internet packaging would be born from websites booming. iPhones and Coca-Cola would be good examples of internet packaging in terms of how they are packaged from the factory to the internet. Typography was influenced by packaging through main events and industrial routes. Package design has been the main reason of influence of comsumersim of it's growth today.

Abstract Name: Qubit Readout Techniques for Donor-Based Quantum Architectures in Silicon

Donor-based qubits in silicon are a promising architecture for quantum information science. As with all qubit architectures, the ability to readout the qubit state is a crucial requirement. Typically, the charge state of the donor is determined by measuring current through a nearby charge sensor that is coupled to the donor. That measurement is then paired with spin-to-charge conversion that allows for the inference of the donor electron spin state. More recently, other techniques for detecting tunneling events in these systems have also been developed for use in spin-based quantum information systems. In this talk, I will discuss our efforts to implement various techniques in our lab, including gate and ohmic reflectometry techniques as well as typical electron transport methods.

Abstract Name: The Influence of Poggio Bracciolini's Handwriting into a Typeface

This is an examination of the development of humanist handwriting, specifically Poggio Bracciolini, turning into a typeface for future use. The prominent argument presented is centered around the influence Poggio had on writing regarding graphic design elements. To begin, context about Renaissance humanist principles is necessary for examination of the important of manuscript copying. From there, Poggio’s goals will be discussed surrounding manuscripts, literature, and Latin. Then, his handwriting distinction will be examined in relation to other humanists to understand why his writing became the basis for production. Subsequent uses of Poggio’s handwriting for uses of typeface by later people and prints will finally be addressed. This research demonstrates the influence handwriting has in the art and design sphere. Considering graphic design is a fairly contemporary design study, it is important for early predecessors of graphic design to be discussed. Although personally copying manuscripts is considered an archaic form of graphic design, it is still related to current practices employed within the field.

Abstract Name: Kisaengs' Negotiation of Social Position and Cultural Values in Joseon Society

Kisaengs were influential female artists of written and visual cultural production during the several hundreds of years in the Joseon period of Korea. Scholars have studied kisaengs as being exploited by the government and the wealthy for various self-interests. Some scholars emphasize that the government created kisaengs to produce art outside the constrictions of Neo-Confucian morality, while other scholars focus on how the wealthy used kisaengs' artistic production as an escape from the confines of their life, harming the emotions of both their wives and kisaengs. Thus, scholars present kisaengs as passive producers of art in service of the government and their wealthy counterparts. My research emphasizes the changing cultural role of kisaengs, as active artists who constitute an integral part of the society, producing text and visuals that complemented the artistic production of the period. To demonstrate this change, this study focuses on kisaengs between the seventeenth and nineteenth centuries. To begin, government functions and establishments in Joseon are addressed. Next, I demonstrate how the sixteenth century kisaeng, Hwang Jini, established her reputation, while, simultaneously, gaining her foothold as an artist, while other kisaengs produced text in the service to the government and ruling elites. I, then, demonstrate how Kang Dam-un, a kisaeng from the nineteenth century, developed the distinct identity of kisaengs, even under governmental and elitist surveyance—as seen in their artistic production. At the same time, two male influential painters, Kim Hong-do and Shin Yun-bok, exploited and, therefore, objectified kisaengs to critique the decaying morality in the nineteenth-century government, due to the growing cross-cultural trade.

Abstract Name: Social Media Crypto Frenzy and Financial Decisions on P2P Lending

Financial technology, also called fintech, facilitates quick financial decisions. To further support financial inclusion, some P2P lending platforms have incorporated blockchain and crypto collateral (Gonzalez, 2022). The purpose of this research is to examine behavioral decision making through an experimental setting. Investing and trading apps are commonly used by Gen Z and Millennial users because of their convenience, user-friendly interfaces, and the trust users have on online platforms. Social media is well known for incentivizing herd behavior exacerbated by celebrity recommendations, and this can limit financial inclusion (White and Wilkoff, 2023). This study analyzes the lending decisions by finance students on a mock peer-to-peer (P2P) online social lending. Survey participants are conditioned through testimonials towards pro-social decision making and asked to make three lending decisions. The three loan applications are identical except for a female or male headshot (vs.an icon) and random reports of 50% funding for the female or male loan in

3 days (vs. 11 days for opposite gender and 7 for icon). Previous research surveys students on a mock platform (Gonzalez, 2020) and reports similar heuristics and lifelike decisions in student and general population samples (Gonzalez and Komarova, 2014). P2P platforms that use crypto collateral don't seem to support financial inclusivity. support financial inclusivity further. In the future, more stable digital currencies supported by central banks could further democratize P2P lending, if there is behavioral financial literacy as well. Lender confidence is increased by self-reported financial literacy, and the popularity of a loan among other lenders has an impact on lending decisions. To enhance the financial inclusion of qualified borrowers, P2P platforms need to improve crypto innovations and offer financial literacy on behavioral decision-making

Abstract Name: Language Barrier Disparities for Patients and Families Seeking Medical Care

AbstractBackground: The United States (US) has a high population of non-English speakers that continuous to grow, however healthcare providers do not often reflect the population of non- English speakers. Current translation tools include the use of My Accessible Real Time Trusted Interpreter (MARTTI), in-person translators, family members, or a three-way phone call with an interpreter on the other end of the phone. While better than nothing, these translations methods are not completely effective and often lead to misunderstandings and misdiagnosis. Purpose: With the increasing use of artificial intelligence (AI), a new method of translation can be developed that is cost effective and reliable. Methods: This mixed method study will be conducted in various healthcare settings such as hospitals and clinics to test this new method for translation. Patients must be primarily Spanish speaking and in need of a translator. Participants in this study will be both healthcare workers and patients. Conversations between the patient and healthcare provider will be recorded using video recordings during consultations. Surveys and open-ended questions will ask patients and healthcare providers to rate the accuracy of the AI translation. Conclusions: Finding a solution that uses artificial intelligence in healthcare settings to help translate medical information to non-English speakers is necessary for time and cost- effectiveness. These solutions have the potential to improve patient-healthcare provider relationships and lead to less misdiagnosis. The ability to use AI for translation provides communication in an efficient manner due to the improved response time.Keywords: Non-English speakers, Artificial Intelligence, Language Barriers, Healthcare, Improved Quality of Care

Abstract Name: Assessing Behavior Management Coursework in Teacher Preparation Programs

Teachers often report feeling ill-equipped to meet the needs of children who exhibit challenging behaviors, which can lead to frustration and can impede attempts to provide a safe and nurturing environment for their students. Teachers who report feeling inadequately prepared to manage classrooms or who report a low

ability to manage challenging behaviors are less willing to implement behavior support plans or effective education for all students. Children who perform low academically are at greater risk for behavioral problems, which leads to a cycle of negative experiences for both the student and the teacher. The purpose of this study is to understand how the most attended special education and elementary education teacher preparation programs in the Western region of the United States prioritize and facilitate behavior training in preservice education. This research will be conducted by analyzing coursework related to behavior management to identify whether there are differences in the amount of required behavior classes and the language within the state standard requirements for both special education and elementary education teacher preparation programs. Using a thematic analysis I expect to identify differences between behavior management coursework in special education and elementary education teacher preparation programs. Preliminary results suggest that special education teacher certification programs are more likely to include behavior and classroom management content in their coursework. Nevertheless, teachers in both elementary education and special education encounter behaviors that may disrupt student learning, therefore this research may support the need for additional training resources for elementary education teachers.

Abstract Name: Analyzing Potential Shifts in Abortion Attitudes Among Hispanics/Latinos in the U.S.

The Hispanic/Latino electorate has consistently drawn attention from political candidates due to its increasing influence in American politics. The central research question guiding this investigation is as follows: To what degree did attitudes towards abortion among Hispanics/Latinos shift from 2016 to 2022? Given the diverse array of perspectives within the community, the primary objective of this study is to investigate the shifts in attitudes towards abortion across consecutive election years. While prior studies have delved into abortion attitudes among this ethnic group, none have explicitly scrutinized changes over time during successive election years. By scrutinizing the evolving sentiments of Hispanic/Latino individuals on this issue, the research aims to identify potential correlations or causative links, thereby contributing significantly to our understanding of behaviors and potential voting trends within this minority group. Anticipated within this study is an inclination towards more liberal attitudes among Hispanics/Latinos over the years concerning abortions and reproductive rights. This expectation arises from societal movements such as the Women's March in 2017 and the national outcry following the Supreme Court's 2022 decision to overturn Roe v. Wade. The research utilizes data from the Cooperative Election Study (CES) in 2016, 2018, 2020, and 2022. By focusing on abortion questions that remain identical over time, the degree to which answers have shifted or stayed the same will be made evident. By delving into the nuanced changes within this minority group, the study not only enhances comprehension of their perspectives on reproductive rights but also provides a valuable foundation for anticipating and interpreting future electoral dynamics within the broader American political context.

Abstract Name: The Effects of Sleep State on Somatostatin Interneuron Activity and Memory

Sleep is known to play a critical role in the encoding, storage, and recall of memories. Previous research has shown that sleep deprivation (SD) specifically impairs hippocampus-dependent memory. Our lab has shown that, in SD conditions, memory impairment is accompanied by increased activation of somatostatin-expressing (SOM+) inhibitory interneurons in the dentate gyrus of the hippocampus. SOM+ interneurons have been implicated in regulating hippocampus-dependent memory processes, supporting lateral inhibition between granule cells in hippocampal memory encoding. This project aims to see if sleep deprivation changes somatostatin levels and immediate early gene activation in various levels of the dentate gyrus. Next, we examined whether manipulating SOM+ interneuron activity affects mice's ability to encode, store, and/or recall memories. The goals were tested with gentle sleep deprivation techniques, intracranial SOM+ inhibition, and immunohistochemistry. Results showed that sleep deprivation following learning triggers increased expression of cfos in the granule cell layers of the hippocampus. More specifically, sleep deprivation significantly increased neuronal activity on the superior blade of the dentate gyrus. These results align with previous mRNA experiments from our lab. Next, we saw that somatostatin inhibition does not lead to significant differences in discrimination index; however, these experiments are not complete. The next steps of these experiments consist of, for the first experiment, looking at the overlap of somatostatin and cfos. For the second experiment, it has to be completed, redone, and analyzed via immunohistochemistry to look at the changes of neuronal activity that result from the inhibition of somatostatin in different memory stages.

Abstract Name: Political Meme Theory

Abstract: Memes are an ubiquitous feature of online culture that many know and love. However, while memes are best known as a means to deliver amusement, some have a serious impact on our culture. This paper focuses on a subset of important memes: political memes which increasingly characterize and influence our culture. Accordingly, I argue for a new theory of political discourse, based on the idea of memes informed by political psychology and social epistemology. At the center of this theory is the claim that American political discourse is usefully thought of as a competition of political memes. I call this perspective the “meme’s-eye view” of politics or “political meme theory.” To present this perspective, I first give some background including defining relevant terms and explaining the approach used. Then I show how the competition of memes manifests in partisan rhetoric and in the coverage and reception of news stories. This includes epistemological considerations such as the effects of “echo chambers,” “epistemic bubbles,” and “bullshit.” Additionally, I identify several problems with political discourse as a “meme war” in the context of increased polarization, focusing on common issues with the content and delivery of memes. These include the effects of rhetorical labels and arguments designating partisan affiliation– whether we intend it or not. Finally, a number of specific suggestions for ways to empirically buttress this theory during upcoming elections are given.Keywords: memes, political memes, political psychology, social epistemology, echo chambers.

Abstract Name: Physical and Chemical Activation of Crop Products to Manufacture Engineered Adsorbents for Environmental Applications

The aim of this study was to engineer crop-derived activated carbons (CDACs) from biomass waste for the adsorption of hazardous gases. The CDACs were synthesized from sugar beet pulp pellets through sequential activation after the carbonization of the pellets. The methodology includes physical activation with steam, chemical activation with nitric acid, and chemical impregnation using four different chemical groups as activating agents. The use of sugar beet pulp, a byproduct that typically goes unused, allows for an innovative and economically beneficial approach to the production of activated carbon. Optimal temperature, time intervals, and chemical solutions were the factors that were tested to produce high-quality activated carbon. The pollutants removed by the CDAC were nitric oxide (NO) and carbon dioxide (CO2). Each sample would undergo gas phase adsorption testing wherein each pollutant would run through the sample, and its adsorption capacity was measured. For CO2 adsorption, Magnesium oxide-impregnated CDAC had the highest adsorption capacity and percent removal efficiency before 20% breakthrough, and for NO, Vanadium oxide-impregnated CDAC had the highest adsorption capacity and percent removal efficiency.

Abstract Name: Experimentation phase of the process design methodology for the performance evaluation of medium rocket engine propellants

The Rocketry & Propulsion study research group from Universidad EAFIT welcomes students from different bachelors such as mechanical, physics, chemical, mathematical, industrial engineering, and computer science to take part in small research projects related to aerospace engineering focusing on the study of mid-power solid-propellant rocket systems.Moreover, for the last two years an educational and process-centered methodology has been developed and refined with the purpose of establishing a systematic procedure to propose and build reliable, low-cost propulsion systems with predictable performance.Three main work fronts were defined involving different steps within the design, production, and test of the rocket propulsion system, namely: propellant formulation; instrumentation & metrology; motor design. The first one seeks to validate, through burn rate tests under controlled conditions, the composition of mixtures of fuel, oxidizer, and binder agents. The second one aims through the capability of the instruments under development (Crawford Pump and Static Test Bench); to measure different physicochemical variables of the

performance of solid propellant rocket propulsion systems. The third aim is to test and iterate the design of the prototype rocket engine based on the analysis of the data obtained experimentally.Through an iterative way, each front couple analytical and/or numerical activities with experimental work, providing a strong validation of the whole process. As part of the implementation of the methodology in its experimental phase, different propellant burn tests have been carried out, determining a specific mixture to be characterized in the Crawford pump, which is undergoing hydrostatic tests to verify its correct operation. Additionally, the characterization of different sensors to measure variables such as thrust, pressure and temperature in a test bench and the remote transmission of data for the execution of a static test of the designed rocket engine was achieved.

Abstract Name: The Effects of Resource Scarcity within Low-Income Latinx Communities

Diabetes currently affects 37.3 million people in the United States and has been shown to disproportionately impact minoritized groups, such as the Latinx community. This disproportionate effect of diabetes in Latinx people can be studied by investigating Latinx-enriched communities like Monterey County (61% Latinx according to the US Census), located in the Central Coast of California. Monterey County has a high incidence rate of diabetes of 1 in 8 Latinx diagnosed, and pre-diabetes rate of 1 in 2 Latinx diagnosed (Marino, 2019). This essay investigates the correlation between the lack of nutritional resources and accessibility to health care, two indicators of poor health outcomes, within the Latinx communities in the Central Coast and how lack of such resources may lead to illnesses such as diabetes, which have historically been found to disproportionately affect the Latinx group (Montoya 2011). This research analyzes both a scientific breakdown of diabetes and a discussion of the socio-economic influences that exacerbate rates of diabetes cases within low-income Latinx Central Coast communities. Findings from such studies will not only be applicable to the Latinx community, but may also be used as a resource for study of other low-income communities across California and the broader United States. The goal of this work is to reveal the socioeconomic factors as to why low-income Latinx communities have a greater risk of contracting diabetes and think of new ideas regarding the implementation of new accessible ways to support and understand the masses impacted by socio economic issues.

Abstract Name: Functionalizing Layer-by-Layer Nanoparticles (LbL NP) for Improved Glioblastoma Penetration

Glioblastoma (GBM) is a lethal brain cancer known for its resistance to standard surgery, radiation, and chemotherapy treatment options. GBM's dense, solid characteristics pose significant challenges in delivering drugs to the tumor microenvironment because many medicines cannot penetrate the tumor entirely. When vital medication cannot reach GBM, the cancer metastasizes. Our project utilizes Layer-by-Layer Nanoparticle (LbL NP) technology to engineer nanoparticles with features that improve their efficiency and effectiveness for drug delivery to glioblastoma. First, we layered multiple outer layer ratios of Poly-L-Glutamate (PLE) to Poly-L-Glutamate-PEG-iRGD (PLE-PEG-iRGD) onto LbL NPs containing Poly-L-Arginine (PLR). PLE was used to maximize cellular uptake, while PEG helped maintain nanoparticle colloidal stability. iRGD peptide was used for its tumor-penetrating properties. With a thiol detection assay, we quantified the amount of PLE-PEG-iRGD on our nanoparticles and tested each of our LbL NP batches on in vitro GBM cell lines. Next, we tested the colloidal stability of our LbL NP batches in artificial cerebrospinal fluid. Finally, we utilized flow cytometry to determine the percentage of cells that uptook the LbL NPs. Preliminary results show that outer layer composition and peptide incorporation impacts nanoparticle-glioblastoma cell interactions. Furthermore, we also observe improved nanoparticle stability and cellular uptake in GBM as we increase the amount of PLE-PEG-iRGD on our LbL NPs. Future work will involve loading siRNA and chemotherapeutics onto our LbL NPs. Additionally, we will use 0% PLE : 100% PLE-PEG-iRGD polypeptide as the outer layer for our future NP batches, based on preliminary experimental data. This project lays the groundwork for designing efficient nanocarriers for local and systemic drug delivery to GBM tumors in vitro and eventually in vivo.

Abstract Name: Project CUREOS: Using Job Characteristics Theory to Reflect on Your Current Research Experience and Navigate Future Career Choices

Will the work you do one year or ten years after graduation resemble the work you did as an undergraduate researcher? When you choose a career path, which aspects of your research or internship experience will you want to keep, and what would you like to be different in your future job? Job characteristics theory (JCT) provides a theoretical framework for thinking about the structure of work. Based on JCT, core job characteristics (e.g., skill variety, task identity, task significance, autonomy, and feedback) affect work-related outcomes, including motivation, satisfaction, and performance (Hackman, J. R. & Oldham, G. R., 1975). Our research project titled CUREOS (Characterizing Undergraduate Research Experiences and Outcomes in STEM) aims to better understand how to optimize undergraduate research. We are also building a web-based resource to assist students in exploring careers based on work design preferences. We have created a pilot application that allows participants to complete a survey to characterize their work or volunteer research experience, modify the characteristics based on their preferences, and search a national occupation database for occupations matching the desired characteristics. Our team also plans to explore the relationships between structural facets of undergraduate research design and key student outcomes with the goal of improving the experiences of students in pursuit of STEM careers and increasing the diversity of the workforce. This presentation will provide an overview of JCT and this project. For more information, see https://www.cureos.org/. This work is supported by NSF IUSE #2142404.

Abstract Name: Addressing challenges of CURE instruction in biochemistry courses by scaffolding formative assessments using results from prior CURE implementations

Course-Based Undergraduate Research Experiences (CURE) deliver many cognitive and affective benefits. Effective implementation of CUREs involves scaling research training from “apprentice” to classroom size (12-24 students). When trying to integrate content and scientific process learning objectives, the instructors run into a problem unique to CUREs: different research projects progress at different rates, and some students may not be able to advance far enough in their projects to cover all content-related learning objectives of the course. How does an instructor design assessments and learning activities, when the research outcomes and challenges of a CURE are not known in advance? Using data obtained by students in an earlier CURE implementation allows instructors to build scaffolded activities that break down cognitive challenges into smaller chunks and showcase a range of problems students may encounter once they undertake their own research project. These activities allow students to work in small groups and with the instructor’s guidance to develop deeper knowledge of content and a range of skills required for research. Having a common set of activities allows for scaling the research training without removing the novelty dimension of the CURE. This approach helps reframe experimental “failure” in a positive light, as a cognitive challenge that students can welcome rather than fear. The approach to creating inquiry activities is straightforward and can be adapted for any CURE. I’ll share two examples of CURE course redesign: Protein Techniques and Bioinformatics Applications. The learning objectives in Protein Techniques are centered around protein purification and the CURE is supported by the Biochemistry Authentic Scientific Inquiry Laboratory community (BASIL, https://www.basilbiochem.org/). The learning objectives in the Bioinformatics Applications course are centered around annotating eukaryotic genes and the CURE is supported by the Genomics Education Partnership (GEP, https://thegep.org/). This work is supported by NSF IUSE1915544, 2141871.

Abstract Name: The Relationship Between Value of a Purchase and Acquisition of a Loyalty Account: Is There a Price on Consumer Loyalty?

The purpose of this literature is to explore which variables relating to price may have an impact on the acquisition of a loyalty account. The research will ultimately explain if there could be a potential relationship between the acquisition of a loyalty account and value of a purchase. Analyzing price influences on consumer behavior and typical consumer decision making processes will show what makes an impact on the consumer decision to open a loyalty account with a brand or business. This will support the evidence behind exploring the theory behind pricing of a purchase and loyalty account enrollment through various hypotheses, including: (1) Non-loyal consumers will be less likely to enroll in a loyalty account if the purchase is $100 or less, (2) there will be no difference in the price threshold for enrolling in a loyalty program through different age groups, (3) there will be a difference in the price threshold for enrolling in a loyalty program throughout various income levels, and (4) there will be a difference in the price threshold for enrolling in a loyalty account when the consumer purchases from various product categories.

Abstract Name: Examining the Impact of Data Imbalance on the Accuracy of AI/ML Models through Applying Conventional Methods.

Imbalanced data poses a significant challenge for individuals engaged in Machine Learning, as it often leads to suboptimal model performance. This issue arises because machine learning models struggle to train the minority class effectively, compromising predictive accuracy. The dataset under consideration in this study is derived from the Taiwan Economic Journal's financial data for 6819 companies from 1999 to 2009. The data contains 95 features, such as the ROA, total asset turnover, etc. IBM Watson's platform was used to develop predictive models using various algorithms. The Snap Random Forest Classifier produced a 97.2% accuracy with multiple enhancements, and the Snap Decision Tree Classifier produced a 96.9% accuracy. Each algorithm gave importance to different features. The Snap Random Forest Classifier gave the sum(ROA(C) before interest and depreciation before interest), Net worth/Assets) feature 100% importance in predicting the outcome. Despite good accuracies, confusion matrices, and ROC curves did not produce favorable results because the employed dataset exhibited an imbalance, with a predominant negative class (96.8% negative-class vs 3.2% positive-class). To assess the impact of imbalanced data on the accuracy of the proposed models, an attempt was made to systematically reduce the percentage of the negative class threefold to achieve data balance. Subsequently, the accuracy was scrutinized following each adjustment. Evaluation metrics, such as confusion matrices and ROC curves, were utilized to analyze the model's performance. Additionally, traditional methods for addressing imbalanced data, such as oversampling the minority class, are evaluated for efficacy at each stage. The resulting model accuracies went down by a few percent, but the impact on confusion matrix and ROC curves was at an acceptable level. This comprehensive examination aims to provide practitioners in machine learning with insights into the consequences and potential solutions when confronted with imbalanced datasets.

Abstract Name: ChatGPT Translation of Program Code for Image Sketch Abstraction

The evolution from MATLAB to Python (M-to-PY) has been a critical focus in computational research over the past two decades. Despite this transition's intricate and labor-intensive nature, the resurgence of MATLAB's relevance in high-performance, parallel, and quantum computing has reignited interest in such conversions. Since its inception, MATLAB has been the cornerstone of countless scientific research projects, many of which could experience a renaissance if translated into open-source Python. This language currently

spearheads the AI domain with its comprehensive libraries, frameworks, and transformers. This research elucidates a semi-automated M-to-PY conversion process through an exhaustive case study of a bespoke image skeletonization project. This complex project, encompassing fifteen MATLAB files and a dataset of 1404 images, executes the skeletonization of various images, from humans and animals to insects and cars. The skeletonization sets robust groundwork for future research in 3D motion detection using AI Transformers, which are largely implemented in Python. The AI bot, ChatGPT-4, is central to the translation project, serving as an AI pair programmer. The OpenAI API's unique public availability is critical to our conversion process. We engineered a prototype M-to-PY converter, rigorously tested it against alternatives using test cases generated by the Bard bot, and then used the resulting code for the AI app. This research makes two primary contributions: an M-to-PY conversion with thorough testing and a Skeleton App that can take an image of any object and draw a sketch and a skeleton. This functionality can be harnessed in many AI projects. This work underscores the role of AI tools like ChatGPT-4 in facilitating code conversion processes, especially for those with limited coding knowledge. It highlights the potential for such conversions in paving the way for innovative AI apps to scientific research with mostly MATLAB code.

Abstract Name: An Analysis for the Importance of Providing Culturally Competent Care in the Nursing Profession

In response to the ever changing cultural landscape of healthcare, the nursing profession must undergo transformative changes that equip nurses with the capability to accommodate the needs of our diverse society. The 2023 American Association of Colleges of Nursing (AACN) statement on cultural competence in academic nursing noted that “a diverse and inclusive nursing workforce reduced health disparities, addressed social determinants of health, and improved patients outcomes" (aaacnnursing.org). The project recognizes the importance of cultural competency and focuses on identifying and acknowledging instances where the nursing profession has fallen short as well as improving patient outcomes by providing culturally competent care. My research focuses on marginalized populations that are prevalent in the Lehigh Valley area in Pennsylvania, but can be applied for other areas. Although my research emphasizes specific populations, the project can be utilized and modified to establish cultural competencies for other marginalized groups. Building upon a previous summer project, this research includes a review of relevant literature that addresses the disparities and ties with the societal obstacles associated with these unique populations and the intersection of healthcare. Moreover, this project evaluates relevant nursing literature that has utilized culturally inclusive care in the nursing profession, while also reviewing how the profession can improve and grow in this area. Anticipated outcomes include fostering a dialogue within the nursing profession to spark a change for cultural competency among nurses and the means to achieve this in the different fields of nursing, with an emphasis in a higher academia setting, beginning with Moravian University. This project symbolizes a commitment to change and compassion for our increasingly diverse world and how nurses care for the world around us. The hope is that this project is not solely limited to nursing, but can be altered and applied throughout the medical field.

Abstract Name: Understanding The Role of Phosphatidylinositol Driven Lipid Phases in Triple Negative Breast Cancer Aggressiveness

1/8 American women are diagnosed with breast cancer, with a 2.5% survival rate. ~17% of these diagnoses are triple negative breast cancer (TNBC), the most aggressive breast cancer subtype and most lethal as it lacks overexpression of the normal chemotherapy targets, hormone receptors and Human Epidermal Receptor 2 (HER2). TNBC is characterized by higher grade tumors and an overall increase in metastasis rate. Our lab has previously identified specific phosphatidylinositol (PI) lipids that could serve as biomarkers for highly metastatic phenotypes (PI3,4P2) by characterizing the PI lipidome and correlating those results to migration rates. We also found that increasing PI3P concentrations offset this effect. These results led us to study the lipid phases that these PI lipids induce in the plasma membrane and the downstream effect on cellular plasticity and invasiveness. We hypothesize that increasing PI3,4P2 leads to more plasma membranes fluid phases thereby making it easier to migrate and invade surrounding tissues. We also hypothesize that PI3P increases plasma membrane rigidity. In this study, we cultured both primary (HCC38, HCC1395, Hs578T) and metastatic (MDA-MB-231) cell lines to determine migration rates. The plasma membrane was removed for lipidome analysis. Small angle x-ray scattering (SAXS) characterized the lamellar organization (Bragg peaks). We expect to find that aggressive cells will have fewer yet broader (fluid phase) Bragg peaks. Furthermore, less aggressiveness will correlate with more sharp (rigid phase) Bragg peaks. By characterizing the role of PI biomarkers, we will gain a greater understanding of how these lipids may cause more aggressive phenotypes as well as better understand how to prevent metastasis and use these new biomarkers as therapeutic targets.

Abstract Name: Comparative evaluation of short and long-term Perfluorooctane Sulfonate exposure on Cytotoxicity and Mitochondria Structure Dynamics and function in HepaRG liver cells

Perfluorooctane sulfonate (PFOS), a synthetic fluorine containing organic compound with wide industrial use is persistent and bioaccumulate in living things. Studies have shown PFOS has adverse effects in humans and can lead to toxicity, oxidative stress, and inflammation in a variety of cell types including liver cells,but the underlying molecular mechanism remains unclear. As mitochondria play a pivotal role in sensing cellular response to environment and offer valuable insights into cellular health. The present study evaluated the effect of short term and chronic PFOS treatment on mitochondria structural dynamics,and functional parameters such as ATP levels. Human HepaRG liver cells were exposed to varying concentrations of PFOS (10 nM,100nM, and1000Nm) andcontrol group at varying exposure durations (short-24 hours, 48 hours,72 hours;long-term 96 hours and 1 week) in an incubator (37oC,5% CO2). Cell viability was determined with CyQuant XTT cell assay kit and absorbance at 450nm, and 660nm were measured using spectrophotometer. Mitochondrial structural dynamics were assessed using the Mitotracker orange CMROS dye, and fluorescence intensity was quantified via excitation (4985/20nm) and emission (528/20nm). Following

treatment, mitochondria were isolated using a commercial kit. Mitochondrial volume and ATP content was measured using the ATP Assay System Bioluminescence Detection Kit. Experimental data were analyzed and statistical significance was at p<0.05. Our resultsreveal that exposure to higher PFOS concentration at longer durations led to significant reduction in cell viability,mitochondria structure-associated mitotracker fluorescence intensity and ATP levels than the control group. Cells exposure to higher PFOS concentration (1000nM)over longer durations (1 week) resulted in reduced cell viability and mitochondrial structural dynamics and functional capacity resulting in reduced ATP levels than short term PFOS cells exposed at 24hrs, 48hrs and control group. The results warrants for further studies on long-term PFOS risk assessment on cellular health and diseases.

Abstract Name: Characterization of Coupled Radiative and Conductive Thermal Response in Fiborous Thermal Protection Systems

During the process of atmospheric re-entry, aerodynamic heating phenomena induce high-enthalpy boundary layer flow that encompasses the vehicle. The development of high-enthalpy flow necessitates the use of Thermal Protection Systems (TPS) to protect the payload. TPS materials are constructed from highly insulative fibers that limit heat transfer from the boundary layer to the payload. To characterize the radiative flow interacting with the payload, two experimental campaigns are currently being conducted. The experimental campaigns will consist of a set of local tests at the University of Kentucky Paducah Campus and a campaign in the HyMETS arc-jet plasma tunnel at NASA Langley Research Center (LaRC). The LaRC campaign will characterize the spectral response of LI-2200 to the thermal radiation generation by the arc-jet augmented with short wave-length lamps. The non-linear contribution of the radiation through the fibrous medium LI-2200 will be decoupled from the contri- butions of solid conduction using a modified cut-bar conductivity measurement experimental setup. The results of the two concurrent campaigns will be used to further extend and modify computational models used to design TPS materials.

Abstract Name: Evolution of TetR-TetO System Toward Orthogonal Transcriptional Repression

Recent gene therapy advancements have progressed the treatment of a spectrum of disorders and diseases caused by misregulation of gene expression programs and their transcriptional regulators. However, existing

genetic therapies largely lack tunable control of exogenous gene expression. We are exploiting the Tet-On system as a switch-like tool to explore the limits of flexible exogenous gene expression in mammals. Tet-On allows the expression of any gene to be reversibly, specifically, and differentially controlled on command. In this system, the tetracycline repressor (TetR) binds the tetracycline operator (TetO), impeding transcription of any downstream gene embedded by the researcher, blocking even the strongest promoters. The presence of tetracycline causes TetR to adopt a new conformation that removes it from TetO, inducing gene expression on command. Because of this system's diverse utility, we are in pursuit of developing novel TetR-TetO orthologous pairs that do not interfere with this wild-type circuit and can be used to regulate gene expression in parallel. As a first step to generating TetR-TetO orthologs, we mapped the usage of TetO by TetR in a massively parallel reporter assay (MPRA) by engineering an extensive library of mutant TetOs and quantified the resulting range of TetR regulation through reporter gene expression. From this screen, we identified candidate TetO mutants to direct the evolution of the wild-type TetR towards complementary states to those TetO mutant sequences. Finally, to showcase the zero cross-reactivity between our mutant circuits and the wild-type circuit, we plan to engineer a synthetic genetic circuit in mammalian cells, representative of complex circuits of synchronized cell signaling we observe in biological systems. By generating a novel suite of TetR-TetO mutant pairs, we will create a toolbox of expression "off-switches" for selective and reliable control over modified gene expression toward the pursuit of disease prevention and treatment.

Abstract Name: The Relationship Between Movement Patterns and Sport-Induced Lower-Extremity Injury

My research question explores the relationship between movement patterns and sport-induced lower-extremity injury. I hypothesize a strong relationship between low-quality movement patterns and sport-induced lower extremity injury. As ACL injuries in particular are on the rise, my research seeks to explore how we can curb injury rates by aiming to understand what factors are most influential on low-quality movement. Current scholars posit that there are several factors contributing to low-quality movement, most notably flexibility levels and neuromuscular fatigue. Current research explains that the ACL is vulnerable to injury due to the anatomy of the hips and knees and lack of muscle support structures to protect it from strain during jumping, landing, or cutting movements. As such, I am studying movement patterns that lead to injury, as well as movement patterns that follow the sustainment of the injury. My project explores the movement of the hips, knees, and ankles. My research spotlights the debates of flexibility and fatigue as precursors of injury sustainment, the effectiveness of injury prevention training, and the efficiency of the functional movement screen (FMS) in determining the risk of injury.My research methodology includes surveying and interviewing physicians, physical therapists, exercise physiologists, patients, coaches, and athletes who have experienced or are knowledgeable in orthopedic lower extremity injury. I will generate patterns across responses to analyze what types of movements lead to injury and how one's movement is affected following an injury. Injuries of relevance will be limited between the hip and the toes. The project analyzes data figures on fatigue and flexibility's relationship to injury, which supports current scholarly dialogue, and the purpose of my findings will be mainly to suggest preventive measures for the future.

Abstract Name: Examining Lesbian Activism Throughout the AIDS Epidemic: Exploring Individuals Who Cared for Gay Men Living With HIV and AIDS

In 1981, Acquired Immunodeficiency Disease first emerged in the United States. It was initially labeled GRID (Gay Related Immunodeficiency Disease) because of the diagnosis of Ken Horne - an openly gay male. Many men who contracted the disease were abandoned by their families, friends, and loved ones due to unknown - and often stigmatizing - factors. Doctors and nurses were weary to take care of AIDS patients because of preconceived notions and homophobic assumptions. The activism that lesbians provided to those affected by the disease during its infancy, specifically gay men, has long gone unnoticed by the masses. During the 1980s, being a lesbian and caring for gay men living with HIV and AIDS was a complicated endeavor. Frequently, lesbians caring for AIDS patients faced misogynistic pushback from gay men who felt gay men should be the only leaders in this fight. They also faced criticism from other lesbians who felt they'd abandoned queer women's issues. Yet, despite all the pushback, lesbian activists during the AIDS epidemic continued to thrive by volunteering for organizations such as the Chicken Soup Brigade and the Bailey-Boushay House. Volunteer work wasn't their only form of activism. One individual who stands out is Jewel Thais-Williams, who utilized her LGBTQ+ nightclub as a space to host fundraisers and used money from her business to support AIDS organizations. This presentation will employ a variety of primary and secondary sources to provide historical context to lesbian activism in the 80s. More specifically, it will bring to light the suppressed history of queer women and examine their activism throughout the AIDS epidemic.

Abstract Name: Early life exposure to antibiotics and increased risk of early onset colorectal cancer

Colorectal cancer (CRC) is the second leading cause of cancer related deaths worldwide.1 CRC in patients older than 50 years has been decreasing, however, CRC in patients less than 50 years known as early onset colorectal cancer (EOCRC) has steadily increased since the 1990’s and expected to increase by 90% in colon cancer and 124% in rectal cancer by 2030.2,3 While EOCRC has been linked to typical risks associated with late onset CRC, its causes and mechanisms are still unknown.We hypothesize that increased risk of EOCRC may be associated with exposure to antibiotics (Abx). Antibiotics are indispensable in the treatment of infectious diseases. However, its overuse, particularly in infants and children has increased globally with over 1 million doses prescribed unnecessarily each year.5,6 While Abx are effective against pathogenic bacteria, it also targets the gut microbiota, which are important for proper development of the immune system and metabolic processes. We hypothesize that exposure to Abx early in life alters the gut microbiota causing gut inflammation resulting in increased risk for EOCRC. We further propose that there are developmental windows in life when exposure to Abx increases susceptibility to developing EOCRC. We will test this hypothesis using mouse models of CRC.In this study, we exposed A/J mice to commonly prescribed pediatric Abx at different developmental stages, then injected them with azoxymethane, a carcinogen, to induce tumor

development. Control mice were treated with water or polyethylene glycol. Thus far, our results indicate that multiple exposures to pediatric Abx increased tumor burden in the distal rectum of treated mice. Further studies will determine if a single round of Abx is sufficient to impact tumor burden. RNA sequencing to identify changes in metabolic and/or inflammatory pathways caused by Abx may elucidate the mechanisms underlying increased risk of EOCRC.

Abstract Name: Examining How Shifting Gender Roles in Cooking is an Avenue for Achieving Modern Day Gender Equality

Cooking has been historically understood as the domestic task for women: it doesn't require the brute labor or sharp intellect that a strong, intelligent man is supposed to provide. It is a soft, gentle, and motherly duty for a woman to perform while her husband is earning a living for the family. Given the opportunity to choose between assigning a man or a woman to cook for their family, society would always choose the woman. Yet, recent research reveals an increasing number of men entering the sphere of cooking and subsequently loosening the tight association of women with household cooking. These shifting gender roles in cooking tie strongly with the goals from women in the past who were motivated to work towards greater gender equality. A variety of perspectives were explored and cross-analyzed throughout my research. This includes statistical analysis of the increasing number of men entering the kitchen, a historical feminist speech, as well as personal narratives by both female and male authors. It was concluded that men entering the kitchen as the main family cook is necessary for society to uproot deeply ingrained stereotypes which associate women with domestic tasks and men with the workforce. Further research on methods to mobilize young men to participate in cooking should be conducted to sustain the movement of overcoming gender norms. Thus, when given the opportunity to once again choose between assigning a man or a woman to cook for their family, society would see no difference.
