Immunology is inherently interdisciplinary. The understanding of immunologic processes and immune system components often requires an understanding of foundational knowledge from several science disciplines. UAB offers a unique, 4-year, comprehensive undergraduate immunology major in which students in the Undergraduate Immunology Program (UIP) begin a sequence of 5 core courses, starting with Introduction to the Immune System in their sophomore year. For some students, the Introduction to the Immune System course precedes their completion of introductory science sequences for biology and chemistry. Thus, students enter the course with varying backgrounds in foundational science knowledge. To address potential knowledge deficits, foundational science topics that are necessary to understand complex immunology concepts are incorporated within each of the courses. The goal of this project is to evaluate student understanding of the application of foundational science topics in the understanding of immunologic processes. Sophomore, junior, and senior students in the UIP were invited to complete a 3-part survey that assessed student ability to identify foundational science topics necessary to understand four different immunologic concepts, student confidence in understanding each foundational science topic, and identified the science course in which a student felt the foundational science concept was fully understood. Preliminary findings suggested that there was consensus among UIP students about the requirement of specific foundational science knowledge being critical for understanding certain immunologic processes, which did not correlate with academic level. Furthermore, reported confidence in student understanding of foundational science topics increased in the junior year cohort compared to the sophomore year cohort, but confidence diminished in the senior year cohort. Analyses to evaluate differences in student confidence among cohorts and correlations with consensus on foundational science topics required to understand specific immunologic processes are ongoing.

Abstract Name: Women’s Marital Roles in Classical Period Athens: Male Understanding and Portrayal in Euripides’ Medea and Aeschylus’ Agamemnon

The Classical Period of Athens (500-336 BCE) was an era of sociocultural growth and stability for the ancient Greeks, renowned for its development of tragic theatre. While Classical Athens nurtured the public sociocultural success of male citizens, women adopted a submissive role, confined to their responsibilities as wives and mothers. Women were forbidden from directly taking part in politics, philosophy, and above all, the theatrical scene of Athens. Due to these societal perceptions of traditional gender roles, the literature of the Classical Period was heavily influenced by a male bias. This study investigates the connections between women’s role in Classical Athenian society and the portrayal of female literary characters in tragic theatre by male playwrights. The use of stage costumes, characterization, and narrative of female characters in two Classical tragic plays, Euripides’ Medea and Aeschylus’ Agamemnon, were analyzed to determine if male societal perceptions of women in Greek society influenced the structure of female characters. Through these analyses, it was determined that male bias and traditional gender roles of women in Athenian society established four prominent stereotypes in female dramatic characters: the femme fatale, the conspirator, the victim, and the villain. Tragic theatre was a vital pillar of ancient Greek history, so contemporary understanding of the real roles of women in Classical society are undeniably warped through a male bias. The reality of women’s roles in Classical Athenian society and literature remains a mystery to modern historians.

Abstract Name: Single Cell RNA Sequencing Reveals a Lineage-specific Response to Angiotensin II in Smooth Muscle Cells in the Ascending Aorta of Mice

Background:Ascending aortic aneurysm is a life-threatening disease with no pharmacologic treatment options. The aorta is composed of 3 primary layers, intima, media, and adventitia. Medial remodeling such as, cellular hyperplasia and extracellular matrix disruption have been identified as key features of ascending aortic aneurysms. The primary cell type occupying the medial layer is smooth muscle cells (SMCs). SMCs in the ascending aorta are derived from two embryonic origins, cardiac neural crest (CNC) and second heart field (SHF). SHF-derived SMCs play a vital role in the pathophysiology of AngII-mediated thoracic aortic aneurysms. However, functional differences between the two origins have not been determined.Methods and Results:Ascending aortas were harvested from Mef2c-Cre +/0 mT/mG mice at baseline and 3 days of AngII infusion (1,000 ng/kg/min). After single-cell suspension, cells were sorted based on their origins separated by tdTomato and mGFP signals. Mef2c is the promoter for the SHF origin, therefore cells marked with mGFP were labeled as SHF-derived. Cells fluorescing red were deemed to be not SHF (nSHF). Afterwards, we conducted RNA sequencing on individually sorted cells to identify transcriptomic differences between the two cell origins. Two-way ANOVA for the interaction (infusion x origin) identified 3,703 differentially expressed genes (DEGs) in SMCs. Among them, 295 genes exhibited a unique transcriptional response, being the upregulation by AngII only in SHF-derived SMCs. The top 10 upregulated genes in this sub-cluster included Loxl2, a key enzyme for elastic fiber development. Of note, other LOX members, such as Lox and Loxl1, were downregulated in SHF-derived SMCsConclusions:AngII infusion alters the transcriptome of aortic SMCs in a lineage-specific manner. AngII upregulates genes related to extracellular matrix development specifically in SHF-derived SMCs.

Abstract Name: Nanofabrication Techniques for Advanced Wire Grid Polarizers

Polarization, a fundamental property of light, plays a crucial role in various optical and photonic devices and applications. Wire grid polarizers (WGPs), composed of nanoscale parallel metallic wires, are a widely used device to create or measure optical polarization. One way of implementing these devices is by structuring a silicon substrate into the desired wire pattern through etching, followed by the deposition of metal onto that structured surface. To enable enhanced performance and broader applications of WGPs, smaller, more precise features within WGPs are needed. Building upon existing research, the project investigates the creation of nanoscale structures in silicon to serve as templates for wire grid formation. The project seeks to push the boundaries of silicon etching and metal evaporation techniques to enhance the fabrication process of WGPs.

This research involves systematically optimizing reactive ion etching processes for silicon to achieve sub-micron size features. Significant progress has been made in silicon etching, with developed processes achieving target depths of 100-200nm and demonstrating a precision of ±10nm. Simultaneously, optimized techniques are developed for precise metal layer deposition, emphasizing control over shape, thickness, and location. In addition, through literature exploration, the project aims to identify materials suitable for broader wavelength applications, crucial for enhancing the performance of wire grid polarizers. The advanced fabrication techniques developed in this project aim to significantly expand the application possibilities of WGPs, ushering in a new era of optical device fabrication with improved performance. These findings contribute substantially to the field of optics and photonics, presenting novel tools for manipulating light polarization.

Abstract Name: Spelman College SelfGuided Tour System: A Systems Engineering Approach

There are several locations that provide “self-guided” tours. For instance, when visiting some museums, visitors can purchase and use a system consisting of a small audio device and headset. When the device is in close proximity of a given artifact or exhibit, the device will present facts about the given artifact/exhibit, thus allowing the visitor to proceed through the museum at their own pace, and reducing the need for an in-person or active “tour guide”.Our goal is to create a system like this at Spelman College with the use of guide posts and Raspberry Pi’s. The system development team shall research various Raspberry Pi hardware and software configurations to determine and propose an optimal configuration. We will also be implementing this concept on real world applications such as turn-by-turn GPS directions. Data from the Raspberry Pi’s GPS coordinates will be obtained, compared to known databases, and then facts will be returned.

Abstract Name: Attack, Counter-Attack, and Escalation Between Viruses and Bacteria

The ongoing conflict between bacteria and phages is often likened to a molecular arms race, where bacteria evolve immune systems that block infection and phages evolve immune suppressors that restore the infection. Many phage-encoded immune suppressors are small proteins, and recent work has shown that PARIS is a two-component system (AriA, AriB) that induces cell death upon detection of phage-encoded suppressor proteins. Here we purify the ≈425kDa supramolecular complex and use cryo-electron microscopy to determine structures of a PARIS complex. The core of the complex is composed of 3 AriA homodimers which assemble into a C3 symmetric scaffold while three AriB nuclease subunits are positioned at the interface of each AriA homodimer. Phage-encoded anti-restriction proteins Ocr and LF82 have been shown to activate the PARIS complex, resulting in an abortive infection that prevents phage replication and spread. To determine how the trigger molecules interact with the PARIS complex, strep-tagged triggers were co-expressed with the PARIS complex, and pulldown products were analyzed using size exclusion chromatography and SDS-PAGE. Collectively, this work reveals mechanistic details of an additional layer of bacterial immunity that detects diverse phage-encoded suppressor proteins to induce cell death in the presence of phages that would otherwise escape RM or CRISPR defenses.

Abstract Name: Exploring the Relationship between Socioeconomic Resources, Oxytocin Levels, and Maternal Mental Health Outcomes in Black Women

Black women face higher maternal mortality and morbidity rates and are more likely to experience discrimination in healthcare settings. Black women are more likely to be exposed to socioeconomic factors, such as education, health services, transportation, environmental controls, availability of food, quality of housing, and occupational health regulations, that cause discrimination and increase stress. Chronic stress resulting from discrimination has been associated with negative health outcomes, including lower oxytocin levels, higher rates of depression and anxiety, and other relevant factors. This research has the potential to inform interventions to mitigate the impact of discrimination on maternal health and improve outcomes for black women. The methodology used in this research is a secondary analysis of data from peer-reviewed literary articles conducting research analyzing depressive symptoms of women after birth in white women and black women. Data on women diagnosed with postpartum depression was also collected from the Psychiatric services in Washington, DC. Oxytocin categories (low, medium, or high) and depressive symptoms (CESD scores) came from the National Association of Posttraumatic Stress Journal. Results indicated that women who identified as African American from the United States had a higher frequency of depression symptoms about socioeconomic factors based on studies from the World Health Organization. Studies have demonstrated that women who exhibit lower oxytocin levels, and interventions, such as skin-to-skin contact and breastfeeding, aimed at increasing oxytocin levels may reduce depression and anxiety risk. Results show that sociodemographic factors like age, employment, marital status, and income influence these

disparities highlighting systemic inequities and limited resources. Lower oxytocin levels, affected by discrimination, economic resources, breastfeeding, and support systems, contribute to higher rates of postpartum depression in black women. Addressing these disparities requires tailored care, interventions, and promoting optimal oxytocin release.

Abstract Name: Enhancing Workplace Productivity and Motivation: The Role of Positive Organizational Behavior, Relationships, and Healthy Lifestyles

This research study investigates the multifaceted relationships between positive organizational behavior (POB), workplace relationships, healthy lifestyles, and their combined impact on employee productivity and motivation within the context of industrial/organizational psychology. Through surveys and analysis, this study aims to shed light on the factors that can contribute to creating a more productive and motivated workforce. In a sample of faculty staff from several colleges in Pennsylvania and nearby states, data collection examined the impact of POB, workplace relationship quality, and health-related behaviors on measures of productivity and motivation at work. Positive correlations were expected between POB, workplace relationship quality, health-related behaviors and the workplace outcomes of productivity and motivation. This study contributes to the existing literature in industrial/organizational psychology by highlighting the importance of a holistic approach to enhancing workplace performance. By fostering a positive organizational culture, nurturing interpersonal relationships, and promoting health-conscious behaviors, organizations can effectively boost employee motivation and productivity. Understanding these dynamics can offer practical insights for employers and HR professionals seeking to optimize workplace environments. Ultimately, this research underscores the significance of considering not only job-related factors but also employee well-being and positive workplace culture in the pursuit of enhanced productivity and motivation.

Abstract Name: Analyzing shopping trends across ages

As consumer trends change, more research is needed to determine what shoppers want. This research delved into the shopping preferences of consumers, comparing the allure of online shopping with the traditional in-store experience. I wrote and implemented my survey by collecting data on Amazon Mechanical Turk and analyzing my 199 responses on IBM SPSS. A key discovery was that most shoppers prioritize dodging shipping costs when they shop online, which could be a pivotal selling point for companies aiming to attract more customers and boost sales. Furthermore, I noted interesting variations in behavior and preferences

among different age groups. Younger shoppers appeared to rely more on product reviews to guide their purchasing decisions, while middle-aged consumers seemed more willing to pay for shipping when shopping online. In contrast, older shoppers favored avoiding shipping costs as well as online shopping whenever possible. These findings offer valuable insights to businesses looking to fine-tune their marketing, pricing, and customer engagement strategies based on the age groups they target. Moreover, the study also uncovered age-related reasons why some people still prefer shopping in physical stores, which can help businesses enhance the in-store experience and entice more visitors, ultimately leading to increased sales. This research provides practical guidance for companies to optimize their sale growths both online and in-person as well as displaying where majority of consumers prefer to shop.

Abstract Name: Housing for the Visually Impaired - The Emerald City Estate

The purpose of this project is to design a detached single-family house for someone with a visual impairment. This home is owned by the Lockwood family. One of the family members has type 1 diabetes and proliferative retinopathy. This visual impairment results in fluctuating levels of vision, blurred vision, dark floaters, and progressive vision loss.According to research, almost 20 million Americans have a visual impairment, and 26.43% of people with diabetes develop retinopathy. It is important to consider materials, colors, lighting, furniture, and wayfinding when creating a design for someone with a visual impairment. People with retinopathy may not have a total loss of vision, so it is still important to consider the visual environment. Some important things to consider include making sure to use materials that do not produce glare, using textures that make identifying objects easy, using contrasting colors to highlight separate surfaces, and creating a layout in a way that avoids confusion or dangerous scenarios.The research methodology includes case studies, a review of design guidelines, a meeting with a specialist who works directly with individuals with visual impairments on a daily basis, and a literature review. These research methods were used to research inclusive design features for people with visual impairments. The design results in a home with easy wayfinding that is not only easy for the end user but also safe. This is achieved by utilizing contrasting colors on vertical and horizontal planes to make surfaces and objects easier to recognize. Lighting plans are strategically placed to make lighting adjustable to the user and to avoid glare in the spaces. Lastly the furniture is laid out in a way that creates straightforward pathways that are easy to navigate.

Abstract Name: Furniture Design for Neurodivergent People - "The Peace Pod"

The purpose of this project focuses on developing furniture for neurodivergent individuals to utilize in an open office workplace environment. The research illustrates the need to create furniture that provides comfort and stability while reducing factors that can cause overstimulation.According to research, people who are neurodivergent are more susceptible to mental illness, which poor working environments can induce. These individuals have unique sensory experiences that fluctuate based on their surroundings. Different colors, textures, sounds, and other sensory stimuli can negatively impact many neurodivergent people. When workplace design accounts for sensory sensitivity, neurodivergent individuals can use their unique thought processes as a superpower in the workplace. However, only 1 in 10 businesses consider neurodivergent people in their management strategies. With around 20% of the US population being neurodivergent, that's roughly 1 in 5 people in the workplace who aren't being considered. The research methodology for this project primarily focuses on looking at different case studies. These studies contain information on office pod designs and existing designs that target the neurodivergent population. Research was also conducted by interviewing neurodivergent individuals about experiences within their own workplace and personal experience as someone who is also neurodivergent. The research for this project results in a design for "The Peace Pod," an individual workstation that uses universal design to benefit neurodivergent people. The furniture piece is designed to be inclusive to as many people on as many spectrums as possible, inevitably benefiting everyone. This is accomplished through different materials, colors, and functions incorporated in the furniture piece that are known to enhance the ability of neurodivergent people to excel in the workplace. By understanding their unique sensory experiences and incorporating design elements that cater to their needs, The Peace Pod contributes to a workplace that promotes productivity, well-being, and inclusivity.

Abstract Name: Good Hair or No Hair: An Examination of the Impossible Hair Choices Black Women Adversely Face.

CCCA (Central Centrifugal Cicatricial Alopecia) almost exclusively affects Black women. Environmental factors such as exposure to endocrine-disrupting chemicals (EDCs) may be an important contributor to this health disparity. The objective of this project was to conduct a scoping review to understand the body of literature available on the association between EDC-containing hair products and CCCA. We also sought to understand EDC content in hair products marketed to Black women. We searched "black women," "CCCA," "hair products," and "history of Black women's hair" in PubMed and HOLLIS. We also used the

Environmental Working Group (EWG) to assess ingredients and risk scores for hair products marketed to black women. We found 16 articles that met the criteria of covering the content of CCCA, EDCs, and Black women in the United States. Hair relaxers were the most common EDC-containing product and also had the highest mean EWG risk score. Given the disparity in both the exposure to EDC's and adverse health outcomes driven by Eurocentric beauty standards, more research is needed to evaluate the association between EDC-containing hair products and CCCA.

Abstract Name: Tales of A Title 1 School: George Washington Carver Intermediate

This film is about the changes and differences in a Title 1 elementary school after COVID-19. After the pandemic, schools have been given an unimaginable task to bridge the learning gap caused by the COVID-19 pandemic. During this time, educators were unable to provide the same caliber of teaching and learning. With the world being forced into isolation, schools had to reevaluate how they could provide quality teaching for student learning. School districts had to provide students with individual hotspots and computers to keep up with the technological demand that the pandemic caused. Educators now had to teach virtually rather than face-to-face. Interpersonal relationships were lost along with the ability to differentiate learning to meet every student's academic need. This along with other extenuating circumstances forced teachers to teach to the mainstream (students on grade level). Students with learning differences and impairments were left out/behind along with students who fell below and above grade level. Other factors that contributed to the educational gap were the varying levels of parental involvement and student engagement. Social-emotional growth, academic progression, and increased misbehavior, higher rates of violence, social anxiety, and lack of focus were challenges uncovered. These challenges persist as we are back in schools, face-to-face, along with a pressing issue of chronic absenteeism. Isolation coupled with extreme loss of instructional time has caused students' transition back to in-person school to be rocky. Educators are reteaching what should have been learned during the pandemic while also tending to students' social-emotional and mental growth challenges. This film explores how a Title 1 school located in Chesapeake, Virginia, is handling these daily challenges while working to ensure student success.

Abstract Name: Mental Illness within the Southern Baptist Convention: Understandings, Treatment Methods, and Stigma in Local Church Communities

For generations, Protestants have struggled to accurately understand mental illness. Some have assumed that

mental illness is a form of sin, while others have blamed demon possession for the occurrence of mental illnesses. Along with this, many have treated mental illness as a spiritual illness that can be cured through practices like prayer and Scripture reading. These poor understandings of mental illness have often led to unnecessary stigma towards mental illness, rejection of counseling and medication to treat mental illness, and poor mental health care within church communities. However, along with these false understandings, there are many Protestants who have thoroughly integrated psychological science and faith in a way that enables them to understand mental illness as biological, psychological, social, and spiritual in nature. In this project, attitudes towards mental illness are examined within the Southern Baptist Convention in the last 25 years. The Southern Baptist Convention's spoken and written thought about mental illness is analyzed through a review of past research and primary sources from Baptist leaders and convention resolutions. After analyzing the patterns of the SBC over the last 25 years, I determine whether their assumptions and treatment methods fall within any of the categories formerly listed (sin, demon possession, spiritual illness), or within a more integrative approach. After this, I discuss the experiences of attenders of Southern Baptist churches surrounding mental health and how a right understanding of mental illness is important in adequately meeting the needs of congregation members and making the church a more welcoming place for those with mental illness.

Abstract Name: Les Quatres Communes: How Four Senegalese Cities Grew to Challenge Prevailing Narratives on the Colonizer and the Colonized

When the French began to get involved in transatlantic trade in the 16th and 17th centuries, they initially focused on establishing small trading posts off the coast of West Africa, in modern-day Senegal. Upon the arrival of mostly single French men involved with monarch-enabled Charter Companies, intermarriage became standard practice. This paper focuses on the development of the four settlements of Saint-Louis, Gorée, Rufisque, and Dakar from their origins as early trading posts through the establishment of the Four Communes in 1848, with a special focus on intermarriage and the process of creating a truly créole society. As French men and signares—powerful African women—intermingled and married in the 17th and 18th centuries, they soon gave birth to a sizable métis class. The métis class, characterized by European and African blood relations, possessed the cultural finesse needed to inhabit both European and African cultural spaces, rendering this new group of Eurafricans incredibly influential in each of the cities that eventually made up the Four Communes. By breaking down hierarchical barriers at the family level, early interracial families elevated the status of Africans, paving the way for a colonial policy shaped by the complexity of racial and ethnic identity in the cities that would eventually be known as the Four Communes.

Abstract Name: Interdisciplinary Approaches to Studying Climate Change: Measuring Gaping of Intertidal Mussels

The study of the effects of climate change on indicator species like intertidal mussels can indicate the health of ecosystems, but studying mussels in their natural habitat can be costly and labor-intensive. This project set out to design an automated system to track mussel gaping behavior in a laboratory environment to enable a more complex understanding of their emotional states and responses to heat stress. A system was designed to measure the gaping of a mussel using a linear Hall effect sensor and a small permanent magnet. We experimented with several types of Hall effect sensors to see which would provide the most accurate results for the expected gaping distances. The system was calibrated using an electronic caliper; data collection was accomplished using an Arduino microcontroller. This data comparing the sensors will be presented. The results of this work will eventually be incorporated into a more complete mussel monitoring system used to track the gaping of mussels in response to the application of a dynamic heat ramp that mirrors the intertidal zone's temperature patterns.

Abstract Name: Unwrapping Sweet Success: A Journey through Chocolate Packaging Design

This paper discusses the deep history of graphic design and how it is seen in chocolate packaging. By examining how functionality, design, and information presented overlap when creating chocolate packaging, it is clear how these can influence consumers' perceptions of a product. By evaluating various existing articles, this paper explores diverse historical periods, shifts in design trends, and how they affect customer preferences. The findings from the studies cited offer valuable insight into the relationship between graphic design and consumer behavior when it comes to chocolate packaging.

Abstract Name: Arm Slot Predicts Fastball Induced Vertical Break in Collegiate Pitchers

BACKGROUND: In baseball pitching, fastball performance has been linked to velocity. However, pitchers will likely strive for additional metrics to induce swings and misses. One metric used is induced vertical break, which is the vertical movement of the ball based on spin and the magnus effect when excluding the effect of gravity. Coaches and pitchers commonly theorize that arm slot influences induced vertical break;

however, little data on metrics beyond pitch velocity have been studied. The study aims to identify if the induced vertical break of fastballs can be predicted by arm slot. METHODS: In-game kinematic and ball metric data from sixty-five collegiate baseball pitchers (1.88 ± 0.06 m, 92.9 ± 9.52 kg) were retrospectively analyzed. All fastballs thrown had metrics averaged, giving each pitcher a single representative pitch for analysis. Arm slot was defined as the angle between the vertical axis of the world and the vector of the throwing shoulder and hand (0°=over-the-top, 90° sidearm). Linear regression was used to determine if an arm slot could significantly predict induced vertical break at an alpha level of .05. RESULTS: Results indicate that induced vertical break could be significantly predicted by arm slot ($F(1,63)=102$, p < .001). Arm slot accounted for 61.8% of the variance in the induced vertical break ($r = .786$, $R2 = .618$). For every degree increase in arm slot (less 'over-the-top'), there was a decrease of 0.3 inches in the induced vertical break on fastball pitches (unstandardized $\beta = -0.303$, $t = -10.1$, $p = .001$). DISCUSSION: Pitchers with a more over-the-top arm slot tend to trend towards a greater induced vertical break compared to those with a more side-arm pitching style. This provides supporting evidence that arm slot effects induced vertical break.

Abstract Name: The Impact of Personality on Algorithmic Thinking in Undergraduate Students

The purpose of this study was to investigate the methods and possible correlations between algorithmic thinking and a noncognitive factor, personality, in undergraduate students in an attempt to further the understanding and the teaching of algorithmic thinking. It was hypothesized that the difference in personality traits would impact the students' algorithmic thinking levels, specifically with openness resulting in the highest levels of algorithmic thinking. A correlational design was used to investigate the relationship between the variables. The levels of each Big five personality trait were gauged through an IPIP-NEO-PI personality test. Algorithmic thinking levels were assessed through a series of 11 Cross Array Tasks (CATs), while a singular CAT was used as training. A Pearson correlation test was used to determine if there was a statistical difference between each of the personality traits and the scores from the 11 series CAT assessment in this correlational design. The tests displayed a significant negative relationship between the agreeableness personality trait and algorithmic thinking levels, $r = -0.664$ $p = .036$. None of the other big five personality traits were found to be significantly related to algorithmic thinking. We conclude that high levels of agreeableness may be found to correlate to lower levels of algorithmic thinking.

Abstract Name: Characterizing the neural mechanisms and natural variation in a multisensory behavior.

Multisensory behaviors are critical in vertebrates and invertebrates across the phyla. The simultaneously processing of multiple sensory modalities allows organisms from humans to worms to maximize their perception of the environment and execute important behaviors, during encountering attractive or adverse conditions. Despite this appreciation, our understanding of the neural mechanisms underlying this behavior and how this various across individuals or even species is not fully understood. Our present study uses a combination of genetics and behavioral analysis to understand the neural circuits, molecular mechanisms and how sensory-dependent behavioral strategies vary across different species of the Caenorhabditis nematode. This question will 1) specifically characterize the genes and neurotransmitter pathways that mediate this behavior, and 2) identify differences across Caenorhabditis nematode of a variety of species respond in a decision-making/sensory behavior. In Dr. Harris's laboratory, we examine worms in an assay that exposes worms to attractive(food) and repulsive (2-nonanone) simultaneously, and exam food leaving during worm exposure to a repulsive cue that generates an escape response. Distinct natural isolates will be examined across a behavioral paradigm where worms are challenged with both food and danger cues and there escape behavior will be examined. We have identified multiple genes and neurons involved and identified differences across Caenorhabditis nematodes in food leaving during exposure to the conflicting sensory cues. For example, we have identified C. remanei, C. briggsae, C. yunquensis and C. portoensis behave differently to our normal control C. elegans worms in food related behaviors. Suggesting, different strains of nematode perform these multi-sensory behaviors differently. We will continue to map out the molecular pathways, and overall identify differences in behavioral preference across various species of nematodes.

Abstract Name: A Systematic Review of How Workplace Outcomes are Impacted by the Biohacking Intervention of Mindfulness-Based Stress Reduction

INTRODUCTION: Organizational scholars explore workplace outcomes (e.g., performance, job satisfaction) and how to improve them for employees/managers. Likewise, companies have begun advocating for the betterment of workplace outcomes with biohacks (i.e., using science-based self-experimentation to enhance one's body, mind, and life via techniques such as exercise, supplements, or mindfulness), yet research on the impact of these hacks in the context of the workplace is scant. One biohack, Mindfulness-Based Stress Reduction (MBSR; Kabat-Zinn, 2003), has been shown to improve health in clinical/healthy populations (Grossman et al. 2004), but its effect in an organizational context is relatively unexplored. PURPOSE: The purpose of this review is to determine the extent of research conducted on MBSR's impact at work. METHODS: We conducted a systematic literature review in the SCOPUS database in September 2023 searching for articles that include the MBSR intervention in the work context. Of the 332 articles identified in the search, 309 studies were excluded because they do not assess a workplace outcome. Thus, we reviewed 23 remaining articles (Article samples are: healthcare - 50%; education - 18%; construction/architecture -

9%; management - 9%; mix - 9%; mining 5%.). RESULTS: We find that MBSR has a positive impact at the individual level on workplace outcomes (e.g., performance, job satisfaction, burnout); one study demonstrates a positive impact of MBSR on an organizational-level workplace outcome. The findings are consistent across various occupations (e.g., managers, nurses, and educators). CONTRIBUTION: This review advances knowledge in organizational science as the first to synthesize the current literature on MBSR's effects on outcomes in the workplace. Grossman, P., Niemann, L., Schmidt, S., & Walach, H. (2004). Mindfulness-based stress reduction and health benefits: A meta-analysis. Journal of Psychosomatic Research, 57(1), 35-43. Kabat-Zinn, J. (2003). Mindfulness-based stress reduction (MBSR). Constructivism in the Human Sciences, 8(2), 73.

Abstract Name: Modeling the Adsorption of Sargassum-Derived Hydrochar

Harmful algal blooms (HAB's) are the abundance of toxins released from the overgrowth of algae in bodies of water. Hydrochar (HC), a carbonaceous substance made through the process of hydrothermal carbonization (HTC), has been seen in its effectiveness to mitigate the effects of HAB's by adsorbing the released toxins, stopping contact with the environment. This study focused on HC derived from Sargassum, a species of seaweed, and its effectiveness in adsorbing Methylene blue dye (MB). The results were analyzed in order to predict the potential capabilities of adsorbance of HAB toxins and the impact of parameters in the creation of HC on its adsorption capabilities. Nine versions of HC were created through HTC at three varying levels of temperature, duration of HTC, and sargassum-to-water ratio. The highest performing HC version was made from the maximal of each performance parameter– a HTC temperature of 260°C, for 60 minutes, and a sargassum-to-water ratio of 1:20– with a percentage removal of 99.02% against 100 ppm MB and 95.53% against 300 ppm MB. All versions of HC against 100 ppm and seven of nine versions of HC against 300 ppm exceeded a 90% removal threshold, designating sargassum-derived HC a sufficient adsorbant of MB and indicating adsorbance potentiality against HAB toxins for future study and eventual water treatment applications.Multiple beta regression models were run on different subsets of the data collected– 100 ppm, 300 ppm, and combined concentration– to analyze which performance parameters are significant in the HTC synthesis of Sargassum-derived HC. HTC temperature was shown to be both consistent in significance and a positive correlation with adsorbance performance. This same consistency was not shown for duration of HTC, and sargassum-to-water ratio. This conclusion aids in further optimization of Sargassum-derived HC and its adsorbance capabilities against HAB toxins.

Abstract Name: The Diffusion of Limonene through Paraffin Wax Using Infrared Spectroscopy

Waxy substances are part of many chemical systems of natural, consumer, and industrial importance such as agricultural plants, insects, cleaning products, cosmetics, and pharmaceuticals. Understanding how solutes diffuse through these waxy systems is vitally important. For example, this knowledge can lead to improved performance in insecticide penetration through the waxy cuticle on the surface of insects. In this work, we describe the development of a method to determine the diffusion coefficients of terpenes into waxy substances. This method utilizes an FT-IR spectroscopic imaging system to monitor the flux of terpenes through a slab of wax. Infrared spectroscopy imaging was chosen as a measurement system because it provides not only spatial/ temporal resolution of the flux of the terpene through the wax layer but also is sensitive to the intermolecular interactions between the solute and the waxy molecules, and thus can provide insights about the roles functional group interactions can play in diffusion. A limonene/paraffin wax system will be described as an exemplar. Spectra and results will be shown.

Abstract Name: Foreign direct investment and economic growth; an empirical analysis of the role of local conditions.

This paper explores the relationship between foreign direct investment (FDI), economic growth, and the role of local conditions in recipient countries. I examine whether countries with well-developed financial systems, strong institutions, and low corruption experience stronger positive spillovers from FDI. I conduct a cross-country empirical analysis using a local projection and instrumental variables approach to determine the effect of exogenous changes in FDI flows on growth. In accordance with previous literature, this analysis reveals that the effect of FDI alone has an ambiguous effect on growth under various specifications. However, when considering the interaction of FDI with financial development, institutional quality, and low corruption respectively, countries receiving FDI experience strong benefits. By introducing new instruments for FDI flows and using a local projection approach, this paper addresses the endogeneity issue and the long-term, cumulative effect of FDI on growth in a way yet to be explored in the existing literature.

Abstract Name: Comparison of the Protein Structures of Mammalian Caspases

This research focuses on comparing the protein structures of mammalian caspases, which are proteins that are involved in the process of apoptosis or programmed cell death. There are three main types of mammalian caspases: initiator caspase, executioner caspase, and inflammatory caspase. Initiator caspases initiate the apoptosis signal, while executioner caspases carry out the mass proteolysis that leads to apoptosis. Inflammatory caspases are involved in inflammatory cytokine signaling and pyroptosis, which is cell death caused by a microbial infection.We gathered a data set of proteins from the RCSB Protein Data Bank (PDB) and evaluated their structural similarity using the Triangular Spatial Relationship (TSR)-based method. This method generated a cluster map that was used to compare the proteins based on structural similarity. Other figures that compared the structural similarity of each type of caspase and highlighted the presence of common and unique substructures in each type were made from this data. A phylogenetic tree based on amino acid sequence rather than structure was also generated using the Molecular Evolutionary Genetic Analysis (MEGA) software.From this data, we gathered that the structural analysis using the TSR-based method indicates that executioner and inflammatory caspases are more similar, while the sequence analysis indicates that executioner and initiator caspases are more similar. The common and unique substructures that are identified in the data set provide the structural basis for designing drugs to inhibit all types of caspases and specific types of caspases, respectively.

Abstract Name: Microwave-Assisted, Gold-Catalyzed Intramolecular Etherification of Diols to Afford Aryl-Substituted Tetrahydrofurans and Tetrahydropyrans

The first reports of gold catalysis date back to the beginning of the previous century, but the use of homogenous gold catalysis is relatively new due to the antiquated belief that gold is a prohibitively expensive, chemically inert metal. Recent reports show gold catalysts have demonstrated high catalytic activity in numerous organic transformations, and the structural motifs attainable by these methods are a common building block for the synthesis of natural and synthetic products ubiquitous in biologically active compounds. The methodology presented herein builds off prior studies using gold(I) salts to catalyze SN1-type etherification reactions. A novel one-pot methodology utilizing gold(I) salts has been developed to yield aryl-substituted tetrahydrofurans and tetrahydropyrans, a common structural motif found in antibiotic and antidepressant treatment drugs, from readily available diols. To our knowledge, an intramolecular gold-catalyzed etherification reaction is currently unprecedented in the literature. The intramolecular gold-catalyzed etherification reaction has been optimized using 1,4-diols and 1,5-diols as the starting substrate, 5 mol % of the gold(I) and silver(I) salts, polar solvent, and slightly elevated temperatures generated from microwave irradiation to afford 95% yield of the target cyclic ether. Using these conditions, the substrate scope for this reaction will be presented for fifteen electron-rich and electron-deficient substrates, ranging from 70%–93% yield. All starting materials and reaction targets were fully characterized by 1H-NMR and 13C-NMR spectroscopy. The long-term objective is the synthesis of bioactive natural products and other

various building blocks useful in the synthesis of bioactive molecules, as well as enantioselective transformations.

Abstract Name: Enhancing Interdisciplinary Urban Simulations through Scripting: A Case of Data Integration

This study is part of a larger research project to explore the impact of integrating new data into building energy models at urban scale. The specific focus here is on the development and application of a Python script designed to automate the integration of tree property data into building energy models to enhance the accuracy and efficiency of urban planning and building design.Comprehensive energy simulations in urban modeling involve numerous factors and interdisciplinary collaborations. Managing data across different simulation platforms creates challenges, often requiring understanding the background scripts used to run simulations. The transfer of intermediate data between platforms necessitates scripting knowledge, posing barriers for interdisciplinary teams in urban simulation projects. This study aims to connect scripting expertise with urban simulation concepts, providing a solution to the difficulties of integrating data across diverse simulation platforms. The project methodology entails the creation of a script in Python designed to augment Input Data Files (IDF) generated through an urban modeling interface (UMI) for energy simulation.Along with main functionalities, the script also makes IDF files compatible for simulation in Linux OS environments. Detailed exception and error handling is implemented throughout each step of the program's execution to ensure the augmented data is in agreement with the semantic and scientific requirements of the energy modeling software. In conclusion, this research addresses a critical aspect of urban simulations, facilitating smoother data interchange among various simulation engines. The developed script serves as a practical solution for interdisciplinary teams aiming to streamline their simulation processes.

Abstract Name: Demystifying the Tropics: FTIR Characterization of Pantropical Woods and Their Components for Use in Radiocarbon Analysis

Tree-ring radiocarbon (14C) measurements are used to reconstruct atmospheric 14C levels. Reliable 14C measurements require α-cellulose extraction, which chemically reduces mobile carbon compounds found in raw wood (e.g. waxes, fats, resins, and other soluble organic compounds). Since pantropical trees commonly contain excessive amounts of these compounds, researchers argue that more elaborate chemical treatments

involving organic solvents are required to refine 14C results. However, this has yet to be demonstrated. We address this knowledge gap by using Fourier transform infrared (FTIR) analysis to compare raw wood and α-cellulose extracts obtained by a user-friendly and efficient chemical treatment without organic solvents. The simplified treatment involves 1N acid-base-acid warm baths, acidified bleach at 70°C, and strong base (17% NaOH) treatments at room temperature. We expect that while different raw tree species will contain different compounds, the simplified treatment will be effective in reducing all different species to pure α-cellulose extracts. To rigorously test if this protocol works for a wide range of pantropical tree species, 8 tropical species were selected as well as 3 reference wood materials. Furthermore, FTIR analysis was run on extracts between treatment steps to conclude each step's accomplishments in α-cellulose extraction. We chose woods from different longitudinal and latitudinal settings with various phenological traits. We found that while the FTIR spectra of different species of raw woods showed mild variations, probably because of compound composition, they were largely similar. FTIR results from α-cellulose extracts were basically indistinguishable, meaning that our simplified treatment can be safely used in atmospheric 14C reconstructions across pantropical regions.

Abstract Name: An Allegorical Interpretation of the Tragedy of Icarus Representing Aristotle's Golden Mean

The tragedy of Icarus and Daedalus holds much to be revealed about how to live one's life and the importance of the virtue of temperance. Throughout this paper I seek to develop my own allegorical interpretation of the tragedy of Icarus and Daedalus as it is found in Ovid's Metamorphoses. I will base this interpretation upon Aristotle's golden mean which he discussed in book two of The Nicomachean Ethics. To properly convey these ideas, I will first describe Aristotle's doctrine of the mean, briefly summarize the tragedy itself, and define the important pieces of the story that I will use to create the allegorical interpretation. I will then discuss the different ways that those pieces may interact with each other which will reveal what can be learned from my interpretation of the classic tragedy and how this interpretation showcases the golden mean. Finally, I will close with what inspired me to interpret the story in this way and how reading the story in this way has application for one's life. It is a common pitfall of humanity to set unachievable goals for themselves inevitably leading to a failure to improve resulting in the downfall of one to their old habits. By understanding the story of Icarus through Aristotle's golden mean, one may improve the way in which they set out to create an improvement within their life. This interpretation encourages a method of careful consideration about the full impact of one's decisions on their own life and the lives of those around them.

Abstract Name: The Zoo: A Living Museum or a Bulwark of Conservation

The purpose of this essay is to consider if zoos as a concept hold any value and if their operation can be considered ethical in any capacity. To accomplish this, I will reference John Berger and his conception of zoos and their purpose. Zoos are very limiting when compared to the real world and how animals would act, behave, and feel when seen in their proper context. Berger notes that this shift is due to the separation of other animals from humans. Instead of living alongside us as they did merely two or three hundred years ago, animals now occupy a different role for humans. We take them in as pets, put them in boxes to look at, and make them symbols of human feelings and emotions. Although, zoos are helpful for conservation purposes and keeping certain animal species alive there are millions of animals being raised in captivity. They are posted up in imitations of their environments for humans to view like living museums. Furthermore, upon reviewing the websites of the Smithsonian National Zoo and the North Carolina State Zoo, I am bombarded with them asking for donations, advertising ticket prices, and links to feeding time schedules for these animals. The entire concept of a zoo revolves around treating animals like objects to be viewed. That notion is incredibly problematic in the eyes of many people, which is one reason why zoos are held to incredibly high standards. For a portion of this paper, I will also discuss some of the ethical standards that are held in AZA accredited institutions and the importance of conservation efforts.

Abstract Name: Motivations for Retaliatory Aggression on Social Media among Borderline Personality Endorsers

Social media has become a popular way of connecting with people, but it has also led to an increase in cyber aggression. Borderline Personality Disorder (BPD) is a condition that is characterized by retaliatory aggression, difficulty in interpersonal relationships, and high impulsivity. Those who endorse BPD symptoms experience unstable interpersonal relationships and struggle to maintain connections with others which can lead to problematic behaviors on social media like retaliatory aggression. Understanding the motivations behind those behaviors can help inform the experiences of the diagnosed population, mitigate problematic behaviors, and facilitate healthy social relationships. This study aims to explore the motivations that BPD symptom endorsers most identify with, such as self-protection, affiliation, and status, and the prevalence of retaliatory aggression on social media. The participants will complete a self-report survey that measures their motivations, online revenge behaviors, and BPD symptom endorsement. A correlation analysis between variables will be conducted, alongside a moderation analysis that will identify how the motivations influence the relationship between BPD symptom endorsement and retaliatory aggression. An exploratory analysis will help determine the most prevalent motivation and inform coping strategies for those who exhibit symptoms of BPD. The findings of this study will help to strengthen existing literature about BPD features of impulsivity and reactivity. It will inform treatment and therapeutic methods by identifying the frequency of retaliation and motivations for those who exhibit symptoms of BPD. It will also have clinical implications for how social media use is advised and addressed.

Abstract Name: Investigating Diet-Induced Transcriptional Differences in the Arcuate and Paraventricular Nuclei of Mice with Varying Mitochondrial DNA (mtDNA) Backgrounds

Cardiometabolic diseases (CMD) is the leading cause of global mortality, demanding an urgent response to accelerate research efforts, to investigate the molecular mechanisms underpinning risk factors such as obesity. The mitochondrial genome has been identified as an area of interest for studying CMD and obesity. A recent mouse model, called the mitochondrial-nuclear exchange (MNX) mouse, has been designed to investigate mitochondrial-nuclear genome interactions. Studies suggest mitochondrial-nuclear interactions contribute to transcriptional differences in fat tissue deposits within the MNX mouse model. While several studies have explored this model, the brain, specifically the paraventricular (PVN) and arcuate (ARC) nucleus, have not been investigated despite their role in feeding dynamics and energy homeostasis. These processes are regulated through the expression of signal molecules, receptors, and channels within the neuronal pathways of the ARC and PVN. There remains a lack of understanding of diet-induced differences in the transcriptomes of these structures. To analyze the effects of mtDNA on CMD and obesity, the ARC and PVN will be isolated from brain slices obtained from Wild-type and MNX mice fed a chow diet or high-fat Western diet. Subsequent genetic profiling will utilize Next-Generation Sequencing (NGS) on transcriptomes, followed by advanced bioinformatics analysis. We hypothesize different mitochondrial DNA (mtDNA) backgrounds in MNX mice will lead to changes in gene expression associated with energy homeostasis and feeding regulation in the ARC and PVN, following dietary adjustments.

Abstract Name: A Feminist Survey and Analysis of Syncretic Goddess Worship Among Neopagan Women in the Twin Cities

This project sought to document and analyze women’s religious expression, gender identity, marginalization, and empowerment within the Twin Cities Neopagan community. The emergence of spiritual practices that represent an alternative form of religious expression to organized religion has become an increasingly influential part of American religious life. For women, the syncretic pantheon of goddesses and the practice of goddess worship at the disposal of the Neopagan practitioner have produced a wealth of literature and new approaches to divine femininity and women-centered religious community and devotion. The methodology for this project was an ethnographic survey with an interview component and a questionnaire component. Using a narrative centered approach, the personal experiences recounted in depth through interviews were interwoven with the demographic data collected in the surveys to highlight commonalities and construct overarching conclusions. Firstly, the research showed that participants draw clear connections between their

spiritual and gender identities and therefore view their lived experience as women as a spiritual experience. Secondly, it revealed that Neopagan spiritual practices concerning women's bodies and liberation in particular have allowed participants to process trauma relating to the marginalization they experienced as a result of systemic patriarchy and misogyny. Lastly, the research uncovered the beliefs that commonly inform the practice of religious syncretism among participants; for example, a monistic conception of divine femininity of which individual deities across spiritual and cultural sources are manifestations. In conclusion, the religious innovation and spiritual empowerment practiced by Neopagan women in the Twin Cities contextualize growing trends in American religious life and provide important insights for the developing intersectional study of religious identity and marginalization.

Abstract Name: The Consumerism of Art Deco: An examination of Art Deco Advertising and its Evolution

Art Deco: A style developed during the "Roaring Twenties" and still widely known today. It is a style defined by modern elegance. This paper investigates the style of Art Deco and, specifically, its evolution regarding advertising. By examining Art Deco advertising posters and their evolution from their conception in the 1920s to the post-WWII era, this paper analyzes how society and culture of the period have affected advertising and vice versa. After examining the evolution of Art Deco and its corresponding advertising posters, Art Deco advertising is influenced by the intense consumer culture and soaring economy of the 1920s. The growing economy and influx of products bought allow for an advertising style to emerge that emphasizes elegance and ornament. After analyzing how Art Deco advertising evolved after the Great Depression through post-WWII, it is concluded that Art Deco advertising is fueled by consumerism and defines a period of economic prosperity.

Abstract Name: Analyzing Heat Generated from Electro-Osmotic Flow Utilizing Computational Fluid Dynamics

In the absence of extensive vascularization, the transfer of essential fluid and nutrients within human tissue is severely limited to diffusion across pores and weak interstitial flow. However, electroosmosis has become a promising option in the realm of tissue engineering and regeneration research. Clinicians and scientists have recently began applying an electric field to human tissues to promote stronger interstitial flow via electroosmosis in clinical settings. However, optimization of this process has proven to be a significant challenge due to the generation of heat that accompanies the application of the electrical field. This research

seeks to better understand and quantify the range of voltage where the heat generated by the electric field leads to cell degradation and death. Cells survive and proliferate within a small range of temperatures and heating the cells beyond that range will cause them to degrade and eventually die. When a voltage is applied, heat is generated from the electric field, yielding an increase in the temperature of the nearby cells. Utilizing a computational fluid dynamics software, Sim Center Star-CCM+, a representative model of tissue mimicking a clinical application of electricity to the knee has been created. This model will be used to test different voltages while monitoring the temperature and time; then, these temperatures will be compared to the prior-established values depicting when cells undergo irreversible damage. Analysis will show what voltages clinicians can safely apply for variable amounts of time or whether a pulse-like method of application would be more appropriate. The implications of this research directly affect wound regeneration and tissue engineering and vascularization. By understanding exactly how much heat is generated by different levels of voltage, this research would allow doctors and scientists to know more precisely how much voltage they can apply before risking damage to the tissue.

Abstract Name: Strong Hand, Strong Body? Associations between Handgrip Strength and Body Composition in College Students

Handgrip strength is a simple and quick measurement technique that is associated with health and disease.PURPOSE: To 1) assess handgrip strength in relationship with normative values (ACSM Guidelines) and 2) evaluate relationships between total body composition metrics in a cohort of collegiate athletes (87%) and non-athletes (13%).METHODS: 397 different participants across 13 collegiate sports teams (athletes; 87%) and two non-sports teams (53 non-athletes; 13%) were tested for handgrip strength using a dynamometer. The right and left grip strength were tested 3-times, with the elbow flexed at 90°, and the highest values for each hand were added together to create a total handgrip score (kg). Then, each participant underwent a whole-body DXA scan. All scans were performed and analyzed by a single operator. ACSM guidelines define grip strength for 20–29-year-old males as: ≥115kg=excellent; 104-114kg=Very Good; 95-103kg=Good; 84-94kg=Fair; <84kg=Poor and for females as: ≥70kg=excellent; 63-69kg=Very Good; 58-62kg=Good; 51-57kg=Fair; <51kg=Poor.RESULTS: 280 males (20±4 years) and 117 females (22±8 years) completed testing. The (mean±SD handgrip scores=ACSM rating) for teams are as follows for males (total:92±20kg=Fair): Football (98±17kg=Good); Tennis (76±11kg=Poor); Fencing (75±21kg=Poor); Swimming (82±23kg=Poor); Students (80±19kg=Poor); Baseball (100±16kg=Good); Basketball (100±18kg=Good); Running (60±9kg=Poor). For the female teams (total:51±11kg=Poor): Weightlifters (60±13kg=Good); Swimming (52±8kg=Fair); Softball (64±6kg=Very Good); Students (47±12kg=Poor); Basketball (57±11kg=Fair); Running (41±6kg=Poor); Volleyball (56±4kg=Fair). Regression analyses revealed handgrip strength (kg) was positively correlated with lean mass (r=0.82;p=0.00) and bone mineral content (r=0.0.79;p=0.00) and negatively correlated with body fat% (r=-0.41; p=0.00).CONCLUSIONS: Overall handgrip in competitive male collegiate athletes was rated as “fair” for males and “poor” for females. Handgrip was positively correlated with lean mass and negatively correlated with fat.

Abstract Name: Prion Protein-induced Neurodegeneration in the Central Nervous System of Drosophila Melanogaster: Building a Model

Prion diseases are fatal neurodegenerative disorders characterized by neuronal loss and the accumulation of misfolded, membrane-bound prion protein aggregates (PrPSc) in the brain. PrPC, the normal cellular prion protein encoded by the Prnp gene, has been implicated in binding oligomers, including PrPSc, A oligomers, and α-synuclein assemblies, that form in patient brains with neurodegenerative disease. However, the mechanism by which PrPC interacts with PrPSc and causes neuronal death is poorly defined. The 92N-PrPC point mutation may be a tool to help to elucidate the neurotoxic pathway, as it has been shown to result in spontaneous spongiform degeneration in mice despite the absence of PrPSc and prion infectivity. Due to their low cost, rapid reproduction rate, short life span, and susceptibility to genetic manipulation, Drosophila melanogaster are an excellent candidate for studying prion-induced neurodegeneration. To investigate prion disease in a non-mammalian model, we generated transgenic 92N-PrPC and wild type mouse (WT) PrP control Drosophila lines, which were sequence validated by PCR. Western blot analysis revealed that the 92N-PrPC point mutation is uniquely expressed in the 92N-PrPC fly lines. Lifetime and climbing (motor function) assays have been conducted to test behavioral differences between 92N-PrPC and WT-PrPC and non-transgenic control groups. These experiments show the generation of a mutant prion protein disease model in Drosophila, and future experiments will focus on assessing behavior, histopathology, and signaling pathways towards a goal of understanding how mutant prion protein induces neuronal death.

Abstract Name: Processing-induced taurine encapsulation for energy drink and nutraceutical applications

Taurine is a sulfur-containing β-amino acid abundant in the milk of mammals, and caffeine is a naturally occurring stimulant of the central nervous system, both impacting the cardiovascular system. Encapsulation of these compounds has the potential to slow their release and absorption, as well as potentially increase their bioavailability. The objective of the present work was (1) to develop a standardized procedure for determining taurine and caffeine concentration via fluorescence spectroscopy and (2) to apply high-pressure homogenization (HPH) and processing aids to milk- and taurine/caffeine-containing solutions to determine encapsulation potential. Using fluorescence methodologies, successful standard curves were developed for the concentrations of 0.12 - 25.17 μM taurine and 0 – 100 μM caffeine ($R^2 = 0.9984$ and $R^2 = 0.9837$, respectively). HPH was shown to expose more amino acids for interaction with the target compounds. This interaction between milk proteins and taurine/caffeine provides insight into the feasibility of this process, with the potential to use this process for novel, value-added food ingredients with continued research.

Abstract Name: How Auditory DIstractions Affect Short-term Memory

People commonly study in the presence of distractions, whether those be small sounds in the background or a conversation just across the room, but claim that silence helps them focus better. Previous studies found that auditory distractions have a negative impact on the manipulation of information in short term memory such as mental arithmetic. This study plans to look at whether or not sound has a tangible effect on short-term memory and information recall by taking 60 undergraduate students at a small, liberal arts university, and randomly dividing them into three groups of 20 people. Each group will then be exposed to varying levels of auditory distraction while they attempt to memorize a list of 15 words for 30 seconds and asked to write down as many as they can remember. The control group will work in silence, the second will be exposed to a constant distracting sound, and the third will be interrupted midway through by a short-term distracting sound. Data will be collected in February, 2024. The hypothesis is that the control group working in silence will have the highest number of correctly remembered words of the three groups. If this proves to be the case, it would support the idea that having sounds in the background while attempting to memorize something reduces one’s ability to retrieve information in short term memory, and that silence is preferable when attempting to memorize something.

Abstract Name: The Framing of Decisions and the Psychology of Choice Regarding Novel Treatment of a Deadly Disease

This study examines the impact of question framing, inspired by Kahneman and Tversky's framing study, on participants' willingness to choose specific treatment options.Our primary objective is to investigate whether the framing of questions regarding treatment options influences participants' choices. We hypothesize that subtle changes in question presentation, similar to the framing effects observed by Kahneman and Tversky, will significantly impact participants' willingness to opt for particular treatment modalities. Data for this study were collected through a survey administered to students at Dominican University of California. Participants voluntarily and anonymously self-reported their responses to hypothetical medical scenarios framed either positively or negatively. The survey aimed to capture individual preferences for treatment options based on framing manipulation, with key variables including the framing condition and participants' treatment choices. As the surveys are still being completed, specific results and findings are pending analysis. Once data collection is finalized, we will conduct a thorough analysis to identify patterns, correlations, and effects related to question framing and its influence on treatment choices among the surveyed participants. While the study's results are pending, the anticipated findings hold potential implications for understanding

the role of question framing in medical decision-making, particularly among university students. If our hypotheses are supported, this research could contribute valuable insights into the psychological mechanisms that shape treatment preferences. The study's implications extend to healthcare communication strategies, with potential applications in improving patient engagement and decision-making processes. Future research directions could explore the generalizability of these effects across diverse populations and delve into practical strategies for implementing framed communication in healthcare settings.

Abstract Name: Effect of Tort Reform on Medical Malpractice Lawsuits

The efficiencies of tort reform in the US in regards to medical malpractice have been widely debated, with perspectives examining its effects on the victims, the medical field, and insurers. Using monetary payment and case data collected by the National Practitioners Database, this paper addresses the specific consequences of noneconomic damages caps within states on the behavior of medical malpractice victims with a two-way fixed effect difference-in-difference model, fixing the state the case occurred in and the year of its filing. The results portray the effect of a cap on the number of cases and amount of payment received by the victims, and the regression captures the behavior of victims, practitioners, insurers, and attorneys. Overall, the paper finds the existence of a noneconomic damages cap results in a decrease in payouts per case from practitioners to victims, and there is an increase in the number of cases filed when a cap is in place, implying the behaviors of practitioners and victims in particular are acting in opposition to each other. Possible interpretations of the results include victims reacting to the cap because the cap brings to their attention the possibility of suing, and medical practitioners exercising less care with a cap in place.

Abstract Name: How Accurate Should Historical Dramatized Documentary Films Be? The Case of In the Name of the Father

This presentation examines the challenges involved in cinematic representation of real, but complex, historical events and the acceptability of filmmakers' deviations from factual evidence. Jim Sheridan’s film In the Name of the Father (1993) was based on a 1990 autobiography by Gerry Conlon titled Proved Innocent: The Story of Gerry Conlon. Conlon was one of the Guilford Four, four British citizens who were wrongfully convicted of the Irish Republican Army's (IRA) bombing of a Guildford pub that killed four off-duty soldiers and a civilian. Conlon signed a confession under duress (later considered torture), though still maintaining his innocence. Sheridan drew widespread criticism for his film’s historical inaccuracies in depicting this case. Specific questions that I will address are: 1) to what extent are the inaccuracies in Sheridan's film acceptable considering the goals of the film? 2) to what extent is historical dramatized documentary valuable even if it

takes liberties with the truth? Some critics claim that Sheridan attempted to sympathize with the IRA, with which Conlon was not involved, while others suggest he was attempting to portray both the Irish Troubles and the case of Gerry Conlon, while prioritizing general commentary over specific facts of the case. Using a close analysis of the inaccuracies in the film itself, published interviews with Sheridan, film critiques, and relevant published literature, it is concluded that the inaccuracies largely reflect an attempt to display and comment on the Troubles in Northern Ireland in general through the lens of Conlon's specific case, leading to the alteration of some facts of the case to better depict the historical and political factors that caused the injustice. Sheridan's film will be used as an example of the challenges and pitfalls filmmakers face in capturing complex historical and highly charged political topics.

Abstract Name: Y Como Hacemos: A Study on NGOs in Autocratic Regimes like Venezuela

In strictly authoritarian regimes, the ability to exercise a state's capacity is very important to retain legitimacy and control. However, in places like Venezuela, many day-to-day operations are brought to people by NGOs (non-governmental organizations) and the efforts of non-profit organizations. In this essay, I will examine the relationship between governments that seek to minimize people's liberties through coercive means, while still allowing these non-profit organizations that directly inhibit the government's ability to control people, to operate. Through interviews with members of Venezuelan society, those on the periphery of the government, and leaders in the philanthropic sector, I want to analyze this dynamic to better understand how the relationship between government and civil society functions. Likewise, I will explore the grey area in Venezuelan civil society and the expectations of NGOs in autocratic governments. Mainly, I want to determine whether allowing these NGOs to operate is in the best interest of the state or if this actually proves to be a hindrance to the state's capacity. To propose a framework for understanding the relationship amongst state and social interaction under a strict regime, it is necessary to explore the livelihood of these organizations, and the government, to determine whether civil society's involvement is rooted in complacency.

Abstract Name: DNA Barcoding of the Mosquito Community in Central Oklahoma

Mosquitoes play a pivotal role as pathological vectors, capable of inciting severe epidemics. It is imperative to undertake proper monitoring and identification measures in order to minimize mosquito-borne diseases. DNA barcode functions as a molecular fingerprint enabling accurate and efficient identification of organisms, even when conventional morphological approaches prove inadequate. In this regard, the mitochondrial

Cytochrome c oxidase 1 (COI) gene barcoding has emerged as a potent molecular tool for precise species identification and taxonomic investigations. However, to ensure reliable molecular identification, it is essential to establish a comprehensive collection of validated reference sequences. This study aims to generate a DNA barcode database of the mosquito community in central Oklahoma. Mosquitoes were collected using host-seeking and gravid traps from 11 sites and identified using morphological keys by Darsie and Ward. A tissue homogenizer was used to extract DNA from mosquitoes' legs, and the LCO1498/HCO2198 Folmer primers or LepF1/R1 primers were used to amplify the COI fragments by PCR and Sanger sequencing. Twenty-one barcode sequences were generated, encompassing nineteen species and five genera. Sanger sequences were visualized in Geneious, whereas taxonomic identification and phylogenetic analysis using the Barcode of Life Data (BOLD). Lastly, as part of this study, annotated COI sequences will be uploaded into the BOLD and GenBank genome database, and voucher species stored at Southern Nazarene University. This endeavor to describe the mosquito community and report DNA barcoding data is important for the precise molecular identification of vector species.

Abstract Name: The Impact of Economic Fears on Voter Participation

The financial aspirations associated with the American Dream can motivate hopes of opportunity and prosperity. However, if this dream feels unattainable, it can intensify unwanted effects such as disparities in voter participation. Using the 2021-2022 Chapman University Survey of American Fears, a nationally representative sample of current fears across U.S. adults, I examine the extent to which demographic metrics link to current fears of financial uncertainty. In addition, I analyze how the disparity in current financial and economic fears can impact American democracy through voter participation. Adding to the discourse on economic influence and political behavior, economic-induced voting habits may stem from individual or community factors.I find a moderately strong relationship between historically oppressed demographic groups and higher fear levels of financial uncertainty. Consequently, my essay seeks to demonstrate that economic fears personally affecting minority groups correlate with lower voter turnout. The scope of my research extends to exploring the difference in voter turnout for high fears of community economic stress and personal financial worries through analyzing pocketbook voting and sociotropic voting theories. Analyzing the disparity of economic fears and their impact, one can look to legitimize the promises of equitable opportunities throughout American democracy and help estimate its role in the upcoming 2024 presidential election. Although perfection across opportunities of equity is an unrealistic goal, implicit biases question the legitimacy associated with the American Dream, democracy, and its impact on the future.

Abstract Name: Phishing for Mindfulness: A Comprehensive Study on Mindfulness Interventions and Phishing Susceptibility

Phishing is a branch of social engineering that exploits human error to gain unauthorized access to confidential information by breaching cybersecurity barriers. A prevalent form of attack is through an urgent-themed email that targets individuals with high cognitive loads. High cognitive load means reduced information retention and working memory available for competing stimuli. People with high cognitive load have been shown to behave more impulsively, with less effective emotional regulation. Mindfulness is attracting increasing academic attention for its demonstrated ability to increase memory and executive function, reduce stress, and improve irritability. This study will test the impact of mindfulness interventions and see how individuals engage with online information in order to evaluate participant phishing resiliency. We expect that mindfulness will reduce vulnerability to phishing because it will improve participants' careful consumption of information. Our intervention involves randomized delivery of mindfulness content to students at a Hispanic Serving Institution over the course of two weeks. Following the end of the treatment period, participants in all treatment groups will receive university-approved fake phishing emails over a subsequent 7-day period. We expect mindfulness-treated individuals to click less frequently on phishing links, showing higher resilience to social engineering attempts. Our results will assess whether mindfulness training is a promising combatant toward this cyber risk and assist with decreasing susceptibility toward phishing emails. This study is currently under IRB review and data will be collected starting in early 2024. Our preliminary results will be available by April.

Abstract Name: Passive Cooling of a High Power LED Panel using a Heatsink with Embedded Thermosyphons

High-energy LED panels have many applications, from lighting to indoor farming. However, the LED panels create significant amounts of heat, deteriorating their performance. While active cooling methods, such as fans, are traditionally used, these not only consume more energy but also add moving parts which reduce the lifespan of the system. In this research, a passive cooling technique using a heatsink is investigated. The unique feature of this design is the embedded thermosyphons inside each fin (10mm X 10mm). 144 rectangular pin-fins (with 3mm embedded holes) were attached to a vapor chamber where R134a refrigerant was filled at a low pressure to activate the thermosyphon process at elevated temperatures. The lower vapor chamber was sealed and the LED panel was attached underneath it. To minimize air pockets between surfaces and improve heat conduction, thermal paste was used between the surfaces. The theoretical temperatures along the fins were modeled using MatLab, and then the panel was turned on to acquire experimental data. The temperature data was acquired by using 16 k-type thermocouples that were attached to the tips and bases of 8 different pins around the heat sink. The temperature was recorded using a PCB connected to a Raspberry Pi. The LED panel was turned on and the active cooling fans were removed for this investigation. The data shows that the percentage change along the fins varies between 6.3% to 12.8% depending on the location of the fin along the periphery of the heatsink. The temperature variation along the fins indicates that the thermosyphon process was activated at higher temperatures and the LED panel was cooled down by transferring heat from the base to the condenser section of the thermosyphon. Detailed measurements are being collected for this special heatsink and full results will be presented in the coming conference.

Abstract Name: Investigation of Nitinol Flow Diverters for Aneurysms through Laser Machining

Flow diverters have emerged as a highly effective endovascular technique for treating brain aneurysms, primarily employing braided structures made from materials like nitinol and chromium-cobalt alloys. However, the design parameters for these braided flow diverters (FDs) are somewhat constrained. This research explores the feasibility of producing finely meshed, non-braided nitinol FDs using precision laser machining. This study aims to assess the impact of various laser parameters on the quality of the laser-fabricated nitinol FDs. Through a precision fiber laser machine, fine pores were meticulously designed and created, with variations in laser power, focal distances, laser horizontal speed, passes, and cooling media (air and underwater). The resulting FDs underwent polishing in an in-house custom tumbler, and their surface quality was analyzed using a scanning electron microscope (SEM) and high-resolution images. The study quantified surface burning using a scale from 1 to 10 based on high-resolution images. The findings revealed that laser power and focal distance significantly influenced the prevention of excessive surface burning and bulge formation. While water as a cooling medium offered more flexibility, frequent refilling proved inconvenient due to rapid evaporation. However, fine-tuning laser power and passes with air cooling yielded burn-free, high-quality FD surfaces. This research contributes valuable insights towards the development of non-braided FDs for brain aneurysm treatment, offering enhanced control over crucial parameters in the fabrication process.

Abstract Name: Deletion of Brain Angiogenesis Inhibitor 3 in Mice Decreases Inflammation in White Adipose Tissue

G-protein-coupled receptors (GPCRs) stand as the most targeted receptors for drugs. They play a pivotal role in regulating obesity-related inflammation, which is notably associated with white adipose tissue (WAT). In our previous study, we found that the absence of brain angiogenesis inhibitor 3 (BAI3), a GPCR, resulted in reduced body weight gain and increased energy expenditure. This suggests that BAI3 could potentially contribute to obesity and heighten susceptibility to the development of type 2 diabetes (T2D). However, the role of BAI3 in regulating obesity-related inflammation remains inadequately understood. To investigate whether BAI3 plays a critical role in WAT inflammation, we used CRISPR technology to create BAI3 knockout C57BL6J mice (BAI3-/-) and subjected them to normal and high-fat diets. Subsequently, we assessed the impact of BAI3 deletion on pro-inflammatory and anti-inflammatory markers within their inguinal white adipose tissue (iWAT) and epididymal white adipose tissue (eWAT) by examining the expression of key genes involved in both pro and anti-inflammatory responses (such as IL2, TNFα, MCP-1,

F4/80, IL6, TGF-B, IL4). Ongoing analyses will provide insight into BAI3's influence on inflammation in WAT. In conclusion, our study aims to elucidate the effect of BAI3 on inflammation within WAT. Understanding this relationship will aid in mitigating the risk of developing diseases such as obesity and T2D.

Abstract Name: Real-time Hand Pose Tracking and Hand-Object Interaction Detection via Low-Power Active Acoustic Sensing

Our hands serve as a fundamental means of interaction with the world around us. Therefore, understanding hand poses and interaction context is critical for human-computer interaction. We introduce a minimally obtrusive, low-power wristband designed to provide both continuous 3D hand shape tracking and a nuanced understanding of various hand-object interaction activities. The band utilizes active acoustic sensing, incorporating two pairs of compact speakers and microphones positioned in close proximity to the skin on each side of the wrist. The speakers emit inaudible frequency-modulated continuous waves (FMCW) directed toward the hand, and the resulting sound wave reflections and diffractions are captured by the wristband's microphones, creating distinct patterns corresponding to different hand poses. We then use a customized deep convolutional neural network (CNN) to deduce the 3D hand poses represented by the 3D positions of 20 finger joints while also classifying various hand-object interactions. To evaluate performance in continuous hand-pose tracking and hand-object interaction recognition, we conducted two user studies, each involving 12 participants. The results indicate that the device can continuously track 20 finger joints with a mean joint Euclidean distance error (MJEDE) of 4.81mm or mean joint angular error (MJAE) of 3.79°. Furthermore, it exhibits impressive accuracy, achieving a recognition rate of 97.6% across 12 diverse hand-object interactions, spanning static scenarios, such as firmly holding a cup, to dynamic actions involving movement, such as chopping. In addition, it operates at a significantly low power consumption of just 57.9 mW, with the sensing modules consuming only 10.0 mW, highlighting its smaller footprint compared to previous work. To our knowledge, our device is the first wristband that can both track 3D hand poses continuously and recognize hand-object interactions. Further, we present the design considerations and iterations, and discuss the opportunities and challenges of deploying at scale.

Abstract Name: The Prevalence, Depth, and Duration of Postoperative Hypothermia in Neonates after Cardiopulmonary Bypass

Cardiopulmonary bypass (CPB) is commonly used for surgical repairs of neonatal critical congenital heart defects (CHD). Intentional hypothermia is often induced to preserve end organ function during low blood flow states. Intentional hypothermia is corrected after CPB with the aim of achieving normothermia. Despite rewarming, neonates remain at risk for unintentional postoperative hypothermia. Study purpose: define neonatal postoperative hypothermia prevalence, depth, and duration 48-hours after CPB. We accessed UPMC Children's Hospital of Pittsburgh EHR data between 2016 and 2020 that included 196 neonates ≥ 34 weeks gestation undergoing their first CPB surgery. Hypothermia was defined as < 36.5°C (normothermia defined as 36.5°C to 37.5°C). Hypothermic episodes were defined in hours starting with the first hypothermic temperature up to the first normothermic temperature. The next hypothermic temperature marked the beginning of the next episode. Descriptive statistics for continuous variables are reported using means and standard deviations (SD), as well as medians and interquartile ranges (IQR) when distributional normality was violated. For categorical variables, frequencies and percentages are reported. Average gestational age of 196 neonates was 38.2 weeks (SD 1.32), they had an average birth weight of 3.14 kilograms (SD 0.52), 142 (72%) were white, and 127 (65%) were male. Approximately half (48%) of the neonates underwent a STAT category 2 or 3 surgery (mortality risk score). All neonates experienced at least one episode of hypothermia, and on average 4.17 episodes (SD 2.4). The first hypothermic episode median lowest temperature (depth) was 35°C (IQR 1.2) and had a median duration of 9 hours (IQR 22.19). Postoperative hypothermia was prevalent; there was variability in the lowest documented temperatures (depth) and lengths of time before normothermia was achieved (duration). Researchers should investigate clinical practice procedures as potential explainable mechanisms for temperature instability, as well as define its clinical significance.

Abstract Name: Toll-Like Receptors 7 and 9 Regulate Sex Differences in a Murine Arthritis Model

Rheumatoid arthritis is an autoimmune disease that can lead to deformities. Although the adaptive immune system drives the development of rheumatoid arthritis, the cardinal signs of inflammation are regulated by the innate immune system, which includes the Toll-like receptors (TLRs). We tested a series of mice that were deficient in individual TLRs in the K/BxN passive serum transfer model of arthritis. Serum transfer into wild type mice confers paw inflammation and lasting allodynia. Tlr7-/- , Tlr9-/- and Tlr7.Tlr9-/- mice were injected with K/BxN serum and the paw swelling was serially measured with a caliper and withdrawal threshold tested by von Frey fibers. The allodynia in male wild type mice persists whereas it largely resolves in female mice. In Tlr7-/- and Tlr9-/- mice there is reduced allodynia in both males and females; however, the doubly deficient mice (Tlr7.Tlr9-/-) had markedly reduced allodynia throughout the entire time course. Interestingly, in the Tlr7.Tlr9-/- mice the females had minimal paw swelling differing from the males (F (13, 182) = 11.56 two way ANOVA, P. These results demonstrate that there are sex differences in the development of arthritis in this model and specific TLRs play critical roles in developing allodynia associated with inflammation. Understanding sex differences in the development and symptoms of arthritis could lead to further refined therapeutic decision making.

Abstract Name: Scapegoating as Political Power in Beowulf

The character of Beowulf's Grendel has traditionally been read as that of a monstrous villain. But in my research, I argue that Grendel represents a sinister convergence of social forces scapegoating the supposed "monster" to explain social problems that he played no part in creating. This argument draws upon the work of cross-disciplinary scholars of scapegoating, like the sociologist Emile Durkheim, the political psychologist Gordon W. Allport, and the anthropologist Rene Girard. I trace the social forces that created a need for scapegoating in the Anglo-Saxon epic poem, the convergence of those forces on Grendel, and the process by which his killing was legitimized and preserved through mythology. Beowulf itself is treated as a cultural artifact, by which deductions can be drawn about scapegoating in Anglo-Saxon society at large. I conclude that the Beowulf epic illuminates the economic, political, and social forces that continue to scapegoat groups of people in the twenty-first century.

Abstract Name: The Forbidden Fruit: Art History's Shapfeshifting Motif

Art is, and was wildly important in Catholoicism, but since the church had strict authority extending from the fall of the Roman Empire into the 19th century, religious art was vital then, given the hiearchy of the church. Laity were at the bottom of the pyramid and couldn't read, so imagery provided comprehension of scripture outside of mass. The Fall of Man for example, is a renowned biblical story represented by the forbidden fruit in which Adam and Eve partook, and it can be spotted in countless artistic manifestations throughout those centuries. There isn't a universal icon for a fruit, nor can imagery convey the idea of a fruit as just that--no matter what, one will find that artists chose specific, recognizable forms to represent the fruit of the tree of knowledge of good and evil, allotting new manifestations through each painted vessel.

Abstract Name: Electromagnetic Ionization and Radiation Creation in Neuroblastoma Cancer Cells

Neuroblastoma is a common childhood cancer that has one of the highest incidence rates for children less than one year with poor prognosis as children age. Although current radiotherapy treatments are efficient, many patients are left with unpleasant side effects. Laser trapping is a technique that traps dielectric objects as small as an atom and as big as 100 micrometers with a high-power laser. The laser trapping technique with the addition of magnetic beads was used in this study to initially provide a more efficient treatment for neuroblastoma. This study determined that the amount of radiation received in neuroblastoma cells through laser trapping was significantly reduced. However, throughout this study, it was discovered that these neuroblastoma cells could produce radiation emission, which lasted over six hours with a consistent amount of over 93% energy absorption of an infrared light (low energy) resulting in intense visible radiation (high energy light). Using infrared laser light with the neuroblastoma cells and magnetic beads has the potential to create a new source of energy of white light that has the complete blackbody radiation. The overall results of this study has the possibility of improving cancer treatment, solar energy harvesting, and microchip and battery efficiency.

Abstract Name: Effects of Environmental Disturbance on Bird and Parasite Presence

Zoonoses are parasites that are readily transferred between animals and humans through various forms of transmission. Birds are one group of organisms capable of carrying these parasites and have been shown to transmit Influenza A, West Nile Virus, Lyme Disease, and bacteria genera containing antibiotic resistance to humans. In Florida, both residential and migratory species are able to carry these parasites. Migratory birds include those that utilize the Atlantic Flyway which serves as a migration route for various species in the fall and spring seasons. Within a given area, both migratory and residential species can encounter environmental disturbances such as foot traffic, construction, weed-killing chemicals, and noise and light pollution. These anthropogenic alterations can negatively impact organisms leading to physiological changes including disruptions in reproduction, development, and immune function. Animal, human, and environmental health are inextricably linked such that when one is disrupted, the other two inevitably suffer. Therefore, determining whether environmental disturbance affects the presence and diversity of birds and parasites can provide insight to effects that anthropogenic factors have on both animal and human health. In this study, we are using bird feeders with cameras to monitor species present at The University of Tampa. Fecal samples are collected weekly and analyzed using fecal floatation to identify which parasites are present. Data collected over the course of one year (August 2023 - December 2023) will be analyzed to determine whether bird and parasite presence differs between seasons with or without migration and areas of moderate and high disturbance.

Abstract Name: Enantiomeric Resolution of Spirobifluorene Derivatives via Chiral Auxiliaries: Diastereomers

Spirobifluorenes are macromolecules with material science applications including organic-semiconducting technology such as OLED devices, gas storage/separation, biotechnology, and solar panel energy conversion efficiency. Typically, inorganic molecules are used for these applications as metals have intrinsic conductive properties and organic molecules do not. But, their unique structure allows their molecular orbitals to overlap in such a way that gives rise to useful optical and electronic properties. The aim is to transform their complementary structures to non complementary structures with a particular group of molecules known as chiral auxiliaries. The pair of molecules take on different physical properties and can be separated through practical chemistry purification techniques. Larger scaffolds and topologies of the isolated configuration will be made to study their potential towards the above mentioned applications.

Abstract Name: Using Large Language Models to Augment Reflective Thematic Analysis for Semi-Structured Interviews

Reflective thematic analysis is a common qualitative research approach employed to identify major themes within unstructured data sets, including semi-structured interviews and videos, addressing specific problems. However, the analysis process is often time-consuming, requiring substantial effort to identify shared experiences or feedback ("codes"). Large Language Models (LLMs) such as ChatGPT offer promising avenues to alleviate these challenges. However, current research has shown that LLMs can potentially introduce bias in their analyses. In our study, we propose integrating LLMs into reflective thematic analysis to generate context-appropriate codes and themes from large amounts of qualitative data while maintaining human/researcher oversight to regulate biases in analysis. We continuously refined and passed through well-structured prompts using ChatGPT GPT-3.5 API to generate codes and themes. To evaluate the efficacy of our approach, we performed experiments utilizing a collection of semi-structured interviews that had been previously coded by using an inductive approach. In order to quantify the level of agreement between our augmented approach and the manual coding, we applied Cohen's Kappa statistical test. This statistical analysis measures how well our augmented approach aligns with the manual coding, providing valuable insights into the effectiveness of our approach. The results suggest that using LLMs contributes to a significant reduction in labor and time. However, prompt engineering is needed to improve the efficiency of the augmented approach to thematic analysis with LLMs. It also underscores the need for researchers to continuously oversee and ensure the quality of analysis outcomes.

Abstract Name: Cultivating Synergies Between Organic Architecture and Biology in El Salvador

This collaborative project, developed within the framework of the Fulbright US Student Program and hosted by the Department of Architecture at Universidad Centroamericana "José Simeón Cañas" (UCA) in El Salvador, explores the transformative potential of organic architecture in harmonizing human-made structures with the natural environment in urban settings. Inspired by familial heritage and experiences with indigenous communities, the study investigates how organic architecture can catalyze positive change and enhance the well-being of diverse urban populations. Working in collaboration with the "Fundacion Salvadoreña de Desarrollo y Vivienda Minima" (FUNDASAL), the project involves conducting workshops that emphasize multidisciplinary collaboration. Through interviews with community members and architects engaged in sustainable, nature-inspired housing projects, the study delves into the intricate relationship between architecture and nature. These transformative workshops aim to integrate marginalized voices into the design process and infuse biological principles into architectural solutions. As a Latin American architecture student, the researcher values cross-cultural explorations and the integration of heritage in design. The Fulbright program provides a unique opportunity to foster international academic and professional experiences, laying the groundwork for future graduate studies. The study seeks to encourage collaboration between architecture and biology, highlighting the potential of organic architecture to enrich urban environments and contribute to sustainable, nature-inspired design solutions that benefit both communities and the natural world.

Abstract Name: Advanced Pressure System Optimization in a Bioreactor for Corneal Tissue Engineering

Introduction The prevalence of vision impairment, affecting over 2.2 billion people globally, necessitates innovative solutions in ophthalmology; tissue engineering, particularly for corneal tissue, promises to address this challenge. Building upon our previous development of a corneal bioreactor, this study focuses on optimizing the pressure system integral to cultivating corneal cells. We aim to refine the microenvironment for corneal cell growth, advancing towards generating transplantable corneal tissue.Materials and Methods The redesigned pressure system incorporates sprockets, allowing precise pressure modulation. This system features a compact design with a motor, track, and syringe mount. Integrating this system into our existing bioreactor aims to achieve precise control over the mechanical signals critical for corneal cell cultivation. Cells are grown in the bioreactor system at multiple pressure levels and assessed for protein expression via western blot. Cells are lysed after 7 days in culture, followed by a Bradford assay to determine the total protein in the sample and a western blot with antibodies against α-smooth-muscle-actin, indicating cell phenotype(fibroblasts). Results and Discussion Initial trials have demonstrated the system's efficacy in

maintaining cell viability and cultivating fibroblasts. Transitioning from fibroblasts to keratocyte cells is crucial in corneal repair and is a significant step forward. Protein analysis of our samples helps us to determine the optimal pressure to achieve the desired transition of fibroblast cells to keratocytes. Our results indicate that the optimized bioreactor mimics the native corneal biomechanical environment, strengthening the cell viability for the transplantation of corneal tissue. Conclusion This research marks a significant advancement in bioreactor technology for corneal tissue engineering. Optimization of the pressure system brings us closer to the goal of creating transplantable corneal tissues. Future studies will focus on expanding tested pressures and integrating other signals, such as light, with advancements for worldwide vision restoration efforts, especially for donor-dependent transplants.

Abstract Name: Efforts Towards multi-lingual and -cultural South Korea: Insights from immigrant bilingual coaches and Korean Government Officials working in Health Family Support Centers

Health Family Support Centers in South Korea play a pivotal role in promoting multilingualism and multiculturalism in South Korea that practices Korean-only assimilation policies. With an increased influx of multicultural immigrants, these centers provide assistance and services to immigrants. These centers also serve as a hub for both immigrants who have gained proficiency in the Korean language and culture also work there as bilingual coaches and translators, and dedicated Koreans fostering cultural harmony. Thus, it is crucial to examine experiences and perspectives of employees striving for immigrant equity in South Korea at these centers.This study explores the perspectives and experiences of employees in Health Family Support Centers across South Korea, specifically eight bilingual coaches in different cities and five government officials in the northwest region of Seoul. Data was collected through individual interviews lasting 70 to 120 minutes with the bilingual coaches, originating from countries like China, Japan, and Vietnam, along with a 130-minute focus group interview with government officials. It aims to understand how these experiences contribute to our knowledge of challenges and opportunities in promoting equity for immigrants and implications for policies related to multilingualism and multiculturalism in ethnolinguistic minority family contexts.Thematic coding in our qualitative analysis revealed that the coaches found their work rewarding but faced challenges like heavy caseloads, lack of early childhood education expertise, and coaching in incompetent languages. Korean government officials, drawing on their experiences as directors, noted issues such as insufficient resources including funds for employees, heavy caseloads with both proficient and non-proficient tasks, employee numbers, awareness, and the need to support immigrant mothers. This research has broader implications for policies and programs supporting ethnolinguistic minority families and children in promoting multilingualism and multiculturalism beyond South Korea.

Abstract Name: Elucidation of Bacterial Species Composition in Soil Samples From The Village Community Gardens

Soil ecosystems provide habitats for diverse groups of biota, including bacteria, archaea, fungi, microalgae, protozoa, nematodes, and bacteriophages. These ecosystems are complex and involve abiotic and biotic

inputs. Bacteria of diverse species perform many important ecosystem services, including improved soil structure, soil aggregation, and recycling of water and soil nutrients. Soil health is linked to crop fertility as well as environmental and anthropogenic hazard resilience. Bacterial species diversity contributes to functional biodiversity and can be used as a sensitive indicator of stable ecosystems. The Village Community Gardens of Rochester, MN provides gardening space at multiple locations for families to produce culturally relevant food with an added aim of achieving sustainable agricultural practices. We aimed to elucidate the bacterial species composition within the soils of three Community gardens. Soil samples were collected from each of the three locations. Serial dilutions were performed and used to isolate individual colonies by plating on complete media. Universal primers targeting the 16S rRNA gene region were amplified using PCR. Chromatograms were analyzed, and the National Institute of Health Nucleotide BLAST was used to identify isolated species. A phylogenetic tree was generated depicting species relationships of bacteria cultured from The Village Collaborative Gardens. There were observational differences in species composition between the three garden sites. Interestingly, Bacillus taxonomy is under persistent revision; our phylogenetic results using 16S sequence information with high Bootstrap values support Priesta being a unique clade. As numerous factors influence microbial soil populations and contribute to overall soil health, growers were interested in learning of our results.

Abstract Name: Integrating Neural Networks and RNA Sequencing Analysis to Decode the Cardiac Impact of BubR1 in the Adult Heart

Heart disease is the leading cause of mortality in the adult population and its incidence increases with age. Recent studies have identified the mitotic checkpoint protein Budding uninhibited by benzimidazole Related-1 (BubR1) as a regulator of aging. Mice engineered to have lower levels of BubR1 (termed hypomorphic mice) exhibit early on-set of aging phenotypes such as cataracts, curvature of the spine, shorter lifespan, and impaired wound healing (Baker, 2004). We have further identified that BubR1 hypomorphic have varied cardiac rhythms and die in a manner similar to sudden cardiac death in humans (North, 2014), suggesting that BubR1 plays a major role in the maintenance of cardiac structure and function. Because BubR1 declines with age, it can be inferred that this decline may mediate various age-related pathologies in humans. Therefore, it is important to further understand how BubR1 regulates cardiac structure and function, and how loss of BubR1 contributes to the increased incidence of heart disease in the aging population. Recent strides in machine learning and bioinformatics have ushered in cutting-edge tools that enhance the analytical capabilities and predictive models for biological data. Notably, RNA sequencing analysis has been employed to discern genes exhibiting significant upregulation or downregulation in hypomorphic mice compared to their wildtype counterparts.The versatility of RNA sequencing extends to exploratory data analysis (i.e. heatmaps and volcano plots) and Principal Component Analysis (PCA), all of which are utilized to identify key genetic regulators and to visualize the data in a comprehensible and concise manner. In addition, the convolutional neural network can be used to distinguish between diseased and healthy hearts to provide a predictive model intended to eventually become a diagnostic tool. Overall, machine learning and bioinformatic analysis will provide insights into a role for BubR1 in cardiac function, offering potential diagnostic tools for age-related heart disease.

Abstract Name: Monkey: The Chinese Sisyphus The Absurd Hero in Wu Cheng'En's Journey to the West

With strong roots in the mythologies of Taoism and Buddhism, the classic Chinese novel Journey to the West is a religious allegory as well as a satire of 16th century Chinese society. The text is both a serious retelling of traditional folk tales and an absurd comedy about a group of ramshackle pilgrims on a quest for scriptures and enlightenment. Throughout their journey Sun Wukong (Monkey) demonstrates a lighthearted detachment from the dangers of his journey and an indifference for the myriad of demonic encounters he has on the way. His detachment from the difficulties of his life and happiness make Monkey very similar to the absurd hero of Sisyphus in Albert Camus' essay The Myth of Sisyphus. Before their punishment, both Monkey and Sisyphus enjoy incredible power as they play tricks on the gods. Because of their wanton abuse of power invokes the wrath of heaven, both heroes are condemned to the mundane as they seek to earn their penance. When faced with the absurd world Monkey retains that "his fate belongs to him"[1] despite the heavy hands of gods that attempt to control him. This realization brings Monkey to the highest plain of existence possible, which Camus describes as happiness, and to Monkey describes as immortality. Whether an ancient Greek myth, or a classic novel about a sentient stone monkey, all can relate to the plight of Sisyphus and that of Monkey. The absurd hero indeed can manifest itself in any and every living person. [1] Camus, Sisyphus, 106.

Abstract Name: Best practices on prevention of pressure injuries in the ICU

AbstractPurpose: To determine the effectiveness of repositioning, moisture control, and knowledge/attitude promotion by exploring best practices of hospital-acquired pressure injury (HAPI) prevention methods in the adult intensive care unit (ICU) among various literature. Practice Change: Implementations such as 2-3 hourly repositioning, moisture absorption pads, and staff education programs can help in the mitigation of patient risk of pressure injury development during their hospital stay. Strength of the Evidence: We performed a literature review of studies that assessed pressure injury prevention methods. We identified three common methods - (1) barriers that protected the patient's skin from moisture improving skin integrity resulting in a reduced risk of HAPI development among applied patients, (2) repositioning performed on a scheduled basis was found to be a determining factor during data collection, and (3) education programs with attitude promotion facilitated nurse compliance with HAPI prevention. Implementation Strategies: Implementation of moisture barriers uncoated paper in the sacral area can be used during patient care, education programs of

preventative with pathophysiology of HAPIs can be given to staff, and reminders for repositioning all can be implemented in ICU practice. Stakeholders: ICU nurses will attend education programs for HAPI prevention and must be compliant with repositioning and moisture barrier application that impacts the prevalence of HAPIs in the ICU adult patient population. Evaluation: All these three interventions have shown effectiveness and implementation of at least one of these interventions can significantly reduce the risk of HAPIs giving the nurse options to choose from according to the situation.

Abstract Name: Finding New Options in Biotherapeutics: Exploring Partially Morpholino-Modified Oligonucleotides as Potential RISC Users

The potential of biomolecules in the world of targeted gene regulation therapeutics has grown massively in the last twenty years. As of September 2022, fourteen oligonucleotide drugs were FDA-approved. Among these fourteen, multiple contained morpholino modifications to the nucleotide backbone, which creates a hexose in place of the usual pentose. These drugs have shown major promise in treating rare genetic diseases, such as Duchenne muscular dystrophy, by altering mRNA processing through base complementary and thus generating protein binding interference. Most of these drugs rely on the fully-morpholino modified oligo's negligable affinity for endogenous proteins, which promotes their longevity and reduces their off-target effects.Very few studies have been done on the binding properties of oligonucleotides that contain a mix of morpholino-modified nucleotides and non-morpholino nucleotides. These hybrid molecules contain much promise for a potential middle ground between siRNA-like molecules, which bind to the RISC complex and perform mRNA degradation, and fully morpholino oligonucleotides, which rarely interact with proteins and thus don't perform RNA degradation. Optimizing the balance of morpholino modifications with non-morpholino nucleotides could result in a ‘best of both worlds’ scenario, where the modified oligonucleotide can bind to the RISC complex, and exhibit resistance to degradation from RNases. This would push the morpholino modification into a new use, from its current place in RNA interference to a potential usage in RNA degradation. To determine the potential for partially-morpholino modified oligonucleotides as siRNA variants, I tested several siRNAs containing various amounts and patterns of thiomorpholino modifications for their capabilities to knock down protein expression. I will also complete full rtPCR analysis and an AGO-2 binding assay using a fluorescent oligo. I have shown that all these modifications exhibit protein knockdown, and I anticipate that the rtPCR and AGO-2 binding study will distinguish the mechanism of knockdown.

Abstract Name: Vehicle Searches on the Border: Applying Fourth Amendment Search Exceptions between

States with Differing Marijuana Laws

This research paper examines the application of the Community Caretaker Doctrine and the utilization of this 4th Amendment exception in officer's efforts to combat drug trafficking across state borders within the jurisdiction of the 7th Circuit. The Community Caretaker Doctrine, traditionally applied within law enforcement for ensuring public safety and welfare, has the potential to be extended in use when addressing drug trafficking. This paper employs a comprehensive legal analysis that utilizes relevant cases throughout the United States as applied to the 7th Circuit legal precedents. Through this analysis, the study aims to clarify legal standards applied under the Community Caretaker Doctrine to be applied to vehicle stops and drug discovery. Varying jurisdictions are wrestling with legalization of marijuana, for example the smell of marijuana alone is not probable cause for vehicle searches in states where the substance is legal. The findings of this research contribute to a deeper understanding of the role that the Community Caretaker Doctrine plays in law enforcement efforts to ensure public safety and welfare intersected with the issue of drug trafficking across state borders. The University of Wisconsin-La Crosse is uniquely positioned in a metropolitan area that encompasses two states with differing approaches to the legalization of marijuana, from legal recreational use to the prohibition of medical usage. Additionally, the findings of this work have the potential to unveil legal insights into the future of the application of the Community Caretaker Doctrine and other 4th amendment search exceptions. Furthermore, the study's outcomes aim to guide legal and policy recommendations that foster a more consistent and responsive approach to curbing the unlawful and extensive use of 4th amendment exceptions.

Abstract Name: Functional Analysis of the pdk-1 gene in Brugia Malayi

Lymphatic filariasis is a human disease caused by blockage of the lymphatic system due to infection by the parasitic nematode Brugia malayi and related parasites. We are using the nonparasitic nematode Caenorhabditis elegans as a model organism to study the pdk-1 gene in the insulin/IGF-1 signaling (IIS) pathway. The IIS pathway regulates the dauer stage in C. elegans. This stage parallels the infective (iL3) stage in B. malayi, allowing it to survive within the mosquito vector until transportation to the human host. Using bioinformatic analysis, gene sequencing and polymerase chain reaction I have been able to compare the amplified gene sequences in B. malayi to predicted C. elegans gene sequences. Of the seven predicted isoforms of B. malayi I have supporting evidence that confirms that at least isoform A is expressed in B. malayi. I am currently preparing recombinant DNA constructs to test the function of Bma-pdk-1 isoform A in a cell culture system. Understanding the role of pdk-1 in the IIS pathway may contribute to potential future research that could assist in the treatment and/or management of lymphatic filariasis.

Abstract Name: Analysis of Lightweight Cryptosystems for IoT Applications

The widespread use of resource-limited devices in the Internet of Things (IoT) era has raised concerns regarding data security. To address this, lightweight cryptosystems have emerged as a solution to provide sufficient security while using minimal resources. This research focuses on studying lightweight cryptosystems that employ two types of encryption methods: block ciphers and stream ciphers. Block ciphers are encryption algorithms that work on fixed-size data blocks and require both devices to share the same secret key. In contrast, stream ciphers encrypt data byte by byte using a keystream.In this study, we designed and implemented two block ciphers and two stream ciphers using the Vivado toolchain and Nexys 4 DDR hardware. Our goal is to assess the security features of these ciphers and compare their effectiveness in safeguarding data. Through this exploration of lightweight cryptosystems and our evaluation of different encryption algorithms' performance and security, we aim to contribute to developing secure communication protocols tailored for resource-constrained devices in the IoT ecosystem.

Abstract Name: Scroll Trance: The Relationship Between Screen Time, Social Media, Anxiety, and Depression

The present study investigates the relationship between screen time, social media usage, and mental health. High levels of screen time have been associated with an increased likeliness of mental health symptoms, specifically with prolonged, long-term use. The overall increase in social media usage has skyrocketed alongside the influx of cases of suicide and depression. Frequent use of social media has been suggested to increase the symptoms of depression and anxiety. This study hypothesizes that greater levels of screen use will be related to higher levels of anxiety and depression, and high social media usage will be related to higher levels of anxiety and depression than other forms of screen use. A survey was created asking questions regarding the number of hours spent on screen usage and social media, and the Depression, Anxiety, and Stress Scale short form (DASS-21) will be utilized to measure recent levels of anxiety, depression, and stress. Participants will be asked to provide their screen time hours from their phone data and their usage of specific applications, including social media platforms. The sample size is expected to be around 120 participants, ranging from the ages of 18-65, mostly residing in the Bay Area, varying areas of Northern California and the rest of the United States. The expected results of this study are that individuals who have higher levels of screen time have higher levels of stress, anxiety, and depression. Furthermore, individuals who use social media as their primary mode of screen time are expected to have the highest levels of anxiety and depression, with symptoms increasing as the time usage goes up. This research will be beneficial to future exploration of the association between screen usage and mental health to aid in methods of prevention for individuals affected by prolonged social media and screen time.

Abstract Name: Mediating Medicine: Patient Perceived Level of Comfort and Confidence in Healthcare Interactions

Whether filing medical paperwork or understanding the scope of diagnoses, confidence in healthcare systems influences individuals' health behaviors and healthcare interactions. Current evidence indicates that patients with high confidence levels are more likely to engage in healthy behaviors such as exercising, eating a balanced diet, and seeking medical care when needed. Confidence is impacted by factors that contribute to feelings of self-worth and support: socio-demographics, health status, and overall quality of life. The purpose of our study is to describe the relationship between patients' confidence and level of comfort within their healthcare interactions. We conducted a qualitative study by distributing surveys to patients within the Medical Specialties Clinic at the University of Kentucky (UKY), approved by the UKY IRB (#88078). Our goal enrollment is 200, with the data presented here reflecting 34 for a preliminary analysis. We found significant relationships between patients' preference for being accompanied by family and anxiety with the need for medical clarification or further questioning. Patients who reported needing clarification from their provider also preferred to accompany a family member to their appointments. (r =0.659, p =<0.001). Moreover, they reported feeling more anxious about healthcare interactions. (r =0.421, p =0.013). Future analysis with an increased sample size will group patients to describe any associations between sex, race/ethnicity, and geographic location on confidence within healthcare interactions. The results of our preliminary analysis demonstrate the need for improved therapeutic alliance between patients and healthcare providers. This relationship is bidirectional and allows patients to express their health concerns and build trust with their providers and the broader healthcare system. Our study results can lead healthcare providers to adapt their approaches and ensure that individuals receive the support they need to make informed health decisions and have positive healthcare experiences.

Abstract Name: Utilizing Machine Learning for Review-Based Rating Prediction

Since sentiment analysis tools often differ from the nuanced evaluations conveyed by user-provided five star ratings, this study aims to analyze the two by comparing the sentiment between text reviews and numeric star ratings. The second objective focuses on predicting star ratings using machine learning to offer a valuable tool for products or businesses on different platforms that lack native rating systems. To conduct this study, the Yelp dataset is retrieved from the Yelp Open Dataset, which contains 7 million reviews and 150K businesses, and consists of five large files, including a file with the Yelp reviews. This file is input into a Python program that contains four state-of-the-art sentiment analysis tools: TextBlob, Vader, NRC Lexicon,

and Stanza. The sentiment analysis values that are generated are then analyzed using a Python program to calculate the Pearson correlation coefficient, indicating that overall, sentiment analysis tools do not show strong correlations with star ratings. Therefore, this study employs machine learning techniques to develop a more accurate model that will predict 5-star ratings. The large language models that are used in this study are BiLSTM (Bidirectional Long Short-Term Memory) and BERT (Bidirectional Encoder Representations from Transformers). To train these models, the Yelp reviews and their corresponding star ratings are utilized. After the machine learning models are created and their performance on the test sets are assessed, the overall accuracy is 66.54% for BiLSTM and 71.42% for BERT, indicating that the BERT model yields more accurate results than the BiLSTM model. To further this project, we use other machine learning techniques to make a more accurate model for predicting 5-star ratings so that it can be used for products or businesses on different platforms that do not have a star rating.

Abstract Name: Exploring the Impacts of Neuronal, Huntingtin Aggregates on Adult Drosophila melanogaster from Cells to Behavior

Huntington's Disease (HD) is an inherited, monogenic disease affecting thousands of Americans (~1/10000) yearly. Mutant Huntingtin protein contains a stretch of glutamine repeats that, when expanded, becomes unstable and forms inclusion bodies associated with the pathophysiology of the disease. We modeled HD pathophysiology using larval and adult forms of Drosophila melanogaster expressing control and pathogenic versions of human huntingtin tagged with RFP. We tracked huntingtin aggregate proliferation in the nervous system (NS) of Drosophila from eggs every 24 hours and determined a linear progression in the size and number of aggregates in the developing brain, motor axons, and at the neuromuscular junction. Using live imaging of fluorescently labeled huntingtin, we determined that axonal aggregates significantly impaired trafficking of organelles like synaptic vesicles, mitochondria, and dense core vesicles. To assess the downstream implications, we conducted electrophysiological recordings from muscles using intracellular voltage recordings and muscle force recordings and observed significant impacts on neuromuscular transduction. Larval crawling patterns were significantly impacted, showing impairments in movement speed and total distance traveled. To extend our findings to the adult form of Drosophila, we expressed huntingtin-aggregates in the wings to circumvent their lethality when expressed in the NS. The size and number of Htt-positive puncta increased to a greater extend in the pathogenic version of HD flies compared to controls. Here we have shown significant molecular, cellular, physiological, and behavioral deficits associated with pathogenic human huntingtin expression in the nervous system of Drosophila. Our work serves as a robust model to assess the progression of HD, and as a rigorous tool for potential genetic and therapeutic treatments for HD disease progression.

Abstract Name: How Attachment Theory Affects Relationship Status

Numerous studies have gone into the significance of attachment theory. Attachment theory states that how caregivers respond to children's bids for attention shapes how they connect in all relationships; moreover, this affects their relationships and well-being long-term (Bretherton, 1992; Kurth, 2013; Wilson-Ali et al., 2019). Due to the weight attachment theory, this study aims to address how attachment theory can impact relationship status. Relationship status is often defined by whether a couple is dating, cohabiting, married, or divorced. Studies have shown that relational status can correlate to relationship competency, greater life satisfaction, and lower levels of loneliness (Beckmeyer & Cromwell, 2018; Adamczyk & Pilarska, 2012). This study specifically looks into how attachment theory affects relationship status. Recruitment for the present study involved snow-ball methodology where undergraduate students from four universities were invited to share an online survey via social media. The following selection criteria were required in order to participate in the research: currently be in a romantic relationship and be between 18 – 70 years old. The sample consists of 838 participants (females = 61.6%, males = 38.4%). The mean age of participants is 25.92 (SD=9.068), the average length of the participants' relationship is 5.56 years (SD=6.06). Participants reported their relationship status as follows: 43.6% married, 37.5% dating in a committed relationship, 14.7% cohabitating, and .8% dating after a divorce. Results will be quantified in the next month and data will be analyzed to understand the significance of attachment upon relationship status.

Abstract Name: Cross-Species Investigation and Analysis (CoSIA): An R package and Shiny App that Provides an Alternative Framework for Cross-Species Transcriptomic Comparison Studies

High throughput sequencing technologies, such as RNA sequencing, have allowed cross-species comparative transcriptomic studies to be developed. However, due to challenges pertaining to biological and technical factors, there are numerous problems with comparing gene expression across species. Previous cross-species comparative studies have implemented multiple methods for gene-expression-based studies by examining evolutionary relationships between the species and employing rigorous statistical assumptions to account for species-level differences in the expression. However, these methodologies use direct comparisons, which are affected by batch effects and differences in gene expression patterns. Therefore, we have developed CoSIA (Cross-Species Investigation and Analysis), a Bioconductor R package and Shiny app that provides an alternative framework for cross-species transcriptomic comparison of non-diseased wild-type RNA sequencing gene expression data across tissues and species using variability, diversity, and specificity metrics. Users are able to employ these relative comparison metrics (variability, diversity, and specificity) using data from Bgee to visually and quantifiably compare across five different commonly used biomedical model organisms (Mus musculus, Rattus norvegicus, Danio rerio, Drosophila melanogaster, and

Caenorhabditis elegans), in addition to Homo sapiens. CoSIA provides a key tool for measuring and visualizing the variation in a gene's expression profile to better determine suitable model organisms for studying a specific gene or variant and allows users to make better comparisons between species using gene expression.

Abstract Name: Effects of Psychological Disorders on Reachability Judgements

Understanding peripersonal space and object perception is crucial in daily life. Previous studies indicate that individuals with major depressive disorder (MDD) perceive objects as being farther away. This study investigates whether post-traumatic stress disorder (PTSD), often comorbid with MDD, affects reachability judgments and object perception similarly. We also examine how tool use alters perceived object distance and the underlying neural mechanisms in a clinical population. Participants, categorized into four depressive symptom groups, performed a behavioral task to estimate distances of objects placed at varying lengths, both with and without a tool. Additionally, a task-based fMRI assessed brain activity while participants viewed objects on a screen, indicating perceived distances via a button box. Contrary to expectations, PTSD did not influence reachability judgments. However, the PTSD group exhibited heightened activation in sensory, motor, and visual processing brain regions compared to the non-PTSD group. Intriguingly, objects were perceived as more distant when participants held a tool, except when within and beyond 80cm, the boundary of peripersonal space. Comparing the mild and minimal depression groups revealed significant differences in distance estimation, with the mild group reporting shorter distances. Neuroimaging showed increased activation in areas associated with inhibition, sensory processing, and self-awareness in the mild depression group. These findings suggest that tool use extends perceived peripersonal space and that depressive symptom severity influences object distance estimation and brain activation patterns. This research enhances our understanding of spatial perception in clinical populations and highlights the complex interplay between mental health conditions and sensory processing.

Abstract Name: The Mediation Effect of Mindfulness in the Relation Between Adolescents' Inhibition and Working Memory

Background. Adolescence represents a critical period for cognitive development of executive functioning, marked by increases in impulsivity and decreases in self-regulation behaviors. Poor inhibition has been linked to deficits in working memory (WM), and recent studies propose mindfulness as a possible strategy to enhance facets of executive functioning. Thus, higher levels of mindfulness might mediate the relationship between inhibition and WM. Methods. The current study investigated the mediation effect of mindfulness in the relation between inhibition and working memory. As a part of a larger study, 128 adolescents ages 9-13 completed two computer-based cognitive tasks to assess inhibition, the Go/No-Go and the Stroop test, and a memory retrieval task to assess WM, Digit Span. They also self-reported mindfulness using the Child and Adolescent Mindfulness Measure (CAMM). Mediation analyses predicting performance on the WM task were performed, with inhibition as a predictor, mindfulness as a mediator, and age and gender as covariates. Results. Mindfulness did not mediate the relation between inhibition and working memory. The Go/No-Go task was positively correlated to WM and inhibitory control correlated positively with WM. Discussion. Contrary to the hypothesis, mindfulness did not mediate the relationship between inhibition and WM. The current study utilized a self-report measure of mindfulness, while others have studied comparison groups with a mindfulness intervention. The adolescents may have misestimated their self-reported mindfulness abilities or failed to use these skills for the tasks. The study's findings suggest youth may need to learn how to exercise mindfulness practices to use them effectively.

Abstract Name: Empowering Youth through Social Justice: A Mixed Methods Case Study of the Deaf Community Travel Trunk Project

This project, undertaken as part of an honors contract, aimed to develop a Travel Trunk centered around one of the core strands of humane education: Social Justice. It contains a carefully curated collection of materials, resources, and interactive lessons designed to captivate students' interest and inspire exploration of critical topics. In this case, the project focused on raising awareness about the deaf community.The undergraduate student, enrolled in the Deaf Education program, approached this project with a deeply personal connection. Having completed the RedRover Reader training, which emphasizes the incorporation of social and emotional learning through literature, she selected the book Listen: How Evelyn Glennie, a Deaf Girl, Changed Percussion as the centerpiece of the Travel Trunk. This book not only highlights the achievements of a deaf individual but also aligns with the goal of fostering empathy, kindness, and understanding. To engage students, an immersive activity was developed. Students were introduced to Evelyn Glennie through a YouTube video, gaining insight into her life and accomplishments. They also had the opportunity to interact with various percussion instruments, including a vibra-slap, maracas, and more. Some students wore noise-canceling headphones to simulate the experience of deaf individuals, enhancing their understanding of how music can be approached in the deaf community.In addition to the interactive elements, the undergraduate student created pre- and post-surveys to measure students' perceptions of the abilities and challenges faced by people within the deaf community. These surveys were administered to an elementary classroom as a selected case study. The data gathered was analyzed using both quantitative descriptive statistics and qualitative coding to identify emergent themes.The project exemplifies the power of education to promote inclusivity, empathy, and social justice, and highlights the importance of initiatives like the Travel Trunk in fostering a more just and inclusive society for all.

Abstract Name: Searching for Harmony in the Outdoors: An Exploration of Hunting and Fishing Participation in Michigan

Hunting and fishing are important because of the physical and mental health benefits that they offer to participants and the monetary support that they provide for conservation in the United States. At the federal level, some of the funds allocated to all 50 states for conservation are derived from two large funding models, embedded in the Pittman-Robertson and Dingell-Johnson acts. In these models, the amount of funding depends on how much hunting and fishing participation there is in each year. With hunting declining nationally and fishing participation below peak 1990s numbers, conservation may run out of funding soon. In an effort to increase participation, scholars have gathered information about the motivations and constraints of hunters and anglers, and have studied the behavioral intentions of prospective hunters and anglers; however, little research has attempted to connect the motivations and constraints of prospective hunting and fishing participants to that of the current participants. Therefore, it is the purpose of this study to understand the constraints and motivations of hunters, anglers, and general outdoor recreationists through a survey of Michigan recreators. In addition, rather than only asking about constraints, the survey will ask each participant to identify solutions that they believe are most likely to improve their access to and enjoyment of outdoor recreation areas. The results of this study are expected to inform the development of successful campaigns that recruit and retain hunter and angler populations, thereby spreading the known physical and mental health benefits of these forms of recreation and preventing the evaporation of funds for conservation.

Abstract Name: Advancing Molten Salt Reactor Technology: Experimental Thermal Conductivity of MSR Salts

Molten salt reactors (MSRs) are being investigated for use in clean energy to replace the common pressurized-water nuclear reactors in the United States. MSRs use high-temperature, low-pressure molten salt coolant to provide safer and more efficient energy production. However, many MSRs salt compounds lack tested thermophysical properties, including thermal conductivity. Our research focuses on experimentally measuring MSR salt thermal conductivities using a modified transient hot-wire technique. We use a needle probe, equipped with a thermocouple and heating wires, immersed in molten salt compounds at temperatures running from 400–700℃. Thus far, we have tested the thermal conductivity of LiCl-NaCl (eutectic and 91%LiCl composition), NaCl-KCl (eutectic), LiCl-KCl (eutectic), LiF-NaF (eutectic), and FLiNaK. These test results indicate higher than expected thermal conductivities and consequential further investigation into the physical properties of our probe to improve the experimental design and data evaluation. This research and experimental method will provide accurate and precise experimental results of MSRs molten salt thermophysical properties to populate the national database used by MSR developers which will help further the possibilities and practicalities of MSR technology.

Abstract Name: Financial Success Based on Maslow's Hierarchy of Needs

Financial success and what factors contribute to it can be assessed from many different angles.This study assessed how an individual’s financial success in adulthood, with the help of financial success indices, is correlated with an individual’s adolescent years according to Maslow’s Hierarchy of Needs. To better understand this relationship, a survey was administered to 519 participants between the ages of 35 and 45 at the time of the survey. Results confirmed the correlation between an individual’s upbringing and their financial success in adulthood. Different factors contributing to financial success in adulthood include but are not limited to having basic needs met, such as shelter, sufficient food, strong relationships, and a sense of self-esteem. Additionally, this study established competing hypotheses to determine whether some individuals who experienced a lack of satisfying their needs in their adolescent years were still financially successful in adulthood because of the desire to compensate for the lack experienced during adolescence.

Abstract Name: Testing the Effects of Different Languages of Music on Learning and Memory in Bilinguals

Researchers have long debated the effects of music on learning and memory. This study aims to test the effects of music in different languages and speeds on visual and reading task completion, specifically in regards to bilinguals. An experiment was conducted using 30 English-Arabic bilingual participants that ranged from 20 to 30 years of age, all with college level educational backgrounds. They were split into three groups that had to complete two tasks: one being a visual/problem solving task and the other being a reading/memory retrieval task. Participants in the first group had to listen to one medium paced and one fast paced Arabic song while completing the two tasks, one song would accompany each of the two tasks. The second group had the same conditions of the first group with the main difference being that the songs were in Russian and the third group completed the tasks while not listening to any music. The study managed to support one of the four hypotheses it aimed to test. Results supported the first hypothesis that participants who listened to music while performing comprehension tasks would perform poorly. Based on the results, the second hypothesis that music would help with visual tasks was rejected, instead showing significant results of the opposite. The third hypothesis that music in an incomprehensible language would make it easier to focus on the tasks was also rejected. Lastly, The fourth hypothesis which suggested that faster music would make task completion quicker was rejected, also showing significant results of the opposite. In conclusion, the results yielded significant evidence that music is detrimental to cognitive processes in learning and memory regardless of language and pace, contrary to popular belief.

Abstract Name: Gender, Body Shame, and Sexual Anxiety: A Mediational Model Among College Students

Previous research on sexual anxiety among emerging adults has consistently reported gendered differences in sexual anxiety levels with women reporting significantly higher levels of sexual anxiety than their male peers. As sexual anxiety is linked to several aspects of sexual functioning and enjoyment, this gendered discrepancy bears further investigation. Past literature has explored factors that may be influencing sexual anxiety in emerging adults, and body shame has emerged as a potential contributing factor. Using Objectification Theory as a basis, in this article, we seek to understand the coexisting relationships between gender, body shame, and sexual anxiety. We hypothesize a model wherein body shame may act as a mediator between gender and sexual anxiety. Through recruiting 293 participants aged 18-26 at a public Southern university to complete an anonymous online questionnaire, a mediational model test between these factors was conducted. Results indicated that body shame fully mediates the relationship between gender and sexual anxiety, and body shame is significantly correlated with sexual anxiety across both genders. Consistent with previous literature, women were also more likely to report higher rates of body shame and sexual anxiety than men. These findings provide a clearer understanding of the impact of body shame on emerging adults' sexual anxiety, which has important implications for educators, mental health professionals, and researchers.

Similarly, these results highlight how body shame stemming from gendered differences in sexual objectification may be contributing to higher rates of sexual anxiety among women.

Abstract Name: Influence of Adverse Childhood Experiences on Date Rape Recognition and Victim Blame

The present study examined how adverse childhood experiences (ACEs) affect recognition of date rape and victim blame in a sample of diverse college students. ACEs are important to consider in regards to sexual assault perceptions since they can have lasting, negative effects on personal health and wellbeing. The sample (N = 193) included college students at California State University, Fullerton. There were 112 (57.7%) participants who reported low (1 or less) ACEs, and 82 (42.3%) who reported high (4 or more) ACEs. Participants completed an online protocol utilizing the ACE scale, an attitudinal measure of rape survivors, and a questionnaire in response to a date rape scenario. It was hypothesized that: (H1) Participants with low v. high ACEs would endorse greater blame of a date rape victim/survivor; (H2) Participants with low v. high ACEs would be less likely to recognize date rape as rape per se. The results supported H1 ($t(96) = 2.96$, $p = .01$); participants with low v. high ACEs expressed more (victim) blame toward the date rape survivor. The results did not support H2; low v. high ACEs participants did not differ in date rape recognition. The majority of participants, irrespective of ACEs, did not consider the date rape depicted in the vignette as rape. The present results may be beneficial in promoting collegiate date rape awareness and reducing marginalization of date rape survivors.

Abstract Name: Effect of psychedelic therapy on male Betta splendens aggression as compared to traditional pharmaceuticals

Mental health disorders such as depression, anxiety, and mood disorders have been on the rise, and current success rates of antidepressant therapy for all populations ranges between 40 to 60 percent. These antidepressants, such as serotonin selective reuptake inhibitors (SSRIs), work to slow the reabsorption of the neurotransmitter serotonin from the synaptic gap, allowing serotonin to have a greater impact in the body (Chu and Wadwha 2021). Similarly, atypical antipsychotics used in depression treatment act on serotonin and dopamine receptors (Zhou et al 2015). Current methods of depression treatment still leave a sizable portion of

patients without relief, necessitating research into alternatives. Psychedelic therapy suggests success because many psychedelics are serotonin receptor agonists they bind to the serotonin receptor and mimic the effect of serotonin (Madsen et al 2019). Psychedelic therapy is a closely monitored procedure where patients experience a "trip," or a carefully guided, out-of-body experience resulting from psychedelic use (Johnson et al 2008). Researchers have questioned if psychedelic-driven remissions are caused by a change in neurochemistry or are simply the result of a profound psychological experience. To investigate this process, sixty male betta fish were divided into five treatment groups: control, 11 doses of an antidepressant, 11 doses of an antipsychotic, 11 doses of a combination of antidepressants and antipsychotics, or 1 low and 1 high dose of a psychedelic. Their behavior was recorded and analyzed before, during, and after dosage and both alone and paired with a conspecific. Ethogram data from the final aggressive displays suggests an impact of the psychedelic on behaviors such as frequency of turning.

Abstract Name: Housing Design For A Child with Retinopathy of Prematurity

The purpose of this project is to design a home for a family of four, with two working parents, a 4-year-old daughter, and a 10-year-old son with retinopathy of prematurity.This disease affects babies born prematurely, in some cases it is curable and in others it can lead to lifelong visual impairment. The child in the user profile with this impairment experiences full vision loss and has special needs in the home such as; clear and wide walkways, materials that differentiate spaces, reachable counters and storage, and being able to navigate the space with a cane. Research for this project focused on quality of life which led to the design choice of featuring large custom textile art pieces in the home. The research around the effects of textile art has been collected through case studies and literature reviews specifically focused on textile art and people with any visual impairment. The research findings indicated significant positive change to overall wellbeing when introducing experiencing textile art in some way. With careful consideration around the textiles used in each piece, all featured works are designed to withstand the love given to them throughout the family's time in the home. The experience of interacting with textile pieces has shown to increase serotonin and provide feelings of independence, growth, meditation, and relaxation. It is also said by users that featuring textural art in the home provides a space for intentional time with the senses. Contrasting materials on furniture in various rooms were also utilized to help distinguish different furniture pieces as well as different rooms of the house. From the designs for this project, the expected outcome is the family inhabiting the home can help their children grow their independence and have safe, sensory, and friendly spots in their house that accommodate their family’s needs.

Abstract Name: An Investigation into the Mechanisms of Electron Transport in Highly Doped AlGaN:Si (Al% > 65%)

Highly conductive contact layers are an integral aspect of modern electronics. AlXGa1-XN, due to its ultrawide bandgap (5-6 eV) and high breakdown voltage (10MV/cm2), is a promising material for the production of UV LEDs and high-power electronics. Previous research shows an increase in activation energy for conduction with increasing aluminum mole fraction, thus making highly conducting contact layers a challenge. Current methodologies, up to this point, have focused primarily on electrical measurements (e.g. temperature dependent hall effect). This research, in contrast, seeks to better understand electron transport in heavily silicon doped, high aluminum content AlXGa1-XN (X > 0.65), specifically by monitoring the neutral donor concentration with 10 GHz electron paramagnetic resonance (EPR). EPR can measure more directly the behavior of the carrier species, in our samples being the neutral Si donor. Samples were doped on the order of 1018 – 1020 [cm-3] and were measured from room temperature to 4K. The temperature dependence of the neutral donor EPR spectra linewidth and intensity were measured, and statistical models were used to understand the mechanism of transport in these high Al mole fraction AlGaN samples. The results of this research indicate the presence of impurity band conduction and electron hopping as well as the presence of compensating centers.

Abstract Name: Small-Scale Motion Capture Enclosure for Pediatric Heart Simulator Kinematics

A pediatric heart simulator is expected to serve as a platform to evaluate the mechanical mitral valve in advance of a mitral valve replacement surgery. In this regard, the purpose of a small-scale motion capture enclosure is to study intricate iterations of contractile motion of a pediatric heart simulator. Additionally, the extracted motion data can be used to identify the optimal mechanical mitral valve for a specific patient. Motion capture enclosure that specializes in precision and submillimeter scale can help study the dynamics of the heart simulator that replicate hearts' twisting behavior, especially at their apex. We conducted both small angular rotation and translation tests within the enclosure to determine tracking accuracy. We performed the translation test by moving a small rigid disk which had approximately the same diameter as a heart simulator along the XYZ plane. This test revealed that our system can capture the movement data in a micrometer scale in microseconds. The rotation test was conducted by spinning a flat disk by 45 ° and testing its accuracy of angle changes. We found out that there was an error of less than 0.25 ° when rotating the object in small scale. Currently, we are investigating how we can apply the motion capture system to volumetric measurement tracking. We have recently detected an average volume deflation rate of about -0.144 mm3/s. The similar physical and mechanical properties of a balloon will be used to help formulate an experimental set up for the heart simulator. Understanding changes in balloon volume can provide further insight on geometry and dynamics of the synthetic heart simulator after both the diastole and systole periods. We expect that our work will contribute to a biotechnology setting and insight into the mechanical behavior of heart simulators devised for mitral valve replacement surgery.

Abstract Name: Effective Methods to Predict how Aging Mechanically Stabilized Earth Walls will Degrade.

Mechanically Stabilized Earth (MSE) walls have widely been used across the United States and globally as earth retention systems in numerous civil engineering projects since the 1970's. MSE walls comprise mainly of structural fills reinforced by tensile inclusions, such as steel strips and steel grids. Such walls are prone to several aging-related deterioration mechanisms that need to be understood to develop an effective asset management plan for them. One of the key deterioration mechanisms in MSE walls is the corrosion of steel reinforcements with time. While significant research has been conducted to study the corrosion of steel reinforcements buried in soils, it has continued to be one of the most vexing challenges in the asset management of MSE walls for its high uncertainty and variability both spatially and temporally. Current corrosion models that are used in the design MSE walls are overly conservative to take account of the uncertainties associated with corrosion. However, it is impractical to use such overly conservative models for the evaluation of steel reinforcement corrosion in existing MSE walls, which have been built since the 1970s, for asset management purposes. This research focused on evaluating the effectiveness of existing corrosion models of buried steel reinforcements in MSE walls and proposing an improved model that can realistically reflect the expected corrosion of steel reinforcements considering wall fill type, moisture, resistivity, chlorides content, sulfates content, pH, and organic content. Corrosion data compiled from the literature were used in the development of the proposed corrosion model. These data involved corrosion rates and fill properties obtained from numerous MSE walls across the United States. Additionally, corrosion data from two recent MSE walls failures in New York were used to validate the proposed model.

Abstract Name: The Only Exception: Colson Whitehead's Portrayal of Modern-Day Slavery Through the U.S. Prison System

"Except as punishment for a crime." These six words are often forgotten, inconspicuously slipped in between the famous lines of the 13th Amendment: "Neither slavery nor involuntary servitude" and "shall exist in the United States." The 13thAmendment was designed to protect Black Americans from future injustice, but this small phrase created a loophole that allows people in power to continue oppressing Black citizens through the use of the prison system. In his novel The Nickel Boys, Colson Whitehead uses the stories of Black boys imprisoned in Nickel Academy to reveal the oppression of Black Americans through the U.S. prison system, which continues the legacy of slavery through systemic racism and generational trauma. The experiences of the boys sentenced to Nickel Academy serve as manifestations of the effects of prison on Black Americans and demonstrates how the prison system enforces the social and economic legacies of slavery. Black people are incarcerated today at disproportionate rates, often because of social conditions Black citizens have been subjected to since slavery, such as poverty and broken families. This is apparent for Black boys at Nickel Academy, since each boy came from a devastating background that made them susceptible to incarceration. During incarceration, inmates in Nickel Academy and today are subject to corruption at individual levels, with abuse from officers, and systemic levels, as prisons use incarcerated individuals as slaves in massive cheap and free labor rings. Even after release, former inmates struggle tremendously to live fulfilling lives and move up the social and economic ladder. In The Nickel Boys, Turner was lucky to escape alive, but

failed to live a happy life as the trauma of prison lingers throughout all factors of his life. Because of racism in the prison system, Black Americans still live out the impacts of slavery generations later.

Abstract Name: The Effect of Free Agency on Franchise Valuation: A National Basketball Association Case Study

National Basketball Association (NBA) executives are troubled by the economic decisions surrounding the free agency market. While having a set salary cap, owners and general managers must allocate funds to at most 15 players on a roster. Deciding who to add to their rosters and at what cost to the team are important questions for squad performance and economic achievement. While framed as a sports-economics problem in this analysis, this paper will aim to outline the relationship between how a new acquisition's cost and characteristics are related to a team's change in value. A variety of metrics indicate that the quantity of 'key' players, those in the highest salary bracket, is correlated with revenue and increased value for the rosters. Expanding on the previously conducted research, this analysis evaluates every free agent signing for the 30 NBA teams since 2013. Looking at over 1,500 free-agent deals, this study will compare the contract details and monetary value with attributed changes in team valuation. The results will be a useful tool in identifying the types of players that will make individual teams the most money, and ultimately, whether or not NBA executives act rationally in an economic framework to maximize their franchise's value. Extrapolating this idea, these methodologies and analysis can be replicated for most business models allowing executives to make better and more informed financial decisions.

Abstract Name: Empowerment Through Sex Education: Analyzing the Lack of Comprehensive Curriculum in Utah

This research project delves into the intricate web surrounding the lack of comprehensive sex education (CSE) in the state of Utah, employing an intersectional, equity-centered system thinking approach. The researchers, former members of the LDS church and products of Utah's public education system, bring personal experiences to contextualize their study. Their methodology involves primary interviews with recent alumni, healthcare providers, educators, and administrators, supplemented by an extensive literature review and analysis of publicly available interviews.This research provides a thorough analysis, comparing CSE with abstinence-based education. It reveals that Utah's current limited sex education is rooted in a historical context of colonialism, purity culture, and theocratic influence, resulting in detrimental consequences such as

increased rates of queer and gender discrimination, sexual violence, and societal ignorance.The research uncovers the deeply embedded influence of the LDS church on Utah's sex education policies. This further perpetuates purity culture, restricts LGBTQ+ inclusivity, and obstructs discussions on consent. The stakeholder analysis highlights power dynamics, emphasizing the influence of theocratic leadership over lawmakers and educators.The research uncovers an alarming gap between stakeholder perspectives and policy decisions, as evidenced by the widespread support for CSE among parents, health professionals, and teachers, juxtaposed against the theocratic governance prioritizing abstinence education. The researchers propose strategic levers of change, emphasizing the need to challenge the theocratic status quo, engage conservative parents through culturally resonant awareness-raising methods, and empower progressive parents to advocate for inclusive sex education.The research highlights existing interventions, like federally funded programs, advocacy for state policy change, grassroots initiatives, and therapeutic services. Stressing the importance of strategic approaches to accelerate progress in a system gridlocked by theocratic hierarchy. Advocates must navigate cultural values, community building, and strategic engagement with key power players to bring about a transformative shift towards comprehensive sex education in Utah.

Abstract Name: Parental Divorce, Sibling Relationships, and Depressive Symptoms

Parental conflict and divorce can be some of the most adverse experiences in a child’s life. Around 40% of children will experience parental divorce before adulthood and even more will experience seeing parental conflict in their homes. Exposure to parental conflict was found to significantly increase episodes of major depressive disorder. However, positive relationships with older siblings may buffer against the negative effects of parental conflict. Older siblings may be a protective factor for their younger sibling because they are one of the longest standing supportive relationships someone can have. Older siblings have also been found to provide strong emotional support and assistance for their younger siblings. The proposed study plans to investigate if parental conflict will be associated with depressive symptoms and if older siblings may serve as a protective factor reducing the association between parental separation and depressive symptoms. Participants will be 150 undergraduate students for the University of Wisconsin-La Crosse and based on demographic characteristics of this population it is expected to get participants between ages 18-24 being predominantly white women. To examine the hypothesis, will complete an online Qualtrics survey assessing parental conflict, sibling relationships, and depressive symptoms. Multivariate regression will be used to examine the associations among these variables. We expect that people who have experienced parental conflict will be associated with more depressive symptoms. In addition, we predict that the association between parental conflict and depressive symptoms will be weaker when participants report more positive relationships with an older sibling. I plan to conduct a multivariate regression to find a relationship between parental conflict, depressive symptoms, and sibling relationships. This research has the opportunity to highlight that even if siblings do not live in the same environment, they still can create an impact on each other later in life.

Abstract Name: #istandwithukraine: A trend, or a statement?

On February 24, 2022, Russia invaded Ukraine. A long-standing dispute over a border had turned into yet another violent conflict. Feeling the effects of the war, people everywhere had questions, ones that were not being answered by the people in power. They turned, then, to the source of all information: social media. This study employed a cultural studies approach. The theory of cultural studies takes into account how culture influences other facets of society including social media content. Observing culture as it manifests in social media discourse allows for understanding how vastly different people perceive the world. 200 tweets from the time period of February 16-May 16 were collected using the key words “Ukraine”, “Russia”, and “World War 3” as well as the hashtags “#WorldWar3”, ”#UkraineWar”, ”#istandwithukraine”, and “#istandwithputin”. This study concluded by emphasizing that the implications of social media discourse should not be understated or forgotten about and that cultural themes from within social media discourse spread easily, giving them the power to directly shape public opinion on international conflicts like this one.

Abstract Name: The History of Native American Betterment in Wisconsin and its Future

Wisconsin is known for its forestry, cheese, and being Midwest nice. What is often overlooked is the history of Native Americans and their involvement in the state. In this project, I focus on how Native Americans historically have worked to better their lives in Wisconsin as well as what are they currently working on and hoping to improve upon in the future. I review existing literature to construct a timeline of Native American involvement and betterment to have a better understanding of their history. By analyzing action plans made by organizations that oversee the eleven federally recognized tribes in Wisconsin, I outline current programs and goals of the organization to predict where the future of Wisconsin Native American betterment will go. I find that tourism has historically been important in Wisconsin and is seen as vital to the future for economic development as well as a teaching tool to build community relations. I also discuss the importance of small business development and start up methods that reservations can use to help keep money coming in and staying on reservations. In addition, since COVID, there has been an increase in programs focused on epidemiology and health within reservations. This research sheds light on a group that is often overlooked and can gain support by having others be more knowledgeable on their situation. Overall, the betterment of Wisconsin Native American lives is dependent on taking advantage of their location as well as working with others outside of the community.

Abstract Name: Cardiothread and Lifesmile Oral Microbiome Medical Device Development in a Community College STEM Undergraduate Research Lab

A model curriculum for undergraduate medicine and biotechnology research produced two medical devices proposals. First, using cell culture methods and 3D printing, the students cultivated a living suture, "Cardiothread", for repair of heart valves. Cardiothread puts the patient's own cells into the newly sutured heart valve for accelerating tissue merging and healing. Cardiothread is designed to be incorporated into a spool on the DaVinci surgical robot and feed a special suture attachment. The second device "Lifesmile" the students developed de novo was based on analysis of twelve of their own supragingival tooth oral microbiomes using Illumina Next Generation Sequencing. The microbiome data revealed two keystone bacteria (Streptococcus sanguinis and Fusobacterium nucleatum) as the primary bacterial species above the gumline. The surface of healthy teeth has an abundance of Streptococcus sanguinis bacteria while unhealthy teeth are overrun with the dangerous anaerobe Fusobacterium nucleatum. The latter has been associated with risk of preterm labor, cancer, and neurological illness. To address the need for a more rapid and portable analysis, the "LifeSmile" point of care testing device was invented. Lifesmile technology isolates DNA from the tooth sample and provides a signal readout on the two bacteria channels using LAMP, CRISPR and FRET Fluorescence techologies. The Cardiothread and Lifesmile projects illustrate the pursuit of relevant tangible research by STEM undergraduates at the Community College in collaborative efforts with community physicians and researchers. This model of instruction is consistent with the aspirational guidelines of the "Vision and Change" goals of the National Science Foundation for develoiping novel open ended research exercises in the entry levels of instruction and the “Project Based Learning” Community College initiatives. The outcomes achieved by the students participating in Lifesmile and Cardiothread include multiple conference awards, high rates of University transfer and degree completion, and employment in research career trajectories.

Abstract Name: Building a Brighter World: A Young Person’s Guide to Public Health

Despite an abundance of children’s literature in STEM fields, few picture books exist about broad public health topics. Building a Brighter World addresses this gap by presenting social determinants of health, e.g. housing, education, and food access, alongside worldviews for advancing health equity. Using age-appropriate language, paired with illustrated images, the goal of this project is to create a tool that makes public health accessible for a six to eight year old audience. To prepare for the project, we researched books (such as If You Give a Mouse a Cookie and the Baby Scientist series), films (such as Ponyo and Mitchells vs. The Machines), and art references that exhibited a tone and visual language that would help elevate our project’s messages. We also drew from resources created by the Centers for Disease Control and Prevention and the American Public Health Association to guide the public health content addressed within the book. Using the digital drawing program, Procreate, we drafted early designs and storyboards, as well as finalized illustrations before organizing each spread in the layout program, Adobe InDesign. Throughout the process,

our interdisciplinary team of visual artists, writers, and our public health mentor met to discuss visuals and revise each page's text, one scene at a time. As this work unfolded, this structure provided us with the space to explore new ways to introduce complex and relevant topics to a young audience in hopes that they will see themselves as lifelong contributors to health equity. Through dissemination in early childhood courses and library storytime events, this book will spark conversations about how issues of accessibility and discrimination impact health, and encourage younger generations to imagine a brighter future for all communities.

Abstract Name: "We Shall be as a City on a Hill:" Understandings of Nationalism in America in the Post-Cold War Years

Nationalism is a subject of growing interest and significance in American politics and in the world. By studying the arguments and use of language by these three particularly influential scholars of nationalism in the past thirty years (since the end of the Cold War), I hope to gain an understanding of their ideological backgrounds to their intellectual arguments, where they diverge and where they agree, along with how they use the same or similar sources to come to different conclusions on the subject of American nationalism. How do the most influential authors on the subject of nationalism understand it, and what do they think is the best response to it, culturally and politically? Much of the literature on the subject looks at nationalism through history, or studies the ideals and beliefs of nationalists themselves. My work fits into the existing literature as a description and analysis not of nationalists or nationalism itself, but of the most influential scholarly writings on the subject. In this project, I will analyze the arguments and language of Anatol Lieven, Paul D. Miller, and Will Kymlicka in order to develop an understanding of the ideology as they see it. The works I will be studying are, often, not written for a strictly scholarly audience, but also for lay people, helping shape the population's perception of culture and politics. My background in political philosophy informs my thinking on these three influential writers on American nationalism. I will show how Anatol Lieven, Paul D. Miller, and Will Kymlicka use the same information to come to independent conclusions. While their understanding of the term "nationalism" is, broadly speaking, similar, the three come to differing conclusions regarding what Americans should do about it.

Abstract Name: Exploring the Role of CTCF in the Formation of Topologically Associated Domains in Metazoans

In most vertebrate species, genomes are organized in 3D space into topologically associated domains (TADs),

self-interacting genomic regions that facilitate the interaction between cis-regulatory elements and target genes. The formation of TADs has recently been attributed to loop extrusion, specifically through the action of the DNA-binding protein CTCF and the Cohesin complex. In brief, loop extrusion occurs when the Cohesin complex reels chromatin into a loop such that initially distant parts of the chromosome are now in close spatial proximity. The loop extrusion process is interrupted when Cohesin encounters CTCF, allowing for the creation of distinct, self-interacting domains across the genome. Cohesin and related complexes engage in loop extrusion in all kingdoms of life, while CTCF has primarily been conserved in metazoans. In certain species, TAD formation is unexplored despite these species being known to have CTCF. For example, the role of CTCF and Cohesin in TAD structures in many invertebrate species remains unclear. To tackle this question of whether those species can form TADs in the presence of CTCF, we express their respective CTCFs in human cell lines otherwise lacking human CTCF. We will then perform Hi-C experiments, a sequencing-based method to quantify 3D genome interactions, to test for the ability to form TADs. We expect that if CTCF is capable of driving TAD formation in a given species, CTCF derived from that species would form TADs in our assay. However, if TADs are not formed in the presence of a species' CTCF, we can speculate that another mechanism rather than loop extrusion may be responsible for the formation of TADs in that species. We will expand on this work by examining whether CTCF is inherently necessary for the formation of TADs by looking at TAD formation in specific invertebrates where the CTCF factor has been lost.

Abstract Name: Analyzing the Population Genetics of Northern Map Turtles in the Lower Susquehanna River

Reptiles comprise the most threatened vertebrate group on the planet, facing substantial environmental and anthropogenic barriers such as habitat loss and modification, pollution, and human recreation. The Maryland state-endangered Northern Map Turtle (NMT) is threatened by anthropogenic activities and impact (recreational boating and the presence of the hydroelectric Conowingo dam) as well as environmental challenges (increased storm intensity and rapid spread of disease) in the lower Susquehanna River. NMTs specifically face increased levels of these threats due to their use of different sections of the river to optimize survivability; each section used is affected by a combination of the barriers mentioned above. This ultimately impacts population genetic parameters in unknown ways. This project analyzes the population size and delineation of NMTs in the Susquehanna to better understand potential human-induced selective pressures on this species, which will aid in creating informed management decisions to limit future NMT population decline. DNA from field-collected NMT tissue samples was extracted and sequenced to obtain DNA fingerprints. Sequenced data was bioinformatically analyzed to estimate effective population size, population geographic boundaries, and genetic diversity. Results suggest the presence of a single, small NMT population (NE ~ 28 – 57 individuals) that may have recently experienced a population reduction and be susceptible to further decline from deleterious inbreeding. Genetic diversity in this population is comparable to other populations within this species, however, it should continue to be periodically monitored for signs of increased inbreeding.

Abstract Name: Does Stimulant History Affect the Anxiety-Like Response to Nicotine in Male Rats?

Amphetamine, commonly known as Adderall, is a stimulant frequently prescribed for the treatment of Attention-Deficit Hyperactivity Disorder (ADHD). The use of amphetamine prescription has increased 2.5-fold in a decade and is a largely abused drug. ADHD is diagnosed in 10% of children in the US and is more prevalent amongst boys and younger individuals. Those with ADHD frequently have anxiety and over ¾ of amphetamine users report anxiety symptoms. Additionally, those with ADHD smoke cigarettes at rates significantly higher than their non-diagnosed peers and experience a greater reinforcing effect from smoking. Animal models can be used to understand biology and pathophysiology, while controlling for variables more easily than clinical models. The current study aims to analyze how a history of amphetamine exposure affects the anxiety-like response to nicotine in male rats.Amphetamine exposure was administered via 14 days of repeated injection (4 mg/kg, IP), and nicotine was administered via a single injection (0.1 mg/kg, SC) 15 minutes prior to testing. Behavioral testing on the elevated plus maze (EPM) was conducted to analyze anxiety-like behavior. Time spent in the open arms of the EPM and entries into the open arms of the EPM were measured, and ANOVA statistical testing was conducted to analyze for a significant effect of history of amphetamine and/or nicotine injections, as well as an interaction between the two. Though nonsignificant, results suggest that both amphetamine history and nicotine injection alone may increase anxiety-like behavior. Additionally, nicotine after a history of amphetamine exposure increased anxiety-like behavior, compared to amphetamine or nicotine alone. This study could provide insight into why those prescribed amphetamine are at increased risk of nicotine use, as well as anxiety. Further studies will need to be done to further assess this interaction and help understand this drug treatment with anxiety.

Abstract Name: Reframing Rhetoric: A Study in the Exclusionary Nature of the Rhetorical Canon

The traditional canon of rhetoric, much like the canon of literature, has been exclusionary to many voices of those in minoritized communities, specifically those wishing to voice their experience about being minoritized. I propose a reframing of what many scholars consider to be rhetorical texts and speeches to include more non-traditional mediums. In order to reframe what is deemed “rhetoric,” it is important to first give rhetoric a working definition, which, I argue, is the act of persuasion, which can be carried out through any medium of communication. The beginning of this definition, “the act of persuading,” is agreed upon by many scholars, as it is specifically pulled from the classic rhetorical work of the Greco-Romans. My argument can be seen mainly in the second half of the definition, in which I state that, for a text to be considered rhetorical, it need not be confined to any medium or genre. Historically, much of what is studied in the rhetorical canon comes from either nonfiction, philosophy and/or relatively formal speeches or texts. To truly incorporate voices of those who are minoritized in the study of rhetoric, one must push these bounds by viewing alternative texts, such as graphic novels, paintings, films, poetry, or fiction texts as rhetorical works. To study this exclusion and prorpose ways of incorporating less-traditional rhetorical texts, I believe it is beneficial to first look at the recent shift to reframe the literary canon for guidance. One scholar who touches on one such idea is Emilie Bergman, in her article: “Reshaping the Canon: Intertextuality in Spanish

Novels of Female Development" (1987), which discusses the importance of allowing not only minoritized voices, but allowing for those with intersecting identities to voice their experiences.

Abstract Name: Synthesis of 1,1-diphenylpropan-1-ol via a solvent free mechanochemical Grignard reaction.

While pivotal to the field of organic chemistry as one of the few carbon-carbon bond forming reactions, the traditional method of Grignard reagent synthesis has disadvantages. One main shortcoming is the use of anhydrous diethyl ether as a solvent which is a known neurotoxin, forms dangerous peroxides, and is highly flammable. Recent literature in the use of mechanochemistry in Grignard reactions suggests a more safe and cost-effective synthesis. In this work, the tertiary alcohol, 1,1-diphenylpropan-1-ol was synthesized via a ball mill grinder without the use of anhydrous diethyl ether. The final product was characterized by both infrared and nuclear magnetic resonance spectroscopy. This indicates a successful alternative to the long-established method of running Grignard reactions. The complete results of the synthesis will be presented.

Abstract Name: Thermally Induced Carbonate Precipitation as a Method to Control Hydraulic Properties in Enhanced Geothermal Systems

To effectively cultivate geothermal energy from natural systems, engineered fractures are hydraulically implemented to improve access of water through a network of channels in the heated rock. The result of manipulating the permeability of a geothermal reservoir in this way is referred to as Enhanced Geothermal Systems (EGS). Through this collaborative research project, Montana State University and Berkeley National Laboratory aim to increase understanding of thermally induced carbonate precipitation (TICP) in the application of influencing permeability in EGS. The implementation of microbially induced calcium carbonate precipitation (MICP) has been widely explored for sealing fractures in the subsurface, for example in leaking oil and gas wells. However, the temperatures present in EGS are too high to support most microbial metabolic functions, leading to the research of thermally induced calcium carbonate precipitation (TICP). Urea, when heated in solution above 100 degrees Celsius can be thermally hydrolyzed to promote calcium carbonate precipitation. Mineral precipitation at hotter temperatures has an application to controlling permeability in the deeper subsurface and EGS. Data has been collected through batch testing of the thermal kinetics of the reaction between urea and calcium chloride at various concentrations (1M and 3M), temperatures (150 to 195 degrees Celsius) and in the presence of granite. Batch testing was performed by filling stainless steel reactors, heating them and pulling them from the oven at various time points to assess

the remaining concentration of urea. The results of the batch experiments were used to design a flow-through, high-temperature granite core sealing test to model enhanced geothermal systems. One core experiment has successfully confirmed the ability of TICP to reduce permeability in a granite fracture, and future testing is anticipated to provide analytical support to the hypothesis. This presentation will describe the analysis of urea hydrolysis and the preliminary data from the core sealing experiment.

Abstract Name: Black Hair, Women, and Products in Design

This essay explores the intricate relationship between black women, their hair, and the design, uncovering the historical and cultural motives that have shaped this dynamic crossing. From the symbolic richness of tribal hairstyles in the 16th century, exemplified by the Himba women, to the transformative period of the 1900s when black women sought to break free from societal constraints, the narrative traces the evolution of black hair as a powerful expression of identity.The discussion centers around pioneers like Madam C.J. Walker and Annie Turnbo, who revolutionized the hair product industry and navigated the challenges of promoting their products in a society dominated by racial biases and men. The analysis extends to the role of design in shaping the image of these products, with a focus on strategic marketing that propelled brands into the cultural consciousness.Furthermore, the essay highlights the broader impact of black women in design, from product creation to architecture and fashion. It addresses the persisting challenges black designers, particularly women, face in gaining recognition and equitable representation in the design industry.Drawing on contemporary examples and voices from the design community, the essay emphasizes the multifaceted nature of black hair as a source of inspiration, empowerment, and resistance. It sheds light on the complexities of identity and the continued struggles black women face in a design community that often downsizes their contributions. In conclusion, the essay calls for increased awareness and recognition of black women designers' immense talent and resilience, challenging the industry to bridge the glaring gap that persists despite cultural evolution.

Abstract Name: The Impact the of the Arab Spring on Women Empowerment in the MENA Region

Middle Eastern governments typically score at or near the bottom of indices measuring women’s rights and political participation. The Middle East also contains a large saturation of authoritarian regimes. The Arab Spring challenged these regimes' structures as they included vast female participation, but there is little existing research to understand the Spring's impact on opinions of women's participation and empowerment in the region. This study aims to add to existing research on this topic by analyzing Arab Barometer data from 4 questions dealing with opinions of women’s participation in society gatherers before, during, and after

the Arab Spring. I employ difference in difference t-tests to highlight statistical differences in change of opinions before and during the Arab Spring. Additionally, I draw on twenty semi-structured interviews (conducted in Jordan in 2022) to supplement this quantitative analysis in an attempt to identify causation between the Arab Spring and changes in public opinion towards increased women's empowerment. The quantitative analysis illustrates a correlation between the Arab Spring and opinions of women's empowerment, but the shifts of opinions are both negative and positive. The data suggests that the negative impact is connected with the second half of the Arab Spring when the governments were subject to more instability. The interview results suggest a complicated relationship in the minds of Jordanians between the Arab Spring and public opinion of women's empowerment.

Abstract Name: Identifying the Role of Cyberbullying in Interpersonal Risk Factors for Depression and Suicide: Social Support as a Buffer

Poor mental health and suicide are major concerns among adolescents, especially among racially/ethnically minoritized youth. Interpersonal factors, such as cyberbullying, perceived burdensomeness (PB), and thwarted belongingness (TB), influence risk for depression and suicide. However, limited research examines the relationship between these factors amongst racially minoritized youth, or considers whether social support impacts these relationships. The current study examines whether racial identity and social support moderate the relationship between cyberbullying and both TB and PB. It is hypothesized that a) cyberbullying is associated with higher levels of TB and PB for racially minoritized youth, and b) social support buffers the effects of cyberbullying on TB and PB. The Teen Social Media Experience (TSME) study included a total of 367 adolescents (ages 14-17; Mean=16.02 years; SD=.85), who completed an online survey assessing social media experiences with cyberbullying, interpersonal risk factors (PB and TB), and social support. Linear regressions and moderation analyses were used to examine the current hypotheses. Results indicated that cyberbullying is positively associated with PB (B=5.84, SE=8.12, p<.001), but not TB (B= -.02, SE= .82, p<.05), controlling for depression. Social support is negatively associated with PB (B=-.74, SE=.36, p<.001) but not TB (B= -.04 , SE=.15, p<.05). Neither race nor social support moderated the relationship between cyberbullying and PB (B=-.75, SE=2.7, p<.05; B=-.57, SE=.95, p<.05) or TB (B=-.76, SE=1.36, p<.05; B= .51, SE=.57, p<.05). Results of this study suggest that cyberbullying and social support do influence perceived burdensomeness, which may be an important target for prevention of depression and suicide for adolescents. Findings also advance our understanding of how cyberbullying affects PB and TB to inform possible areas of intervention and suicide prevention.

Abstract Name: Inhibition of Acid Ceramidase to Improve Herpes Oncolytic Virus-Based Therapy in Recurrent Glioblastoma

Glioblastoma (GBM) is the most common malignant brain tumor in adults and, unfortunately, patients have a median survival of about 15 months. One mechanism through which GBM cells can avoid cell death is through a dysregulated sphingolipid metabolism, specifically an increased sphingosine-1-phosphate (S1P) and decreased ceramides. Ceramide hydrolyzation by ceramidases produces sphingosine, which is then phosphorylated to S1P by sphingosine kinases. Inhibiting ceramidases to decrease S1P and increase ceramides is a potential strategy for anti-cancer therapy. We published that inhibition of the acid ceramidase ASAH1, via genetic targeting with shRNAs or with the blood-brain barrier permeable drug carmofur, decreased glioma growth and migration. Interestingly, ASAH1 expression in macrophages was recently found to facilitate encapsulation of herpes simplex virus-1 (HSV) in multivesicular bodies, thereby mitigating the herpes disease. These data suggest that ASAH1 inhibition in GBM could also improve the efficacy of oncolytic HSV therapy. We therefore explored the effect of pharmacologic and genetic inhibition of ASAH1 on the ability of oHSV G207 to decrease the growth of GBM cells isolated from patient-derived xenografts. Our preliminary data demonstrated a significant decrease in GBM cell growth upon treatment of cells with the combination of carmofur and G207. Our data also suggested that recurrent GBM xenolines with shRNA knockdown of ASAH1 are significantly more sensitive to G207 in comparison to non-targeting controls. Considering G207 is safe in both adult and pediatric glioma patients and carmofur is used internationally for the treatment of colon cancer, we believe that our findings are highly translational.

Abstract Name: Exploring Experimental Film Firsthand

The project's primary purpose is to utilize the medium of cinema to reframe and illuminate novel aspects of the human experience by contributing a unique, original work and expanding upon the genre of experimental film. In addition, the project provides hands-on experience to actively explore the medium and utilize and strengthen skills and knowledge relevant to my fields of focus, such as film studies, technical communication, and creative writing. The primary influence and inspiration for the project came from experimental filmmakers such as David Lynch, Maya Deren, Marcel Duchamp, Man Ray, Luis Buñuel, Salvador Dalí, Alexander Hammid, and Terrence Malik. The ongoing research is achieved using an iPhone 14 Pro Max with a 1.33x anamorphic lens adaptor and a Rode shotgun microphone for recording video and audio, Black Magic Design's Davinci Resolve 18 for video editing, and utilized actors for onscreen performances. During my research, I have successfully expanded many of my skills, including writing scripts, directing actors, producing a film production, camera operating, set designing, visual/audio recording and editing, cinematography, film score composition, as well as time, personnel, and resource management. In the future, the project will serve as an example of my technical capabilities within my portfolio and be shared online to contribute to the continuing experimental film conversation.

Abstract Name: Genderqueer Impression Management

The research question of this study is: “How do genderqueer (GQ) people in the Los Angeles Metropolitan Area engage in impression management when socializing with cisgender people?” The study is informed by existing sociological theoretical frameworks regarding GQ identity, cisnormativity, stigma, and intersectionality. Related existing evidence includes Spencer Garrison’s (2018) study on authenticating trans identity narratives, Ashley Austin’s (2016) study on genderqueer identities within the context of oppression and invisibility, and Sonny Nordmarken’s (2019) auto-ethnography. While some functions of genderqueer stigma have been identified, there is a lack of research on how genderqueer people navigate and manage such stigmas. This study provides the field of sociology with unprecedented evidence-based research on engagement in impression management from the perspectives of GQ people.Data was collected in June and July of 2023 and consists of 38 in-depth Zoom interviews, each approximately 40 minutes in length. Participants were at least 18, GQ, and living in the Los Angeles Metropolitan Area. Recruitment took place over social media and was supplemented by snowball sampling. The first cycle of coding was open, descriptive, inductive qualitative data coding, followed by a secondary cycle of focused, analytic coding. Codes were then arranged into superordinate and subordinate categories according to their typologies and taxonomies as “touchable concepts” and more abstract sociological concepts. Thematic analysis was utilized to reveal major findings. Findings include that GQ people in the LA Metropolitan Area engage in four major impression management (IM) strategies when socializing with cisgender people: anticipatory, behavior, appearance, and verbal. Participants were found to adjust their physical and verbal presentations in real-time and in preparation of interacting with cisgender people. This proposed presentation will elaborate on the conclusions of this study by explaining and providing examples of the four superordinate and seven subordinate codes that emerged from the data.

Abstract Name: The Effectiveness of Recognize, Allow, Investigate, and Nurture (RAIN) Meditation on the Subjective Units of Distress Scale (SUDS) Levels of University Students

The purpose of this project was to objectively measure the effectiveness of guided meditation on the heightened stress levels of university students. Mindfulness exercises under the umbrella of Dialectical Behavior Therapy (DBT), such as the Recognize, Allow, Investigate, and Nurture (RAIN) meditation, have

predominantly been employed to improve distress tolerance. The Subjective Units of Distress Scale (SUDS) measures the intensity of internal experiences, including anxiety, anger, agitation, stress, or other painful emotions. Despite this intuitive connection, prior empirical studies have seldom used RAIN and the SUDS collaboratively. We hypothesized that SUDS scores would significantly change over time, and the RAIN group would have the lowest final stress levels. A sample of 60 undergraduates (Mage = 23.27 years; 80% female) were recruited and placed into two groups: experimental or control. Standardization procedures included the time of day, room lighting, temperature, and question administration format. We recorded and presented an original 8 minute RAIN meditation audio narrated by a Certified Hypnotherapist. A two (group: meditation or no meditation) by three (time: SUDS) factorial design was utilized. Participants provided their SUDS levels thrice: after filling out demographics, being primed with captioned images intended to induce stress (null), and the meditation or equivalently timed class lecture. A two-way ANOVA determined a significant effect for time, a significant interaction between group and time, but no significant effect for group by itself. The results supported our main hypotheses, especially because the RAIN group had the lowest final SUDS-levels. The theoretical implications incorporated validating the effectiveness of DBT RAIN by suggesting that this therapeutic approach is effective in managing and alleviating emotional afflictions. Additionally, clinical practitioners may incorporate meditation more prominently into therapeutic interventions, especially for individuals experiencing high levels of distress.

Abstract Name: Synthesis and Evaluation of Polyaspartate Peptoid Polymers

Polyaspartic acid and its derivatives, such as peptoid polymers, have garnered attention for their potential as antimicrobial agents due to their biocompatibility and structural versatility. This research project delves into the synthesis and evaluation of novel polyaspartate peptoid polymers, aiming to unveil their antimicrobial potential and shed light on their structure-activity relationships. The primary objective is to explore the impact of these novel polyaspartate peptoid polymers on Pseudomonas aeruginosa biofilms, investigating their potential as disruptors or inhibitors of biofilm formation. Furthermore, an examination of their susceptibility to proteases aims to determine their stability and potential application as protease substrates. Central to this investigation is the comparison between peptide versions of polyaspartic acid and the peptoid versions being synthesized. Elucidating the differences in their structures and properties will provide valuable insights into the tailored design of antimicrobial materials. The study's methodology involves synthesizing polyaspartate peptoid polymers of varying lengths to evaluate their efficacy against microbial growth and biofilm formation. By systematically varying the length of these polymers, the aim is to discern the relationship between polymer structure and antimicrobial activity, thereby contributing to the understanding of structure-function correlations in these materials. The discussion will contextualize these findings within the realm of antimicrobial materials, elucidating their potential implications for combating microbial infections and devising novel strategies for antimicrobial applications. This research endeavors to advance the understanding of polyaspartate peptoid polymers as potential antimicrobial agents, unveiling their structural intricacies and evaluating their efficacy against microbial biofilms, ultimately paving the way for the development of innovative antimicrobial materials.

Abstract Name: My Body is My Life: A Journey Across Different Spaces

My body tells my story. The story begins with moving from one place to another; two different spaces mapped together with me being the connection. The co-authors and I performed our bodily practices distinctly across the different spaces we inhabited. The paper aims to unpack the complexities of our bodies and how it moves from one space to another. Some of the questions the research raises are : What is a body? How static or dynamic are our bodies? How does mobility and shifting from a space to another affect our internal and external look to our body and how we perceive it? Is that bodily act intentional or is it just a random act entrenched in the bodily routine? How do people use their bodies in a space that is censored and observed and how does the body change in a different space? When are we very aware and conscious of how we articulate and show our body and when do we lose this consciousness? The co-authors and I, through photography and cartography, are mapping our different experiences passing through layers of religion, secularization, sexuality, politics, social class, capitalism, consumer culture, and environmental changes. The research goes on to unpack different questions such as: How and in what space and context do we intend to perform particular acts of our bodies and when do we lose this intention and move to the subconscious? When does one's being become a subject of power? Is it inherently a subject of power or do we build this agency that claims this sort of power? The making and sketching of maps enables generative conversations around place and experience. I use it to make the movement between spaces in conversation with itself and to show the deep personal experience of this movement.

Abstract Name: Going Back to Nature: Comparing the Antimicrobial Effect of Miswak to Commercially Used Toothpaste and Mouthwashes

Individuals' quality of life can be influenced by oral hygienic practices. Poor oral health contributes to disease etiologies including insulin resistance, cardiovascular disease, and neurodegeneration. Oral microbiota colonization begins at birth and is usually established by one year. Over the centuries, a diversity of items have been used for dental care including chewing tree twigs, using animal bone fragments as picks, and homemade rinses. Today toothpaste, toothbrushes, mouth rinses, and dental floss are extensively used. In ancient times, Egyptians chewed Salvadora persica, also known as Miswak, to enhance oral hygiene. Miswak refers to the Arabic word for chewing stick and use of the stick is currently recommended by the World Health Organization. Chewing upon the stick frays the end to form a brush; the mechanical action of using the brush along with the antimicrobial properties are believed to contribute to the betterment of oral hygiene. Methanol and aqueous extracts have shown anti-inflammatory and anti-infectious activity in human subjects. The antimicrobial activity of Salvadora persica intact living branches and store-purchased sticks has yet to be examined in comparison to current commercially employed oral health products. In this study I am to 1) elucidate the antibacterial efficacy of Salvadora persica and 2) elucidate the antibacterial efficacy of commercially available oral hygienic toothpastes and mouthwashes. To carry out this study, I selected 16 species of bacteria and one species of yeast. I will conduct susceptibility testing using standard Kirby-Bauer disk diffusion techniques. I hypothesize that Salvadora persica will deliver greater antimicrobial activity

compared to commonly used toothpaste and mouth rinses. In the dental field, if my hypothesis is supported, this knowledge and agent could be utilized as a preventative measure against oral infections, such as strep infection, avoiding the need for antibiotic use.

Abstract Name: The Importance of Heritage Language Maintenance to Cultural Identity

Recent research indicates that heritage language maintenance plays a significant role in a person's cultural identity. However, most studies on this topic have been conducted either outside the U.S or by interviewing parents of young children. Few studies have explored the attitudes of adult bilinguals in the U.S. with respect to their sense of cultural identity as linked to their own heritage language use. In this ongoing project, we attempt to fill this research lacuna. To date, we have interviewed nine adult bilinguals with different heritage languages (Persian, Spanish, Arabic, and Mandarin). The interviewees differed in their levels of connection to their cultural communities, but all were fluent users of their heritage language. Results so far indicate that maintenance of the heritage language is seen as an important link between self and the community—especially in regard to keeping the connection with the elders and to the religious practices and cultural traditions. Furthermore, all participants indicated their plans to maintain their heritage languages in the family by passing them to their children. Given the fundamental connection between heritage language and cultural identity, we propose that mainstream public education should strive for including heritage language maintenance as a key part of the curriculum, especially in a multilingual and multicultural environment of California. Such inclusion is essential in the promotion of equitable and antiracist attitudes in the modern society.

Abstract Name: Rebel Politics: Types of Rebel Political Institutions in the Syrian Civil War

The majority of rebel governance scholarship—the study of rebel regimes—focuses on rebel groups' provision and collection of public goods, including infrastructure, healthcare, and taxation. This project contributes to the field of rebel governance by examining rebel political institutions: bodies responsible for making and enforcing political decisions. It seeks to identify and explain the types of political institutions constructed by the Free Syrian Army (FSA), the Islamic State (IS), and the Syrian Democratic Forces (SDF) between 2011-2019, and what the structures of these institutions reveal about the political ideology of these rebel groups. While the IS has been heavily studied, groups such as the FSA and SDF remain understudied.

Using a typological analysis, this paper compares the three groups, shedding light on previously marginalized cases, while simultaneously adding to the existing scholarship on the IS. The typology developed for this research includes three types of rebel political institutions: executive, legislative, and judicial. For each rebel group, one or more political bodies are identified and explained according to each type. This paper then analyzes what the structure and decision-making processes of these institutions indicate about each rebel groups' respective political ideology. In doing so, it tests existing theories of why and how rebels implement governance to begin with, ultimately confirming that ideology is indeed a key factor in determining rebel governance outcomes. Findings further suggest that rebels with more democratic institutions—such as the SDF's civilian legislative councils—have less revolutionary ideologies in comparison to rebels with institutions rooted in strict military hierarchies—such as the IS. Such revelations are crucial, in light of the fact that all three rebel groups continue to play a role in the ongoing Syrian Civil War—most notably the SDF.

Abstract Name: The Effect of COVID-19 on Student Achievement Across the US

The COVID-19 pandemic caused a nationwide school shutdown in 2020. This caused students across the country to be out of school for an extended period of time and have to navigate a new style of remote learning. This came with some drawbacks, such as low income students suffering due to not having access to online education as well as some students not receiving the support and supervision at home that they would usually receive from their teachers. Teachers were also facing their own set of challenges, such as having to adjust their teaching practices and falling victim to burnout in some instances (Miyah et al., 2020). In this study, data provided by the National Center for Education Statistics for the years 2019 and 2022 are analyzed using linear regressions to measure the effects of COVID-19 on student test scores in math and reading. The dependent variables are math and reading scores for grades four and eight, and the independent variables include student teacher ratio by state, regional dummies, and per pupil expenditures. In addition, a difference in differences equation was also created examining the impact of how each state handled the COVID-19 shutdown. State governments addressed the shutdown in different ways, which caused some schools to be remote longer than others. Preliminary results show that COVID-19 caused a significant decrease in student achievement scores. Relative to southern states, western and midwest states had a larger decrease in achievement scores. Potential policies could be developed ensuring teachers across the country are receiving adequate training as well as modifying their teaching styles to adjust to post-pandemic education.

Abstract Name: ‘Locked Out’ Broken Down: Gender-Specific Estimates of Felon Disenfranchisement

Felon disenfranchisement is the practice of removing the right to vote from those who have a felony-level criminal record. Scholars have estimated the size of the disenfranchised population overall and have documented its racialized impact alongside disenfranchisement’s consequences for election outcomes and public safety. However, previous scholarship does not account for the gender variation in disenfranchisement between states, examining gender only at the national level. We create estimates of state-specific felony disenfranchisement broken down by gender using state-level data on correctional populations (prison, felony probation, parole, felony jail) alongside demographic life tables tailored to each post-sentence state’s disenfranchisement law. Importantly, our life tables allow recidivism and mortality rates to vary by gender, thereby accounting for gender differences in the life span and reconviction over the life course. We find that, commensurate with gender breakdown in state punishment patterns, male disenfranchisement rates are higher in every state as compared to female rates of disenfranchisement. However, the portion of women who are disenfranchised post-sentence compared with all women who are disenfranchised is significantly higher than the corresponding proportion amongst disenfranchised males. We attribute this difference to the longer life spans of women and generally lower rates of reconviction, as women reach post-sentence status sooner, leave it less often through reconviction, and live longer than men. Further, states with the greatest discrepancy between male and female disenfranchisement rates only disenfranchise those currently confined to prison or jail, indicative of the greater gender disparities in incarceration rates as compared to probation and parole rates.

Abstract Name: A Systematic Review of the Impact of Stress on Young Adult Women

Stress can be a double-edged sword. On one hand, stress is unavoidable and can often be invigorating and energizing. On the other hand, too much stress can turn into a physical, mental, and emotional burden. In fact, today’s mental health crisis has become a silent pandemic in the lives of young women. In addition to “normal” stressors that we all face, young women are disproportionately affected by mental health issues simply due to all the other inherent stressors and inequalities that come with being a girl or woman in the world today. This study entails conducting a systematic review of peer-reviewed research conducted within the past 5 years focusing on stress and women ages 18-35. Issues related to risk factors, diagnosis, coping, treatment, and long-term impacts were considered. We started with citations from electronic searches and from examination of reference lists of primary review articles using mostly MEDLINE and Psych (n=~1000); retrieving full manuscripts for detailed evaluation; excluding any reviews/commentaries; cross sectional studies; stress is not the only exposure factor; etc. Information was coded, including country, year, study design, study population characteristics, total sample size, stress measurement methods of these studies, and outcome data., resulting in a final sample of 15-20 studies. We will conduct a supplemental exploratory survey about KSU women students (N=50) to compare to the results of the systematic review, especially on how mindfulness and gratitude play a role in decreasing stress. The results better describe stress among young women, particularly about the effectiveness of internal coping mechanisms as young women learn to navigate daily and long-term stressors. Considering the high incidence of reported stress as well as the complex interplay between gender and life events, this study highlights the need for additional research to support gender equality in mental healthcare.

Abstract Name: Exploring the Effect of Exosomes and Radiation on Glioblastoma Cancer Cells

Glioblastoma is the most common and aggressive type of brain cancer, with higher incidences in aging adults over 75 and little to no long-term survival or cure. The median survival time under the current standard of care, surgical resection and chemoradiation, is 15-18 months. Glioblastoma tumors consist of multiple cell types, including mature brain cells in cell cycle arrest and cancer stem cells (CSCs) that replenish cancer cell populations. Radiation induces cancerous non-stem cells into a cell fate called glioma-initiating cells, where they begin to express stem-like phenotypes. These glioma-initiating cells proliferate at an aggressive rate and are the reason for cancer recurrence, making them a necessary target for new and more effective therapeutics. This research studies the effect of exposure to exosomes, which are extracellular vesicles that carry proteins and RNA, on CSC conversion. Irradiated glioblastoma cells were exposed to varying concentrations of exosomes isolated from glioblastoma CSCs in vitro. The results showed a decrease in ZsGreen protein expression, a marker for stem-like phenotypes, as exosome concentration increased. Exposure of glioblastoma cancer cells to exosomes post-irradiation decreased the rate of transition to glioma-initiating cells. This suggests that CSC exosomes may signal that stem cells are present, decreasing the need for the formation of glioma-initiating cells. Further research is necessary to better understand the role of exosomes in glioblastoma tumors. However, this result may suggest exosomes as a potential way to delay or reduce the aggressive nature of glioblastoma cancer recurrence.

Abstract Name: Investigating Food, Greenspace, and Mental Health Access in Covenanted and Non-Covenanted Communities

Ramsey County, situated in St. Paul, Minnesota, has a long history of racial covenants in housing deeds, which has had lasting effects on resource distribution, leading to disparities in food access, greenspace availability, and mental health services. To investigate these disparities, we used visual and narrative analysis to compare the density of food access, green spaces, and mental health facilities between a covenanted and non-covenanted neighborhood. We then calculated the density of resource access per every 10,000 people. We found that food, green space, and mental health access differed between the Como and Thomas Dale neighborhoods in Ramsey County. Como has fewer grocery stores (0/10,000) and convenience stores (3/10,000) compared to Thomas Dale (4/10,000 and 6/10,000 respectively). Como has a greater density of parks (20/10,000) and mental health (11/10,000) access as compared to Thomas Dale (3/10,000 and 4/10,000, respectively). The study identifies disparities in food access, greenspace, and mental health resources,

emphasizing the need for equitable urban planning, fair funding, and community engagement to create a healthier and more inclusive future for Ramsey County.

Abstract Name: Degradation of Polyfluorinated Substances using nano Zero Valent Aluminum

Degradation of polyfluorinated substances (PFAS) has gained interest recently as PFAS is related to various heath problems and cancers, and does not break down easily in the environment. The carbon-fluorine bond makes them very strong and stable, which allows them to exist for thousands of years without degrading. The current methods for degrading PFAS are costly and require large amounts of energy. Using nano zero valent aluminum (nZVAl) to degrade PFAS is beneficial as it is cost effective and easy to synthesize. Aluminum is capable of forming plasmonic hotspots that generate an extremely large electric field enhancement, creating a small spot of very large temperature for small periods of time. This temperature is large enough to degrade PFAS without needing the amount of energy current methods require. nZVAl has recently shown to be successful at removing contaminants and soluble organic matter from water samples. PFAS degradation is monitored by LC/MS and a fluoride selective ion electrode. A 100 ppb sample of PFOS was completely degraded to below the detection limit of the LC/MS/ This method could lead to improvements of removing PFAS from the environment and can be used at water treatment centers.

Abstract Name: Investigation of Dopamine Transporter Inhibitors to Enhance the Aging Brain

Dopaminergic signaling in the human brain declines 5–10% every ten years, particularly when associated with age-related cognitive decline. Since dopamine (DA) is involved in regulating synaptic plasticity, which is important for learning and memory, reinstating DA neurotransmission should improve cognitive decline as the brain ages. Importantly, neurological deficits impair mental health, diminish productivity, and decrease social interactions; this leads to a lower quality of life and an unwelcome socioeconomic burden. Since declining brain dopamine signaling during aging is associated with the onset of neurological deficits, the search for selective dopamine transporter (DAT) inhibitors to restore endogenous DA levels and improve cognitive function is the goal of this research. Herein we describe data science experiments performed that involve mining publicly available gene expression data from microarray experiments reported in the National Center for Biotechnology Information (NCBI) Gene Expression Omnibus (GEO) repository (https://urldefense.com/v3/__https://www.ncbi.nlm.nih.gov/geo/__;!!PF9Lxw!4OtG4UGJwerYVTYhY-5dcuxwgCEZgCuPa8SllA-CYV1sRBzz8iLYrKcSfflQR1S57uCRCCh0AAvgOS_gJnSxgD_PRHngovg$). Our strategy may lead to the repurposing of a Food and Drug Administration (FDA)-approved drug to

mitigate the impact of aging on the brain. Thus far, we have uncovered two drugs that warrant further study. In addition we will report the results of ongoing biological studies of diphenylmethoxypiperidines synthesized in our lab in an attempt to uncover DAT inhibitors which show promise in increasing dopamine levels in brain regions associated with cognition.

Abstract Name: Investigating the Impact of Covid-19 Among Communities of Color

Despite continued public health surveillance and intervention efforts, there has been a differentiation in the overall impact and health outcomes across people and places in North Carolina. Communities of color (COM) (i.e., Black, Hispanic/Latinx, and Native American communities) have been disproportionately impacted by hospitalizations and deaths due to COVID-19. For example, Black North Carolinians make up 22% of the population and so far, 22% of the people who have died from severe complications of COVID-19 are Black or African American. Data indicate that Hispanic North Carolinians account for about 15% of all cases, despite making up less than 9% of the population. Data (especially data on race/ethnicity, age, gender) is critical to understanding the impact of COVID-19 across the U.S. but also to inform the appropriate response, planning and allocation of resources. Present gaps in surveillance data, point to the need for more inclusive surveillance methods and strategies. To that end, the North Carolina Department of Health and Human Services developed the HBCU Health Equity Data Consortium to assess the differential impacts of COVID-19 on COM. The project is reliant upon key partnerships to support the ongoing activities and future inclusive surveillance initiatives across the state. Participants were adult residents living in a western geographic region of North Carolina. Both probability-based and non-probability-based sampling methods were used. The survey was administered primarily as a web-based survey using Qualtrics with a number of responses collected through hard copy surveys and phone interviews. A $35 visa gift card was offered as an incentive. Surveys were collected from 3333 participants. Preliminary results will be provided in addition to lessons learned regarding community engagement strategies for data collection in historically marginalized populations. Finally, strategies for implementation processes and sustainability for the HBCU Consortium will be shared.

Abstract Name: Varied central breathing responses to carbon dioxide (CO2) in tadpoles with and without nicotine exposure

When breathing control centers in the human brain sense heightened levels of CO2, they respond by signaling for lung breaths. This response could be affected by the exposure of nicotine on the development of these regions in the brain. For this project we evaluated nerve signals from the brainstems of bullfrog tadpoles that innervate breathing muscles. Tadpoles, like humans, should increase their breathing rate in response to high CO2 (hypercapnic) environments. We are testing whether control tadpoles have the expected response to CO2 and if tadpoles exposed to a moderate amount of nicotine (30 mg/L) for 10 weeks will have the same central breathing response. Two extracellular suction electrodes are placed on cranial nerves (V & VII) in the excised brainstem from control and nicotine exposed tadpoles to measure the lung burst activity between normal (1.5% CO2) and hypercapnic (5% CO2) conditions. The expected response for control tadpoles would be an increase in the breathing rate when exposed to hypercapnic environments. We hypothesize that chronic nicotine during development will not affect normal CO2 breathing patterns but will blunt the response to hypercapnic conditions. This impairment diminishes the capacity of the body to offload CO2. An inability to offload CO2 creates a toxic state (respiratory acidosis). We are exploring the factors that could affect the expected response in the control group as well as the nicotine group. The results could indicate whether tadpoles are a good model organism to study human breathing responses. Abnormal breathing control center responses to increased CO2 could have a role to play in Sudden Infant Death Syndrome (SIDS), therefore future directions for this study could have applications in SIDS research.

Abstract Name: Numerical and Experimental Investigation of Hydrodynamic Collisions with an Air Table Apparatus

Wet particles, i.e., particles coated with a thin liquid layer, are abundant in a variety of industrial (spray coating and pneumatic transport) and natural processes (eg avalanches and mud slides). To accurately predict the bulk-scale properties of such wet granular flows, it is both interesting and important to examine the microscale dynamics of collisions between two or three spheres. In this research we perform experiments using a pendulum launcher apparatus on elastohydrodynamic collisions (both head-on and oblique) for a dry acrylic sphere impacting another acrylic sphere coated with a thin layer of silicone fluid. An air table apparatus is used to neglect frictional and gravitational forces as assumed in simulations. The problem is governed by an interplay between the particle inertia, material properties of the solids, viscosity of the fluid and the thickness of the fluid film, which determines whether or not particles will rebound after collision. The theoretical model uses numerical methods to combine lubrication theory of fluid mechanics and Newton's second law to model the collision between two wet spheres. There are two primary objectives of this investigation. Firstly, to determine the wet coefficient of restitution and how it depends on the particle Stokes number—a dimensionless number that indicates the ratio of the particle inertia force to the viscous force (controlled by pendulum). Secondly, to get quantitative agreement with theoretical models of (Davis and Sitison 2020, Davis 2023) for non-zero rebound velocities. Preliminary investigation shows good qualitative and quantitative agreement with our theoretical model including observations of all possible outcomes: stick rotate, stick rotate separate and contact bounce.

Abstract Name: Implementing Wayfinding and Color Theory into School Design to Create an Engaging Experience for Students

Current higher education facilities are outdated and hard to navigate because there isn't enough clear direction. This causes students and guests to have difficulty finding where they are going, especially in larger schools, which is a safety concern. Specific colors are shown to improve test scores, and help neural function, as well as many other things, this is why usage of color theory is important for school design. This project aims to explore how wayfinding strategies and color theory can improve the physical and mental well-being of the school's daily users. Through reviewing articles, conducting case studies, holding interviews, and touring vocational schools the agriculture learning facility was designed to enhance safety and learning outcomes by applying wayfinding and color theories. The patterns and color palettes using green, yellow, and purple were utilized in corresponding hallways, common areas, and classrooms to emphasize specific learning goals by improving comprehension, promoting problem-solving, and gathering the attention of the students. The school's colors of blue and orange are used in central areas to instill a strong sense of school pride while improving neural function, boosting creative thinking, and promoting precision and focus. The inclusion of signage that showcases which classes are down each hall helps orient users who may be color blind and therefore can't see the corresponding colors of the hallway. Clear wayfinding designs are intuitive and nonverbal to help the users access various spaces within the building. Changes in the materials and colors help to orient users in the space. Longer sightlines are implemented to encourage curiosity and exploration, which can reinforce a user's mental map of the facility. In conclusion, implementing these wayfinding and color theory techniques into the facility's design will improve the users' physical and mental well-being, which is required for a successful learning environment.

Abstract Name: Waterways as Highways: Community-Driven Urbanism at Noh K'uh and the Mensäbäk Basin

Studies on the Preclassic Maya reveal that social organization—the ways people interact and relate to each other—is often reflected by patterns of movement in the urban landscape. However, little is known about how people moved in the urban space of Noh K'uh, a Late Preclassic (400 BC-AD 250) city in Chiapas, Mexico. This paper first presents the discovery of four new archaeological features through the generation of a slope map in the Geographic Information System (GIS). Least Cost Path (LCP) analysis is then employed to reveal two key themes. First, the randomness of movement patterns on the landscape suggests the lack of a centralized approach to urban planning. In other words, there was no central authority that imposed rigid control over movement and infrastructure through the construction of a road system. Second, waterways played a key role in facilitating ancient traffic. Complementing the existing body of knowledge about Noh K'uh, LCP analysis sheds light on the existence of a corporate society that strategically utilized its urban space as a means of reinforcing communal identity and collective governance. In addition, the potential use of the water system to facilitate accessibility and social integration in the larger Mensäbäk Basin reveals a

unique approach to regional urban planning among Maya cities in the Late Preclassic, a period marked by population growth and increasing centralization.

Abstract Name: Lower extremity isokinetic assessment of a NCAA Division III swim team; comparing previous lower-extremity injury status, swimming style, and grade class

Introduction: Lower extremity muscular strength, power, and endurance have been shown to significantly contribute to swimming performance, propulsive forces of swimming, and knee pain and injury risk factors. Purpose: The purpose of this study was to determine if a relationship between lower extremity muscular strength, strength balance (quadriceps vs hamstrings) and swimming styles, grade class, previous lower-extremity injury, and gender exists. Thirty NCAA Division III swimmers of differing injury status, gender, academic class, and swimming styles completed an isokinetic evaluation of the lower extremities. Methods: The swimmers were tested for knee extension-flexion isokinetic strength at 60 degrees per second for 5 repetitions and endurance at 180 degrees per second for 20 repetitions. Results: Swimmers with knee pain or injuries prior to isokinetic evaluation exhibited lower muscular strength of the quadriceps and hamstring muscles than swimmers with no previous knee pain or injury (p=0.048, p=0.025, p=0.012). No significant differences in isokinetic performance between first-year and upperclassmen swimmers (p> .05). Swimmers of both swimming styles showed greater right quadriceps strength levels than swimmers of primarily symmetric or asymmetric styles (p=0.02), with left quadriceps muscle strength trending in the same direction (p= 0.076). Results demonstrated three athletes with > 20% difference in strength from left to right quadriceps femoris (knee extension) and five athletes with > 20% difference in strength from left to right hamstrings (knee flexion). Resolving possible issues found in the lower extremity muscle groups could lead to increased propulsion and swimming performance. Conclusion: The data found in this study highlights the need for attention to lower extremity muscular strength analysis in the potential prevention of injury, rehabilitation, and improved sports performance in a Division III men's and women’s swimming program.

Abstract Name: Piperine Reduces the Inflammatory Effects of Cigarette Smoke on Immune Cells: Implications of Multiple Sclerosis Pathology

Multiple sclerosis (MS) is a chronic inflammatory disease that affects the central nervous system, commonly referred to as the brain and spinal cord. Inflammation causes demyelination of the nerves leading to neuronal damage and disability in patients. Inflammation, demyelination, glial activation, and oxidative damage are

authenticated markers for MS. Smoking cigarettes is a lifestyle factor with severe health consequences. Smoking increases the susceptibility to developing MS and worsens the disease prognosis with severe health consequences for the general population. Cigarette smoke has over 4,000 chemicals that cause abnormal cell responses and tissue damage in the lungs, which drives pathology in MS. Our lab has shown that MS patients who smoke have elevated levels of S100 proteins in the blood. S100s are damage-associated molecular pattern proteins (DAMP), which drive severe inflammation in the central nervous system of MS patients. Black pepper (Piper nigrum) contains 5%-9% of the bioactive alkaloid, piperine, which may have neuroprotective, anti-inflammatory, and antioxidant properties. The goal of this project was to determine if piperine reverses the inflammatory effects of cigarette smoke. To test this hypothesis, we assessed piperine's in vitro effects on human peripheral blood mononuclear cells (PBMCs) cultured in cigarette smoke extract (CSE). Specifically, we cultured PBMCs with either 0%, 20%, or 40% CSE in the presence or absence of increasing concentrations of piperine. In the absence of piperine, CSE induced PBMCs to secrete the inflammatory DAMP, S100A9. Strikingly, we found a dose-dependent reduction of S100A9 by piperine in PBMCs cultured with either 20% or 40% CSE. This data provides evidence of a novel anti-inflammatory mechanism of piperine that inhibits DAMP release by immune cells induced by CSE. Our study gives cellular experimental evidence, that although it can be challenging to quit smoking, black pepper components can mitigate the detrimental inflammatory effects of smoking.

Abstract Name: The Correlation of Political Beliefs, Religious Beliefs, and Pseudoscientific Beliefs

Many types of medicine or medical treatments are considered pseudoscience, meaning that their effectiveness is not supported by scientific findings, although they may claim to influence mental and physical health. It is a common and controversial topic of conversation. Belief in pseudoscience can have a massive impact on society, leading people to endorse treatments that have no basis in science. It is our goal in the current study to analyze the correlation between political beliefs, religious beliefs, and pseudoscientific beliefs. Previous research shows Republicans as more likely to listen to their top political authorities as well as show a decline in adherence to the COVID-19 guidelines and increased belief in false information about COVID-19, which was associated with their pseudoscientific beliefs. Similarly, previous research suggests that people associated with right-wing beliefs support conspiracy theories more than their left-wing counterparts, in particular that younger right-wing males and those less satisfied in life show a high correlation in their belief of conspiracy theories. In our current study, we measure participants' pseudoscientific beliefs about various alternative and complementary medical approaches, as well as their political affiliation and religious beliefs. To collect data necessary to test our hypothesis, participants are given an online survey to complete via Qualtrics. Preliminary analyses of the data collected so far (N = 91 college student participants) suggest positive correlations between religiosity, endorsement of conservative political views, and belief in some types of medical pseudoscience. We will continue to collect data and in spring 2024 prepare a poster presentation with the goal of presenting at NCUR. We hypothesize that those who are religiously affiliated will also show stronger pseudoscientific beliefs and have a right-wing political perspective.

Abstract Name: “This green tomato does not look ready to pick!”: Children’s learning and engagement in gardening and cooking

Research has shown that gardening is an engaging activity with benefits for young children’s learning, including cognitive and social development. Using a mixed methods approach, the aims of this study were to observe children’s learning and social interactions during gardening activities in preschool and to facilitate home-school connections through a cooking activity at home using seasonal ingredients. A photovoice methodology was incorporated to gain an understanding of children’s interests and perspectives. Children used child-friendly digital cameras while in the garden and during the cooking activity at home. The participating preschool included one teacher and 10 four-year-olds, and one parent/caregiver from each household completed the informed consent and survey of typical gardening and cooking activities. Data sources included researchers’ video recordings of children’s interactions in the garden, the children’s photographs at school and home, and the parent surveys. Qualitative analyses included in-vivo coding and a “sort and sift, think and shift" approach developed by Maietta and colleagues (2021). Emergent themes from these analyses included 1) children’s inquiry and discovery; 2) interest in and knowledge of nature; 3) aesthetics and perspective-taking; and 4) social interactions. Inquiry and discovery were evident through children’s questioning, finding and harvesting vegetables, and developing agency in using the cameras. Children demonstrated knowledge of nature through identification of plants and animals (e.g., finding a beetle). Aesthetics and perspective-taking included close-up angles (e.g., a sunflower drooping in the garden or the ingredients in the cooking activity) and photographs incorporating light and shadow. Social interactions were captured in photos of cooking with parents and siblings and peer interactions in the garden. Overall, the photovoice method enabled a deeper understanding of children’s curiosity and perspective-taking. Implications of these findings for preschool teachers and families will be highlighted.

Abstract Name: How to calculate the proton rms charge radius

The proton’s charge radius is a highly contentious issue. The most accurate experimental method involves carefully analyzing a proton’s muonic orbitals. Such a system is called muonic hydrogen—where the lone electron of a neutral hydrogen atom is briefly replaced by an unstable muon. This was first achieved by Pohl et al. in 2010. The most precise muonic determination of the proton rms charge radius is 0.84087 fm, with an uncertainty of about 460 parts per million. This result was published by Antognini et al. in 2013. Prior to these muonic hydrogen experiments, the consensus proton rms charge radius was about 4% larger with an uncertainty of about 1%. This had mostly been determined by analyzing a proton’s electronic orbitals and by electron scattering experiments. The 2010 and 2013 muonic hydrogen analyses ignited the proton charge radius puzzle. In 2022, a re-analysis of older experimental electron data determined a proton rms charge radius consistent with the smaller muonic value. Even with the experimental resolution of the proton charge

radius puzzle, a purely theoretical calculation has remained elusive for over a century. This project solves this century-old physics problem. It will be shown how to perform a purely theoretical calculation of proton rms charge radius that is entirely consistent with the most accurate experimental determination. This will be done by further developing the ground-state quantum vortex (GSQV) proton model published by Verrall et al. in 2023. This ground-state model seamlessly merges with the well-established chiral effective field theory and lattice quantum chromodynamics at higher energies. It extends the standard model of particle physics without conflict and without adding higher dimensions. Polar charge-exclusion zones are a keyfeature of the GSQV proton model. This charge geometry enables proton rms charge radius to be accurately calculated from proton Compton wavelength.

Abstract Name: Biochar Adsorption for Carbon Capture and Sequestration from Local Biomass Sources Utilizing Low-Frequency, High-Amplitude Vibrational Mixing

Biochar materials provide reliable and renewable technologies for the capture of greenhouse gases such as Carbon Dioxide (CO2). Greenhouse gas emissions produced from human activities are a major contributing factor to global warming and climate change. According to the emission-reduction goals in the Paris Climate Agreement, annual greenhouse gas emissions released into the atmosphere must be reduced 45% by 2030 and eliminated by 2050. The use of Carbon capture and sequestration (CCS) processes aims to capture and store this atmospheric carbon dioxide within biological materials such as biochar. Biochar particles provide a high specific surface area to adsorb gaseous CO2 via direct air capture, but the kinetic rates of adsorption must be optimized in order to make this technology an efficient and viable solution. This study demonstrates using low-frequency, high-amplitude (LFHA) vibrational mixing of CO2 onto biochar to improve these kinetic rates of adsorption. Tests were conducted on hemp feedstock biochar samples exposed to various mixing conditions using a LFHA vibrational mixer. Variable mixing parameters included sample mass, mixing time, and vibrational intensity. Our research found that peak average CO2 uptake on the samples achieve 58% higher adsorption quantities of CO2 than previously recorded values using non-vibrational methods. Additionally, the kinetic rates measured using first-order pseudo second-order pseudo models are improved from 0.13 min-1 to 0.15 min-1 and 0.002 min-1 to 0.007 min-1, indicating the adsorption reactions take place more rapidly.

Abstract Name: Elucidating the Pathogenicity of Missense Variants in the Nucleotide-Binding and Transmembrane Protein Domains of ABCG5 Associated with Sitosterolemia

Consuming vegetables poses a challenge for individuals with sitosterolemia, a rare autosomal recessive genetic disorder characterized by heightened intestinal absorption and decreased biliary excretion of plant sterols and cholesterol. Pathogenic mutations in the ABCG5 and ABCG8 genes have been found to result in sitosterolemia. ABCG5 and ABCG8 form the ATP-binding cassette transporter protein ABCG5/ABCG8 that functions to efflux plant sterols and cholesterol from the liver and small intestine. This study seeks to characterize the missense swaps G91E, F399C, R419C, and R419G regarding level of pathogenicity. These variants were selected based on specific placement within the functional domains of ABCG5. Pathogenicity scores were compared to two pathogenic variants using Mutation Assessor, MetaLR, REVEL, CADD, PolyPhen, and SIFT. ConSurf predicted the amino acid position of each missense swap to be conserved with some being buried, structural, or exposed. Molecular dynamics simulations revealed deviation in the movement of the variants with respect to the wild-type. Our results suggest that the variants are pathogenic regarding sitosterolemia. These findings contribute to the understanding of genetic factors influencing sitosterolemia and underscore the importance of further investigations to elucidate the clinical implications of these variants for improved diagnostic and therapeutic strategies in managing this rare genetic disorder.

Abstract Name: Determining the Effect of Type I and Type III Interferons on Thymic Selection

Autoimmune diseases are initiated when the immune system mounts a response directed against host tissues. Although autoimmune diseases impact an estimated 50 million Americans, little is known about precisely how the immune system becomes dysregulated to cause disease. The thymus is an organ specialized for T cell development and selection, and plays a crucial role in generating an immune system that is safe for the host. During thymic selection, progenitor T cells with unique TCRs undergo two types of selection; positive selection functions to eliminate T cells that do not bind host MHC complexes, while negative selection works to eliminate potentially harmful T cells that recognize self antigen with high affinity. Both of these processes result in elimination of T cells with unwanted specificity through apoptosis. Curiously, interferon cytokines - which have major impacts on both T cells and antigen presenting cells - are produced constitutively in the thymus. Little is known about the effect of interferons on thymic selection. In an effort to understand how Type I (alpha/beta) and Type III (lambda) interferons impact the elimination of unwanted T cells, we utilized a flow-cytometric assay to detect apoptotic cells in mice deficient in interferon receptors. In these experiments, detection of active caspase 3 (only present in cells that are undergoing apoptosis) and CD5, a marker of TCR signaling, were used to distinguish cells undergoing positive or negative selection. We observed higher levels of negative selection in interferon receptor deficient mice than the wild type. These data suggest that thymic interferon impacts the number of cells that are killed through apoptosis during negative selection. These findings have important implications for our understanding of immune tolerance to self-antigens.

Abstract Name: INVESTIGATING THE EFFECT OF PRO-LONGED TENSILE STRAIN ON THE VASCULAR ENDOTHELIAL GROWTH RECEPTOR 2 AND THE MECHANICAL MEMORY OF ENDOTHELIAL CELLS

Recent studies have shown that vascular endothelial cells (ECs) are mechanically sensitive to strain. Vascular endothelial growth factor (VEGF) and the VEGF receptor 2 (VEGFR-2) on ECs are critical regulators of angiogenesis, which is necessary for cancer progression. Strain occurs in the tumor microenvironment (TME) because of highly contractile cancer-associated fibroblasts (CAFs) deforming the extracellular matrix. On VEGFR-2, Y1054/Y1059 is a phosphorylation site necessary for full kinase activation, while Y1214 can be activated via mechanical stimulation. Cells have a mechanical memory, which is the ability to react to a mechanical stimulus and then adjust phenotype to control future cell behavior. We hypothesize that a mechanical memory is observable via changes to phosphorylation of VEGFR-2 at Y1054/Y1059 and Y1214 when ECs are exposed to prolonged tensile strain treatment in combination with exogenous VEGF treatment. We studied this by using the FlexCell (FX-6000T) system to treat samples with cyclic strain at 9% and 0.3Hz for 0hr, 24hr, or 72hr. The strain treatment was designed to mimic CAF induced matrix distortions and respiratory rates. We utilized immunofluorescent staining and Western blotting to look at VEGFR-2 phosphorylation.The strain treatments somewhat decreased phosphorylation levels in ECs in immunofluorescence studies and Western blots, indicating the effects of strain and a strain memory can potentially alter prolonged activation of VEGFR-2. Specifically, 24hr strain treatment increased the phosphorylation levels of VEGFR-2 at Y1054/Y1059 when no exogenous VEGF was added compared to the ECs that were not strained. An observed decrease in total VEGFR-2 after 72hr strain treatment and exogenous VEGF compared to strained cells that did not get VEGF may represent enhanced activation; after the receptor is activated, it becomes internalized and degraded to prevent feedforward signaling. These results demonstrate the importance of considering the mechanics of the TME when designing anti-angiogenic therapies in cancer.

Abstract Name: Modeling Sandstorm Frequency in Africa

Sandstorms can pose significant risks to human safety. Predicting sandstorms allows authorities to issue warnings and take precautions to protect people and would allow people to take preventative measures. This research aims to implement a model to predict the frequency of sandstorm incidents. A combination of multiple factors, including wind speed and direction, temperature, humidity, and the availability of loose sand or dust, can impact sandstorms. These conditions can vary widely from one region to another and can change

rapidly, making it challenging to predict when and where a sandstorm will occur. The Sahel region experiences numerous dust events each year. Many sandstorm incidents in this region impact public health, infrastructure, agriculture, and transportation. Hence, this research is focused on the Sahel region and West Africa. Because the response variable, the monthly frequency of sandstorms, is an integer value, a negative binomial model was used to implement a count model to predict monthly sandstorm frequency. The optimal combination of predictors was selected by comparing the goodness of fit of different models using AIC. The predictors that were identified significant to predict sandstorm frequency include wind direction at 10-meter resolution, Inter-Tropical Discontinuity mean difference, dew point anomaly, wind speed 700 hectopascals, wind speed 850 hectopascals, interaction of wind speed 850 and wind direction 850, interaction of wind speed 700 and wind direction 700, and precipitation with negative impacts on the dust days, while drought index, and the interaction between wind speed 10m and wind direction 10m had a positive effect on the prediction of sandstorm frequency. The proposed model demonstrates promising results and provides a strong foundation to investigate the impact of climate factors in triggering sandstorms in North Africa. Our future research will be focused on improving this model using remote sensing.

Abstract Name: Climate Monstrosities in Native American Literature

Native American peoples have a long history of violence brought upon them by European colonizers. It is a past that has created scars so deep that its effects still occupy the lives of their ancestors. Native American writers have tended to depict the conjunction of the past and future by reflecting events that have changed the indigenous experience and existence. In science fiction’s sub-genre of climate fiction, Native American writers often choose to reflect significant historical events in futuristic writings through the depiction of monsters, or villainous beings, as allegorical figures for colonizers. The methods I used involve the research and understanding of the allegorical literary device, as it is central to the notion that these fictional characters are meant to be representative of the colonizers. I have also utilized the research of Grace Dillon, who coined the phrase “indigenous futurism,” in order to understand the history behind different forms of indigenous futurist writings, as well as the trends that seem to be displayed regarding the content and literary devices utilized. In analyzing two comics and one novel, I found that Native American climate fiction narratives are often a reflection of colonialism. The authors seemed to replicate the invasion, settlement, and destruction of the colonizers on Turtle-Island, and shift it to the future. The monsters that roam the land are visions of destruction and greed. Their objectives center around the annihilation of the indigenous peoples, and their presence often involves the destruction of the environment around them—similar to the European colonizers' timeline and intentions. However, no matter what turmoil the indigenous groups are confronted with, they always rise against the villains to victoriously take back their land and culture, usually with a woman leading the charge.

Abstract Name: The Effect of Judaism on Politics in Israel.

The project examines the influence of Judaism on politics in Israel. The Nation-State law states, “The state of Israel is the nation-state of the Jewish people, in which it actualizes its natural, religious, and historical right for self-determination.” (“Israel's Basic Laws,” 2018). Religious communities in all countries affect the government and politics, Israel is especially affected by religious communities due to the religious history of the land and the people. The data in the project will include census data, personal opinion polls, and literature covering religion and politics in Israel. Using a mixed approach allows for a broader understanding of the political climate in Israel concerning religion. Israel was created based on religion and showing the connection between religion and politics through a mixed approach will allow a more nuanced view of the country. The research could reveal a shift in the government towards theocracy rather than a democracy with an emphasis on the Jewish population as opposed to the whole population. The position of several academics is pro-Israel or anti-Israel, and I will give a nuanced conversation about the support of the Jewish people in their right to self-determination without disenfranchising the minority groups inside Jewish society and Israeli society.

Abstract Name: Microscale Fiber Alignment in Composite 3D Printing

Innovations in 3D printing of fiber reinforced composites have created great interest in both professional and hobbyist applications. In these composites, different microfiber fillers, such as glass and carbon fiber, are used to optimize tensile strength, heat transfer, impact toughness, and electrical properties, over those provided by a polymer-based filament material. This performance enhancement is most pronounced when the reinforcing fibers are aligned along desired directions, which is difficult to achieve with traditional, radially symmetric 3D printer nozzles. We propose a passive method to control fiber orientation during the printing process, using a different nozzle geometry. In particular we describe the fabrication of a fiber re-orienting modification to a traditional nozzle, which is made from single-crystal silicon using photolithography and anisotropic etching. We discuss the physics and engineering challenges involved in implementing this approach into traditional 3D printers, and the results of testing on polylactic acid filaments reinforced by carbon-fiber and fiberglass fillers.

Abstract Name: Gender Dynamics and Viewer Engagement in Professional Wrestling: A Study of Male Audience Engagement

Professional wrestling has enthralled its millions of international fans with its unique blend of athleticism and theatrical storytelling. Beneath this captivating world, complex gender dynamics in wrestling have received limited scholarly attention. World Wrestling Entertainment (WWE), a historic company notorious for its transformative impact on professional wrestling, has faced criticism for discriminatory depictions and derogatory epithets portrayed by their on-screen personalities, particularly affecting women wrestlers. The pivotal moment in addressing these issues was the 2017 Revolution of Women, led by the Four Horsewomen, a group of then emerging female wrestlers. While this watershed moment symbolized industry efforts to address long-standing gender-related problems, sexist attitudes towards women in professional wrestling persisted.This study aimed to explore the intricate relationship between gender dynamics and male viewer engagement in professional wrestling. More specifically, male engagement levels were examined during matches where female wrestlers competed against one another and matches where females acted as valets to male wrestlers (a supporting ringside role). I speculated that the young adult Black male participants would exhibit higher engagement during matches with female wrestlers. A disguised-observational design was employed. The independent variable was the role of a female in a wrestling match (wrestler or valet). The dependent variable was the engagement of two groups of young adult Black males. Thirty male college students (N=30), aged 17 to 23+, were selected using non-probability convenient sampling from an all-male HBCU institution in the American South. Participants were divided into two groups: Group A watched a female vs. female wrestling match, while Group B watched a male vs. male wrestling match with a female valet. Data collection is still in progress. This research contributes to the understanding of evolving roles of women in the industry and the ongoing challenges in achieving equality and recognition.

Abstract Name: The role of cellular antagonists in some human conditions- Cold Defense

Specialized receptors on the outside of cells facilitate temperature management in humans and a cold response(shivering and vasoconstriction) can be detrimental to their recovery. Thermoregulatory defense mechanisms of shivering occur at about 1˚ C below systemic vasoconstriction and so are considered to be a “last resort” response. If treatments can be applied that alter this level of last-resort response, this would help treat human conditions like neurogenic fever, cardiac arrest, and neonatal ischemic encephalopathy. Previous research has shown that certain agonists block shivering and cold-defense metabolic stress in rats and can induce a torpor-like response in the same species (torpor is a short-term reduction of metabolism). This study tested the hypothesis that the cold-defense threshold of the agonist molecule (N6 cyclohexyl adenosine or CHA) can be reduced. Rats were kept in temperature-controlled enclosures at 29 ˚ C with the same light/dark regimes. The next day, rats were injected with the agonist, and the temperature was reduced in increments from 28˚ C to 4˚ C. (8˚C increments from 28˚C to 16˚C and then 4˚C increments after that). Each temperature was maintained for 30 minutes. The cold defense was assessed by measuring the rate of O2 use and escape behaviors. Results show that the agonist (CHA) lowers the induced cold defense from 16°C to below 4°C. These results suggest that treatment can minimize the time to reach the target temperature without a cold-defense response (shivering and vasoconstriction).

Abstract Name: Native Sovereignty: An Analysis of the Legal Rights and Challenges of the Bad River Band Regarding Enbridge Pipeline 5

The Bad River Reservation was established in the 1854 Treaty of Lapointe. Located in northern Wisconsin, the reservation houses 500 miles of rivers and streams, as well as 38 miles of Lake Superior shoreline. The Bad River watershed has immense ecological and cultural value. It also houses Line 5, a pipeline that spans 645 miles across the upper Midwest, first constructed in 1953. The pipeline moves approximately 22 million gallons of crude oil and natural gas daily. Line 5 has been the subject of intense, meaningful environmental and tribal discourse in recent years. Opponents of the pipeline contend that the unique geography of the region indicates that an oil spill is probable, and they argue that the effect of such a spill would be catastrophic. Enbridge's proponents have strongly challenged these claims. A complex legal discussion highlighting the nature of tribal sovereignty has emerged from this conflict. The issue is currently being litigated in the state court system; however, Enbridge has posited another solution. They have proposed a relocation project that would fully remove the pipeline from the reservation borders. Opponents of the relocation project assert that while this relocation project would no longer be on tribal land, it would continue to impact the watershed. This project analyzes the legal rights and challenges of the Bad River Band. By researching the development of Anishinaabe tribal rights, environmental concerns surrounding Line 5, and precedent and jurisprudence surrounding native sovereignty, we can understand the conflict in context.

Abstract Name: The Evolution of Transatlantic Data Sharing Frameworks through Legal Challenges

After the Snowden revelations, data sharing became a contentious topic in Europe sparking a multipart judicial review of the legal frameworks governing it. This project aims to track the evolution of the EU-US data sharing policy due to legal challenges from the Schrems I and II court rulings. While prior research discusses singular cases on data privacy or sharing, this paper combines the use of both cases and the examination of the frameworks to give a more fully developed analysis of the frameworks' pertinence to EU-US data sharing. Moreover, previous scholars discussed the legality of data sharing in relation to intelligence sharing programs but never tracked the change through official legal frameworks. This paper will analyze both the Schrems I and II court cases in addition to the three main frameworks governing EU-US data sharing to look for changes and/or similarities to wording about the 7 original principles. Then, comparing the analysis from all three frameworks, this paper concludes about the legal validity and implications of the most recent framework. The legal prose of the original principles may have become more complex because of an increase of more stringent boundaries and clarity about the processing of personal data. As the world continues to develop technology, the need to share data will grow congruently with it; thus, the framework governing data-sharing between the US and the EU sets standards for both businesses and intelligence

agencies effecting security relations, the definition of privacy rights and how the American and European economies interact.

Abstract Name: Not All Asians are 'Crazy Rich': Differences in the Returns to Education of Asian Americans

For over 62 years, the model minority myth has concealed the diversity of Asian Americans in both cultural diversity and economic disparity. One of the largest issues that has been covered up is the substantial income disparity among Asian Americans. This paper delves into an investigation of labor market returns to education across five distinct Asian ethnicities, utilizing the latest decennial census data and employing Ordinary Least Squares multivariate regressions. Past research has found lower returns to education for Asian Americans compared to white people while holding for the attainment of higher education. In this analysis, an emphasis was put on Southeast Asian ethnicities, which have been under-researched in the context of Asian American economic experiences. Additionally, attention is given to Asian ethnicities positioned at the higher end of the median household income spectrum. The findings reveal compelling insights into the varied impact of higher education on income across diverse Asian groups. I find that Cambodians with bachelor's degrees experience the largest additional returns to their education. On the other hand, Japanese women who hold bachelor's degrees exhibit very small returns to their educational attainment. The benefits of attaining a bachelor's degree differ notably by ethnicity within the broad Asian category, further endorsing the importance of disaggregating data on Asian Americans to identify and address disparities. My research unveils the disparities in labor market returns among different Asian ethnicities, something that would not be uncovered with the typical analyses by race and ethnicity. This provides policymakers and stakeholders with the opportunity to bridge labor market gaps and increase educational equity amongst Asian Americans.

Abstract Name: Microwave-Assisted Synthesis of Fluorescent 8-aryl-7-deazaguanines

Nucleotides are the molecular building blocks of DNA. The aim of this project is to design fluorescent nucleotides that mimic their natural counterparts. These compounds can be used to study the structure and function of nucleic acids. Microwave-assisted conditions were adapted to our previously published synthesis of 8-aryl-7-deazaguanines via cyclocondensation of phenacyl bromides with 2,4-diamino-6-hydroxypyrimidine in refluxing 1,4-dioxane. A notable advantage of this synthesis is the ability to assemble 8-aryl-7-deazaguanines in one step with minimal work up. However, the prolonged reaction time required to

achieve satisfactory yields (24–96 hours) presents a major drawback. The aim of this study was to perform a cyclocondensation reaction of 8-aryl-7-deaazaguanines via microwave reactor to decrease reaction time. Upon microwave irradiation at 150–200°C, 8-aryl-7-deazaguanine products were obtained in high yield above 90% and within a reduced reaction time of 15–60 min. The second aim was to synthesize 8-heteroaryl substituted 7-deazaguanines not explored in our previous work and characterize via UV-fluorescence spectroscopy. Three new fluorescent 8-aryl-7-deazaguanines were produced and characterized, confirming our original hypothesis that compounds of this class are typically fluorescent, regardless of aryl substituent.

Abstract Name: Ring-opening Regioselectivity of Benzofused Cyclopropane Derivatives

Our research is focused on determining ring-opening regioselectivity of benzofused 1-arylbicyclo[n.1.0]alkane derivatives. Cyclopropanes are highly strained structures frequently used in drug development. Understanding their reactivity improves their reliable application in organic chemistry research. Our studies aim to understand how varying the ring size (n) influences the rate and direction of bond fragmentation. The target cyclopropane derivatives can be prepared by a four-step synthetic pathway. Heating these compounds in acidic conditions (AcOH, pTsOH, or HCl) induces the ring opening. Gas chromatography-mass spectrometry (GC-MS) and proton nuclear magnetic resonance (NMR) are the primary instrumentation tools for following the ring opening reaction. Our analyses track reaction progress over time and determine major and minor products for each reaction. The goal of the investigation is to optimize the conditions for these ring-opening reactions and to exercise control over the direction of fragmentation.

Abstract Name: Developing Low-cost 3D Printed Microscope for Imaging Cell-laden Droplets in a Cell Culture Incubator

Cell culture incubators provide a suitable environment for culturing cells. Many studies require monitoring cell growth throughout the incubation process. Conventional microscopes are not designed to work in the tight and moist space within an incubator. Imaging cells outside the incubator presents a challenge in monitoring the continuous growth of the same cell group. Dedicated incubator microscopes have been developed to overcome this challenge. However, these microscopes are often expensive. Our study aims to reduce this limiting factor by developing a low-cost microscope using inexpensive components and 3D printing. We tested our incubator microscope by imaging and tracking alginate droplets encapsulated with human pluripotent cells (hPSCs). hPSCs have a remarkable proliferation potential and capacity to differentiate into multiple cell types within the human organism. The incubator microscope was configured in an inverted fashion to facilitate live-cell imaging. We incorporated a tunable lens for electronic focusing. A 45-degree mirror to redirect the light towards the camera and make it more compact. Image acquisition was controlled by a Raspberry Pi single-board computer. A white LED was used as illumination source. The microscope was packaged into a 3D printed case. Waterproof tapes were used to cover gaps, minimizing the effects of the moist environment. Cell-laden alginate droplets were generated using air-jetting bioprinting technique under 4L/min airflow and with 2.0% alginate. Droplets were transferred to a 12 well-plate filled with cell culture media for cell culture and imaging. Imaging lasted for 48 hours. The incubator functioned as expected during imaging. The temperature and moisture did not seem to affect its performance. Incubator imaging showed many cell activities within the droplets over the 48 hours, including growth, division, and movement. In conclusion, we demonstrated that our low-cost incubator microscope is a viable solution to imaging and studying the growth dynamics of cells in an incubator.

Abstract Name: Using the Long Beach Wound Score as a Primary Assessment Tool to Predict Prognosis of Diabetic Foot Ulcers

Accurately assessing diabetic foot ulcers (DFU) is vital for proper wound care or intervention, however minimal assessment tools exist. This research tests the Long Beach Wound Score (LBWS), an innovative objective wound scoring system aiming to accurately assess the severity of a wound in different care facilities, including outpatient care, and inpatient care with severe cases. The LBWS seeks to provide a tool for initial evaluation of a wound and determining proper care. The LBWS consists of 5 assessments including appearance, size, depth, sepsis, and perfusion, assigning each a maximum of 2 points. A 10-point scale was generated, with 10 being the best outcome. Previous research on LBWS effectiveness for inpatients was compared to its performance for outpatients in two facilities over a 12-month period, a government facility and a private hospital. Effectiveness was measured by predicting patient outcomes at an initial assessment and the accuracy of those predictions in a follow-up appointment. After comparing initial assessments using the LBWS and actual outcome, the positive predictive values for outpatients were 94.7% for the private facility and 95.5% for the government facility. Accuracy of the assessment was 80.4% for the private facility and 80.0% for the government facility. Among different outpatient institutions, the results remained relatively equal, which was also the case when comparing the data to previous inpatient data.The LBWS demonstrated its reliability in wound assessment with high positive predictive values and accuracy. The scoring system was effective in different healthcare facilities, demonstrating its versatility. Based on results for the 5 different factors of a DFU, better management and care could be administered. After patient follow-up, the LBWS could quantify Minimal Clinical Important differences by monitoring whether the severity of wounds improves with interventions. It could also compare interventions for effectiveness, through Comparative Effectiveness Research.

Abstract Name: Exploring the role of the secondary RNA structure in the regulation of the M2-2 gene in RSV

The respiratory syncytial virus (RSV) infects the lungs and primarily affects infants, older adults, and immunocompromised individuals. However, less is known about RSV biology than other respiratory viruses like influenza. The current study aims to explore the role of secondary RNA structure in regulating the M2-2 gene in RSV. The secondary RNA structure has not been extensively explored in RSV despite the importance it may have as other viruses, like the influenza virus, have shown secondary structures to be critical to their replication cycles. Here, we hypothesized that a secondary structure 160 base pairs upstream from the M2-2 start site is critical but only in a transcript spanning from the F gene to the M2-2 gene rather than on the M2 bicistronic transcript itself. Using M-fold RNA structure prediction software suggests that the structure at 160 bases upstream from the M2-2 start is present but only in the F/M2-2 transcript and not the M2 bicistronic. Using Scan-Fold on 3000 different RSV strains confirms that this structure is not present in the M2 transcript. To confirm the prediction software, we developed four transcripts: a M2-2 with a 10 base pair upstream start site, a 260 upstream start site, a 160 base pair upstream start site, and a transcript spanning from the F gene into the M2-2 gene. Transfection studies will allow us to further determine which transcript controls M2-2 translation and followup studies using RNA SHAPE analysis are planned for further verification. Understanding the pathogenesis of this significant pathogen might provide additional knowledge to aid in the development of vaccines or therapies for RSV.

Abstract Name: How Does Past Police Discrimination Impact LGBTQ+ Psychological Well-Being at Large Pride Events?

The Gay Games were founded in 1982 to create safe spaces for LGBTQ+ athletes/spectators to gather and/or compete. While the Gay Games aim to create safe spaces for LGBTQ+, we don’t know how discrimination impacts attendance and/or enjoyment at the Gay Games. In 2023, the Gay Games are happening for the first time in Latin America in Guadalajara, Mexico, giving us a unique opportunity to examine discrimination against LGBTQ+ and its effects on psychological well-being among an under-examined population of Pride participants. Considering police presence at large events, as well as frequent discrimination of LGBTQ+ by law enforcement, tensions exist about these officers who one would believe would be there to protect LGBTQ+ events. This brings me to my research question: how is past police discrimination associated with psychological well-being among Gay Games athletes/spectators and LGBTQ non-attendees from Mexico. Using cross-sectional data from over 100 Mexican Gay Games attendees and LGBTQ non-attendees

collected in November and December 2023, I will conduct a 2-way ANOVA to determine the effects of two independent variables–police discrimination and participation in the Gay Games–on psychological well-being based on the responses from the WHO-5 scale. We expect Mexican Gay Games participants who have experienced police discrimination will be less likely to experience psychological benefits during the Gay Games than those who did not. We also expect that there will be an interaction effect where non attendees experience lower WHO-5 score, regardless of discrimination experience, compared to the other participation groups. It is expected that this research will describe how supposedly safe spaces are affected by previous experiences with discrimination. This research can show how beneficial it will be for officers to collaborate with LGBTQ+ communities in order to help create a more positive, safe environment at major Pride events.

Abstract Name: Bed Bug Movement Response to CO2 with Implications for Unmanned Ariel Vehicle Systems

In the last decade, there has been increasing research interest in the coordinated use of multi-unmanned ariel vehicles (UAVs), as modern aerospace systems recognize the advantage of networking many small and simple agents working together. Biologically inspired design has been used in the past to successfully create a variety of swarm algorithms. Previous biological research has focused on the behaviors of ants and bees. Bed bugs were proposed as a novel source of inspiration because their behaviors exhibit many of the desired characteristics of UAV swarm performance. The common bed bug, Cimex lectularius L., (Hemiptera: Cimicidae), is an ectoparasite that lives among vertebrate hosts, most commonly humans. Bed bugs aggregate based on several host attractants, with CO2 being the most attractive host cue that elicits the most movement. Bed bugs demonstrate sophisticated group decision-making while considering these criteria. Their responses to these factors can be quantified by recording their movement patterns based on a CO2 stimulus. Various CO2 concentrations were allowed into an enclosed testing arena through ports at the end of the apparatus. Responses to CO2 were recorded for individual and grouped bed bugs, based on gender and hunger status at every 305 mm within the testing arena. It was hypothesized that the collective decision-making movement process of bed bugs can be observed because their olfactory system will detect CO2 and aggregation pheromones. Preliminary results show that bed bugs that are 610 mm from the CO2 source will travel shorter distances, much faster, and with more angular movement, compared to bed bugs with no CO2 source. This research will not only help improve on bed bug behavior and pest management practices, but UAV swarm system designs will benefit from algorithms that are created from these bed bug movement patterns that will allow for better coordinated movements and decision-making.

Abstract Name: Acute Leukemia in Hispanic Children and Health Disparities in South Florida

Research has demonstrated various health disparities affecting the outcomes of Hispanic patients with leukemia including access to healthcare, socioeconomic status, incidence, and mortality. These disparities have indicated a significant negative impact on health outcomes including decreased survival, higher incidence rates, as well as, treatment-related mortality of Hispanics within the United States. The objective of this study is to assess the extent of health disparities that affect the health outcomes of Hispanic pediatric patients with AL in South Florida. The researcher intends to retrospectively analyze patient medical records from the oncologist group at XYZ Children's Hospital from 2012 to 2022 by investigating the participants and their health outcomes through 5-year survival, incident, and mortality rates in terms of treatment-related mortality. This study will be observing health disparities including insurance status, type of insurance, access to treatment as well as preventative medicine through primary care visits and socioeconomic status based on place of residence. The researcher hypothesizes that health disparities will have a negative impact on health outcomes for Hispanic pediatric patients with AL within South Florida. This study can help providers understand how health disparities affect their patients and work towards the improvement of healthcare policy to alleviate the effects that occur within the Hispanic population. Providers can also create treatment plans considering the evaluation and management of the patient's needs. These findings can also serve to help shape health policies that prevent barriers caused by social determinants of health.

Abstract Name: Impact of COVID-19 Related Anxiety in Adults with Schizophrenia

The COVID-19 pandemic has led to disruptions in daily life and heightened anxiety in many segments of society. Due to symptoms of asociality and physical comorbidities commonly associated with people with schizophrenia (PwS), PwS might be at heightened vulnerability to these pandemic-induced disruptions and anxiety. While there is potential for PwS to have increased psychological vulnerability during the COVID-19 pandemic, relatively few studies have assessed its impact and associated anxiety in PwS. Using data collected in 2021 and 2022 from a longitudinal study of PwS and non-psychiatric comparison participants (NC), we examined levels of COVID-19 related anxiety and impact on PwS and NC. Specifically, we did this by analyzing results from participants' responses on two questionnaires: the COVID-19 Impact Scale (CIS) and COVID-19 Anxiety Scale (CAS). Both questionnaires were completed by 120 participants (56 PwS, 64 NC). Our participants were closely matched on gender between groups, though our PwS sample had significantly less years of education and more participants from marginalized racial/ethnic groups than our NC sample. In ongoing analyses, using data from the same participants that completed the COVID-19 Exposure Questionnaire, we will compare the degree of COVID-19 exposure and vaccination between PwS and NC, and explore the interrelationships of anxiety, impact, exposure, and vaccination. Analysis of COVID-19 Exposure Questionnaires is ongoing. We hypothesized that PwS would have higher COVID-19 related anxiety and report greater impact than NC participants. We also hypothesized that PwS would have lower rates of exposure and vaccination than NC. Our analyses to date have shown that PwS does not have

significantly higher COVID-19 related impact based on the responses collected on the CIS; however, our analyses of responses collected on the CAS showed that PwS have significantly higher COVID-19 anxiety than NC. Results of ongoing analyses on exposure and vaccination will be presented.

Abstract Name: How Marketing Influenced the Top 20 Box Office Films 2022

Hollywood filmmaking is a billion-dollar industry, yet there needs to be new research regarding how marketing can impact box office success. This research project identified marketing themes that assisted film success and investigated how specific marketing tactics can hinder a film's success. Films that rank in the top 20 at the box office are identified as the most financially successful for that year. The goal of this research project is to identify marketing strategies that are successful at increasing ticket sales and film awareness. We identified the total domestic revenue, opening weekend figures, ratings, and themes to understand if and how the marketing campaigns were successful. Themes were identified from interviews with marketing professionals in the film industry. "Can you provide examples of successful guerilla marketing tactics used for films in 2022?" This is just one of the questions asked to help better understand trends within the top 20 box office films 2022. The goal is to have this research published in a marketing journal. By publishing this research in a journal, the discussion regarding film marketing and its potential to increase future box office revenue success can be continued. Additionally, new directions for continuing this research will be revealed.

Abstract Name: An Observational Study on the Relationship between Stress Levels and Human-Animal Bonds Based on the Perspective of People Who Have Companion Pets

The purpose of this study was to identify differences in stress levels based on the perspective of people living in the United States who have companion pets regarding human-animal bonds, aiming to investigate gaps in human-animal bond implementation in the social work profession. Human-animal bonds are formed between animals and humans through natural or ongoing interactions. The researchers conducted an online survey, shared through social media platforms, and distributed paper flyers amongst adults. Using a Likert survey design, a quantitative measure was assigned to each question, ranking the participants' experience in stress levels before and after bonding with their companion pets. The researchers hypothesized implementation of human-animal bond into the social work field as a strength-based tool could aid clients therapeutically as a supplemental component towards an established treatment plan. Relying on memory and self-report, the researchers found statistically significant differences in stress levels correlated to human-animal bonds and

stress levels. Participants who had companion pets experienced lower stress levels after bonding with their companion pets, and reported an increase of stress levels if they did not have companion pets. This research identifies key areas on the implementation of human-animal bond interventions lacking in social work practice. Universities and institutions could be interested in the data collected from the research for the consideration of applying the subject of human-animal bond as an interdisciplinary study in social work programs. Such application could include elective courses in the universities, to better prepare students in applying systematic approaches into the field.

Abstract Name: The War on Vulnerability: Feminism, Love, and Overcoming the Domination of Patriarchy

What does a society look like when our father's are abundant with love? As bell hooks' writes in The Will to Change, the value of a father's love goes up the more scarce it becomes. This dynamic props up the foundation that our patriarchal complexes come from. It forces people of all ages, all genders, to work underneath the strain of fear in hopes of capturing a shimmer of love and escaping the wrath of patriarchy. This matrix of domination forces society to uphold and perpetuate restricitve values of gender expression and identity through means of Patriarchal Survival. Through the investigation of early models of masculinity and it's curation of values such as: Avoiding Femininity, Homophobia, Restrictive Emotionality, Aggression, Non-Relational Attitudes Toward Sexuality, and Seeking Achievement and Status, the model of fear that patriarchal masculnity operates on becomes much more transparent in our everyday lives. This model thus forces us to be hyperaware of our percieved vulnerability due to risk of becoming a target of domination, shame, violence, and oppression. The history of masculinity is well-documented, but rarely thought of as a subject of importance in many feminist circles. People of all demographics engage with patriarchy, but few can identify the subliminal ways it ingrains itself in our culture, our words, and our actions. Feminist scholarship provides the opportunity for society to expand their understandings of intersectional feminism, patriarchy, and how gender solidarity can prove itself as a productive tool in achieving a truly equitable feminist society, especially when we foster the foundation for change. By examining the history of masculinity, as informed by bell hooks and Dr. Robert Levant, one can precisely learn how to identify the ways in which one consciously and subsconscioislly engages with and or promotes toxic patriarchal masuclinity within themselves.

Abstract Name: Surface Modification of Austenitic Stainless Steels

The service life of stainless steels can be extended by surface modification. In this study, a vapor deposition process was used to modify the surfaces of different austenitic stainless steels. The effect of the coating process parameters on different austenitic stainless steels was investigated. The relationships amongst the coating temperature, time and the alloy composition were the focus of this study. The microstructure and thickness of the aluminide coatings were characterized using optical and scanning electron microscopy. Identification of surface phases was carried out using X-ray diffraction. Conclusions will be drawn in regard to the relationship between coating characteristics and the stability of the austenitic steels.

Abstract Name: Legal Education for the Conservation of Urban Streams. The Case of "La Volcana" Medellín, Colombia

The research question posed is: By what legal instruments and pedagogical methods can urban watersheds be protected and conserved within the framework of Sustainable Development Goal 11 concerning Sustainable Cities and Communities? This project originates from evident pollution in streams, where the utilization of existing legal safeguards by people is not often observed, likely due to limited awareness. Consequently, a legal manual is intended to be developed to empower communities in the application of legal instruments for the defense of streams.The occupation pattern in the Metropolitan Area of Valle de Aburrá, characterized by a transition from rural to urban sectors with poorly planned human encroachments such as channeling and domestic wastewater discharge, has led to watershed contamination. This contamination poses public health risks by catalyzing various diseases while damaging ecosystems.The study is focused on the polluted La Volcana stream, prompting action from EAFIT University's Law and Environment Group. The methodology adopts a positivist epistemological lens, collecting observable facts and data through techniques inherent to the Social Sciences and Law, complemented by interdisciplinary contributions from fields like sociology, biology, and psychology.Expected outputs include the identification of contaminants in La Volcana and the creation of a legal protection manual for waterways, aiming for improved coordination between local public and environmental authorities, with replicability across other Valle de Aburrá streams. The discussion of results will take place in the context of urban environmental management, evaluating the proposed legal instruments against the Sustainable Development Goals and their transferability to other metropolitan areas. Emphasizing the symbiotic community-watershed relationship and advocating behavioral shifts towards sustainable water stewardship will be key focal points of the discussion. The overarching goal is to empower communities in the endeavor to address rampant watershed pollution through legal remedies.

Abstract Name: An EEG Investigation of Sleep Quality Memory and Executive Function.

Memory consolidation happens during both non-rapid eye movement (NREM) and rapid eye movement

(REM) stages of the sleep cycle. Inadequate sleep can impair memory processing and other cognitive functions. This experiment expanded on previous research by correlating several measures of sleep quality (rather than a single measure of sleep duration) with memory and executive function. The purpose of this experiment was to determine if 7 variables of sleep quality (subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleeping medication, and daytime dysfunction) are correlated with performance on a recognition memory task and two tasks of executive function. A second purpose was to determine if physiological markers of successful memory retrieval differ among individuals as a function of their sleep quality. Participants completed a computerized auditory or visual memory task that was divided into study and test phases. During the study phase, 256 pictures or sounds were presented one at a time and participants were asked to commit them to memory. During the test phase, studied stimuli were randomly presented with new stimuli. Participants were asked to indicate via a button press whether each stimulus was "old" or "new." EEG signals were recorded via a 32-channel Brain Vision system while participants completed the task. After the memory test, participants completed a digit span task, a trails-making task, and the Pittsburgh Sleep Quality Index. The results indicated behavioral and physiological effects of sleep quality on long-term recognition memory and executive function. The results of this study will improve our understanding of the connections among sleep quality, memory, and general cognitive ability and will allow a better understanding of the relationship between sleep and general cognitive ability.

Abstract Name: Vulnerability to Toxic Masculinity: How Politics, Employment, and Religion Relate to Men’s Gender Role Discrepancy

The present study examined men’s individual and societal perceptions of masculinity and how they relate to demographic variables. When men’s individual perceptions of how masculine they are do not line up with what they believe society’s perceptions of masculinity are, it creates gender role discrepancy (GRD). Previous research has found that GRD is positively correlated with mental illness (Macdonell Mesler et al., 2022), but what’s missing from the literature is an examination of how GRD varies across demographic groups. Through this research, we discovered how some groups of men are more vulnerable to GRD than others. This study examined individual perceptions, societal perceptions, GRD and their relation to political affiliation, employment, religion, and age. We recruited a sample of 227 people that identified as men and we distributed an anonymous online survey with questions about masculinity, mental health, avoidant coping, and demographics. After examining the data, for political affiliation, we found that Democrat men endured the most GRD compared to Independents and Republicans. We also found that Republicans individually felt the most masculine and Democrats felt the least masculine. Republican men viewed society as more masculine than Independents and Democrats. For the employment demographic, we found that unemployed men felt individually less masculine than men employed full-time and part-time. Additionally, the data revealed people who are religious have less GRD than men who are somewhat religious or have no religion. For age, there was not a statistically significant correlation for GRD, individual beliefs, or societal beliefs about masculinity. This research is aimed at uncovering which groups of men experience more gender role discrepancy and thus offers new insight into where future research should be focused to assist men who are more vulnerable to mental health problems.

Abstract Name: Competitive Female Athlete Knowledge of and Experience with ACL Injury Prevention

The rates of ACL injuries among female athletes have increased dramatically over the last decade. These injuries often require surgery and up to a year or more of recovery and rehabilitation. Furthermore, many athletes are unable to return to the level of competition they were at before their injury. Studies have shown that injury prevention programs help decrease an athlete's risk of ACL injury by strengthening the body and teaching movements that prepare the body to subconsciously react and protect itself from major injuries. However, further study shows female athletes lack knowledge of these injury prevention programs. A survey titled, Female Athlete Knowledge Base & Past Experiences with Knee Injuries was sent to college and high school coaches of female athletes ages 18 and older. Results showed female athletes have a general understanding of ACL injuries due to the injury's prevalence and the athletes' and/or their teammates' past experiences sustaining these injuries. Although these participants show knowledge of ACL injuries, the majority of subjects have never participated in an ACL IPP, and 86.2% are not currently participating in any specific ACL IPPs at all. The results from this survey can help clinicians, coaches, and athletes further understand not only the success of ACL IPPs but also the specific areas in which competitive female athletes lack knowledge or awareness. Additionally, these results can help clinicians and coaches develop more individualized prescriptions of IPPs based on what the results say about specific athletes' knowledge, understanding, and involvement.

Abstract Name: The Prevalence of Tetracycline-resistant E. coli as a Correlative to Land Usage, Nutrient Levels, and Resistance Profiles in the Blanchard River Watershed

Tetracyclines are an important antibiotic group that have been implemented in livestock, agriculture, aquaculture, and medicine since their establishment. The use of tetracyclines in human medicine has greatly decreased in recent years due to the development of resistance, but tetracyclines remain one of the most used antibiotics in livestock production. There is evidence of a significant association between tetracycline consumption and the presence of tetracycline-resistant E. coli isolated from livestock. These resistant microbes are harbored within the livestock but also released into animal fecal waste. With current fertilization practices as well as continued issues with leeching in watersheds, there is a need to monitor in vivo aquatic systems, especially those in agricultural areas, not only to monitor the prevalence of tetracycline-resistant E.

coli but also to develop more succinct and effective monitoring and management guidelines. The Blanchard River serves as an excellent model system suitable for monitoring antimicrobial-resistant microbe sustainability within a highly agricultural area that serves as a contributor to the Lake Erie basin. Previous research has determined that the river provides a suitable habitat for antibiotic-resistant microbes including tetracycline-resistant E. coli as all 116 sampling sites harbored resistant populations. Four AOCs (Areas of Concern) were identified to harbor multi-drug-resistant microbes including MRSA and tetracycline-resistant E. coli. These AOCs were tested to determine correlations between land usage, nutrient levels, and resistance profiles.

Abstract Name: Study of the effect of ionic liquids in plant DNA extraction

High-quality plant genomic DNA extraction is a crucial component of plant biomolecular analyses such as genotyping, sequencing, mutation screening, and plant pathogen detection. Conventional plant cell lysis and DNA extraction methods require large amounts of plant sample mass, which is not feasible in DNA analysis of rare, native plants and plants with high archeological importance. The miniaturized matrix solid-phase dispersion (MSPD) approach featuring ionic liquid (IL) and magnetic ionic liquid (MIL) solvents is a simple and rapid method that was developed to isolate genomic DNA from milligram fragments of plant tissues. The MSPD approach shows advantages in applications such as forensic science, early detection of plant pathogens, and phylogenetic studies involving ancient plants, highlighting the significance of expanding this approach. The IL and MIL solvents used in the method play a major role in this approach's success, particularly for plant tissues rich in polyphenols and polysaccharides such as Lemon balm and Bur oak. It is hypothesized that the chemical structure/composition of the solvents affects DNA extraction and enrichment, as the cation component of the solvent directly interacts with the DNA during dispersion using the MSPD approach, and the anion affects qPCR, which is used for quantitative and qualitative DNA analysis. qPCR compatibility was tested by carrying out reactions for plant genomic DNA with a series of ILs from a training set, and the trihexyl(tetradecyl)phosphonium bis(trifluoromethylsulfonyl)imide ([P6,6,6,14+] [NTf2-]) IL by comparing their cycle of quantification values. Successful amplifications for the tested hydrophobic ILs suggest that they are qPCR compatible, and further optimization will be carried out for hydrophilic ILs. This project seeks to identify the mechanistic variables of IL cations and anions that give rise to DNA enrichment and permit the solvents to be compatible with direct qPCR analysis.

Abstract Name: The “Same Old Shit”: Seeing Jean-Michel Basquiat’s Artworks Through His Black Vision

Ancestry and skin color tell artists they are African Americans, but what about their art signals it as uniquely African American? My essay explores Jean-Michel Basquiat's artwork and pinpoints what makes his creations African American. I investigate how Basquiat, emerging from the street art scene with SAMO©, rose to prominence in the art world, challenging societal norms and addressing prevalent issues like capitalism, racism, and police brutality. Delving into Basquiat's prolific career, my analysis focuses on key paintings such as Irony of Negro Policeman, King Zulu, and Riding with Death to unravel the artist's distinctive perspective as an African American creator. The assertions of Black writers such as W.E.B. Du Bois and Henry Louis Gates, Jr. are the lenses through which I interpret Basquiat's works. Basquiat uses African American rhetoric such as irony and signifyin(g) to address societal contradictions and racial complexities. His struggle with double-consciousness and artistic double aims enable his art to showcase the Black creator's dual struggle to create and elevate his race in a predominantly White society. My analysis also examines Basquiat's foreshadowing of his untimely death and draws parallels with other influential Black figures who prophesied their own demise. Examining multiple aspects of his artistic endeavors, my essay underscores the enduring relevance of Basquiat's messages, emphasizing how each work serves as a timeless reminder of the persistent challenges in racial relations.

Abstract Name: Investigating somatosensory innervation of adipose tissue

Upward trends in the prevalence of obesity and type 2 diabetes have underscored the need for research aimed at enhancing our understanding of adipose tissue. Adipose tissue plays a key role in maintaining whole-body metabolism and communicates bidirectionally with the central nervous system (CNS). Conventionally, the brain-fat crosstalk involves sympathetic fibers of the CNS sending efferent signals and adipose tissue communicating its metabolic state to the brain by secreting hormones. Although sympathetic innervation of adipose tissue has been extensively studied, due to a lack of specific manipulation tools, the presence and physiological relevance of somatosensory innervation from dorsal root ganglia (DRG) remains controversial. To address this challenge, we developed viral and imaging strategies to manipulate sensory nerves in an organ-specific manner. By visualizing the entire axonal projection from DRG soma to subcutaneous adipocytes, we demonstrated that adipose tissues have robust sensory innervation. Functionally, selective ablation of these neurons enhanced thermogenic and lipogenic transcriptional programs in fat, suggesting that sensory innervation acts as a brake on sympathetic activity. Furthermore, we have shown that subcutaneous fat receives abundant innervation from Piezo2-expressing neurons. Interestingly, Piezo2 loss of function recapitulates transcriptomic changes observed in ablation of fat-innervating sensory neurons. Our work challenges the canonical view that afferent signals from adipose tissue are primarily mediated by secreted hormones and motivates further research about somatosensory innervation of fat.

Abstract Name: Investigation of Attention Bias Variability in Social Anxiety Disorder

Attentional bias (AB) towards threatening cues has been studied as a primary cognitive mechanism of social anxiety disorder (SAD). However, research shows varying results for AB, raising the question whether AB is a static phenomenon. In recent literature, a concept of Attention Bias Variability (ABV) was proposed to explain the dynamic and fluctuating nature of AB towards and away from threat. A few studies have found that ABV was linked to anxiety-related disorders, but little is known about the relationship between ABV and SAD symptoms. This study investigated the link between SAD symptoms, AB, and ABV. Based on a diagnostic interview, participants were divided into a social anxiety disorder group (SAD), or a non-socially anxious group (NSA). Participants completed self-report questionnaires, as well as a dot-probe task with pairs of neutral and threatening facial stimuli. AB indices were calculated using the conventional method, and two recently developed ABV computation methods. An independent t-test was conducted to compare variables between groups. A Pearson's correlation analysis was conducted to examine the relationship between AB(V) and SAD symptoms in each group. Results showed that individuals with SAD displayed higher attentional vigilance toward threatening stimuli compared to the NSA group. Although ABV scores were not significantly different between groups, ABV indices showed differing patterns of association with SAD symptoms across groups. Naim et al. (2015)'s ABV index score was linked to SAD symptoms (e.g., fear of negative evaluation) in the SAD group, whereas Zvielli et al. (2015)'s index score was associated with anxiety sensitivity for social situations in the NSA group. Findings indicate that the sensitivity of ABV in associating with SAD symptoms may vary depending on the ABV computation method and diagnostic status of SAD. Further research is required to replicate the current findings and identify the most reliable method to compute ABV.

Abstract Name: Mechanisms of Breast Cancer Cell Death by Mammalian Orthoreovirus

Estrogen receptor positive (ER+) breast cancer is one of the most commonly diagnosed types of breast cancer in the United States and can recur and metastasize 10-20+ years after initial diagnosis. Novel therapeutic strategies are needed to prevent recurrence and metastasis. A possible solution is mammalian orthoreovirus (MRV), a replication-competent natural oncolytic virus. The mechanisms of MRV-induced death are not well elucidated. Our studies aim to explore the different cell death pathways elicited by MRV, and our goal is to explore the effects of MRV in the ER+ breast cancer cell line MCF7 using inhibitors of apoptosis, necroptosis, and the NFκB pathway. We have studied the effects of different inhibitors using cell viability assays and western blotting. Our preliminary results indicate MRV promotes apoptotic cell death in MCF7 cells and that IKK inhibition enhances MRV-induced cell death. Our ongoing research aims towards testing different doses of inhibitors and adjusting the time course experiments in our cell viability assays. Furthermore, we are performing cell fractionation experiments to understand how MRV affects the NFκB

pathway using cytoplasmic and nuclear extracts. We anticipate these results will provide insights into the pathways associated with MRV-induced death.

Abstract Name: Ketamine-Assisted Therapy and its Accessibility to Communities in Georgia

Ketamine therapies, clinics, and resources are unobtainable to those most in need of their potential benefits due to the barriers of price, availability, and clinic location. This is proven through the recent ketamine drug shortages, the biased locations of ketamine clinics in high-income areas, and the excessive costs of ketamine. Demographic and geographic data has been collected from ten ketamine clinics to compare the greater access that certain communities have over others in the state of Georgia. The research techniques used are the collection of quantitative data and qualitative data from clinics in Georgia to analyze ketamine costs and treatment protocols in the context of geographic and demographic information. In addition, a rhetorical analysis of ketamine patent products will be conducted to further illustrate the presence of barriers associated with limiting access. When research is completed, it is expected that communities in most need of ketamine treatment will be excluded through its inaccessibility. This research will bring awareness to the effects of ketamine shortages and its impact on many communities in Georgia and beyond.

Abstract Name: The Myth of “Beauty”

Some say that beauty is in the eye of the beholder. But what happens when the beholder is not in control of the definition of “beauty” prescribed to them by mythologists? Major brands in the beauty market reinforce the theory outlined in Mythologies by Roland Barthes through advertisements that signify an underlying message of what beauty should be to sell their products. This essay explores how Barthes’ theory of myth can be used to evaluate the beauty industry. Previously, the beauty industry was mainly directed toward women exclusively. The author proposes that stagnant perspectives of gender in the beauty industry are based on societal views of the terms “woman” and “beauty” which had at one point fallen victim to becoming myth when a new level of signification was added. Slowly but surely, the beauty industry is becoming more inclusive as old myths about who can participate in the industry are changing along with definitions of beauty. The author of this paper explores how Barthes’ theory of Mythologies is present in the beauty industry at different levels. These levels include looking at how advertisements focus on specific products and the myths they create, how the concept of “beauty” is itself a myth, and lastly, how the concept of “woman” is a myth. Each of these ideas are reflections of how Barthes’ theory of myth pervades all aspects of culture and how certain myths are interconnected. The author also argues for the importance of educating the public about how myths can be used to sell products in the beauty industry.

Abstract Name: Fun with Foods Nutrition Intervention with Mr. Blaine's Summit High School Class

Project Purpose: The central purpose of our intervention was to improve the nutritional knowledge, self-efficacy to make healthy dietary choices, and sense of community connectedness of our target population through evidence-based interactive, educational, and observational activities.Background: Our intervention targeted students at Summit High School in Flagstaff, Arizona, to increase their nutritional knowledge. Nearly half of students in our target population come from low socioeconomic backgrounds, which increases their risk of food insecurity. Food insecurity is linked to poor health outcomes, such as depression, cognitive development problems, anemia, diabetes, obesity, and hypertension.Methods: We worked with students in Mr. Blaine's physical education class at Summit High School over a 3-day period in which we spent an hour and a half with them each day. Our main activities included a nutrition education PowerPoint on day 1, a Jeopardy game on day 2, and on day 3, a cooking demonstration accompanied by a mindful eating exercise, as well as distribution of the class cookbooks that our team curated using meaningful recipes provided by the students on day 1.Conclusions: We evaluated the effectiveness of our intervention by conducting pre- and post-intervention surveys via Qualtrics and a game of Kahoot to measure learned knowledge. Of the 5 students who participated in both the pre-and post-Kahoot activity, we calculated an average increase of 32.5% in nutritional knowledge. Of the 8 students who completed the pre-and post-intervention Qualtrics surveys, participants scored 60% or higher regarding community connectedness and self-efficacy. An implication from these aspects of our research is that overall nutritional knowledge, self-efficacy in making healthy dietary choices, and a sense of community connectedness increased over the course of our intervention.

Abstract Name: The Right to Sex (Education): The impact of Christian activism on Constitutional religion clause jurisprudence through sexual education

When Dobbs v. Jackson overturned Roe v. Wade in 2022, questions of reproductive autonomy at the Constitutional level became more critical than ever, including the question of teaching reproductive health in public schools. This research seeks to understand the influence of Christian activists on sexual education in American public schools and any implications on the interpretation of the religion clauses in the United

States Constitution.I will begin by constructing a historical understanding of both Christian beliefs around sex as well as the developement of the sex education movement. Through this method, I will be able to contextualize the eugenicist and homophobic roots of both the early Protestant sex education movement and the later Evangelical Christian abstinence-only sex education movement to emphasize how these ideologies are reinforced by any relevant federal policies and jurisprudence throughout the 20th century. I will conclude the historical background with the 1996 Social Security Act, which has since granted over two billion dollars in federal funding to Evangelical abstinence-only sex education programs in public schools. I will then analyze a series of Supreme Court cases dealing with sex education and the religion clauses in public schools through the historical lens of the sex education movement and Christian activism.I hypothesize there will be a visible shift in the late 20th century interpretations of the First Amendment religion clauses. I will track this shift through today to create a framework for understanding how future sex education cases may be handled as a result of the existing jurisprudence. Finally, I will argue that the jurisprudence discussed in this research codified the pathologization of any non-White, monogamous, heterosexual sex, shaping an exclusionary Constitutional personhood and created a Christian religious super-right.

Abstract Name: From Honeybees to the Feasts: The History of Mead

The History of Mead is complex for such a simple alcohol made up of only honey, water, and yeast. Despite its simplicity, mead has been an important drink throughout Eurasia as early as 7,000 B.C.E. Through its age and use of natural fermentation, historians are still unsure on its origins due to the theory of multiple discoveries and knowledge transfer through multiple civilizations. Through its presence, mead was used for survival, religion, culture, and class in its respective locations and time. People of the Neolithic used the drink to satisfy their sweet tooth and enjoy. Classical Civilizations believed it to be mysterious and as the 'nectar of the gods'. Vikings and Celts also saw mead as the drink of the gods, and had grand feasts within their mead halls. Anglo-Saxons would write poetry of mead and battles. Ancient Indian Civilizations would write them in their old sanskrit texts. The Welsh used mead as a symbol of their people and nation in the creation of the United Kingdom. The British would lastly use it as a way to display wealth and class through recipies such as those from Sir Kenelm Digby. Today, mead is still easily acceptable and made, with myself creating three batches of regular mead, vanilla mead, and cinnamon mead and having others taste test the drink. Mead has remained steadfast in its use through the ages and will remain as the drink of the gods and the drink for the people.

Abstract Name: Historical Perspectives on the Treatment of Mental Illness at Rochester State Hospital

This project investigates the institutional treatment of mental illness in the late 19th century by examining untapped manuscript patient records on patients who died during their treatment at the now-defunct Rochester State Hospital (Minnesota). More broadly, the study sheds light on the state of mental diagnosis and therapy during the custodial phase of mental hospitals in the United States. We analyze the digitized archival sources, looking for particular themes and terms and place them in a broader historical context. This document analysis focuses on what these patient cases tell us about the era and similarly what presumptions and viewpoints about mental health are embedded in the documents. Additional published primary sources including superintendent reports and newspaper articles help crosscheck and contextualize the manuscript material. While the Minnesota Historical Society in St. Paul, MN contains hundreds of these patient records, we have limited our scope by focusing on the 76 patients who died during their treatment and were buried in a cemetery whose location is still unknown. In sum, this study contributes to historical understanding of the treatment of mental illness in the United States on the basis of patient records from the 1880s; it gives voice to the "lost" patients and potentially ignites interest in finding their gravesite and honoring their lives; and it could inform ongoing debates about the merits of community-based mental health care versus inpatient hospital care.

Abstract Name: "Why did he do it?"–A Look at Rape Myth Acceptance and Media Influences

There is an obvious tie between rates of rape myth acceptance and the rates of rape and sexual assault. Because of this, an importance has been placed on discovering why these rape myths exist and what can be done to combat them. The aim of this project is to evaluate the influence of media on rape myth acceptance, and whether there is a significant effect in the way women are presented and perceived on how willing people are to accept, or reject, victim blame ideologies. This type of study has been done in the past, but with the ever changing political and social environment in the United States, continued research and discussion on this topic is crucial. This between groups experimental design aims to analyze the relationship between media exposure (music videos) and rape myth acceptance, as well as the influence of sexual conservatism and sexist beliefs on the acceptance of rape myths. Participants will be exposed to one of four music videos: two of the videos illustrate either benevolent or hostile sexist beliefs, one displays women in an empowering way, and one is a control. Data collection began on October 31, 2023 and is ongoing. Data collection will be completed and analyzed by the time of presentation.

Abstract Name: Nailing the Business: Intergenerational Influences of Vietnamese Manicurists in Orange County

My research brings into focus the immigrant niche of Vietnamese women in the nail industry, specifically within Orange County, to explore how Vietnamese perceptions of gender and culture affected their domination of the nail industry throughout generations. It examines different intergenerational perspectives and factors influencing first, second, and third generations of Vietnamese-American women following this career, especially because younger generations in the business are more likely to be American-born with different opportunities compared to previous immigrant generations. This study contributes towards understanding the development of Vietnamese communities in the US and Vietnamese cultural perceptions of gender and labor shaping this ethnic niche. I study these experiences through conducting oral history interviews with two nail salons in Orange County's "Little Saigon," as well as one nail salon school in the area, to find various intergenerational perspectives and backgrounds related to the nail salon industry. These interviews cover questions related to Vietnamese perceptions of gender roles and work experience in shaping this ethnic niche, and examine Vietnamese women from different age groups and levels of the nail salon, including owners, technicians, and customers. Commonalities in interviews with older generations included being more raised by Vietnamese cultural emphasis on nail work being a flexible, simpler career fulfilling a "woman's role" to allow women to come home and take care of family, while results with younger generations included the prevalence of nail schools and salons within Orange County and its prominent Vietnamese population provided a familiar and accessible means of earning money.

Abstract Name: Battery As iNtegrated Structure High Endurance Experimental UAV, Robotics

The current state of Unmanned Aerial Vehicles faces a critical challenge that limits the ability for extended flight times. Drones relying on electric power sources must pause their flight to intermittently recharge, resulting in disturbance of their ongoing mission and extending their mission time drastically. To enhance the flight and mission duration of UAVs, developing a quick-charge power station will provide extensive flight time and eliminate long charging disturbances during ongoing missions. Our solution to reduce UAV's mission time is designing the Robotics Ground System (RGS), which provides a safe location for the drone to autonomously land and have its battery swapped efficiently compared to basic charging hours. Powered with renewable energy, the system creates a solution to lengthen the flight endurance of drones. The design of the RGS consists of three sub-systems: Ground Control Station (GCS), Battery Vending Machine (BVM), and Battery Transfer Pod (BTP). The GCS is designed with 7x7 AR modular blocks that the drone's camera will detect to land. Once landed, the robotic arm from the BTP will autonomously extract the battery from the drone, traveling on a short rail to relocate the battery to an open chamber on the BVM. The BVM, which can store up to 8 different Li-Po batteries, will rotate its carousel to dispense a fully charged battery for the arm to

grab and return to the stationed drone. This process reduces the drone's mission time by eliminating long hours of charging by replacing batteries within 2-minute intervals. With shorter mission times, drones complete tasks for society quicker and more efficiently.

Abstract Name: Hot Electron Chemistry on Bimetallic Titanium Nitride Core-shell Nanoparticles

The increase of CO and CO2 pollution has become a prevalent global climate issue. CO pollution can be mitigated by converting CO or CO2 into CH3OH (methanol) through catalysts. Plasmonic photocatalysis can be used to assist in creating green fuels. Our plasmonic photocatalysts are bimetallic transition metal core-shell nanoparticles. These nanoparticles' unique optical and catalytic properties contribute to their photocatalytic abilities that efficiently generate hot electrons for use in excited state chemistry. This project focuses on bimetallic core-shell nanoparticles with Titanium Nitride (TiN) as the core metal. As of now, ruthenium (Ru), rhodium (Rh), and nickel (Ni) have been used as the shell metal. The TiN/Ru and TiN/Rh nanoparticles (NPs) are synthesized using reflux reactions, washed using a centrifuge, and characterized using Scanning Electron Microscopy (SEM), Energy-dispersive x-ray spectroscopy (EDS), Transmission Electron Microscope (TEM), and Ultraviolet Absorption Spectroscopy (UV-Vis). Characterization of the synthesized bimetallic core-shell NPs depict favorable size, shape, and elemental distribution. The photocatalytic efficiency of the bimetallic core-shell NPs will be assessed through the combustion of oxygen and CO oxidation and hydrogenation reactions using a reactor chamber equipped with mass spectrometry and Raman spectroscopy in the near future. Through the use of bimetallic core-shell nanoparticles, we aim to understand their properties and use these promising catalysts to assist in creating renewable fuel.

Abstract Name: Developing a Population Frame of Ranked-Choice Voting in the US: Preliminary Analysis and Methods

Our research delves into the evolving landscape of ranked-choice voting (RCV) in the United States, aiming to address a lack of consistent and comprehensive data on RCV elections. Much current research on RCV elections focuses on individual races or jurisdictions rather than comparing the nature of RCV elections nationwide. To address the lack of data and analysis of RCV elections, we constructed the first complete population frame of RCV elections in the US. From this pool, we collected detailed data on a random sample of RCV elections, offering detailed insights into variables like rounds, candidates, and ballot order. Our methodology involved meticulous examination of sample ballots, official results, news reports, and election

codes to determine election format and data reporting practices. Our analysis reveals that only about 35% of RCV elections necessitate more than one redistribution of votes, challenging the assumption that RCV consistently leads to multi-round contests. Notably, we identify a robust relationship between the number of candidates and the rounds required, suggesting strategic implications for campaigns in RCV elections.The study also underscores the challenges associated with collecting comprehensive data on RCV, exposing reporting inconsistencies and highlighting the need for standardized election data reporting methods across the US. We advocate for the establishment of national RCV standards to enhance transparency and accessibility in data reporting. We also evaluate our proposed method for consistently counting RCV rounds based on the number of times votes are redistributed between candidates. By creating the first complete population frame of RCV elections in the US, and offering a comprehensive analysis of our data, we provide valuable insights into the dynamics of RCV contests. As RCV gains prominence, understanding its implications for democratic processes becomes imperative, making this study a crucial step towards more informed public policy.

Abstract Name: Advancing Golgi Isolation Techniques in Postmortem Cortex for Enhanced Precision in Schizophrenia Research

Schizophrenia is a severe psychiatric disorder associated with high rates of disability and early mortality. One of the major molecular findings in postmortem schizophrenia cortex is the disruption of protein modification and trafficking to the synapse. The Golgi apparatus is imperative in protein modification and transportation, making it a key focal point for studying disrupted cell processes in schizophrenia. However, the most commonly used methods in cell fractionation fall short in achieving optimal Golgi isolation. Our research explores the optimization of Golgi isolation in postmortem dorsolateral prefrontal cortex brain tissue by transitioning from a previously unsuccessful standard cell fractionation protocol to an immunoprecipitation method utilizing magnetic beads. The aim is to achieve separation of Golgi from other cell constituents, enhancing the purity of Golgi fractions. In the past, markers pertaining to the Golgi appeared in the same fraction as synaptic markers when analyzed, leading to an investigation into the usefulness of alternate approaches. Immunoprecipitation using magnetic beads with attached antibodies recognizing transmembrane proteins specific to the Golgi has been successful in isolating Golgi in previous animal studies. Our current goal is to translate this approach for studies involving human postmortem brain tissue in conjunction with our previous cell fractionation approach. The efficacy of this approach will be assessed through western blot analysis measuring markers of Golgi and other cellular components in order to provide insights into the successful isolation and identification of Golgi-specific proteins. This methodological shift holds promise for advancing cell fractionation techniques in human postmortem brain tissue, offering improved precision and reliability in Golgi-related studies.

Abstract Name: Why sex matters with climate change: Eco-physiological difference between sexes in a sexually mobile plant species

Climate change has led to increased temperatures, heavier precipitation, more frequent and severe droughts, and abnormal heating and cooling events. All of these add stress to plants. Previous research has shown that the added stressors more adversely impact plant species with separate sexes. Many separate-sexed plants are agriculturally important, including cannabis, spinach, ginkgo, and asparagus. Understanding how the different sexes function may help us predict how climate change may impact males and females differently. To do this, we study a plant species known as striped maple. Striped Maples are mainly separate-sexed trees, native to northern Michigan, an understory species, and have environmental sex determination. (ESD) Environmental sex determination means each plant in the species has the genetic information to be male and female and a cue from the environment dictates which sex is expressed. Individuals may change sex from year to year based on these environmental cues. These attributes above make striped maples a perfect study species to examine sex-based differences in physiology. We traveled to five field sites in northern Michigan and took demographic information on more than five hundred trees. For over a hundred of those trees, we measured photosynthetic rate, growth, stress levels, and light exposure to look for physiological differences between the sexes. Notably, this lab has found females have significantly lower growth rates and photosynthetic rates than males and trees that are not flowering. These data are consistent with the idea that there is a substantial cost to reproducing as a female, suggesting that females may be disproportionately affected by climatic stressors. As female is the preferred sex in many separate-sexed agricultural species (e.g. hops, holly, and kiwi, among many others), we might expect these crops to be negatively affected in the coming years.

Abstract Name: TellX: Disaster Response Drone

In times of crisis after an earthquake, many search teams do not have the manpower or time to go through the rubble efficiently enough to rescue initial survivors. Some people may survive the beginning tremors but be stuck under debris and die before they are found. This has been the case for hundreds of people in earthquakes recently, such as those in Morocco and Turkey. Our drone helps search, identify, and pinpoint survivors and communicate with rescue teams to begin the operations that will end in the victims' discovery and recovery. Our project uses the Tello drone[1], which connects to the user's electronic device via Wi-Fi. Our drone is able to fly to locations that have been affected by an earthquake and take a quick stationary aerial glance at the situation. Any movement will be detected by the electronic device. It will then fly to that specific area and use its image detection to see if there is a person stuck there. If there is, it will send a message with a GPS pin back to the electronic device, which then notifies the rescue team of the location of where to look. It will also send a picture of what the drone detected to be reviewed by people of the research

team, ensuring there are minimal false positives. If there is not a person there, it will continue its search. Due to its small size and ability to get both aerial and ground views, the drone can search rubble that human search teams are not able to search. Our poster demonstrates the functionality of the drone in simulated destroyed areas.

Abstract Name: Suicide Rates and Risk Factors in Yavapai County, Arizona: 2017 through 2023

Suicide mortality rates in Yavapai County, Arizona are almost double that of the rest of the state and over double that of the rest of country. This study collected mortality data from January 1, 2017 through July 1, 2023 and examined it for trends to determine at-risk demographics. Mortality data was primarily collected from the Arizona Department of Health Services and population data was collected from the 2020 U.S. Census. After collection, data was analyzed for applicable trends, including what percentage of total decedents comprised specific demographics and which demographics were more likely to commit suicide.A total of five hundred and forty-two (542) decedents were reported in the time frame. It was found that most decedents were male, over 55 years old, and committed suicide with a firearm. The next most common methods were suffocation and poisoning. While veterans did not compose a majority of decedents, they were found to have a higher rate of suicide than non-veterans. Veterans make up around 11% of Yavapai County's population but were around 26% of suicide mortalities.There were no obvious trends based on the time of year, and outside of a small increase in suicide deaths in June 2020, there did not appear to be any obvious connection between the COVID-19 pandemic and overall suicide rates in the county. During 2020, however, there was both an increase of suicide of people aged 25 to 34 and a decrease in people aged 55 and older. While the increase of suicide mortality rate in younger demographics may be attributable to stressors of the pandemic, the reason for the decrease of suicide mortality rate in older demographics is unclear. Further research recommendations include expanding the timeframe of the data and obtaining data on more demographic categories.

Abstract Name: Impact of Ocean Acidification on the Foraging Behavior of Mud Snails

Mud snails are important and abundant scavengers in soft-sediment habitats along the Atlantic coast. They use their chemosensory abilities to detect food cues, but it is possible that this ability will be diminished by ocean acidification in the near future. Acidification affects cue-sensing ability of some fish and invertebrates (while others are relatively unaffected), and previous research found that mud snails struggled to sense

predators in acidified water. This study investigated the foraging behavior of mud snails under increasingly acidified conditions. Time lapse photography was used to observe snail movement as they searched for food under control and acidified conditions. ImageJ was used to track the snails, map their routes, and calculate their foraging efficiency. This method allowed us to visualize foraging behavior and observe ocean acidification impacts in a new way. Contrary to what we believed, the mud snails were more efficient under acidified conditions. However, they also moved at a slower rate than the control group. It is noteworthy that the differences in foraging efficiency between the acidified and control group was very small along with the differences in speed. Our findings suggest that the foraging behavior of mud snails will change slightly under more acidic conditions, however there may need to be a larger drop in pH for them to significantly alter this behavior. If snail foraging is reduced under future ocean conditions, it could lead to a shifting ecological role for this abundant gastropod.

Abstract Name: What is Equity-minded Active Learning?

The Teaching Equity-minded and Active Mathematics (TEAM) Tool is a research-backed classroom observation tool used to aid instructors in reflecting on their instructional practices towards adopting more equitable and active learning strategies into their classroom instruction. Given the increased calls for active learning and equity-minded instruction, our research team inquired about how faculty actually define the two terms and what teaching strategies they used to enact equity-minded active learning in their classrooms. In this poster, we share the reported definitions and strategies from one-on-one interviews of mathematics faculty members who have all expressed a desire and commitment to greater equity and active learning in their classroom instruction. We compared faculty's reported definitions and strategies to the teaching practices and strategies defined in the TEAM Tool. While over half of the reported strategies overlapped with the teaching practices listed in the TEAM Tool, seven of the eight TEAM Tool strategies that were not mentioned by the faculty related specifically to equity-minded instruction. This may indicate that the active learning strategies may be easier to enact than the equity-minded strategies. In addition, faculty reported strategies that were not represented on the TEAM Tool. Our findings indicate that we can continue to improve the teaching practices listed on the TEAM Tool to incorporate more practical ways for instructors to engage in equity-minded active learning. Further, an updated TEAM Tool will help us to stay current as we continue to support professors transitioning their teaching to improve student learning.

Abstract Name: Sodium to Potassium Ratio Is Associated with Increased Blood Pressure in Males but Not in Females

BackgroundElevated blood pressure (BP) is a significant risk factor for cardiovascular disease. The effects of high sodium (Na) on BP are widely recognized. However, potassium (K) intake is also a factor in hypertension. Recent studies show that the Na/K ratio consumed may be more predictive of hypertension than solely sodium intake. This study examines the association between the Na/K ratio and BP in males and females.MethodsWe utilized a cross-sectional design to evaluate self-reported diet records for 73 male and 183 female students. Sodium and potassium intake were calculated using Diet and Wellness Plus, and BP measurements were taken. Partial correlations were conducted between systolic (SBP) and diastolic blood pressure (DBP), and the following variables: Na, K, and Na/K. SBP means were compared between high sodium consumers and low sodium consumers with the same Na/K ratio using independent samples t-test.ResultsNeither male nor female participants' SBP or DBP were associated with Na or K intake (p>0.05). However, an increased Na/K ratio was associated with higher SBP in males (r=0.254, p=0.29), but not in females (r=0.04 p=0.79). When the Na/K ratio was paired, participants consuming over 3000 mg of sodium had higher SBP (121.1 ± 12.9) than those who consumed less than 3000 mg (115.9 ± 10.7, p=.004).ConclusionsIn males, the Na/K ratio was predictive of increases in blood pressure. This was not seen in females. Although the Na/K ratio seems to be more predictive of this parameter, within the same Na/K ratio, having lower Na consumption was associated with lower SBP. This illustrates the complex interaction between BP regulation and nutrition, emphasizing the significance of lowering sodium intake and maintaining a balanced Na/K ratio for optimal heart health.

Abstract Name: Rape Kit Testing and the Becker Rational Crime Model

Rape is considered to be the most underreported crime, with lasting effects that impact the wellbeing and livelihood of victims. Despite this underreporting, the US has a nationwide backlog of untested Sexual Evidence Kits (commonly known as Rape Kits). I study the incidence of sexual violence and rape through the Becker "rational crime" model which states that increased probability of detection should have a deterrence effect that reduces potential offenders propensity to commit a criminal act. From 2008 to 2023, there have been huge efforts by many jurisdictions across the country to clear the evidence backlog and process all held rape kits. This poster discusses the relationship between the rate of rape kit processing and reported instances of rape using precinct-level data from the Department of Justice.

Abstract Name: Plant exploration in central Honduras: Collecting and conserving maize landrace diversity

Food security in the coming decades is a global concern. Expanding the area of cultivated land to feed the growing global population is an unsustainable approach. High-yielding and climate resilient crops must be developed to satisfy this demand. Germplasm conservation is an important factor in promoting global food security, as it is the fundamental resource used by plant breeders to develop high-yielding cultivars with resistance to biotic and abiotic stresses. The purpose of this project is to enhance the diversity of tropical maize germplasm in international genebanks. Despite its geographic proximity to the regional center of diversity in Guatemala, maize germplasm from Honduras is underrepresented in extant collections. The proposed collection locations complement prior collections, focusing on the department of Comayagua, Honduras, which is underrepresented in the existing USDA and International Maize and Wheat Improvement Center (CIMMYT) landrace collections.Collection locations were determined using a landrace gap analysis and consultation with technical advisors from the Honduran agricultural research organizations ASOCIALAYO and FIPAH. Samples of the germplasm collected and regenerated will be deposited in the genebank of the U.S. National Plant Germplasm System (NPGS), the Zamorano University germplasm collection, and the in situ collections of NGOs. Furthermore, the proposed efforts place an emphasis on capacity building for germplasm conservation within Honduras by assisting with the regeneration of existing ex situ collections and strengthening professional relationships between Honduran NGOs, small-holder farmers, Zamorano University, Iowa State University, and the NPGS.

Abstract Name: Does Greater Phylogenetic Distance Affect Competition Outcomes in Fungal Communities?

Fungi have played a critical role on Earth due to their diversity and decomposing ability. Fungal communities, particularly saprotrophic fungi, compete for resources and assist in organic matter decomposition. However, the role of phylogenetic relatedness on competitive interactions in fungal communities has not received much attention in research. The concept of phylogenetic overdispersion explains that species within a community tend to be less related than expected by chance. Similarly, Darwin's naturalization hypothesis suggests that taxonomically distinct invaders might experience reduced competition and resistance. In this study, we chose three different saprotrophic fungal species: Aspergillus niger and Fusarium keratoplasticum (from the same family), and Pleurotus ostreatus (from a different phylum). These species were chosen based on decomposition abilities and phylogenetic distances based on the ITS region of DNA. These species were cultured and placed in seven combinations to assess their ability to decompose and compete as individual fungal populations and as combined communities (e.g., A, B, A+B, B+C, and A+B+C). Each species was placed near a sterilized piece of paper such that competition was evaluated by analyzing the paper coverage in Petri dishes over three weeks. Each Petri dish was analyzed individually

based on the average percentage of paper covered and, within combined communities, the percentage of paper each species covered. Interactions between each species and the percentage of the paper covered was recorded for further analysis. Assessing paper coverage allows for individual species' abilities to decompose and compete to be seen. We hypothesized that decomposing and competitive abilities would be the strongest with A. niger. Despite the fast growth rate of A. niger individually, preliminary results suggest that it was outcompeted when paired with other species. This research highlights the potential nuances in fungal interactions dictated by phylogenetic relationships, shedding light on the principles of phylogenetic overdispersion and Darwin's naturalization hypothesis.

Abstract Name: Tetratricopeptide Repeat Domain Variant of O-GlcNAc Transferase Casual for a Congenital Disorder of Glycosylation

The OGT gene encodes for the enzyme O-GlcNAc Transferase that is essential for human and most multicellular organism's life and is responsible for the addition of O-GlcNAc onto target cellular proteins. The O-GlcNAc modification plays a role in numerous processes and diseases including diabetes, cancer, neurodegeneration, and neural development. Previously reported mutations in the N terminal Tetratricopeptide Repeat (TPR) domain of OGT have been found to cause X-Linked Intellectual Disability (XLID). More recently, clinicians have identified 3 mutations in the C terminal catalytic domain of OGT. We hypothesize, based on molecular modeling, that the enzyme will not be able to efficiently bind the sugar nucleotide and transfer O-GlcNAc to proteins. Thus, the variants will alter the O-GlcNAc levels on intracellular proteins. To test this hypothesis, we will express the variants, T570A, Y835C, and A952V, in human cell lines to better understand the effects of the mutations in comparison to our positive control, wildtype, and negative control, catalytically inactive K852M. We have created plasmids via site-directed mutagenesis to express the recombinant OGT enzyme variants. We will use western blots to assess the levels of O-GlcNAc normalized to the amount of recombinant OGT expressed in mammalian cells. This can help us better understand the role that these mutations play in the intellectual disability phenotype. By understanding how the variants alter O-GlcNAc levels and enzyme function, potential therapeutics can be created, and we will better understand the role these mutations play in the phenotype of this form of CDG (Congenital Disorder of Glycosylation).

Abstract Name: Hidden connections: investigating shrub expansion into grasslands

Shrub encroachment is occurring in ecosystems worldwide however, it is particularly detrimental for barrier islands because they migrate and resistance posed by shrubs could result in island fragmentation. One of the abotic drivers for shrub encroachment on Hog Island, Virgina is warmer winter temperatures. Instead of shrubs dying back they expand into grasslands. Biotic factors may also be important for shrub encroachment. What is currently unknown is the role of grasses in facilitating increased root infection of mycorrhizal fungi, a vital organism for increasing nutrient uptake by plants in nutrient poor environments. A hoop house experiment was set up to determine the extent to which grasses facilitate the growth of seedlings of Morella cerifera, a native shrub, by increasing contact with grass roots. Grass roots are associated with mycorrhizae fungi which could increase the root infection of M. cerifera. Control M. cerifera seedlings were grown with contact with grass roots and experimental seedlings were grown isolated from grass roots. The growth metrics were height, biomass, and canopy area. After seven weeks the average height growth for the control group was 5.24 (±0.50 cm) and the average height growth for the treatment group was 3.56 (±0.47 cm). The seedlings with access to grass roots grew significantly taller than seedlings isolated from M. cerifera roots (p<0.05). The average canopy area for the control group was 87.73 (±1.61 cm) whereas the treatment group was 85.93 (±2.50 cm). These differences were not significantly different meaning that the plants are growing taller but not wider. This could be due to competition with grasses for light. Grasses appear to have a positive effect on shrub growth potentially impacting their encroachment into grasslands.

Abstract Name: Stalled Progress? Five Decades of Black-White and Rural-Urban Income Gaps

We examine the contribution of the U.S. tax and social safety net to ameliorating racial and geographic household income gaps. Using nearly five decades of data from the Current Population Survey Annual Social and Economic Supplement, we make a comparative assessment of after-tax and transfer Black-White and rural-urban household income gaps in relation to similar gaps based solely on household earnings. Our results paint a mixed portrait of economic progress of Black and rural households relative to their White and urban counterparts over the last 50 years. The tax and transfer system in any given year provides substantial redistribution to low-income Black and rural households, which has resulted in a narrowing of level gaps over time. However, those same level gaps have been exacerbated in the upper tail of the distribution, suggesting the tax code does not undo the underlying economic forces pulling White and urban incomes apart from Black and rural households in the top half of the distribution. This is borne out in the stagnation of rank positional gaps across race and geography.

Abstract Name: Silent Killer - Exploring the Epidemic of Loneliness on American College Students

Post-covid American society is currently experiencing what national officials have declared a public health crisis. This research aims to explore the impact of America's Epidemic of Loneliness and Social Isolation on college students by identifying awareness, stigma, and salient perceptions. Research spanning the last several decades has converged revealing the vast and significant health and well-being outcomes associated with social isolation and loneliness. A lack of social connection and the loneliness it inflicts has been linked to many adverse and dire consequences for individuals and society. Loneliness has the potential of shortening life expectancy by 29%. Time spent connecting socially has been declining for decades and has now plummeted to record-breaking lows. Unbeknownst to many, the increasingly widespread loneliness epidemic is likely impacting most of the population and infecting every level of society. Approximately half of Amerians self-reported loneliness prior to covid, with the current generation of young people being among the most adversely affected. A mixed methods, longitudinal design will be used to study a large group of undergraduate college students from a western university. Two surveys will be conducted on the large target population and one interview on a smaller portion of the group. Instrument development will derive from the Stigma of Loneliness Scale which incorporates UCLA's Loneliness Scale. Scaling and multiple choice will be used in surveys. The surveys will implement a test-retest strategy intended to evaluate the potentially mitigating role of awareness. At the end of the first survey, awareness will be provided in the form of current data released by the US government related to the loneliness pandemic. Approximately a 4-6 week interval will occur prior to the subsequent survey. To gain greater insight, individual interviews will be conducted shortly after the second survey on a small group of the participants using mostly open-ended questions.

Abstract Name: Emotional Intelligence Among College Students

Prior research has shown that emotional intelligence is significantly important for college to have in order to cultivate healthy social skills that play a role in relationships. This current study explores emotional intelligence among college students. This study has two objectives: (1) to examine the effect of appraisal of own emotions on utilization of emotions. (2) to explore how appraisal of others' emotions and emotional regulation affects a college student's social skills. It was hypothesized that appraisal of others' emotions and emotional regulation would significantly predict social skills. Emotional intelligence was measured by the Emotional Intelligence Scale (Copper et al. 1998). The sample included 59 college students from a Christian university. A simple linear regression and multiple regression test were used to analyze the data. The study found that appraisal of own emotions does significantly predict utilization of emotions (b1= .32, p<.05). The findings also revealed that appraisal of other's emotions and emotional regulation plays a significant role in determining a student's social skills. (p<.05). We concluded that emotional regulation significantly predicts social skills controlling the appraisal of others' emotions. These findings can help universities implement more personable ways for students to engage with other students to foster those relationships as well as access to more support resources.

Abstract Name: Museums and Ritual Objects: Examining Curatorial Practices and Reanimating Religious Art

Placing religious objects in museum and gallery spaces limits the ways these objects are experienced and transforms their meanings, shifting them from their particularized religious contexts into works of art expected to adhere to narrowly defined assessments of aesthetic or art historical value. As part of a multi-year research project, I had plans to curate an exhibition that would re-contextualize ritual art. The exhibition would be informed by a process of re-animation, which involves displaying the objects in a way that aligns with their original function and uses phenomenological approaches to engage a visitor's conscious and unconscious experience with the art. While developing the exhibition, however, I was invited to collaborate on an event that would take place in our university's multifaith space on the occasion of their tenth anniversary. This opportunity shifted the trajectory of my exhibition and required a community-engaged model for curatorial work rather than a traditional model. Collaboration required that I gather feedback on the ways the objects were displayed, which then informed a second re-installation of this exhibition. I will present specific examples from this exhibition that sparked new conversations based on community feedback; including a Yaka divination board juxtaposed with a medieval sacramentary, and Judaica displayed alongside objects associated with Islamic prayer. This process clarified that community co-curation is essential when working with ritual art in a cross-cultural context. While presenting its own challenges, community co-curation ensured the decentering of a singular voice, engaging a wider range of perspectives, and a more successful display of the similarities and differences between works of diverse religious traditions.

Abstract Name: Analyzing Ionospheric Drift Using Ionosonde Data

The environment in the top layer of the Earth's atmosphere, which we call the ionosphere changes from hour to hour and from day to day due to its interaction with Sun. As a part of this research, we are studying ionospheric drift velocity at different latitudes and times using ionosonde data. We are using the data for stations ranging from -30 deg latitude to +30-degree latitude. Our initial analysis shows drift velocity could go up to 150 m/s. We have found the highest changes in velocity happen before or after sunrise, and sunset. Also, drift velocity changes nearer the equator region. Further analysis has revealed that the seasonal variation of drift does affect drift velocity and that the greatest drift velocities seem to be during the summer months of the upper hemisphere and in the winter months of the southern hemispheres. The magnitudes found at the Santa Maria station in December reach higher velocities relatively consistently across the month, reaching a maximum velocity of 49 m/s. The results of this research project will be important in terms of space plasma studies and space weather predictions, which play a significant role in radio and satellite communication as well as GPS navigation.

Abstract Name: From Patterns to Polygons: A Recontextualization of Historic Relics Through Digital Technologies

Bridging the divide between history and the modern world is what this research project aims to achieve at its core. We were able to achieve a partnership with the National Historic Landmark, Sloss Furnaces in Birmingham, Alabama. We worked with Sloss Furnaces to archive wooden foundry patterns from the early 20th century using 3D technologies as well as our combined knowledge and proficiencies. This project permits interdisciplinary collaboration, preservation of historic relics, and educational outreach on many fronts. During our time in Birmingham, we took our Ein Scan 3D scanner and began the process of scanning the patterns Sloss Furnaces has accumulated in their facility. We were able to render a total of 12 digital scans during our first trip and plan to continue to pursue a complete digital archive. Once we returned to Kennesaw, we began the restoration of the pattern files through digital modeling practices. The immediate outcome of this project will produce files of scanned wooden patterns that will be 3D printed and digitally archived. By taking these wooden patterns that have degraded over time and restoring them digitally through advanced technology, like mesh repairing in Virtual Reality, Sloss Furnaces has been given the opportunity to preserve, use, and bring awareness to irreplaceable pieces of history. Since the making of these wooden patterns is a practice of a bygone era, the patterns are in a state of disrepair and can no longer be restored in the fashion that they were originally. Our efforts of preserving them digitally allow for these to be used in educational programs, metal arts programs, and historical record keeping. To our knowledge, this distinct preservation process is not being practiced, therefore, we hope to create a new dimension of learning opportunities for all visitors to Sloss Furnaces.

Abstract Name: Chemotaxonomy of the Dinoflagellate Togula britannica as Based on Sterols and Galactolipids

Dinoflagellates are one of the largest groups of algae that encompass marine and freshwater, and photosynthetic and heterotrophic taxa, which are found in almost every water body on earth. On a monthly basis in phycology journals, newly identified taxa are reported, often after morphological and/or phylogenetic study. Even though it’s the most longstanding method for identifying dinoflagellates (and other algae), identification of new species based only on morphology could be inaccurate and misleading because of convergent evolution of truly different dinoflagellate species toward a particular cellular shape. Previous identification of the dinoflagellate Togula britannica was accomplished using a combination of morphology

and phylogeny, leading to its separation from the genus Amphidinium, which shares morphological features. However, there are other tools, namely chemotaxonomic characterization of various lipids such as chloroplast-associated galactolipids and membrane-associated sterols, that can serve as a valuable complementary method in identification of dinoflagellates as based on morphology and/or chemotaxonomy. To this end, we have obtained an isolate of T. brittanica which has not been characterized phylogenetically nor chemotaxonomically and have performed chemotaxonomic characterization of these lipid classes. Identification of its sterols has shown compounds commonly associated with certain species of Amphidinium; these include 4α-methyl-5α-cholest-8(14)-en-3β-ol, 4α-methyl-5α-ergosta-8(14),24(28)-dien-3β-ol (amphisterol), and 4α-methyl-5α-ergosta-8,14,24(28)-trien-3β-ol. However, characterization of its galactolipids has shown C18/C18 (sn-1/sn-2) polyunsaturated fatty acid-containing major forms of mono- and digalactosyldiacylglycerol that are uncommon to Amphidinium, which generally possesses C20/C18 major forms. Phylogenetic characterization of this isolate is still ongoing. T. britannica is an alga that has had ambiguity surrounding the phylogenic and chemotaxonomic tree since its discovery. Our objective is to provide resolution for whether this particular isolate of T. britannica is chemotaxonomically separate from the genus Amphidinium.

Abstract Name: Analysis of Miranda Rights Comprehension: Using Lawyer-Based Instruction Amongst High School Students

Previous research studies conclude that high school students waive their Miranda Rights at enormous rates. Ultimately, teenagers do not comprehend their Miranda Rights leaving them both vulnerable and susceptible to physiological coercive interrogation attacks during interrogation. This research paper explores this identified gap in a method that is easy to interpret, while also providing high school students with the opportunity to gain information about Miranda Rights. The research question constructed and investigated is: How will implementing lawyer-based instructional sessions in high school classrooms assist in improving student knowledge of their Miranda Rights, while also boosting retention of the information after time has lapsed? This research paper uses a quasi-experimental design study in conjunction with a repeated measurement design to demonstrate the beneficial effects of high school students receiving instruction on their Miranda Rights by a lawyer presentation. Initially, four hypotheses were constructed and in the end, all hypotheses were supported. The statistical findings concluded that students in the experimental group performed significantly better than the control group in the post-test assessment. In addition, the research findings revealed that high school students found learning about their Miranda Rights from a defense attorney useful and valuable.

Abstract Name: Food Fights: Feeding Competition in male Mantled Howler Monkeys (Alouatta palliata)

Food quality plays a big part in the activity budget and fitness of Mantled Howler Monkeys (Alouatta palliata) and may contribute to a higher frequency of food competition. Data was collected at Camaquiri Conservation Initiative (CCI) to study howler monkeys' feeding behaviors in three different trees (fruit, flowers, and leaves). Over the course of seven days, focal sampling at five-minute intervals was conducted. Additionally, all occurrence data was collected between intervals to catch missed behaviors that did not occur on my set intervals. These observations were conducted on the first male howler monkey seen in the group. The distance to the nearest monkey was recorded once the focal male mantled howler monkey was identified. This was done to determine if there were any signs of feeding competition when the distance to the nearest monkey was less than one body length. The data also showed that 100% of aggression seen was observed only in leaf trees, contrary to what I believed would be the case. So, what we can take away from this is it might not only be the quality of the food resources that are important to mantled howler monkeys but also the spatial distribution and abundance of the food source. If the distribution of food is more even, it is not efficient for the individual to defend resources. Whereas if there is more patching of resources, the individual could expend less energy defending resources and, in turn, display more instances of aggressive behavior (Strier, 2016). In summary, our results did not support our hypothesis but showed that there are more variables to feeding competition, like the distribution of resources and the efficiency of defending resources.

Abstract Name: The Influence of Race on the Vietnam War Draft in Prince Edward County, Virginia

African American men were drafted for the Vietnam War at disproportionate rates as related to their population size and white counterparts. By 1965, in the midst of war, African American men accounted for 31% of the ground combat population, and 24% of fatal casualties, while only making up ~12% of the U.S population. This disparity came as a consequence of the composition of local draft boards and Project 100,000. By the end of the war, 246,000 men had been drafted under Project 100,000, with 41.2% of them non-white. Additionally, local draft boards failed to represent the demographics of their communities. In Oct 1966, only 1.3% of local draft board members were black, out of 16,636 members. My research question will examine how race influenced the Vietnam War draft in Prince Edward County, Virginia. Prince Edward has an extensive history of civil rights struggle, seen through the 1959 public school closure, following Brown vs. the Board of Education. The battle for public education among black students of the community significantly impacted the perceived qualifications for military service, thus perpetuating the Project 100,000 narrative. Previous literature has primarily displayed a national focus, however my research narrows the historical scope and provides insight into the community structure. The research relied on primary sources, such as oral histories with African American veterans and draft board documents. Sources were gathered on a local level, through local organizations, public records, and community members. The composition of the local draft board and the significant history of racism in Prince Edward County led to the disproportionate draft of African Americans in Vietnam. By analyzing the experience of local African American veterans in Vietnam, this study communicates the persistence and consequences of racism in the 20th century.

Abstract Name: Anime and Lo-fi: Cross Cultural Connections

Both anime and lo-fi hip hop have become ubiquitous in the pop culture vernacular, yet neither have had much scholarly effort devoted into how they became so rooted in our pop culture. Furthermore, the two are associated with each other in terms of their place in pop culture as well as how they are presented aesthetically. This research study aims to find the reason why these two different art forms from two distinctly different cultures found each other, and how they became intwined in the eye of American pop culture, as well as the aesthetic and thematic connections the two share.

Abstract Name: Impact of Excessive Screen Time on Childhood Development

Objective:The aim of this evidenced-based research project is to educate parents on the impact of excessive screen time on childhood development in an effort to provide alternatives that will enhance the cognitive development and wellbeing of young children. Purpose: Previous research acquired made a mark on the importance of screen time and its deficits related to the outcomes of childhood behavior, maturity, and physical wellbeing. The consensus of many studies follows the idea that recognition of the advantages and disadvantages of screen time may fall directly upon the caretakers of the child. The review of literature states the importance of education and mindful mediation to be recognized in order to improve childhood development. With such, parents and caretakers need adequate education regarding the negative impacts of excessive screen time and age-specific alternatives to ensure the adequate cognitive development and wellbeing of their child. Method: Use of the evidenced-based practice design includes a pre-test and post-test strategy to identify the change in parental knowledge following education on childhood development, screen time, and age-related interventions to promote positive childhood development. Expected Results and Relevance: Implementation of mediation and education related to decreased screen time will increase the parent's knowledge and provide a framework for additional education and further studies related to excessive screen time in childhood development.

Abstract Name: Hypersonic-Borne HEMP Threat Analysis, Wargaming Scenarios, and the Breakdown of Mutually Assured Destruction Doctrine

Borne by Chinese hypersonic glide vehicle, a High-altitude Electromagnetic Pulse (HEMP) weapon detonated in the atmosphere over the continental U.S. eviscerates the American electrical grid for 4-10 years, incurs trillions of dollars in damage, and results in the death of up to 90% of Americans within a year, all according to the Congressional EMP Commission's report and multiple DHS/DOD/DOE studies. As "competition below the threshold of war" which also happens to nullify America's war-waging capacity, Electromagnetic Pulse (EMP) assaults place the United States in an awkward quandary, without electricity, communications, or viable retaliatory options. Existing detection dragnets strain to track hypersonic glide vehicles and, due to various EMP scenarios, if the lights were to suddenly flicker off, there may remain uncertainty as to the perpetrator's identity. Even once America eventually attains hypersonic parity with China and Russia, due to the nuanced nature of hypersonic HEMP warfare (especially when launched from the Sino-Russian border), traditional mutually assured destruction and deterrence paradigms fatally fissure and ultimately implode. Ensuring an equitable outcome – where China's electrical grid is equally inoperable – is simply unfeasible considering the first-strike nation's intrinsic advantage, ambiguity in launcher's intent, the truncated timeline for response (when compared with traditional ICBMs), and China's unique manufacturing and policy positioning which allow them to weather EMP reprisal essentially unphased. This presentation unpacks the geopolitics, game theory, and rocket science surrounding asymmetric hypersonic HEMP warfare, detailing how mutually assured destruction paradigms fail, and offers a three-pronged solution to the existential threat facing America.

Abstract Name: Investigating Rural Mountain-West Patient Care Experiences Surrounding Diagnoses of Müllerian Anomalies

The purpose of this research was to examine the patient experience of those diagnosed with Müllerian Anomalies (MAs) in Montana. MAs are congenital uterine anomalies that occur in about seven percent of the female population and can cause pelvic pain, prolonged bleeding, and sub- and infertility. Patients with MAs often require specialized care throughout their lives.For this research, thirteen patients from across the rural Mountain West were interviewed, and their responses to all questions asked were analyzed to determine key themes. Both audio recordings and written transcriptions of the interviews were used. An analysis using quantitative methods was used for all interviews, and four of these interviews were analyzed using qualitative methods. In the quantitative analysis, several key themes were identified. An interesting theme is that, due to the shortage of providers specializing in MAs in the Mountain West, as well as the rurality of the area, 61.5% (n=8) of patients experienced long travel distances to access care, with the average distance being 175.5 miles. Additionally, 76.9% (n=10) of patients experienced difficulties in regard to health insurance, mainly due to insurances not covering fertility treatments that were necessary due to the MA. In the qualitative analysis, the topics most frequently discussed by patients were miscarriage and infertility, both of which are associated with MAs. Patients also frequently discussed how their diagnosis and treatment affected their mental health, as well as how providers did not inquire about their mental and emotional well-being.The findings will contribute to a broader understanding of the patient experience in Montana and inform strategies to enhance care and support for those with MAs. This research aligns with ongoing projects aimed at

improving healthcare for rural women with complex gynecological conditions and identifying health information gaps for patients with MAs.

Abstract Name: An Investigation of the Availability and Suitability of Patient-Centered Material for Patients Diagnosed with Müllerian Anomalies

Müllerian Anomalies (MAs) or congenital uterine anomalies, affect around seven percent of women and cause pelvic pain, prolonged bleeding, and sub- or infertility. MAs are considered a Difference of Sex Development, and women with these diagnoses are categorized as a National Institutes of Health Sexual and Gender Minority (SGM) population.Preliminary work conducted by our team revealed that the Internet is the primary source of information for MA patients. There is limited online educational information for this population, and the available content varies in consistency and patient-centeredness. The National Library of Medicine created the Health Education Materials Assessment Tool (HEMAT), which consists of a yes/no checklist to determine the suitability of written online information. We administered this test for online MA patient information, thereby identifying challenges to be addressed in creating content for this population. The Flesh-Kincaid calculator - which uses syllable count, word count, and sentence length - was used to further assess materials and determine the level of education required to comprehend the content. The online material assessed was obtained from sources in the Network of the National Library of Medicine Region 4, as our funding was specific to that region.The vast majority of online sources did not pass the HEMAT, demonstrating their unsuitability for patients. Out of the thirty-one sources provided by clinics in Region 4, only nine passed the HEMAT. The reasons for failure included the lack of definition of medical terms and the use of visual aids that did not enhance comprehension and engagement. The results from the Flesch-Kincaid calculator revealed only seven of the eighty materials assessed were written at a reading level that could be comprehended without a college education.These results highlight that access to suitable online education materials is an additional burden faced by members of this health disparity population.

Abstract Name: Capitalism and Optimism: Economic Factors' Effect on Feelings of Personal Achievements

With housing prices on the rise and wages at a standstill, college students may experience a bleak future ahead of them. These students look to graduation and they should be expecting the celebration of a lifetime milestone, but for some this ceremonious event just doesn’t hold the same weight as it used to. The primary objective of this study was to observe the economic factors that may affect the optimism and feelings towards

personal achievements of Bridgewater State University undergraduate students. This study used Qualtrics online surveys advertised through school emails sent by professors, physical fliers and posting on the Bridgewater State Community app through the Fall 2023 semester for collection of data. The independent variable, feelings towards economic factors in the U.S, was captured through questions asking respondents their feelings on topics such as the housing market and job market through ordinal levels of measurement. The dependent variable, feelings towards personal achievements, was captured through questions asking respondents their feelings towards college graduation and their future. The analysis for this study utilized Qualtrics cross tabulation tools in order to run Chi-Square goodness of fit tests in order to test the statistical significance between the two variables where p-values of .05 and below marked significance. Findings indicate that students who reported very poor feelings towards the U.S. housing market and job market held strong statistically significant relationships with those who reported uneasy feelings towards being a college graduate, regretting not attending a trade school and seeing a college degree as the only way out of school among other revelations. Findings call for greater support not only by schools but U.S. policies in order to help those most in need to foresee an achievable path towards financial success.

Abstract Name: Galectins 1, 3, and 9: Role in Pregnancy Immune Suppression and Parallels in Cancer

Immunosuppression is vital in pathophysiology of cancer, pregnancy, and related pregnancy complications. Pregnancy is a normal, biological process that can be studied as a model which mimics the immunosuppressive pathways of cancer. Pregnancy complications like Villitis of Unknown Etiology (VUE) and Chronic Histiocytic Intervillositis (CHI) consist of the breakdown of immunotolerance which can help identify the mechanisms involved in cancer immune evasion and targets of immunotherapy.Cancer systemically shifts the immune response to an immunosuppressive tumor-supportive microenvironment. This is analogous to pregnancy as it is unfavorable for the immune system to attack the fetus. In pregnancy complications, we see a shift from TH2/M2 to an induced immune activation response, TH1/M1.Galectins, part of the lectin superfamily, extensively studied in pregnancy, play a role in the immune suppression of cancer. These proteins decipher information encoded by glycosylation machinery via a conserved carbohydrate recognition domain (CRD) which translates to proper cellular function. Dependent on the cancer, and tumor microenvironment, the upregulation of certain galectins is associated with both immune activation and suppression. In pregnancy, galectins are recognized as an important factor in establishing immune tolerance at the feto-maternal interface, resulting in successful pregnancy.To understand the microenvironment in pregnancy and cancer, multi-plex immunofluorescence (MxIF) was utilized on pregnancy and tumor slides. Multiple tumor and trophoblast cell lines were cultured and treated with galectins with various in vitro assays. ELISA and flow cytometry were utilized to measure cytokines and cell surface markers, respectively.MxIF demonstrates that immune tolerance pathways at the feto-maternal interface and tumor microenvironment are similar in the upregulation of galectins and CD206 in both normal pregnancy and cancer as opposed to Th1/M1 upregulation in pregnancy complications and lymph nodes without tumors. In vitro assays suggest that galectins promote Th2 and M2 upregulation in T-cells and macrophages, respectively.

Abstract Name: The Enduring Power of Fairy Tales

Despite the passage of time, the stories presented in fairy tales have persisted in the minds of both children and adults. People often feel personal connections to these stories, recognizing aspects with which they can identify or from which they seek advice. My project explores how these connections are built over an innate psychological scaffolding that is fundamental to the human experience. This idea was popularized in the early 20th century by Carl Jung, a Swiss psychiatrist and psychoanalyst. He describes archetypes, or universal symbols or patterns that are present in the collective unconscious of all humans. The story of Beauty and the Beast was originally written in 1740 by Villeneuve for young adults of the French middle class and aristocracy. Since then, the story has been rewritten countless times across many countries, languages, and genres. Despite the many variations, several aspects of the tale persist. These enduring aspects are integral to the story itself, representing Jungian archetypes and their associated interactions with one another, labeled archetypal patterns. These archetypes manifest themselves throughout different renditions of the story from the lens of masculinity and femininity. Differences in the written actions of characters may provide insight regarding accepted gender norms at the time, or opinions of them. These depictions can be compared with those of today, where feminism has been most impactful and masculinity is very much in its own phase of reconstruction.My project examines these themes through a study of Jungian archetypes, as well as previous works concerning their relation to fairy tales, and specifically Beauty and the Beast. In addition to textual and literary analysis, the project will explore the perspectives of philosophers and psychologists- through both interviews and published material- to use perspectives from these disciplines to fund new ways of approaching this issue.

Abstract Name: Understanding Pupil Response Patterns in Autism

Autism Spectrum Disorder (ASD) features atypical social and emotional processing, which can be reflected in the pupil dilation response (PDR) to external audio-visual stimuli. This project aimed to quantify how different features in naturalistic movies affect pupil dilation using an eyetracking dataset collected in 22 healthy controls and 13 high-functioning ASD participants. In particular, we extracted changes of the pupil diameter at a high sampling rate (600 Hz) while participants were watching 18 sounded, short YouTube movies. After data preprocessing and normalization, we found that the pupil diameter is affected by various factors in the movie, including lighting, changing of scenes, sound volume, emotion arousal, etc. Compared to the control group, the ASD group in general has greater dilation when the emotion arousal is high and

when a new human subject appears. These preliminary findings can thus form the basis of fine-grained future analysis that will comprehensively characterize the importance of different features in inducing atypical pupil dilation patterns in ASD.

Abstract Name: Investigating Pattern Separation Ability in an Epileptic Mouse Model of Dravet Syndrome

Dravet Syndrome (DS) is a severe childhood neurodevelopmental disorder caused by a deletion of the SCN1A sodium channel gene. Phenotypically, DS is characterized by behavioral features of autism spectrum disorder (ASD), treatment-resistant epilepsy, developmental delays, intellectual disabilities, and motor dysfunction. The heterozygous Scn1a+/- mutant mouse strain encapsulates some of these key clinical features of DS in humans. Previous studies have demonstrated that the hippocampal dentate gyrus (DG), critical to learning and memory, is pathological in DS. Pattern separation, the ability to discriminate similar memory episodes, is housed within the DG; this ability, enhanced in ASD, has not previously been studied in Scn1a+/- early postnatal mice nor in DS patients. Thus, we investigated pattern separation ability in DS mice and hypothesized that Scn1a+/- mice with ASD phenotypes will have enhanced pattern separation compared to their wild-type (WT) counterparts. In order to test this hypothesis, we utilized the Spontaneous Location Recognition (SLR) behavior test, which assesses a mouse's ability to pattern separate based on its innate interest in exploring novel locations. This test involves distinguishing differences in the locations of objects between "sample" and "test" arena setups. Marble burying, elevated plus maze (EPM), and open field (OF) tests were conducted alongside SLR to assess locomotion and anxiety. Results so far show no significant difference in the ability of WT and Scn1a+/- mice to pattern separate. Interestingly, mice overall performed the worst on the easiest SLR memory tasks. Furthermore, males showed more anxiety and females displayed hyperactivity relative to their male counterparts. These data suggest that there may not be behavioral abnormalities present in the Scn1a+/- mice, but instead that a sexual dimorphism may be present. Data analysis remains ongoing, and current efforts to correlate cellular-level DS pathology to its behavioral features are in hopes of finding a mechanistic cure to this disorder.

Abstract Name: Factors Influencing Romantic Partner Preferences

Over the past decade, the number of individuals in romantic interethnic relationships has grown, as well as the percentage of Americans who approve of romantic interethnic relationships. Despite these trends, social and behavioral research still indicates an existing stigma surrounding romantic interethnic relationships. This research seeks to identify the factors that contribute to attitudes on romantic interethnic relationships. Specifically, we investigate the influence of gender, race, and racial ideology on participants' attitudes towards romantic interethnic relationships. Fifty participants from diverse backgrounds completed a comprehensive survey on their personal and romantic history, and twelve of those participants were selected for semi-structured interviews regarding their survey responses. Initial analysis of participant responses indicates general acceptance of romantic interethnic relationships, but also concerns regarding cultural differences. Insights such as these are helpful in understanding attitudes towards romantic interethnic relationships on both a personal and social levels.

Abstract Name: The Weight of Our Behavioral Immune System: The Relationship Between Pathogen Disgust and Weight Stigma

In today's society, weight stigma is just as prevalent as stigma against ethnic outgroups and the LGBTQ+ community. Despite growing numbers of obese and underweight individuals, stigma towards these individuals is at an all-time high. A 2020 study by Dawydiak and colleagues investigated the role the Behavioral Immune System plays in stigma, citing pathogen disgust as the primary catalyst of stigmatization. The current study replicates the methods used by Dawydiak et al. (2020) to investigate if pathogen disgust predicts stigma towards obese and underweight individuals. Using the Three Domains Disgust Scale and the AQ-27, we gathered data from 23 participants regarding their stigmatization of four types of individuals described in vignettes: an obese individual with Binge-Eating Disorder, an obese individual with no eating disorder, an underweight individual with Anorexia Nervosa, and an underweight individual without an eating disorder. Results of this study revealed no statistically significant relationships between pathogen disgust and weight stigma. However, our study does add to the complex conversation surrounding the Behavioral Immune System and how it is socially informed.

Abstract Name: Social Media Visual Framing of Missing White Woman Syndrome: A Visual Frame Analysis of #LaurenCho #JelaniDay, #DeneeshaKyle, and #GabbyPetito

Lila HopkinsJana Duckett Ph.D. American media outlets can influence, educate, raise awareness, and shape public attitudes (Bullock, Wyche & Williams, 2001). Media plays a significant role in reflecting and

influencing societal values (McLuhan, 1964), while also in framing what should be important or discussed within a society (McCombs & Shaw, 1993; Tankard, 2001). Due to the racist underpinnings of American society, there has always been a disproportionate emphasis and outrage on the disappearances of White individuals versus their non-White counterparts (Conlin & Davie, 2015; Jeanis & Powers, 2016)). In recent years, the over-saturation of emotional news stories about the disappearances of Caucasian American women has come to be characterized and defined as missing white woman syndrome or MWWS (Slakoff & Fradella, 2019; Sommers, 2016). Framing can be understood as both a "macro-construct and micro-construct" that charges the constructivist relational dynamic between media and its audience (Sheufele & Tewksbury, 2007) however there is a dearth of studies examining how this occurs across social media platforms. The cultural phenomenon to be explored in this project is the variances of social media coverage surrounding the media coverage of four individuals during the first week following the official announcement of their disappearance: Lauren Cho, a Korean-American woman; Jelani Day, an African-American man; Deneesha Kyle, an African American woman; and Gabrielle Petito, a White woman—more precisely the contrasting media coverage of missing persons of color versus a White person. Using Rodriguez and Dimitrova's (2011) visual framing analysis framework this study analyzed the photographs associated with over 4 million social media posts in Meta. The findings indicate a typology of visual frames in social media that represent a contrast in connotative and ideological meaning; more specifically a diminishment of perceived innocence and empathy for missing persons of color compared to the ideological visual framing of morality of a white woman.

Abstract Name: Cecropin Antimicrobial Immunity in Drosophila Flies with Silenced Single-Minded Neurons

All organisms need effective communication systems to coordinate metabolism between organs and maintain energy homeostasis. Surprisingly, many metabolic regulatory pathways are conserved between humans and fruit flies, and flies are a tractable model organism that can be used to explore the relationship between the microbiome, energy balance, and immunity. We study the function of a centrally located neural lineage in the fly that expresses a transcription factor called single-minded (sim). Flies with silenced sim neurons have a shorter lifespan than wild-type flies and develop a biofilm on their food during their short lifespan. It is hypothesized that flies with silenced sim neurons have a compromised immune system as they age compared to wild-type flies and, therefore, a reduced response to microbial infections. Innate immune responses in Drosophila include the production of Cecropin (antimicrobial peptide), regulated by the Toll and Imd immune pathways needed to fight off infection. Cecropin fights off gram-negative bacteria and fungi infections. Therefore, the purpose of this research is to understand the role of sim neurons in microbial immunity, targeting the relationship between Cecropin gene expression, fly genotypes, and consequent death. For this, RNA was isolated from adult wild-type Canton S. flies and flies with silenced sim neurons of different ages (0, 2, 5, 7, and 10 days), and CecropinA expression was quantified and monitored using RT-qPCR. CecropinA expression was low on days 0 and 2 in both genotypes, but expression increased significantly on days 7 and 10 in the wild-type flies, but not the flies with silenced sim neurons. Further research is needed to replicate these results, and the preliminary data suggests that silencing sim neurons affects the expression of Cecropin in flies, increasing their susceptibility to infection. These results suggest that sim function may be needed for energy balance, immune responses, and overall health.

Abstract Name: Co-designing and Building a Friendly Robot To Ease Dementia

Alzheimer’s disease and related dementias (ADRD) present significant challenges for both individuals affected and their caregivers, underscoring the necessity for innovative interventions. There are approximately 55 million older adults in the world living with AD (Alzheimer’s Association, 2022). Our project, the "Friendly Robot to Ease Dementia" (FRED), endeavors to address various challenges through a human-centered design approach by leveraging cutting-edge artificial intelligence (AI) and robotics techniques. FRED will assist with cognitive enrichment and physical activity to improve daily living and quality of life for persons with ADRD and their care partners.Central to our methodology was the active involvement of the ADRD community, engaging individuals with ADRD and their caregivers (n=12) in a participatory focus group. During this collaborative process, we developed two distinct user interfaces for FRED, which were crafted to accommodate varying cognitive and physical abilities within this population.After utilizing a "thinking aloud" protocol with prototypes of both interfaces, invaluable insights emerged. These insights were pivotal in refining the user experience, ensuring FRED's interfaces facilitated effective and natural interactions between users and the robot.Within our presentation, we'll showcase how the participatory group's feedback guided the creation of FRED's new UI designs, tailored to diverse ADRD needs, highlighting their positive responses that demonstrate the potential to significantly improve the quality of life for individuals with ADRD and their caregivers.

Abstract Name: Utilizing a Comprehensive Database to Investigate the “Gold Standard” of Police Trainings Concerning Interactions with Autistic Individuals

Previous research suggests that the current law enforcement (LE) training curricula on encounters with individuals with autism spectrum disorder (ASD) are inconsistent and unstandardized. Moreover, very little is known about the long-term effectiveness of these programs. The purpose of this research was to characterize the range of training protocols currently offered to LE and apply best practices to produce an improved version of an existing program. Training programs were identified, and a comprehensive database was created containing critical characteristics, such as training modality, length, and content. An examination of the data revealed common trends as well as gaps throughout the manuals. The findings were then applied to

revising and improving Dennis Debbaudt’s Autism Risk & Safety Management program, which was chosen due to its wide adoption and scope. Since our review indicated that this training did not contain an interactive activity, we developed and piloted a novel problem-based learning exercise (PBLE) focused on communication-based learning and critical thinking. This was then delivered to local LE, who also completed pre and post-test measures of autism knowledge and self-efficacy. The training received positive feedback and engagement, however, a major limitation to our ability to gather longitudinal data on training efficacy is that LE agencies do not routinely identify or track encounters with autistic people. This leaves a major gap, as the ideal method for examining training effectiveness is to determine, post-training, if encounters involve fewer incidents of unnecessary escalation, use of force, and other negative outcomes. We found that no training protocol identified is linked to the type of outcome measure that would best determine if training is ultimately effective. The implications of our research call for a common practice when tracking autistic encounters with LE, such as coding systems or standardized documentation, so that researchers can address this issue.

Abstract Name: Pura Vida Reimagined: Technology as the New Frontier for Costa Rican Prosperity

In Costa Rica, an innovative model of cooperatives has flourished, anchored in the "Pura Vida" spirit that reflects a relaxed, community-centric lifestyle. Originating in the agriculture sector, and controlled by local stakeholders, Costa Rican cooperatives have historically played a key role in amplifying local economies, nurturing community development and increasing market access for marginalized areas. Although it has brought great benefit to local communities, these cooperatives confront challenges which modern technology could help address, opening the door for technology to be a catalyst for unleashing the next phase of Costa Rica's social and industrial revolution. This research project aims to assess how technology can be utilized by cooperatives to improve project impact, accelerate community progress, refine current operations, and widen market access for local communities. Conducted via a three-month internship with a local tech cooperative in San Jose, Costa Rica, from September to November 2023, this transdisciplinary qualitative case study utilized interviews, surveys, archival research, and participant observations. Its findings suggest that Costa Rican culture, while central to national and social identity, may impede ambitions for business growth, leading to a society which is slow to adapt to new opportunities and technological advancements. Furthermore, the study shows that there is a gap in education about the true potential of such technology to enhance ‘Pura Vida’, causing reluctance in some individuals to embrace change. This resistance highlights the need for a fundamental shift in mindset to unlock new economic, social, and accessibility dimensions in Costa Rican society. In this way, the strategic application of technology within cooperatives emerges not just as a tool for economic and social advancement, but as a vibrant manifestation of the 'Pura Vida' ideals, uniting modern innovation with the enduring values at the heart of Costa Rican life.

Abstract Name: Can Sediment Analysis be used to Further Describe Species Richness of Freshwater Sponges?

The purpose of this project is to explain how sediment analysis is used to further describe the species richness of freshwater sponges. Freshwater sponges are environmental health indicators that are extremely understudied. The Louisiana Freshwater Sponge Project (LFSP) is a longitudinal study describing the diversity of freshwater sponge species in Louisiana water systems. Water systems are surveyed throughout the year. At each site, sponges are collected along with sediment. The sponges are then identified using sponge body and/or gemmule spicules and sequencing the COX-1. One gram of homogenized sediment is dried and then processed with a series of chemical reactions to degrease the sediment and remove all inorganic and organic matter. The prepared sediment is then viewed using light microscopy to identify sponge spicules. The sponge identification is then compared to the spicules observed in the processed sediment. This presentation reports the findings of thirty-seven analyzed sediment samples. While most sediment analyses confirm the collected sponge samples, in many sites, the sediment analysis has provided evidence of additional sponge species, expanding on the species richness for some locations. Analyzing sediment allows us to confirm the presence of species at a particular site without having to collect sponge samples. This process provides a more expansive picture of the species richness at a site regardless of the seasonal parameters at the time of collection.

Abstract Name: Yellow

Yellow has been an influential color in graphic design since its use in cave paintings. For years yellow's appearance in nature has contributed to its use in design and what yellow is most commonly known to be a representation for: Happiness, Excitement, and Creativity. But there are also less commonly known associations for yellow here and in other places around the world. This is based on how it has been used throughout history and where geographically it has been used. Thankfully yellow's reputation was saved by an unlikely athlete which has led to its rather uplifting connotations today. Another way yellow’s representation can be changed is based on the colors it is paired with or the specific hue in which it is used. Today, the color one pairs with yellow can change its meaning entirely. For example, yellow and black are very cautionary while yellow and red are used to signify speed and enjoyment. This use of psychological color pairings with yellow have helped make graphic designers, businesses, and artists more successful today.

Abstract Name: Jim Beam Bourbon Barrel Analysis

Bourbon barrels have been rupturing since their inception; their solidity tormenting the bourbon industry through significant losses of product. The precise reasons behind these failures have remained elusive due to a manual data collection process that has limited the amount of data and its validity. This research aims to automate that data collection process by using machine learning and computer imaging to detect, identify, and analyze the barrels put into production. The application will collect and store structural information on each barrel such as hoop distance, barrel length, stave count, etc. Whereas initially, human error could lead to barrels being skipped or inaccurate measurements, this system will use a series of cameras to detect the barrels and make calculations instantly. By automating this process, we will vastly increase the amount of data available to determine the factors that affect the likelihood of a barrel bursting. Further development of the software could also allow for the recognition of barrels that fit the profile of "likely to burst". Ultimately, this research provides a pivotal step in resolving this issue that has plagued the bourbon industry for so long, aiming to increase the integrity and longevity of barrels industry-wide.

Abstract Name: Metals of the Future in a World in Crisis: Geopolitical Disruption and the Clean Tech Metal Industry

Existing literature has examined how geopolitical issues negatively impact oil and gas markets. As we transition towards renewable energy, ensuring a stable supply of key resources becomes crucial. Particularly, recent geopolitical storms have heightened concerns about the security of these supply lines. Therefore, this paper aims to investigate the effects of geopolitical tension on the high-tech metals industry. Using The MVIS Global Clean-Tech Metals Index (MVGMET) and the Geopolitical Risk (GPR) index proposed by Caldara and Iacoviello (2022) from 2014 to 2023, we employ quantile Granger causality tests and LASSO connectedness models to identify the relationship between geopolitical risks and cleantech metal stock returns. Our results from quantile Granger causality analysis indicate that high geopolitical risks tend to Granger cause extreme upward movements in stock returns. We also find that geopolitical acts and threats exhibit different influences on cleantech metal stocks and the relationship between geopolitical risks and cleantech metal stock returns varies across different sub-periods (before the Paris Agreement, between the Paris Agreement and the COVID-19 pandemic, the COVID-19 period, and the Russia-Ukraine war period). Our results from the connectedness models show that the spillovers between cleantech metal stocks and geopolitical risks vary over time, and have experienced an upward trend during our sampling period. In summary, our research shows that geopolitical risks can influence the price of cleantech metals, which ultimately influence the affordability of clean energy technologies. This has important implications for the transition to a net-zero economy and environmentally-friendly investors.

Abstract Name: ANOMALOUS ULTRASENSITIVE COMPOSITE REACTIONS\ IN CELLULAR SIGNALING

Ultrasensitivity is a crucial cellular mechanism that plays a vital role in signal transduction. Cells employ ultrasensitivity through "switches" that respond to small changes in signaling factor concentrations. Such switches exhibit steep sigmoidal behavior and are characterized by the Hill coefficient. Traditionally, pairwise combinations of these switches were thought to adhere to Ferrell's inequality, which sets limits on their composed ultrasensitivity. However, recent research has disproven Ferrell's inequality, suggesting the existence of biological systems that can combine non-ultrasensitive reactions to achieve high ultrasensitivity. The specific class of reactions that accomplish this optimization remains unknown. In this paper, we utilize mathematical models to explore how variations in molecule saturation as well as reaction gradient impact ultrasensitivity. These variations result in differences in concavity, steady-state values, and composition structure of the functions. Our findings demonstrate that combining robust functions with threshold curves disprove Ferrell's inequality, generating exceptionally high levels of ultrasensitivity. This discovery could provide novel insights into understanding physiological systems that exhibit switch-like behavior and contribute to the defining of a broader set of reactions for which Ferrell's inequality does not hold true. Here, we specifically discuss the composition of two systems: multisite protein binding and absolute robustness.

Abstract Name: A Drug Screening Approach for Enhanced Colorectal Tumor Killing by CAR-NK Cells

Chimeric antigen receptor (CAR)-engineered immune cells have shown promise with amplified recognition and killing of tumor cells in liquid cancers; however, they have had limited therapeutic efficacy with solid tumors due to a hostile tumor microenvironment and poor trafficking to tumor sites. Apart from CAR-T cells, natural killer (NK) cells represent promising alternative effectors cells that can be engineered with CAR technology with several advantages over CAR-T cells. Importantly, NK cells have innate cytotoxic capability and can be utilized as allogeneic off-the-shelf products with a reduced risk of toxicities. However, many are not sufficiently effective and researchers have proposed that combined treatment with chemotherapeutic drug compounds may help to remedy this. Here we propose to target colorectal cancer and its peritoneal metastasis by designing CAR-modified NK-92 cells against novel tumor-specific antigen epitopes and checking for enhanced cytotoxic activity as compared to established CARs against the antigen. We will also identify potential chemical compounds enhancing the therapeutic potential of CAR-modified NK-92 cells against colorectal cancer. A high-throughput screening will be done to identify candidate drugs for our study and then thoroughly tested individually at various concentrations. Then, the cytotoxicity of different combinations of CAR-NK-92 cells and chemical compounds will be assessed, both in vitro and in vivo. We expect to find a

combination therapy with synergistically enhanced efficacy. Results may elucidate a novel molecular mechanism and carry clinical relevance.

Abstract Name: Alterations to Shoulder Muscles following Brachial Plexus Birth Injury in a Rat Model

Brachial plexus birth injury (BPBI) occurs in about 1 out of every 1,000 human births, and damage to the neck or upper trunk during delivery frequently results in muscle weakness, paralysis, or decreased sensation in the upper limb. Previous rodent studies have shown reduced muscle mass and fiber length in the shoulder muscles at 8 weeks following injury, though the timing of injury progression and contributions of unloading to these changes remains unknown. For this study, Sprague Dawley rats received one of four surgeries on one forelimb at postnatal day 3-6: preganglionic (n=12) or postganglionic (n=12) neurectomy, forelimb disarticulation (n=12) to examine effect of unloading without nerve injury, or sham (n=8). Animals were sacrificed at 2, 3, 4, 8, or 16 weeks post-injury, and 11 muscles surrounding the glenohumeral joint were dissected from injured and uninjured limbs: pectoralis major, acromiodeltoid, spinodeltoid, supraspinatus, infraspinatus, teres major, teres minor, subscapularis, triceps, biceps long head, and biceps short head. Muscle mass and length were measured for each muscle. Injured versus uninjured limbs were compared using paired t-tests, and groups were compared with Kruskal-Wallis tests (α=0.05). Analyses are ongoing, but current results suggest that muscle mass is affected in more muscles and to a greater extent than muscle length by preganglionic and disarticulation surgeries when compared to the postganglionic and sham groups. However, both metrics were significantly altered in the injured compared to uninjured limbs for some muscles. These differences occurred primarily in the spinal deltoid, supraspinatus, infraspinatus, and triceps muscles ($p<0.05$). Additionally, these changes are most present at 4 and 8 weeks post-injury. These results indicate that BPBI-related muscle weakness results from both muscular unloading and preganglionic nerve injury, and that the aforementioned weakness occurs as a result of reduced muscle size and mass.

Abstract Name: Destination Determinants: The Role of Culture, Politics, and Identity in Selecting Study-Abroad Locations

This research investigates the question: How do cultural perceptions, social identities, and institutional influences shape U.S. college students' study-abroad destination choices? Drawing on the Push/Pull theory,

Territorial Stigma theory, and Capital theory, this study positions itself within the scholarly conversation about international educational mobility. It seeks to make a unique contribution by correlating students' social, cultural, and institutional capital with their choices, particularly highlighting the understudied impact of faculty members' perspectives on these decisions. The research aims to uncover the multifaceted influences on students' decisions, highlighting the interplay between personal, cultural, and institutional factors. Employing a mixed-methods approach, the research incorporates qualitative interviews with Colgate University students and faculty and participant observations to reveal the nuanced interplay between individual motivations and broader cultural narratives. This methodology enables an in-depth examination of students' preconceived notions and the influence of their social networks and institutional guidance.The expected results of this investigation are twofold: firstly, to confirm the hypothesis that students' perceptions of 'safe' and 'fun' correlate with a predilection for Western, English-speaking countries, while motivations for global awareness direct them towards 'adventurous' non-Western countries. I predict that students have stigmatized subjective opinions on study abroad destinations before departure. Secondly, substantiating the anticipation that students' racial or ethnic backgrounds and the recommendations of their social circles, including faculty, significantly influence their destination choices, potentially challenging or perpetuating territorial stigmas.This research aspires to serve as a blueprint for broader analyses in similar educational environments by delving deep into the sociological underpinnings of study-abroad decisions among Colgate students. It is a step towards creating a more informed and inclusive global academic community where genuine curiosity and understanding drive students' choices rather than unchallenged biases and preconceptions.

Abstract Name: The Effects of Manuka Honey-Derived Flavonoids on Neutrophil Production of Reactive Oxygen Species

Neutrophils are the most abundant leukocyte in the human circulatory system and are considered the first responding immune cells. Neutrophils respond to foreign bodies by producing reactive oxygen species (ROS). The extent to which ROS are present is a crucial indicator of the host reaction to an invading pathogen or implanted medical device. Previous findings from this lab have indicated that flavonoids derived from Manuka honey: pinobanksin, pinocembrin, and chrysin, possess anti-inflammatory properties. From these conclusions, the production of ROS should be reduced in neutrophils exhibiting pro-inflammatory behavior when treated with Manuka honey-derived flavonoids. Human neutrophils were isolated from a peripheral blood sample. Cells were seeded at 100,000 cells/well, and serial concentrations of the flavonoids were added. The cells were stimulated to be pro-inflammatory with 100 nM phorbol 12-myristate 13-acetate (PMA). A positive control group of PMA-stimulated cells without Flavonoids and a negative control group of unstimulated cells were also included. Using a standard oxidation assay, the ROS levels were measured at three and six hours via spectrophotometry. As seen in prior experiments using a neutrophil-like cell model, an overall reduction of ROS levels was detected across flavonoid concentrations. Continuing work will reveal the most effective concentration at which the flavonoids have anti-inflammatory activity for integration into biomaterials for improved biological integration.

Abstract Name: Phonology Variations in Ulanqab Jin

This is a study that focuses on the status of Ulanqab Jin, specifically how its phonology differs among age, socioeconomic status and attitudes towards the language. As a variation of Jin, one of the largest non-Mandarin sinitic languages in the Chinese regions of Inner Mongolia, Shanxi, Shaanxi, Henan and Hebei, Ulanqab Jin is both understudied and is on the track of being replaced by Mandarin. While not having an official status, or writing system, the language is also widely disdained by its speakers. In an age of rapid globalization and the universality of Mandarin, speakers tend to stop speaking it and not pass it to the next generation, as the language lacks both overt and covert prestige. By interviewing 128 residents of Ulanqab from 6 age groups, the study aims to investigate how different elements affected the phonology of Ulanqab Jin. The study utilizes a survey focused on collecting people's background, attitudes and usages of the dialect, and a wordlist made of 261 words four sentences and a free talk section to collect people's sound samples to analyze the phonological organization of each individual. The study aims to use mostly quantitative analysis to compare and explain the correlations between people's pronunciation and their background information. The differences in their pronunciation between reading and free talking will also be analyzed, as well as comparing their Jin pronunciation with their proficiency in “Standard Mandarin " taught in almost all Chinese schools. The ultimate goal of the study is to demonstrate a status quo of this minor Chinese variation and predict the future of it by analyzing its endangerment.

Abstract Name: Analysis of circumnutation developmental profile in Arabidopsis thaliana

Circumnutation is the mysterious back-and-forth elliptical swaying conducted by plant appendages. Even though circumnutation was well written by Darwin over 150 years ago (Darwin, 1880), the purpose of circumnutation is still unknown. To better understand the purpose of circumnutation in shoots, this experiment involves creating a developmental profile of the circumnutating flowering stems in the genetic model plant, Arabidopsis thaliana. The use of time-lapse photography on the X, Y, and Z axis allows the responses of Arabidopsis inflorescences to be tested. The apex of A. thaliana’s inflorescences was traced via PASCO-Capstone (pasco.com). 3D models of circumnutation developmental profiles were made in the research via Cinema 4D. Several phases of circumnutation were identified in this research including “Micro-circumnutation”, “Meso-circumnutation”, “Macro-circumnutation”, and “Horizontal Swinging Stage”. Meso-circumnutation and Macro-circumnutation were considered as “phase 1” of circumnutation, followed by Micro-circumnutation and Horizontal Swing Stage as “phase 2”. 100% of Arabidopsis thaliana showed at least one phase of motion during development. 78.5% of Arabidopsis thaliana showed several phases of motion during development. The average height of the primary inflorescence of the first nutation was identified. Fourier Transformation was conducted to show the most common nutation frequency within Arabidopsis thaliana development.

Abstract Name: Pareidolia: The Face of Architecture

In clouds, nuggets, chips, trees, and more, pareidolia guides people to see meaningful patterns and objects like faces in ambiguous stimuli. Utilizing the power of the face to embody, evoke, and convey feelings, this paper aims to explore the presence and potential impact of face pareidolia in the built environment. Throughout history, studies have shown that faces are actively incorporated into architecture, seen in both the human-like Tata Somba houses built by the Batammaliba as well as the popular nine-square grid layout used for various buildings like the Taj Mahal, Parthenon, or the Basilica of St. Petersburg. Today faces and their corresponding emotions have been identified in the built environment by both human subjects and facial-recognition software, indicating that factors like scene analysis size, time of day, and the ease of face identification can all alter the emotions imparted by architecture. Based on these findings from previous scholarly work, a small experimental pilot study was conducted to explore the comparative impact of pareidolic elements in the built environment. Through computer-aided design renderings where elements were selectively altered, a correlation between the ease of face identification and the emotions imparted to the viewer was established. Based on this preliminary study, this paper demonstrates a need for actively designed subtle pareidolic imagery in architecture. Furthermore, even though most studies of pareidolia analyze 2D images, architecture is a 3D experience, so this study plans to expand to virtual reality to not only collect responses on emotional reactions but also to monitor eye movements indicative of interest. In conclusion, subtle pareidolia should be actively applied in architectural design to impart and improve positive emotions in public places like hospitals or schools, as well as provide a warm and welcoming façade that turns a house into a recognizable home.

Abstract Name: Reasonableness of Christianity:

Is Christianity reasonable? Asking whether Christianity is reasonable means is there enough evidence to support the Christian faith as a position that cannot be easily discounted as opposed to another religious or nonreligious position. Is there enough merit to Christianity as, say, atheism? The question of whether a god exists is an immensely important issue for society no matter what position is taken on the question. This research will be a comparison of differing worldviews concerning religion to help form an opinion on which view is more reasonable to believe in.This research will require me to read various religious doctrines and several written works of prominent apologists of Christianity, atheism, and other religions. I will conduct comparative analysis and cross-examination between these works; identifying what I believe to be strong and weak arguments for each position.Christian apologetics is the demonstration of reasoned arguments for Christianity based on philosophy, science, history, and theology. Given my current understanding of Christianity, I would like to understand the arguments for Christianity better by researching prominent Christian apologists such as C.S. Lewis.Well-constructed atheist arguments and philosophies have been

around for centuries, but in the last couple of decades there has been the rise of the ‘new atheists.’ Among the new atheists, there are 4 that prominently stand out as leaders of the movement: Richard Dawkins, Christopher Hitchens, Sam Harris, and Daniel Dennett. I plan to research prominent works from each of these individuals to understand the modern arguments for atheism.Going into the project, I already had a basic understanding of both Christianity and atheism. I plan to research the doctrines of Buddhism, Islam, and Hinduism to better understand these major world religions and potentially decide that one of them is more reasonable than either Christianity or atheism.

Abstract Name: Investigating the Community that Uses Desert Tortoise (Gopherus agassizii) Burrows at Boyd Deep Canyon Desert Research Center

The federally threatened Mojave desert tortoise (Gopherus agassizii) is a keystone species inhabiting the Mojave and Sonoran Deserts. Desert tortoises excavate burrows, providing unique microhabitats with more stable thermal conditions than the ambient environment for both tortoises and other species to use. For the past two years, we have monitored the community of animals that use tortoise burrows and tracked local temperature in order to better understand how the desert community utilizes this valuable resource. We deployed eight game-cameras at the Boyd Deep Canyon Desert Research Center in Palm Desert, CA, outside of tortoise burrows. Burrow visitors triggered cameras that recorded 30-second time and date-stamped videos, and we identified the species in each video. Between June 2021 and December 2023, (6,003 total trap nights), the cameras recorded over 8,000 videos with animals. We have identified 36 species in the videos that use tortoise burrows: 15 birds, 11 mammals, 7 non-avian reptiles, and 3 insects. In addition, we measured shaded temperature at a weather station located at Boyd Deep Canyon Desert Research Center near the tortoise burrows. We will correlate burrow activity with temperature. This research provides clues about how animals use these spaces, and how burrows may place increasingly ecologically relevant roles as temperatures continue to rise due to climate change. Continued observations of desert tortoise burrows and how burrow use ecology naturally changes across various temperatures will provide a clearer understanding of the role their burrows play in this ecosystem, and how to maximize their benefits in the face of a changing ecosystem.

Abstract Name: Using the Healthy Minds Survey to Understand Student Emotional Wellness

BackgroundRecent Research has demonstrated the prevalence and severity of mental health issues among college students has risen over time and has negatively impacted health and academic performance. Further, the institutional environment is a critical component to emotional well-being. This study is intended to provide stakeholders with a method to measure overall emotional wellness and understand predictors from a common assessment instrument, thus providing a tool for intervention.MethodsData was obtained from the Healthy Minds Study 2021-2022 Academic Year Survey administered at the University of Tampa. 1054 participants (n=1054) were included in the data set following data cleaning and transformations. Factors for predicting student emotional wellness were selected based on literature review, including the selection of Diener Flourishing scores to serve as the dependent variable to measure student emotional wellness. Descriptive statistics were conducted based on stakeholder input. A multiple linear regression was produced and assessed for statistical significance and power to predict student emotional wellness.ResultsThe multiple regression model statistically significantly predicted student flourishing scores in 34% of students with a positive, moderate level of association, F(8,1045)=69.246, p<0.001, adj. R2=0.341, R=0.589, std. error=0.939. Perceived campus support, perceived stigma, sense of belonging, exercise, and sleep were statistically significant predictors of student flourishing scores (y) (p<0.001). ConclusionsIt is anticipated that this study will help to effectively craft group-level interventions and provide a path for continued research on student emotional wellness.

Abstract Name: Examining the Influence of Various Time Periods on Mood Through Best Possible Self

The intervention known as Best Possible Self (BPS) is an activity that requires individuals to envision their future as if all their life goals have been achieved. The BPS prompt has been used in numerous studies since first being introduced by King (2001). In our study, we modified King's prompt, which did not specify how far in the future to think, and gave participants different time frames about which to write. The four groups in our study were 10 years in the future, 50 years in, the original BPS prompt, which has no time frame, and the control group which was to write their plans for the next day. Participants were asked to complete the Positive and Negative Affect Scale (PANAS, Watson, Tellegen & Clark, 1988) and then they were directed to write continuously for 15 minutes about their given prompt. Once the 15 minutes are done the participants completed the PANAS a second time. Both the 10 years in the future group and the original BPS prompt showed significant increases in positive affect t(29) = 2.852, p = .008 and t(29) = -4.403, p = <.001 and significant decreases in negative affect t(29) = 2.227, p = .034 and t(29) = 2.587, p = .015. Interestingly, the 50-year group had an increase in positive affect t(29) = -3.407, p = .002 but no significant change in negative affect t(29) = -.700, p = .489. The control group showed no change in their positive affect t(25) = 1.643, p = .113 as well as no significant change in negative affect t(25) = 1.074, p = .293. This might be due to our sample of college students who could have a test the next day, homework, etc. The purpose of this study is to test whether using different periods of time in the best possible writing prompt will affect changes in mood normally found when using the prompt.

Abstract Name: Energy-Descent: A Differentiable Energy-Aware Loss Function

Sparsification plays a crucial role in improving machine learning energy efficiency. However, conventional methods tend to oversimplify the dynamic resource distribution within neural networks due to simplistic sparsifying regularizers. Additionally, standard pruning methods involve high overhead, and furthermore greater energy costs, due to their nondifferentiable and iterative nature. To tackle these challenges, we introduce an innovative approach situated at the intersection of energy-aware and differential pruning, with the goal of synthesizing their respective benefits. In this paper, we explore how dynamically changing the geometry of the regularization curve in response to the distribution of a node's parameters can upgrade the sparsification process. We propose a novel loss function that differentiably calculates the l0-norm—the number of nonzero components—of a node parameter vector, and uses this in tandem with the variance of this vector to most effectively sparsify its parameters without any sort of pruning overhead.

Abstract Name: The Association Between Online Payments Using Different Payment Types and Six Consumer Assessment Characteristics

During COVID-19, there was a significant uptick in online payments due to the restrictions stemming from the pandemic, which shifted how businesses catered to their customers in person and online. Moreover, there is an ever-increasing need for research on consumer behavior in the digital marketplace and the viability of available payment choices that businesses cater to their consumers' preferences. This paper aims to delve into the relationship between online payments using various types of payments, such as cash, checks, debit cards, credit cards, prepaid cards, money orders, and bank account number payments, during COVID-19 and six characteristics used to assess payment choice. The six characteristics are security, acceptance, getting and setting up, cost, convenience, and payment record. The data used in this analysis is from the 2020 Survey of Consumer Choice published by the Federal Reserve Bank of Atlanta. The data has been through a multistep weighting process to be nationally representative. Then, a logit regression model is used in a cross-sectional analysis to explore the relationship between making online payments and the six assessment characteristics. This analysis will show statistically significant characteristics and control variables that correlate to specific payment types used during COVID-19. Preliminary results indicate a statistically significant association between payment records and cash, payment records and credit cards, security and prepaid cards, acceptance

for payment and bank account number or routing number payments. Also, the control variable for education level showed a significant statistical association between all education levels and all payment types.

Abstract Name: Software Integration for an Adaptive Autonomous System Informed by Unobtrusive Measures of Trust, Workload, and Situation Awareness for Deep Space Exploration

Autonomous systems are becoming part of our daily lives, from automatic vacuum cleaners to self-driving cars. These systems aim to facilitate and support multiple processes while decreasing human input. Autonomous systems also have advantages that can be applied to novel tasks that astronauts will encounter in deep space exploration. We explore human-system team collaboration for resilient, autonomous, and self-maintained deep-space habitats. Previous research into adaptive autonomous systems has considered only a single cognitive state, adapted based on observable states (e.g., task load), or employed multiple sensors simultaneously to estimate cognitive states. Future crewed missions to deep space will involve communication delays, making Earth-based mission control infeasible. We propose an autonomous habitat that keeps the human in a supervisory mode. When something fails, the system adjusts intelligently based on the user's current cognitive states (such as trust, mental workload, and situation awareness) to present the error and the possible solutions to best support human operators. We utilize unobtrusive measures derived from operator background information, behaviors, and interactions with the system to estimate real-time cognitive states. To investigate the hypothesis that an autonomous system that adapts its operation according to cognitive state estimates can improve human-system team performance, we developed a system that manages the environmental control and life support system for a space habitat and helps the user to solve faults. We plan to compare the performance of three conditions across 30 subjects: a non-adaptive control, a random/naively-adaptive control, and an intelligently-adaptive system. Our future work will investigate unobtrusive measures with fewer features that can provide estimation with similar accuracy. It could provide transferability to autonomous systems in multiple fields without the need for multiple sensors.

Abstract Name: Consumer Attitudes & Preferences Toward Sustainability vs. Shopping Behaviors

Considering the major impact different farming practices have on water quality, it is important that farmers receive the support they need from consumers to incorporate more sustainable farming methods on their land. Past research indicates that awareness, preferences, connection, and responsibility are factors that increase

sustainable consumer behaviors. This research builds on these ideas to address how consumer attitudes and preferences toward sustainability compare to people's shopping behaviors. Survey data reveals that even though these factors do elicit sustainable behaviors, there is still a disconnect between consumer preference for sustainably and locally sourced foods and actual shopping habits.

Abstract Name: Investigating the Role of HSR-9 in X-Chromosome Segregation during Oogenesis

During meiosis, defective and inviable progeny can occur if homologous chromosome pairing and synapsis are not done accurately. Checkpoints monitor chromosome pairing and synapsis to facilitate accurate chromosome segregation. 53PB1 is a tumor suppressor protein that functions in DNA repair and cell cycle checkpoints. The C. elegans ortholog of 53BP1 is HSR-9. To determine whether HSR-9 plays a checkpoint role in monitoring synapsis in meiosis, I constructed a double mutant homozygous for hsr-9 and zim-2. ZIM-2 is a zinc-finger protein that binds to chromosome V and mediates its synapsis; zim-2 mutants lead to embryonic lethality due to a failure to pair and synapse chromosome V during meiosis. I also examined the consequences of removing the X chromosome pairing center protein, HIM-8, as HSR-9 is concentrated on the X chromosome pair. him-8 mutants disrupt X chromosome segregation, which leads to a high incidence of male progeny. The results show that HSR-9 does not play a significant role in signaling when autosomal chromosomes fail to pair and recombine. However, there is statistically fewer male progeny produced by hsr-9;him-8 vs. him-8, suggesting a role for HSR-9 in X chromosome segregation. To understand why this reduction in males occurred, I am currently trying to uncover if this is specific to oogenesis and to measure nondisjunction events. To that end, I am generating hsr-9;him-8 and him-8 strains that mark each of the X chromosomes with a fluorescence marker (GFP and dtTomato) to determine if the absence of HSR-9 alters the pattern of chromosome nondisjunction events when crossed to wild-type males. The results from these studies will provide insight into the role of HSR-9 in X chromosome segregation.

Abstract Name: The Divergent Patterns of Fungal Pathogen Presence in Crayfish and Newts

Fungi are ubiquitous in nature and are essential for the overall health of ecosystems, affecting everything from water quality to the health of the organisms. Although many fungi play beneficial roles in nature, some fungi such as Batrachochytrium dendrobatidis (Bd) can cause disease in the members of the ecosystem. This

chytrid fungus continues to be a major contributor to global amphibian declines and lowers the quality of life of many other creatures (e.g., crayfish). As potential carriers of Bd, crayfish are a possible mobile microhabitat to move and persist the presence of Bd in aquatic ecosystems. This project investigated the Bd prevalence on crayfish populations (Cambarus robustus) adjacent to a population of newts (Notophthalmus viridescens) which have been documented to carry Bd. Surprisingly, none of the crayfish sampled over three different surveys (n=60) revealed signs of Bd infection when assessed with pathogen specific real-time PCR (qPCR), while the resident newt population (n=20) had 95% infection rates. Improving our understanding of how this pathogen is moving naturally within an ecosystem and how it is impacting the broader community will aid future conservation efforts.

Abstract Name: Characterization of PpEC86: An Effector Protein of Phakopsora pachyrhizi Suppressing Soybean Immune Responses

Phakopsora pachyrhizi is an obligate biotrophic pathogen and the causal agent of the devastating soybean rust (SBR) disease. When left uncontrolled, SBR can cause yield losses of up to 90% and can incur billions in economic losses in soybean-growing areas, especially in South America. Part of what makes SBR aggressive is its ability to manipulate plant host immune systems through haustoria-secreted effector proteins. Previous work has identified P. pachyrhizi effector candidate 86 (PpEC86) as a plant immune suppressor. Using transgenic soybeans expressing PpEC86, we performed ROS burst and bacterial infection assays to measure PpEC86 immune-suppressing capabilities in soybeans. Additionally, yeast-two-hybrid followed by a split luciferase complementation assay was performed that identified protein-protein interactions between PpEC86 and a soybean iron superoxide dismutase (SOD). Understanding how effectors work to manipulate host plant immunity moves us one step closer to improving soybean resistance to this devastating fungal pathogen.

Abstract Name: Control, Motherhood, and the Power of Demeter, as portrayed in the Homeric Hymn to Demeter and Ovid's Metamorphoses

Who holds the power in the myth of the abduction of Persephone, and who makes the choices? In the Greek version of this classic myth, the Homeric Hymn to Demeter takes a sympathetic view of Demeter, showing the positive perspective and influence of her motherhood. Rather than sympathizing with a masculine perspective, the Homeric version embraces the feminine perspective, criticizing Zeus' and Hades' actions in

the abduction while bringing to light female solidarity in ancient Greece. It portrays Demeter as in control, as she decisively subverts the Olympian and Greek social order, exercising power over the universe as she uses her stubborn act of wrath to ensure the safe return of her daughter, Persephone. However, Ovid's Roman version of the myth in Book 5 of Metamorphoses undermines Demeter's power, choosing to eliminate her powerful moments of influence, especially in her creation of the Eleusinian Mysteries and in her honorable outcome. In addition, Ovid's version takes a sympathetic view of the masculine perspective, excludes the example of Demeter's motherhood, absolves Zeus and Hades of blame, and eliminates Demeter's control once held in the Homeric Hymn. This essay compares the two versions in their amounts of agency in male and female perspectives, their views on Greek motherhood, and the power of Demeter, setting up the foundation of these views in modern reception of the myth.

Abstract Name: Social Epidemiology can solve racism

Objective: This scholarship aims to advance the understanding of racism's impact on health by using the Social Ecological Model to succinctly define social-structural terms. Researching and mitigating the effects of racism through these collective definitions will create a more accurate effective measure of racism. Background: Social Epidemiology aims at discovering what influences and affects one's health through analyzing social determinants of health. But there are many issues with how current social epidemiological practices are carried out, particularly with the development of social theory and how we define social mechanisms such as race, gender, and rurality. Social epidemiology is a discipline in between a hard science and a social science but many of the definitions commonly used, particularly race and racism, aren't created in conjunction to, but isolated from, other relevant disciplines. Methodology: Through a scoping review of the literature, the key to restructuring definitions of race and racism is to use the Social Ecological Model (SEM) to give clarity on how to research these in a population. The SEM has 5 levels of influence: intrapersonal, interpersonal, institutional, community, and policy. These levels comprise of all of the major layers of influence in society and, by defining social-structural terms in all 5 levels, they can be used to inform new and current interventions for improving equity surrounding race and racism. Conclusion: These new comprehensive definitions informed by the SEM can then be used to create toolkits for measuring racism more effectively.

Abstract Name: Religious Diversity and Culturally Responsive-Sustaining Teaching

As progressive efforts to engage with diversity deepen in the sphere of education, professors and teacher candidates realize that culturally responsive teaching is becoming a core aspect of any successful education department. Culturally responsive teaching ensures that each student is understood and instructed in a way that makes them feel safe and supported. It also addresses the roots of discrimination that may arise from a lack of understanding and education regarding diverse experiences and people. As classroom diversity continues to increase nationwide, competency in culturally responsive teaching becomes paramount in preparing teachers for success. Although religious diversity is essential to educating students in a way that eliminates bias and supports an inclusive environment, it is only sometimes a topic of discussion in teaching programs at the collegiate level. Our previous studies at a Christian liberal arts college found that education students needed a broader understanding of religious diversity through their experiences in the education program. We hoped students majoring in education would have less religious bias than others, but this was not the case. With a sample size of 316 college students (156 education students, 160 non-education students), among them 160 first-year students and 156 seniors, we conducted a two-part multiple choice survey. The first part asked students to determine whether each religious term from various world religions has the following connotations: positive, neutral, or negative. The second part asked students to associate a specific religion with a given term. Our results indicated that despite being in the program for four years, there was little to no difference in perception of different religions.

Abstract Name: Concurrent Validity of Body Composition Measures Across Four Modalities Among Male Collegiate Division III Wrestlers

Background/Purpose: The National Collegiate Athletic Association (NCAA) regulations require a minimum of 5 percent body fat (%BF) to participate in a wrestling season. The purpose of testing pre-season %BF is to provide the wrestlers with information on how much weight they can safely gain or lose to be in a specific weight class. The aim of the present research is to compare the difference in %BF measured by the reference criterion dual-energy x-ray absorptiometry (DXA) assessment against approved body composition testing methods (e.g., skinfold (SKF), bioelectrical impedance analysis (BIA), and hydrostatic weighing (HW)). Methods: Twenty-four university wrestlers (18-24 years of age) participated in this study. Each participant underwent a 60-minute body composition assessment session. Prior to testing, urine specific gravity was measured to ensure optimal hydration status using a refractometer. The testing occurred in the order of upper-body BIA, SKF, DXA, and HW. Results: Four participants were excluded from data analysis due to over-hydration; therefore, 20 participants were included in the analyses. A one-way repeated measures analysis of variance, using an alpha level of .05, indicated a significant difference in %BF across the four modalities. Paired sample t tests were employed for multiple comparisons using Bonferroni-adjusted alpha of .0083. Results indicated no difference in %BF for SKF vs. BIA, SKF vs. HW, and BIA vs. HW (p > .0083).

There was a significant difference in %BF between DXA (M ± SD) vs. BIA (M ± SD), SKF (M ± SD), and HW (M ± SD) (p < .001). Conclusion: In NCAA DIII collegiate wrestlers, DXA overestimated %BF by 2.9%, 3.1%, and 3.7% compared to SKF, HW, and BIA, respectively. Further investigations are warranted prior to implementing DXA as one of assessment methods for pre-season body composition screening for collegiate wrestlers.

Abstract Name: Monitoring Antibiotic Resistant Populations as a Correlative to Water Quality

Agricultural land use can have adverse effects on the surrounding waterways, which may cause environmental and economical disturbances including but not limited to species assemblage disruption, loss of habitat and wildlife, and human health impacts. There is a need to monitor in vivo aquatic systems, specifically those in agricultural areas, to not only provide a more holistic view into the correlation between agriculture land use and aquatic environmental disruption but also to develop more succinct and effective monitoring and management guidelines. The Blanchard River serves as an excellent model system suitable for monitoring antimicrobial resistant microbe sustainability within a highly agricultural area that also serves as a contributor to the Lake Erie water basin. Outside nosocomial infections, minimal research has been completed to determine the reservoirs of MRSA (methicillin resistant S. aureus) and other resistant microbes. One hundred and twenty-six sites within the Blanchard River and its tributaries were monitored for antibiotic resistant microbes including MRSA. All sites had antibiotic resistant populations while twenty-six of the sites harbored MRSA. Sixteen Areas of Concern (AOCs) were chosen in conjunction with the Blanchard River Watershed Partnership to determine if traditional water quality measures of E. coli concentrations, nutrient levels and macroinvertebrate populations correlate with antibiotic concentrations and resistant populations. There is no correlation between land usage or antibiotic concentrations and the presence of antibiotic resistant microbes. There were weak correlations between antibiotic concentrations and pollution resistant macroinvertebrates and a weak negative correlation between E. coli levels and pollution sensitive macroinvertebrates. Shown through multi-year sampling, water systems have proved to be a novel mode of transmission as MRSA persists in equine and bovine populations in the surrounding communities. Taking the next step toward ensuring water quality via preventative measures, we sought to type the MRSA strain to confirm its origin.

Abstract Name: Latent factor decomposition on electronic health records reveals Alzheimer's disease heterogeneity

Alzheimer's disease (AD) is a highly heterogeneous disorder with many co-occurring conditions and risk factors that remain poorly characterized. This substantially limits the ability to identify high-risk individuals and to develop targeted treatments. Electronic health records (EHR) provide an opportunity to disentangle comorbidity relationships in AD patients over time. Here, we quantified the contribution of diverse pre-existing clinical phenotypes to the development of AD in patients in the UCSF EHR database. Using only billing codes found in patient EHRs, we constructed a longitudinal phenotype tensor representing phenotypes for thousands of AD patients over ten years before their diagnosis. To define comorbidity patterns in our AD cohort, we used latent factor decomposition (LFD), a robust unsupervised methodology for distilling large amounts of high-dimensional data like patient EHR trajectories. We performed CANDECOMP/PARAFAC (CP) tensor decompositions using a nonnegative hierarchical alternating least squares algorithm. The resulting factors identified many interpretable AD comorbidities including cardiovascular disease, diabetes, and osteoporosis that were previously identified in the literature. In addition, novel neurological and gastrointestinal phenotype patterns were identified, although further external validation is needed via sensitivity analyses. This LFD approach furthermore provides improved resolution of the temporal dynamics of AD comorbidities and can be applied to a wide variety of chronic and infectious diseases. Overall, such tensor analyses provide a promising tool for resolving disease heterogeneity in increasingly complex datasets with the hope of delivering personalized medicine.

Abstract Name: Activism Without the 'A': Asexuality's Exclusion From College Anti-Sexual Violence Movements

This article explores asexuality's lack of recognition and belonging within three college activist movements in the United States: Yes Means Yes, Take Back the Night, and Abolish Greek Life, describing how these movements erase and invalidate asexual survivors. By presenting how narrow mission statements, generalized language, and allonormative history are used to create anti-sexual violence protests and events in these organizations, their perpetuation of compulsory sexuality and erasure of asexual experiences are revealed. The article addresses how movements that involve relationships and queerness become a setting solely for allosexual bodies, excluding asexuality from the social movements. The article argues that the college movements: Yes Means Yes, Take Back the Night, and Abolish Greek Life are perpetuating narrow, allonormativing understandings of survivors of sexual violence and their experiences, othering asexual-identifying students in college anti-sexual violence movements.

Abstract Name: Integration of Control for Diverse Multi-Robot System

The University of Idaho's Center for Intelligent Industrial Robotics (CI2R) aims to further research in the fields of precision agriculture and industrial automation. One ongoing project is an automated farming robot (FarmBot) which autonomously takes care of crops using light from a temporary, fixed lighting system. A new, Programmable Logic Controller (PLC)-controlled variable height Light-Emitting Diode (LED) lighting gantry robot has been designed and built, thanks to grants from the University's Office of Undergraduate Research, but its software is yet to be fully integrated into the FarmBot autonomous plant care system. The use of a PLC, an industrial automation tool, in this domain serves as an application of industrial automation techniques to precision agriculture. This semester, communication between the FarmBot and the lighting gantry robot will be fully integrated into the recently developed Python Control Module (PCM), which currently only handles the FarmBot plant care routines. This integration will ensure the multi-robot system will avoid collisions as well as allow the light panels to "grow" with the plants as their lighting needs change. The lighting gantry robot is currently installed over a second, unused FarmBot for testing purposes but will be mounted over the original FarmBot upon completion of various consistency and safety tests.

Abstract Name: DNA Analysis of Fungal Diversity in Tuber Borchii Truffle Orchard Soil

Changes in fungal diversity in a soil environment gives insight into potential fungal interactions occurring in the soil. This project examined various aspects of fungal diversity in truffle orchard soil, where loblolly pine trees are host plants for Tuber borchii fungi. Tuber fungi are mycorrhizal, meaning they form mutualistic relationships with host plant roots. The truffle orchard soil is composed of both mycorrhizal and non-mycorrhizal fungal genera. This research aims to identify any trends in relative Tuber abundance among other fungal genera in the soil and any changes or consistencies in fungal genera distribution in the soil as the orchard ages. Oxford Nanopore sequencing technology coupled with large scale DNA analysis was used to identify fungal genera in multiple soil samples from 1–2-year-old orchards and 7–8-year-old orchards. There was a significant increase in relative abundance of mycorrhizal fungi among all fungal genera in the soil as the orchard ages; however, there was significant decrease in relative Tuber abundance among those mycorrhizal fungal genera in the soil in that same orchard age transition. While Tuber remains steady in the soil over time, other mycorrhizal fungi are becoming more prominent, which could lead to competition among mycorrhizal fungi in the soil. Our findings suggest that there will be some level of competition for host plant roots and nutrients occurring between Tuber and other mycorrhizal fungi in the orchard soil when the root network stops expanding and root space becomes limited.

Abstract Name: Adolescent Mental Health

Adolescence is a time fraught with change: bodies, minds, and situations. During this time, mental health issues which may or may not have been diagnosable in childhood become increasingly apparent. Struggles like depression, anxiety, and eating disorders can elevate the typical strifes of adolescent development. Hormonal changes often intensify feelings both good and bad. Socialization and the creation of self-identity become increasingly important and anxiety provoking for many during this period. Some risk factors for mental illness like genetic predisposition are obvious. Others, like feeling out of control of one's own environment, are less so. Equally nuanced to risk factors are possible methods of recourse. Deciding when an adolescent is exhibiting symptoms of mental illness which require severe intervention or medication can be incredibly difficult when the emotional life of even a typical teenager appears from the outside to be so inherently tumultuous. Prioritization of an individual's mental health is incredibly important at all ages. However, there are unique social factors and developmental characteristics adolescents face which color and differentiate their experience from those in other age groups. The purpose of this literature review and summary of existing psychological research is to demonstrate the differing cognitive processing between adolescents without diagnosable mental health issues and those that do suffer. By exploring these differences, along with the risk factors leading to the development of mental illnesses and possible physical and social consequences of allowing mental illness to go untreated, behavioral health scientists and providers can better understand the unique condition of adolescent mental health. According to the American Psychological Association, more than 20% of American teenagers have seriously contemplated suicide. Anything that can be done to reduce this number and improve the quality of life of adolescents who are struggling is of the utmost importance.

Abstract Name: Manipulating the Connection: The Effect of Profile Privacy and Affect-Intense Language on Perceptions of Deception

Although large media and community attention to online grooming and human trafficking has soared in the last few decades, little attention has been paid to the specific communication tactics used by perpetrators to lure their victims. Prior to the rise in popularity of social media, human trafficking mainly occurred through face-to-face interaction. However, with increased social networking platforms, there have been links to human trafficking and its pursuits (Olsen et al., 2007; Quayle et al., 2014; Kehl, 2020). Social networking sites, such as Instagram, allow human traffickers to form relationships with their potential victims by creating fake social networking profiles and engaging with them through manipulated conversations. It is necessary to understand how individuals perceive these profiles and conversations due to the dangerous nature of the interaction. An experiment was conducted where 272 participants viewed fictitious Instagram conversations (high affect vs. low affect intense conversations) between a potential victim of online grooming and a

perpetrator, as well as a fictitious Instagram profile of a perpetrator (private vs. public). Participants were asked to rate their perceptions of trustworthiness, immediacy, affection, and deceit. There was no significant statistical effect size between the type of conversation/profile, and trustworthiness or deceit. However, there was a significant statistical effect size between immediacy and the high affect conversation condition (p> .03). The overall findings show that the participants viewed the perpetrators' messages as warm and affectionate, however, no indication of deceit or deception was inferred. Furthermore, the findings support the concept that studying deception in computer-mediated contexts is challenging, yet significant, especially in connection to crimes such as online grooming and human trafficking.

Abstract Name: Rare Bilateral Asymmetry in Brachial Plexus Branching

The brachial plexus is a network of nerves that innervates the upper extremities of the body, providing motor and sensory function to these areas. In most patients, the plexus originates from the ventral rami of the C5-T1 nerves. Pathologically, trauma to the nerves in the plexus may cause loss of strength and/or loss of sensation in the arm. Literature indicates that as many as thirty-eight variations in brachial plexus branching exist. Variations in branching are mostly harmless, however, some may be more susceptible to injury than others. Although brachial plexus morphology is well-documented, little literature exists on rare cases of bilateral asymmetry in branching. The original aim of the study was to record variations in brachial plexus branching with a focus on the ulnar, median, and musculocutaneous nerves, including their respective measurements. As the study progressed, an asymmetrical anomaly was observed in the terminal branch section of the nerves of a patient. The study used 20 upper limbs of 10 patients: 4 females and 6 males from the cadaver lab. The axillary section of the brachial plexus was exposed by students enrolled in an anatomy course before the study began. Through further dissection, the musculocutaneous, median, and ulnar nerves were exposed. Stopping points for measurements were determined by the first indication of branching from the main terminal branches: musculocutaneous nerve branching in the biceps brachii, and ulnar and median nerves in the carpal region. Measurements were recorded on an Excel spreadsheet table for data analysis. The frequency of the variations recorded is consistent with existing literature, along with the measurements of the terminal branches. Although the abnormality in branching asymmetry may not have affected the quality of life of the patient, this finding may aid in the development of neurosurgical procedures involving unexpected asymmetrical branching in the brachial plexus.

Abstract Name: Salt-Water Acclimation in Atlantic Salmon Sheds Light on Claudin Shifting and Tight Junction Membrane Proteins Composition

Tight junctions (TJs) are composed of three cell-adhesion molecules (CAMs) which regulate paracellular permeability in epithelial and endothelial cells. These are claudins (CLDNs), occludin (OCLN), and junctional adhesion molecules (JAMs). There are 25 isoforms of CLDNs in mammals, all suspected to have different strengths in cell adhesion. Currently, the comparative strength and characteristics of the interactions between different CAMs are unknown, and no easily replicable model of a TJ has been created. To address this question, we resorted to bacterial expression of CLDN proteins. These quantitative techniques developed in our laboratory were applied as a proof of concept to the case of the Atlantic salmon (Salmo salar or SALSA). During migration between fresh and saltwater (smoltification), the TJs in the SALSA skin change claudin composition–upregulating claudins 3 and 10. Through our measurements, we determined that these two claudins are more capable of maintaining their cell-adhesion strengths in the increased salinity of ocean water. Furthermore, in humans, disruption of the blood-brain barrier (BBB) leads to many different pathologies. The TJs of the BBB support are maintained by CLDN5. Post-stroke, CLDN1 is upregulated in the BBB and chronic leakiness of vessels ensues. Using our bacterial method, we showed that claudins 1 and 5 are incompatible and show no interactions, while other pairings of human CLDNs formed compatible mixtures. Our results suggest that quantification of the TJ cell-adhesion of CLDNs is possible and can be used to interpret or further studies of complex mixtures of CLDNs.

Abstract Name: Tuning Substrate Neutrality for Block Copolymer-Based Surface Patterning

Polymer self-assembly is a critical area of study in the microelectronics domain, specifically for semiconductor fabrication, surface patterning, and advanced lithography applications. Neutral surfaces are critical for controlling the morphology of block copolymers, and this is typically achieved using a precursor layer of random copolymer brushes (RCP). However, this method is highly batch-dependent and is not sufficiently reproducible or consistent. To address this problem, we used homopolymers of polystyrene (PS) and poly(methyl methacrylate) (PMMA) brush blend solutions to create a similar neutral surface with improved consistency. In addition, we investigated the effect of direct immersion in acetonitrile on the hydrophobicity of the sample. In this study, polystyrene (PS) and poly(methyl methacrylate) (PMMA) brush blend solutions were spin-coated onto silicon wafer. These were then thermally annealed under vacuum and cooled. After cooling, the samples were subjected to three rounds of immersion in toluene, with sonication for 10 minutes to remove excess ungrafted chains. Next, the hydrophobicity of the sample was investigated by collecting water contact angle measurements. The samples were then immersed in acetonitrile, followed by toluene, using the same method as previously mentioned. Water contact angle measurements were collected after each immersion. These results were directly compared with those of RCP brushes treated with the same method. Initial results indicated that direct immersion in acetonitrile decreased the measured contact angle, indicating a change in the chemical environment of blend brushes. This observation is unique to the homopolymer blends due to their ability to reorganize under selective solvents. Ongoing studies investigate the replicability of neutral surfaces created with a polymer brush blend layer and the merit of using direct immersion to tune hydrophobicity.

Abstract Name: How Engineering Student Mental Health Help-Seeking Beliefs Change Over Their First Year

Rates of anxiety, depression, and suicidal ideation have increased significantly among college students in recent years. Although existing studies have found that undergraduate engineering students report similar rates of mental health distress as their peers in other majors, distressed engineering students exhibit lower rates of mental health help-seeking. Previous qualitative research has discovered stress- and shame-filled environments in engineering programs that have aided in normalizing mental health issues and undermining students' mental health. Using the Integrated Behavioral Model (IBM) as a theoretical framework, this quantitative study investigated first-year engineering students' beliefs about mental health help-seeking and identified which beliefs most predicted their intention to seek professional treatment. First-year engineering students were surveyed at three time points– September 2021, December 2021, and May 2022– to examine how mental health help-seeking beliefs changed as first-year engineering students adapted to engineering culture and their college environment. Additionally, this study aimed to identify significant differences in the mental health help-seeking beliefs of male and female first-year engineering students. Key findings included a narrowing gap between the distress rates of male and female students over time and significant changes in the predictors of help-seeking intention. Student beliefs about whether others would expect them to seek help were most predictive of help-seeking intention initially, giving way to student attitudes about mental health help-seeking as the top predictor by May. These findings offer important insights into the beliefs of first-year engineering students about seeking professional treatment for mental health concerns, which will inform the design of interventions to encourage mental health help-seeking.

Abstract Name: Examining the interactions between symptom masking, quality of life, mental health and other lived experiences in adults with Autism Spectrum Disorder

This study investigated the relationship between symptom masking, overall quality of life, mental health (i.e., stress, anxiety, and depression) and other lived experiences in adults with Autism Spectrum Disorder (ASD). The World Health Organization describes ASD as a group of conditions that are characterized by having difficulty in social interactions and communication as well as restricted or repetitive behaviors. Masking (also referred to as camouflaging) is when a person tries to hide or mask their symptoms or personality to fit in to societal norms. Camouflaging is common in ASD. Further, recent research revealed a negative relationship between camouflaging and quality of life in individuals with ASD. However, the effects of symptom camouflaging on mental health have been understudied in ASD as have the relationships between age of diagnoses and these variables. Continued research is therefore needed to unpack these nuanced relationships.

In this study, 150 participants with ASD were recruited through an online platform, Prolific, to complete a battery of self-report questionnaires regarding ASD symptomatology, symptom masking habits, mental health, quality of life and other demographic questions. Regression analyses evaluating the relationships amongst variables will be discussed. This project adds to the scientific literature on ASD by illustrating how camouflaging may affect not only mental health but also broader lived experiences.

Abstract Name: Architecture and Graphic Design: History, Principles, and Purpose of the Visual Creations

Graphic design and Architecture are both art forms; they can be umbrellaed together, or are they disciplines that have more history, principles, and purpose within themselves than just the creation of visual aspects? More than just a creation of visual indulgence. But in what ways do they differ, and in what ways are they the same? When looked at historically, how do we ignore the integration and relationships between both? Design disciplines and visual powerhouses are both immediate, and most would not see these in the same field. Ultimately, they are not, but we see how they reflect and relate to each other over time and the changes that spur each other into the next evolution of their industry. The visual element of architecture and the integration of design solutions architects and those in the industry choose to integrate design principles in practice to make space for people in human evolution. As the human experience evolved, so did the ability to intellectualize that experience. Then, the ability to conceptualize, express, and ultimately communicate these human experiences is how written language developed into what we know today. Typeface and imagery started to show more in the built environment, integrated or executed on and within buildings, which was the springboard for an economic shift. The human experience was becoming more about what was being presented to you. Advertisement was the integration of graphic design and architecture; it was the built environment and the visual communication of the building or who it represented. Graphic Design and Architecture are more than visual aspects; they are their history, principles, and purpose. They are the human experience of evolution, communication, feeling, and an expanded expression of the experience.

Abstract Name: Discovering Novel Protein(s) that Bind to Nur77 in Immature CD4+ Single Positive T cells

The immune system plays a critical role in protecting the body from infections. T cells are an important part of this system, capable of directly killing or aiding in the destruction of pathogens. To reach maturity, immature T cells must undergo several developmental stages, including the CD4+ Single Positive (SP) stage. Nur77 is a protein that regulates various cellular functions, including inducing cell death and promoting cell proliferation and differentiation in immature double-positive (DP) T cells. Recently, our group found that Nur77 is also expressed by CD4+ SP immature T cells. However, there is currently no research on the interactions between Nur77 and cellular proteins within CD4+ SP T cells. To begin to elucidate the function of Nur77 in CD4+ SP T cells, we employed a discovery approach with a yeast-two-hybrid (Y2H) screen that allowed us to find novel protein(s) that interact with Nur77 in CD4+ SP cells. The Y2H library screen identified prefoldin 5 (Pfdn5) as an interacting partner binding to Nur77 in CD4+ SP T cells. Pfdn5 is part of a chaperone complex that assists with protein folding and has been implicated in promoting or suppressing certain cancers. Future directions could include performing immunohistochemistry for PFDN5 and Nur77 in tumor cells to determine their localization and expression levels. We could also look more carefully at the binding site between Nur77 and PFDN5 by making truncated versions of the proteins or introducing mutations in PFDN5 or Nur77 to try and disrupt their interaction and examine the downstream effects on T cell development. Understanding how Nur77 and Pfdn5 work together in CD4+ SP T cells can lead to a better understanding of T cell development and potential therapeutic targets for cancer.

Abstract Name: Facial Recognition Based Smart Lock

Vulnerability of traditional door locks against lock picking and minimizing lost key replacement cost, and remote locking or unlocking capabilities have persuaded house owners towards a smart door lock-based system for ensuring security at their home. Primarily these smart locks use fingerprints, keypads, or RFID tags to authenticate homeowners and open or close the locks. Due to the nature of the authentication, it is difficult for senior citizens as well as people with disabilities to use these door locks. In this paper, we propose a smart door lock system using Face Recognition for security and accessibility purposes. To design the smart door lock system, we adopted the OpenCV library. Furthermore, we have also designed a prototype for the proposed smart door lock using a Raspberry Pi. The prototype is equipped with a motion sensor, a

camera module, a relay, and a solenoid lock. As the lock is powered by a battery, to reduce power consumption and prolong the battery life, the device switches between an active and idle mode based on activities detected by the motion sensor. We have also developed a user-accessible mobile app using which users can control the lock remotely via their phones and create new authorized users. We also developed a liveness detection test to ensure nobody can gain access by showing a picture of the authorized user. Through experimentation, we demonstrate that the device can determine specific authorized users with 94% accuracy and the average time for the device to detect the user and unlock the door is 2.09 seconds.

Abstract Name: The Effects of Phone Activity on Perceptions of Athletic Performance

Previous research has found that individuals who use their cell phones more tend to have lower GPA, higher anxiety, and lower life satisfaction (Lepp et al., 2013). Kates et al. (2018) similarly found that mobile phone use has negative effects on educational outcomes. Mobile phone use is also related to poor physical fitness (Bravo-Sánchez et al., 2021). Among college athletes excessive recreational screen time is a risk factor for increased anxiety both during and outside of competition (Gao et al., 2021). It is hypothesized that there will be a negative correlation between phone activity and perceptions about athletic performance. Participants are undergraduate student-athletes who participate once a week for a three-week period. Participants complete a Phone Activity Questionnaire and the Athlete Perception of Performance Scale (Rice et al., 2021). Athletes in fall, winter and spring sports are being recruited to participate. The current sample consists of 33 college student athletes, aged between 18 and 23 years old on the women's volleyball and men and women's soccer teams. Data from week one was analyzed. To examine the association between phone activity and athletic performance correlational analyses were performed. A positive correlation between daily phone notifications and guilt about athletic performance ($r(33)=.41$, $p=0.05$) was found. Thus, the more phone notifications the athlete has the higher level of guilt they have about their athletic efforts. There was also a negative correlation between shame and no concern about athletic performance ($r(33)=-.74$, $p=0.01$) and a positive correlation between daily average screen time and shame about athletic performance ($r(33)=.35$, $p=0.05$), indicating that phone use is associated with shame about athletic performance. Thus, there is some support for the hypothesis. This is an on-going study, with more data to be collected during winter and spring sports.

Abstract Name: THE ROLE OF COGNITIVE FUNCTIONS IN SITUATION AWARENESS IN INDIVIDUALS WITH ATTENTION DEFICIT HYPERACTIVITY DISORDER

BACKGROUNDAttention Deficit Hyperactivity Disorder (ADHD) is characterized by spans of inattention, impulsivity and hyperactivity patterns. Individuals with this condition present cognitive abnormalities that reflect in behavioral features making the role of ADHD crucial in an individual's performance of difficult tasks that require extended periods of attention, information processing, and response. Situation Awareness (SA) refers to the ability to perceive, understand, and predict potential changes in one's environment. SA demands mental resources like attention and information processing [1]. Tasks that require a high level of SA and therefore demand these mental resources may pose a challenge for people with ADHD, since the periods of attention and inattention are more likely to rapidly shift. ADHD occurs in approximately 2.5% of adults and, "...can be an excluding medical condition among pilots due to the risk of attentional degradation and therefore impact on flight safety" [2]. In aviation, the pilot requires good SA in the three main levels: perception of information, comprehension of the situation, and projection of the situation [3]. While investigations [4] have studied ADHD in terrestrial operator tasks, there is relevancy to spaceflight since ADHD is not an exclusionary criteria for astronaut selection, but there is limited information evaluating the performance of individuals with ADHD in all three levels of SA.Studying SA in individuals with ADHD would help understand the cognitive processes that contribute to difficulties in tasks requiring focused attention and mental workload. Research could provide insights into the individual's physiology and brain functioning during these situations enabling them to better manage these situations. METHODSThis study collects physiological data from subjects: function near-infrared spectroscopy, electroencephalography, electrodermal activity, respiration, eye-tracking, among other task-performance metrics, while they engage with a modified MATB-II simulation (aircraft simulation). This approach aims to capture differences in SA between individuals with ADHD and neurotypical counterparts.

Abstract Name: Determining if exosomes from GLUT3 expressing glioblastoma cells increases the migration of macrophages

Glioblastoma (GBM) is an aggressive and invasive cancer characterized by rapid tumor growth. GBM cells present with altered glucose metabolism compared to normal cells. GBM cells' highly coordinated invasiveness results from cell-intrinsic properties and microenvironments. It has been discovered that glucose neuronal transporter 3 (GLUT3) upregulation enables cancer cell growth, correlating directly with its role in invasion and metastasis. The protein level regulation of GLUT3 may have significance in the highly heterogeneous tumor microenvironment of GBM, including nearby immune system components to a growing tumor. Macrophages, or phagocytic immune cells, are affected by tumor progression. Tumor associated macrophages (TAMs) primarily stem from bone marrow monocytes and can polarize to immunosuppressive states, fostering tumor aggression. Various cell types, including cancer cells, secrete exosomes to transfer signals between cells. We found that tumor derived exosomes have a potential role in tumor aggression by influencing macrophage-mediated immune response. Additionally, GLUT3 has a role in mediating GBM invasion that appears independent of its role in glycolysis. The effect of GBM exosomes on macrophages is studied to understand how exosomes influence macrophage function. Transwell migration assays can be used to investigate the migration of macrophages following GLUT3 overexpression BTIC derived exosomes. Additionally, analyses of gene quantification and protein modification with qPCR and western blotting, respectively, address the potential genetic and proteomic contribution in GBM invasion. This knowledge enhances the understanding of cell behavior and gene and protein alterations by tumor-derived exosomes, potentially leading to novel cancer treatments. Investigating the hypothesis that exosomes from GLUT3

expressing glioblastoma cells increase the migration of macrophages may lead to therapeutic opportunities for macrophage modulation and better immune responses for patients.

Abstract Name: Role of Effort in Motor Learning - Split-belt Gait Analysis

Motor learning is a crucial aspect of human development and rehabilitative medicine. Understanding motor learning directly contributes to the design of non-invasive rehabilitations for individuals with movement impairment, such as Parkinson's or post-stroke patients. This research aims to understand how physical effort impacts motor learning. During the experiment, healthy participants walk on a split-belt treadmill which has a separately controlled belt for each foot. Force plates under each belt recorded ground reaction forces and motion capture cameras tracked leg movement. Participants (n=45) wore a weighted vest, with effort differentiated by the amount of added weight. Participants were divided in 3 groups corresponding to different effort conditions: low (5% body weight), high (15% body weight), and control (no weight added). The experiment was divided into time blocks during which the belts ran at the same speed or at different speeds. Differences in speed perturb the gait cycle, inducing an artificial limp. Participants' response to the gait perturbation was assessed via measures of asymmetry in parameters of the gait cycle such as step length, trailing limb angle, and ground reaction forces. Learning was evaluated by comparing the evolution of adaptation between groups. We hypothesized that higher effort would accelerate motor learning by increasing the metabolic cost of asymmetric walking; however, current results reveal no differences in step length adaptation between effort groups. My ongoing work is focused on the analysis of trailing limb angle as well as joint kinematics and dynamics.

Abstract Name: Efficient Hyperparameter Optimization through Sparse Sampling and Robust Tensor PCA

Modern deep learning models are often complex, involving numerous hyperparameters. The task of optimizing these hyperparameters is a significant challenge for practitioners in the field. Classical hyperparameter optimization methods like grid search suffer from the curse of dimensionality, where an extensive search of the hyperparameter space can become very computationally expensive. We address this issue by only calculating the loss for some entries of the grid. The test losses obtained from these models form a sparse loss tensor. Using Robust Tensor PCA, we estimate a low-rank approximation of the loss tensor from the available values. This low-rank representation reconstructs the missing entries so that the best hyperparameter set can be chosen. Our method achieves a two-times speedup compared to dense grid search on a 1000-entry hyperparameter search space at almost optimal accuracy. We further explore this method in

the context of neural network classifiers, particularly focusing on its application to the MNIST dataset. Our experiments reveal that the loss matrices and tensors possess a low-rank structure and can be effectively approximated using our approach, providing a better trade-off between accuracy and search time for hyperparameter settings. This method offers significant improvements in efficiency, particularly for larger neural networks and complex datasets.

Abstract Name: Functional Aging & Mindfulness for Seniors Through Intergenerational Events: A Pilot Study

Both aging adults and youth are experiencing a rise in mental health issues, with depression, anxiety, and loneliness affecting 25% of aging adults and 40% of youth. Additionally, both age groups are witnessing an increase in obesity and overweight status, with 44.3% prevalence in seniors and 19.7% in youth. The research underscores the positive impact of adopting healthy behaviors, such as physical activity (PA) and healthy eating, on mental and physical health. The Functional Aging and Mindfulness for Seniors (FAMS) intervention aims to promote healthy aging through intergenerational interactions to enhance the physical, mental, and social health of aging adults and youth. This qualitative study, conducted with 20 aging adults and 27 high school students, explored intergenerational engagement in activities like icebreakers, trivia, physical activity, and healthy eating. With a Systematic Engagement Measurement for Intergenerational Time (SEMIT), researchers observed behavior, mood, and interactions, generating variables such as mood and behavior. The results revealed differences in engagement levels based on the type of activity. Specifically, the healthy eating session showed less interaction and lower mood among youth and seniors versus the physical activity session. These findings provide insights into effectively engaging intergenerational participants in health-related activities. The study emphasizes the significance of maintaining healthy habits throughout a lifespan to enhance overall quality of life.

Abstract Name: Synthesis and Characterization of Tin Selenide’s Frictional and Thermal Properties

The current most efficient energy production techniques operate, on average, at 44% efficiency. This means close to 60% of energy is lost as waste heat. Thermoelectric materials can directly convert waste heat into electricity, generating an electrical potential from a thermal gradient applied across the material. They have no moving parts, unlike traditional energy sources, requiring little maintenance, thus making them very robust methods of energy generation. Tin selenide (SnSe) is a prime candidate for a thermoelectric generator,

having one of the highest recorded efficiency values. Thermoelectric efficiency is based off a figure of merit equation, weighing factors such as a materials electrical and thermal conductivity. To improve energy conversion efficiency values for industrial applications, fully understanding the physical properties of thermoelectric material is of the utmost importance. This can be achieved through novel synthesis and analysis techniques such as Atomic Force Microscopy (AFM). AFM is a diverse method for material characterization, it allows one to obtain information about a sample's physical interactions at the nanoscale. Two extensions of AFM measurements are Scanning Thermal Microscopy (SThM) and Lateral Force Microscopy (LFM). SThM process allows for in-situ analysis of topographical and thermoelectric characteristics, while LFM capitalizes on a more flexible probe to allows for an understanding of the frictional properties of the material.

Abstract Name: Domestic Abuse in West Africa

Domestic violence is a hidden global epidemic, affecting people of all races, genders, and nationalities. Women are particularly vulnerable to violence in the domestic sphere according to reports from the World Health Organization, United Nations-Women, and multiple governmental agencies. Domestic violence is especially pervasive in Sub-Saharan Africa, yet literature suggests that it may not be perceived as such a serious issue. To have a better grasp on the prevalence of domestic violence and people's perceptions of it, I conducted mixed survey research on the online platform SurveyMonkey using a snowball sampling technique. The survey targeted people from Burkina Faso, Mali, and Senegal, but it attracted a disproportionate number of Burkinabe and people whose education levels were above average. Data analysis showed that most participants viewed domestic violence as a serious issue in their country and felt that victims should receive support. However, a few people did not view it as an issue or thought victims deserved it, and many more opted to drop out of the study mid-way through, making it difficult to draw conclusions. The rate of victimization was lower than the national average though more participants reported knowing someone who has been victimized. No statistically significant differences were found between male and female participants. Future research should use a more representative sample and reduce drop-out rates to improve external validity.Key words: Domestic violence, Gender-based violence, West Africa

Abstract Name: Lucian Bernhard: A Better Understanding of The World of Graphic Advertising

This essay follows the journey of Lucian Bernhard, a major figure in the world of graphic design. Focusing on his unique style and the crea on of the Sachplakat genre, the essay shall explore how Bernhard's minimalist approach changed the world of adver sing, se ng the ground rules for future design movements.

Aside from his contribu ons, this essay also dives into Bernhard's personal and professional life, revealing how his crea vity came to be. As the essay unfolds, we slowly unfold the layers of Bernhard's life, leading to a deeper understanding of why he did what he did. Bernhard's story sets the ground for designers around the world because of his ar s c vision and unique style, shaping the world of adver sing as well.

Abstract Name: Hopf plumbings and generalized Hopf bandings

Knot Theory is a branch of mathematics dedicated to studying properties of knots. One way to understand knots is by seeing what surfaces we can fit around the knot with the knot as the surface's boundary. A rare type of this kind of surface is called a fiber surface. A surface fibers if we can split up all of S3, which can be thought of as R3 plus a point at infinity, into exact copies of that surface. Starting with a disk (a surface that looks like a filled-in circle), we can build fiber surfaces through operations called Hopf plumbings and generalized Hopf bandings. In both of these operations, we attach a special kind of twisted band to a fiber surface in a particular way, which produces another fiber surface. Performing Hopf plumbings and its inverse operations, Hopf de-plumbings (where we cut along one of these twisted bands), is enough to produce every possible fiber surface. So, it must be possible to express a single generalized Hopf banding as a sequence of Hopf plumbings and Hopf de-plumbings. While we are still working on answering that question, we have discovered that performing two specific generalized Hopf bandings results in the same surface as performing two specific Hopf plumbings. Although this material is not traditionally taught at the undergraduate level, this poster will walk through all the necessary background so that our result is accessible to undergraduate students of all majors.

Abstract Name: The world bank and its promotion of privatisation as a tool of poverty alleviation.

Processes of economic integration have given space to cross border interactions and a collective sympathy for global poverty. However, the arm's length relationship between international actors of global development, and their sociocultural realities do not reflect the various episodes of globalisation promoting economic and cultural connectedness. Indeed, the world bank turns the normal conditions of globalisation in on itself to prevent the subject being approached from diverse directions and made amenable to rational transformations or any plural construction. This has given force to the belief that this uneven exchange of knowledge is an occasion of negative homogenisation. The banks promotion of privatisation as a tool of poverty alleviation is a character of this logic. This paper is particularly concerned by what is incompatible within these terms and how the elements brought together belong to different orders of reality, liberalise sectors without public

participation, and do not resolve into any positive correspondence as much as they reproduce the dislocation between economic actors and marginalised populations. At any rate, this identical contradiction opens the bank up to new forms of questioning and this paper draws together numerous concerns from the substance of policy making.

Abstract Name: q-PCR assay exploring Planarian ability to clear Uropathogenic Escherichia coli (UPEC) in the presence of the protein TcpC

Bacterial resistance is a threat to healthcare systems and global health. Uropathogenic Escherichia coli (UPEC) is the leading cause of urinary tract infections, and due to antibiotic treatment, there has been a notable rise in the levels of antibiotic-resistance seen in the environment. Studying this bacteria's molecular mechanisms could provide insight into how to counteract the threat of bacterial resistance. Uropathogenic E.coli produce a protein known as TcpC. TcpC is a Toll/interkeukin-1 receptor domain-containing protein (TIR) which acts as a virulence factor by inhibiting innate immune host immune responses. To study TcpC in E. coli we used the model organism planaria. Planaria are an emerging model organism for host-pathogen interactions due to their efficiency at clearing bacteria. Because TcpC blocks innate immune responses in mammals, we hypothesized that TcpC would also block planarian immune responses, and that when fed a variant of E. coli lacking TcpC bacterial clearance will occur faster versus when fed E.coli with TcpC. For this project, we are developing a new protocol to use quantitative PCR (qPCR) to analyze the clearance of bacteria in planaria. We identified PCR primers that amplify DNA from our bacteria and that we can use to quantify bacterial levels cleared from planaria over time. Our preliminary results suggest that qPCR results with these primers show results that are consistent with a much more tedious method for quantifying bacterial clearance that requires serial dilutions and plating of planarian extracts to count remaining bacteria. We are continuing to use these different experimental procedures to test our hypothesis that TcpC might affect bacterial clearance in planaria. Further studies characterizing immune responses in the planarian model that might be affected by TcpC might offer clues to new therapeutic strategies that could be used to counter UPEC infections with less reliance on traditional antibiotics.

Abstract Name: Investigating the Impact of Race and Gender on Psychological Safety in Engineering Design Teams

This research addresses the persistent challenges of diversity and inclusion within engineering, particularly

the historical underrepresentation of racial and gender minorities. Focusing on the critical issue of psychological safety, this study explores the intricate relationship between an engineer's racial and gender identity and their well-being within engineering design teams.Drawing from existing research, this study builds on the work of Navarro et al., who delve into how gender and racial backgrounds impact students' persistence in engineering programs. Additionally, Cole and Marhefka et al. emphasize the importance of psychological safety in engineering design education. Yener's research underscores the complex interplay between gender, psychological safety, and the experience of feminine role stress.The research questions are: How does an engineer's racial and/or gender identity influence their level of psychological safety and well-being within engineering design teams? Moreover, how does this level of psychological safety relate to the overall group dynamic? How do intersectional identities, such as being a woman of color or a non-binary person, shape the experience of psychological safety in engineering design teams? The participants of this study are Mechanical Engineering and Integrative Engineering students who are members of the Senior Design teams at Lafayette College. All participants have provided informed consent prior to the commencement of data collection. Surveys are administered to gather quantitative data, including demographic information and participants' perceptions of psychological safety within their engineering design teams. A subset of participants, specifically students of color and non-male students, will undergo interviews guided by predetermined questions.The expected results include the following statements: An engineer's racial and/or gender identity influences their level of psychological safety and well-being within engineering design teams, and intersectional identities (e.g., being a woman of color or a non-binary person) influence the experience of psychological safety and well-being in engineering design teams.

Abstract Name: Role of PACAP in Cociane-Induced Plasticity Underlying Drug-Seeking Control

Cocaine-induced neuroplasticity often results in altered glutamate signaling, which likely contributes to substance abuse. Glutamate, the primary excitatory neurotransmitter in the brain, engages in nearly every form of brain function, rendering it a challenging target for drug development. Glutamate and the co-released neuropeptide pituitary adenylate cyclase-activating polypeptide (PACAP) project to the nucleus accumbens (NAc), a brain region known for interfacing motivation and action, which is heavily implicated in addiction-based behaviors. PACAP binds to its primary receptor (PAC1R) located on neurons and astrocytes. PACAP infusions into the NAc core attenuates cocaine-primed reinstatement and potentiates glutamate receptor NMDA currents in a key projection circuit, the direct pathway, linking NAc to other circuits that regulate behavior. Given that PACAP’s attenuating effects on cocaine relapse may involve PAC1R activation on neurons, astrocytes, or both, this project investigates the possibility that cocaine-induced changes in PAC1R expression in the NAc core alters the activity of the direct pathway. To do this, cocaine-historied rats received injections of cholera toxin b (CTb) conjugated with Alexa Fluor488 into the substantia nigra pars compacta and ventral pallidum, which are brain regions innervated by the direct and related NAc pathways. The CTb/Alexa Fluor488 complex will be transported in a retrograde fashion, thereby fluorescently labeling the relevant NAc cells. After 10 days of incubation, NAc efferent neurons were isolated from other cells using fluorescence-activated cell sorting and were used to quantify PAC1R mRNA with RT-qPCR. We hypothesize PAC1R mRNA levels in NAc core neurons will decrease in cocaine- compared to vehicle-treated rats. Activation of neuronal PAC1R has been shown to reduce Mg2+ blockade of NMDA receptors, enabling activation at lower membrane voltages to reduce neuronal excitability. Lower levels of PAC1R mRNA may

reduce PAC1R density on neurons and decrease control over neuronal excitability in NAc - a hallmark of cocaine addiction.

Abstract Name: Hemp’s CBD Production Levels Correlation with Abiotic Stressors

Cannabis sativa is known to have many different health benefits, such as calming anxiety and being an anti-depressant. It is one reason the industry of cannabidiol (CBD) products is growing so quickly as it is. Hemp is a variety of Cannabis sativa that contains very low amounts of tetrahydrocannabinol (THC) (<0.3%) and will not get you the “high” marijuana is known to provide its consumers with. Growing a medicinal plant at home, such as hemp, would allow the cost of buying medicinal products to be significantly lowered for the common household. As well as be a more sustainable practice due to a more closed-loop circle of growing and consuming practice. This study analyzes two everyday household abiotic stressors that can turn people away from growing this plant indoors: water amount and the pH level of the water used. These projects both ran simultaneously and took place under greenhouse conditions. The plants were grown in soil with an irrigation system to monitor the water provided, a phosphate buffer to alter the water pH levels, and the CBD and THC amounts were analyzed through gas chromatography-mass spectroscopy once the plants flowered. The findings of this research aim to help make CBD, a beneficial chemical compound, more accessible for people to grow and use at home individually. It is under the assumption that hemp can not be grown at home due to households not having the “perfect growing conditions”, while this research hopes to prove that growing hemp under different abiotic stresses will not have harsh effects on the amount of CBD being produced by the plant. Therefore still being a beneficial household plant that can provide easy access to herbal medicine for people worldwide.

Abstract Name: Do Mutations to an Extracellular Matrix Protein Affect Oligodendrocytes in the Brain?

The proper maturation of oligodendrocyte precursor cells (OPCs) into myelinating oligodendrocytes (OLs) is crucial for the development and function of the nervous system. While the regulatory mechanisms governing OPC maturation and axonal myelination have traditionally been explored through the perspectives of transcription factors and secreted molecules, the extracellular matrix (ECM) plays a fundamental role in influencing cellular life and maturation in various contexts. Chondroitin sulfate proteoglycan 4 (CSPG4), a hallmark gene used to identify OPCs, encodes NG2, an ECM protein that interacts directly with surrounding cell-surface and ECM molecules. Signaling downstream of Cspg4 has known effects on the OPC

cytoskeleton and gene expression, positioning it as a key player in orchestrating the development of oligodendrocyte lineage cells (OLCs). Notably, in vitro studies have suggested that surface expression of Cspg4 inhibits OPC maturation. Based on this background, our hypothesis posits that Cspg4 inhibits OLC maturation in vivo. To investigate this, we employed zebrafish as a model system and assessed OLCs in cspg4 mutant larvae. Our findings revealed that mutant larvae exhibited concurrent levels of both OPCs and OLs. Currently, ongoing research involves measuring morphometric features of OPCs and myelinating OLs in live mutant larvae and their wild-type siblings. The pilot data shows that cspg4 mutants OPCs are more spherical and cspg4 mutants OLs make more myelin sheaths (of average length). This approach aims to provide deeper insights into how the ECM, particularly through the influence of Cspg4, contributes to the development of OLCs and the myelination process.

Abstract Name: Hope Through Artion: Healing communities through Art

Healing through art with your community creates resiliency over challenges ahead. Over the years, American cities have experimented with ways to combat climate change. The Hope through Artion Project recognized that art is a catalyst for change. Nature and humanity have always connected, so now is the time to imagine new ways to help our environment. Our mission is to connect communities in efforts to transform the world by rethinking, visualizing, and taking action. Focusing on unique aspects of the neighborhood persona continues to drive what direction we should look forward to in art experimentation. We strive to establish new perspectives and show that change must become collaborative. The benefits of our efforts are enjoyed and enhanced by the communities we impact. What are the limitations and possibilities for mobilizing the public to care about the environment through art? Norfolk State University fine art students facilitated our first community art engagement activity with the Berkley community, which featured creating a community mural and two interactive surveys to encourage thought surrounding food insecurity and environmental justice. We had the chance to speak with over 100 participants over two days and gathered 62 survey responses. Through social practice art, art is born through experiences shared through communal interaction rather than visual significance. We aim to promote art to enhance unity within our world so that future generations will understand we are better together moving forward. By producing public art that reflects a community persona, history, and identity, these landmarks become foundations for new engagements rather than aesthetics of gentrification. Hope through Artion stands with art education to influence progressive change within communities.

Abstract Name: Calculating the Trajectory of a Gram-Scale Interstellar Spacecraft Moving at Relativistic Speeds

PoMiN is a relativistic N-body gravitational dynamics solver that uses a Post-Minkowski approximation to general relativity (GR) and is accurate at ultra-relativistic speeds. It was originally written in the C language, but recently has been ported to the Julia language. An application of interest for PoMiN is the computation of trajectories of relativistic spacecraft, such as those proposed by the Breakthrough Starshot Initiative and NASA's Project Starlight. The goal of the Breakthrough Starshot Initiative is to develop an interstellar spacecraft capable of traveling to the nearest star in less than a human lifetime. It proposes building a gram-scale spacecraft that is attached to a light sail and accelerated to 0.2c, either by a ground- or spaced-based laser array. The spacecraft is microchip-sized and equipped with miniaturized sensors and communications. It would have minimal propulsion of its own; therefore, after the initial acceleration, the spacecraft would be left to make the 20-year trek to Proxima Centauri, approximately 4.25 light years away, with minimal course corrections. The question to be answered is: how can the trajectory of the spacecraft be computed? To compute the trajectory of the spacecraft involves accounting for gravitational dynamics between many bodies, for example, the Sun, Earth, Moon, other planets in our solar system, Alpha Centauri A and B, Proxima Centauri, and the spacecraft itself -- all while the spacecraft is traveling at 0.2c. These conditions qualify PoMiN as an ideal tool to solve this problem. To begin the investigation, a set of initial data of all of these bodies was created. Online astronomical databases were used to obtain orbital elements, masses, and accurate positions and velocities. This presentation will discuss the initial conditions, detailed results, challenges, and implications.

Abstract Name: Single-cell transcriptomes of antiviral NK cells responding to an MCMV infection reveal the development of Ly49HHi memory-like NK cells

Natural Killer (NK) cells play a crucial role in the early management and clearance of mouse cytomegalovirus (MCMV) infection. Ly49H+ NK cells can specifically recognize and eliminate infected cells presenting the MCMV m157 glycoprotein. Following activation, Ly49H+ NK cells undergo a clonal expansion and form a reservoir of memory-like cells that exhibit enhanced capabilities of targeting future infections. The molecular mechanism by which memory NK cells develop and their transcriptomic profiles have not been fully defined. Here we infected C57BL/B6 mice at different time points with MCMV and performed single-cell RNA-sequencing (scRNA-seq) on NK cells isolated from their spleens. Unsupervised clustering revealed a distinct memory-like Ly49HHi subset that was found at elevated levels seven days post-infection. This Ly49HHi subset had high expression of Cd3e, Cd3d, CD74, Emb, Batf3, and Ltb. In addition, our developmental trajectory analysis of Ly49H+ NK cells revealed a unique branchpoint leading to the development of Ly49HHi memory NK cells. These findings enhance our understanding of memory NK cells and have the potential to influence their future therapeutic applications in cellular immunotherapies.

Abstract Name: The Relationship Between Previous Experiences and Familiarity on Conceptions and Beliefs of ChatGPT

The proliferation of Artificial Intelligence (AI) is reshaping human interactions and experiences. These effects are already being felt in educational settings, but little is understood about them. The present study helps fill this gap by examining the perceptions and beliefs surrounding ChatGPT, aiming to unravel misconceptions about its capabilities based on the level of user familiarity. In online surveys, we will ask participants to answer questions regarding their familiarity with ChatGPT. They will also be asked to evaluate the accuracy of statements about what ChatGPT can do such as “ChatGPT can produce accurate responses all the time” and to rate the extent to which different uses such as utilizing the AI tool to generate an outline for an essay for one of their classes will affect students’ learning abilities. We expect that individuals who are less familiar and have little experience with ChatGPT will be more likely to have misconceptions about what it can and cannot do. We additionally expect individuals who are less familiar with the tool to rate examples of ChatGPT usage more negatively in comparison to those who have more familiarity. The implications of these findings for our research are twofold. Firstly, it highlights the importance of addressing misconceptions about ChatGPT among individuals who are less familiar with the AI tool, to provide them with accurate information regarding its capabilities. Secondly, it underscores the need to consider familiarity as a factor when evaluating the potential impact of ChatGPT on learning abilities in educational settings.

Abstract Name: The Impact of a Web Accessibility Indicator on Purchase Intentions

Web accessibility is the practice of designing websites so that all individuals, especially people with disabilities and the elderly, can use them with both mainstream and assistive technology. While firms that pursue web accessibility stand to gain market share and avoid litigation, most firms have been reluctant to thoroughly implement web accessibility features. This study explores how firms can communicate their commitment to web accessibility to consumers without disabilities. Prior research indicates that displaying a web accessibility certification badge on a website positively affects the firm’s perceived corporate social responsibility (CSR). This project examines the impact of a web accessibility indicator on consumers’ purchase intentions. Grounded in the attitudinal model, the research links beliefs about CSR to attitudes and purchase intentions. Four key variables are considered: website utility, website quality, corporate social responsibility, and trust. Additionally, participants’ attitudes towards the website are measured. The primary dependent variable is purchase intentions. A randomized experiment will involve participants viewing the

website of an online book retailer, with the treated group being randomly assigned to a website with an accessibility indicator, and the control group assigned to a website without an indicator. Following the website content, all participants will respond to questions that test the theoretical framework. The analysis will be carried out using t-tests and linear regression. I hypothesize a positive relationship between the following: a) the presence of an accessibility indicator and at least one of the belief-related variables; b) beliefs and attitudes; and c) attitudes and purchase intentions. The study aims to elucidate the broader impacts of web accessibility features, particularly in influencing consumer perceptions and decisions. By demonstrating the positive effects of accessibility indicators on consumer behavior, this research can encourage more firms to adopt inclusive web practices, thereby advancing digital accessibility.

Abstract Name: Arab American Identity on Depression and Anxiety Through Experience of Racism

Individuals who identify as Middle Eastern, North African, or Arab (MENA) living in the United States navigate complex religious, social, and cultural contexts as they develop from childhood through adulthood. The experiences and identities of MENA individuals are influenced by global political events such as 9/11, the War on Terror, or refugee experiences (Awad et al., 2019; Marvasti, 2005). These experiences are associated with higher levels of depression and anxiety. This secondary study examines the correlation between the Arab American identity and depression and anxiety through the experience of racism.This study was a secondary analysis of data collected as part of the Detroit Arab American Study (see Baker et al., 2003). Data was collected in 2003 and included a representative random sampled Arab Americans living in the tri-county Detroit region. It was originally conducted to assess the impact of 9/11 on the lived experiences of Arab Americans. It consisted of n=724 adults who self-identified as Arab American, 53.2%(n=385) identified as female, and 45.3%(n=328) identified as male.We conducted a structural equation model to test two main hypotheses: increased Arab American identity would be associated with higher levels of depression and anxiety, and the relationship would be mediated by experiencing anti-Arab racism. Our model (see figure 1) found an adequate fit to the data ($\chi 2[66] = 3{,}129$, p<.001; CFI = .94, TLI = .92; RMSEA = .053; SRMR = .06. Further, the relationship between Arab American identity was fully mediated by anti-Arab racism experiences for depression (b=0.031, p = .017) and anxiety (b=0.029, p = .007). A strong Arab American identity was associated with significant increases in anxiety and depression. These relationships, however, were mediated by having anti-Arab racism experiences in the post-9/11 environment. As anti-Arab racism rises, individuals identifying as Arab Americans continue to experience anxiety and depression.

Abstract Name: The Influence of Age and Biologic Sex on Presenting Symptoms of Subarachnoid Hemorrhage

Subarachnoid hemorrhage (SAH) is an abrupt and often devastating hemorrhagic stroke resulting from a blood vessel rupture that leaks into the arachnoid space. While patients report a range of symptoms, the hallmark symptom of SAH is sudden, often severe headache. Outcomes after SAH have differed by age and biologic sex, but differences in presenting symptoms has not been well reported.The purpose of this study was to examine if there are differences in presenting symptoms by age or biologic sex at a single stroke center.Demographic and clinical data was collected from the patient, caregiver or chart including symptoms and reason for seeking medical care prior to SAH hospitalization.This retrospective analysis included 491 SAH patients (72.5% female). Age was dichotomized to greater than or less than the mean age of 53 years. Headache was reported in 86% of this sample followed by nausea (47%), vomiting (46%) and stiff neck (33%). The presence of headache was also the most frequent reason for seeking care (49%) followed by a report of unresponsiveness (25%). Most patients reported consistent (53% or worsening (26%) symptoms prior to admission. ANOVA analysis using SPSS v26 showed significant differences in symptoms by patient age. Patients <53 years were more likely to report headache (p=.013), blurred vision (p=.013) and seizure activity (p=.038) than patients in the older group. Patients > 53 years were more likely to report confusion (p=.017) than those in the younger group. There were no significant differences in symptom reports by biologic sex.This analysis found that headache remains the most commonly reported SAH symptom. This analysis also suggests, that age may influence the symptom experience, with younger patients reporting the presence of a wider range of symptoms than older patients after SAH. How or if this influences recovery warrants additional investigation.

Abstract Name: ATRIP Expression is Correlated to Breast Cancer Staging and Hormone Receptor Status but not Patient Demographics

Newly identified in March 2023, ATRIP has become a breast cancer gene of interest. It is observed that variants of ATRIP have led to identification of people experiencing further genetic risk for breast cancer. This gene, called also the ATR Interacting Protein, is a relevant gene involved in the DNA reparation process. The presence of ATRIP (ATR) triggers a cellular response to DNA damage and forms an interaction complex that detects and repairs damaged DNA, assisting with overall genomic stability for humans. However, when the ATRIP gene undergoes mutations, it is no longer functional, and thus decreases in gene expression. Altered ATRIP weakens the process of oncogene regulation, which creates favorable conditions for the proliferation of breast cancer cells. The primary objective was to compare the expression patterns of the ATRIP gene with breast cancer patient data. The research unveiled additional patterns associated with ATRIP gene expression. To conduct this research, the National Cancer Institute Genomic Data Commons was used to gather and identify national data on breast cancer patient cases, including their demographic information, the severity/stage of the cancer, the procedures/treatments conducted on patients, and ATRIP gene expression. Particularly, the research compares and analyzes the expression of ATRIP in breast cancer patients based on their gender, race, cancer stage, estrogen receptor status, and progesterone receptor status. ATRIP gene expressions were found to be susceptibly lower in patient groups who were at cancer Stage IV and in patients who have an overexpression of estrogen and progesterone receptors. Therefore, understanding ATRIP's role

in breast cancer and pinpointing factors linked to its dysfunction may be a further step towards future targeted treatments.

Abstract Name: Gamification to Enhance Logistics Workers' Performance

Gamification is the use of game design principles and mechanics in non-game contexts to motivate and influence behavior. It involves applying aspects of games such as points and competition in scenarios that aren't normally considered games, most often in a work environment. The specific components of gamification and how they contribute to increased motivation and efficiency are up to debate, as well as the possible ethical concerns.This research connects logistics operations to gamification and investigates the effect of gamification on logistics workers as a tool to enhance performance within a dynamic and demanding industry. Key findings of this research include identification of specific gamification aspects such as points and rewards. This study also dives into the ethical considerations and potential disadvantages associated with gamification in logistics specifically. Ultimately, we seek to provide insights to logistics companies seeking to optimize operations and find out how gamification fits into that goal. The study showed potential for the application of gamification methods positively influencing worker productivity. However, to better understand how gamification could influence logistics workers, more extensive experiments and testing would be required.

Abstract Name: A Study on the Efficacy of Normalized Compression Distance (NCD) to create Phylogenic Trees.

Traditional phylogenic computation methods involve comparing specific sections of a genome such as mitochondrial DNA or specific rRNA sequences. While it is very much possible to compare entire genomes doing so is computationally intensive and time consuming. In this study, we will verify the reliability and

accuracy of using Normalized Compression Distance (NCD) in comparison to traditional methods to create phylogenetic trees. The algorithm will take entire genomic data as input and output a distance matrix that can be used to create phylogenetic trees using an external application. This is done with minimal processing and fast execution of whole genomes. If we get a similar tree as the traditional methods, then we can be confident that the methods currently in use are accurate. If we get a dissimilar tree, it will imply there is some discrepancy between the traditional methods and NCD, which will open avenues for further study into the validity of the NCD-generated trees.

Abstract Name: Lawn Ornament Shooters, Money Pouch, and Light Candles: Discrepancies in Photographic Image Naming

Image naming tasks are used to explore word finding processes. More normed image sets utilize photographs instead of line drawings (Souza et al., 2020). Photographs are more likely to elicit multiple names than line drawings due to richer details (Brodeur et al., 2010; Moreno-Martinez, Montoro & Laws, 2011). Further, images with high name agreement are elicited faster than those with low name agreement, specifically for low agreement items with multiple names (Alario et al., 2004; Madden, Sale, & Robinson, 2019). Norms for modal and alternative names for photographic stimuli are needed. Further, age-related lexical retrieval changes might be reflected in subtle changes in alternative names. The purpose of this study is to provide norms for name agreement and disagreement for older adults on a large set of photographs of everyday objects, the Bank of Standardized Stimuli (BOSS). Eighty native speakers of English, 40-80 years old, and free of neurologic deficits were recruited. Each participant was presented with 600 BOSS photographs and was asked to name each image as quickly and accurately as possible. The responses were transcribed and accuracy was recorded. Preliminary results revealed a mean accuracy of 83% and a modal name agreement of 77% across the 600 stimuli. A fine-grained coding analysis of correct responses into subordinate (bird–sea gull), synonyms (mobile phone–cell phone), and supraordinate categories (potato peeler – peeler), and of incorrect responses into misconceptions (kiwi – coconut), false responses (asparagus – artichoke) and idiosyncratic responses (lawn ornament shooter – toy soldier) is ongoing. Norms across the age range for image naming provide insight into changes and stability of lexical retrieval processes with age to better characterize normal and impaired performance. The disagreement norms will provide valuable insight into the sources of name disagreement and allow for a richer description of visual stimuli commonly used in psycholinguistic research.

Abstract Name: A Rhetorical Analysis of Concussion Awareness: A Cultural Comparison in Popular Media in the U.S. and Argentina

My project assesses the differences in rhetorical strategies and design techniques of concussion rhetoric relayed in the popular media in both the United States and in Argentina. More specifically, it investigates the ways in which writers discuss concussions in magazines (particularly health/lifestyle, women-tailored, men-tailored, general, and sports-focused magazines) and in newspapers. This project incorporates a discourse analysis of both countries' texts, including cultural comparisons, to examine the differences and gaps in information relayed in popular media representations of concussions and other traumatic brain injuries (TBI's). The coding conducted demonstrates that concussion rhetoric differs between the two countries and that it is often solely located in more specialized sources; so, in this case, magazines and newspapers often lack sufficient mentions of concussions/ traumatic brain injuries in comparison to medical journals. In addition, my research analyzes the perceptions and attitudes regarding head injuries in both countries; differences in healthcare systems, trainings, and in the ways concussion rhetoric is relayed to patients and the general public depends on the particular socio-cultural contexts. The findings highlight a lack of sufficient research in Argentina and insufficient concussion understanding both by the general public and medical professionals in both countries. Ultimately, my rhetorical analysis displays the differences between the two countries and informs suggestions for how to improve concussion rhetoric in both Argentina and the U.S.

Abstract Name: In Pursuit of Equity: What Can College Students Do? A Model Proposed by Students From the University of Alabama at Birmingham

Diversity, equity, and inclusion (DEI) and the connection to social justice are important considerations in various contexts, including workplaces, communities, and educational institutions. Alabama, like many other places, has faced significant historical challenges and difficulties, but there has also been a variety of efforts to push forward initiatives to promote DEI as well as social justice across all communities. Student-led DEI initiatives have become increasingly valuable as universities face opposition, and also give students the opportunity to design and lead new and innovative endeavors. Having initiatives like this on campus is a key responsibility that universities have to protect freedom of speech in the face of external pressure, as well as academic growth. One way students have led DEI initiatives on the University of Alabama at Birmingham's (UAB) campus is through the Organized Radical Collegiate Activism (ORCA) conference. ORCA accepts presentation proposals from all students around Alabama who are involved in social justice efforts at their university or in their community. Examples of issues discussed can range from racial/cultural tolerance, LGBTQ+ issues, environmentalism, veteran advocacy, mental health, or any issues students deem to be significant. Such conferences are opportunities for students who may not see social justice as a space for them to learn from their peers about socially prevalent issues that are impacting communities across the state and nation and get involved in small ways. We will discuss the steps involved in organizing a successful social justice conference, its impact on UAB's campus, as well as how to implement the infrastructure of the conference at other universities. Student-led DEI initiatives can play a crucial role in fostering a more inclusive campus community. They provide students with opportunities to develop leadership skills, engage in meaningful dialogue, and contribute to positive change within their educational institutions.

Abstract Name: Sap Line Surveillance: Impedance Spectroscopy Sensors for Real-Time Biofilm Monitoring

Biofilm, an assemblage of surface-associated microbial cells enclosed in an extracellular polymeric matrix (EPS), is known to have pervasive effects in the food processing industry. Specifically, unwanted biofilm growth in maple sap lines reduces the economic syrup value. One technique to monitor biofilm growth in real-time is using microfabricated electrochemical impedance spectroscopy (EIS) sensors. EIS is a method that involves applying sinusoidal perturbations over a range of frequencies across an interface, and the responses are recorded. We integrated these sensors into sap lines to continuously measure biofilm growth, allowing producers to accurately track sap quality in real-time and make decisions on sanitation practices to improve maple syrup quality and economic value. Experiments were performed abiotically and biotically over a 72-hour time in a laboratory-controlled environment. For biotic experiments, Pseudomonas Sp. was isolated from maple sap lines at Michigan State University Upper Peninsula Forestry Innovation Center, and EIS data followed trends that suggest microbial growth when the inoculum was introduced to the system. Our study suggests that microfabricated EIS sensors can establish a reliable in situ quality control system, effectively aid in mitigating biofilm growth in sap lines, and define sap line disinfection protocols.

Abstract Name: The Relationship Between Therapist Within-session Behaviors and Client Outcomes

Therapist variability accounts for 5–15% of the change in couple therapy (Friedlander et al., 2006). Emphasizing in-session therapist behaviors could aid MFT Master's programs focused on molding therapeutic skills, improving outcomes, and promoting change for both partners in couple therapy (Baker, 2017).Efforts have been made to evaluate the therapist's behaviors within-session that impact client change at the initial stage of therapy. The Ratings of Therapists' General Clinical Skills/Qualities Scale (TGCSQ; Evans, Epstein, & McDowell, 2009) measures the therapist's actions focused on common factors. Using the TGCSQ, undergraduate students macro-coded therapy sessions (inter-reliability = .80), with a goal of seeing if factors on the TGCSQ were related to client outcomes, as shown through the Outcome Rating Scale

(ORS). The current study hypothesizes that higher ratings of therapist skills and qualities would be associated with the improvement of client outcomes. The findings of this study showed that on average, clients improved from session 1 to 5, and then leveled off. Higher ratings of the therapists' use of collaboration and structure tactics within-session predicted a shallower leveling-off of client outcomes. Objectively measuring within-session behaviors related to outcomes benefits couple and family therapists-in-training to improve skills. Training programs incorporating a student learning outcome directly connecting the tracking and adjustment of therapist within-session behaviors and client-reported change in therapy could benefit from measures like the TGCSQ. Training programs can connect specific therapist behaviors with client outcomes advancing clinical training.

Abstract Name: Perfectionism Related to Fear of Failure, Anxiety, and Academic Performance in College Students

Previous research supported the hypotheses of this study which stated that: perfectionism will be positively correlated with fear of failure; perfectionism will be positively correlated with anxiety; and perfectionism will be negatively correlated with academic performance. After IRB approval the study was conducted. A total of 111 undergraduate students at a small private university in the southeast region of the United States were anonymously surveyed using a 38-item instrument composed of the International Anxiety Questionnaire, the Performance Failure Appraisal Inventory, and the Multidimensional Perfectionism Cognitions Inventory, with four additional demographic questions at the end. The surveys were completely voluntary and given within approved classrooms of various studies. Of the 111 participants, 42 were males, 67 were females, and 2 chose other or not to disclose their gender. Ages ranged from 18 to 30 years old. Surveys were scored and results were calculated using a Pearson r correlation analysis through the SPSS program. After analysis of the results, hypothesis one, perfectionism and fear of failure being positively correlated was supported with a significant positive correlation. The second hypothesis, perfectionism and anxiety being positively correlated was supported with a significant positive correlation. Lastly, hypothesis three, perfectionism being negatively correlated with academic performance (measured using GPA), was shown to have no significant correlation. Limitations of this study included the small number of classes the surveys were approved to be administered in, small class sizes, inability to use freshmen data due to them not having a GPA with the institution yet, and the possible inaccurate representation of academic performance due to people not checking their education portal for their reported GPA. It is recommended that further study of this topic takes a more accurate measure of academic performance and looks into a possible correlation of these factors related to gender.

Abstract Name: The effect of Sericea Lespedeza on Methane Emission and Health Status in Grazing Boer Goat Wethers

Twelve Boer goat wethers were used to determine effects of feeding Sericea lespedeza as supplemental pellets or grazed forage on ruminal methane emission and health status. There were 4 5-wk periods. Periods 1-3 were on a 0.7-ha grass pasture and period 4 was on a 1.1-ha pasture of Sericea lespedeza. A forage-concentrate pellet was supplemented in period 1 (CON1), 3 (CON2), and 4 (SL-P), and pelleted Sericea lespedeza was given in period 2 (SL-S). Ruminal methane emission was measured with GreenFeed. Pellets were dispensed up to 30 times daily, with 6 sessions of 5-9-g bait drops and a 2.5-h interval. Body weight at the end of periods generally increased as period advanced (35.7, 38.8, 37.9 and 41.1 kg for CON1, SL-S, CON2, and SL-P, respectively). Sericea lespedeza decreased methane emission, with pasture grazing having greater effect than pellet supplementation (43.7, 36.2, 40.9, and 32.5 g/d for CON1, SL-S, CON2, and SL-P, respectively). Likewise, SL consumption decreased FAMACHA score, with a similar effect for both SL forms (3.28, 2.95, 3.21, and 2.86 for CON1, SL-S, CON2, and SL-P, respectively). Body condition score was similar among periods (2.65, 2.64, 2.68, and 2.67 for CON1, SL-S, CON2, and SL-P, respectively). In conclusion, the effect of SL consumption on methane emission probably relates to condensed tannins and greater impact of SL-P could involve a higher dietary level. Similarly, inclusion of SL in meat goat diets has potential to decrease the parasite load and thereby improve health status, also presumably because of bioactive condensed tannins.

Abstract Name: How Themed Classes Influence Students Perceptions of Learning

Themed classes teach class content through the lens of real world topics or popular content (e.g., Psychology of Sesame Street, Taylor Swift, Musical Theater). They aim to increase student engagement and absorption of the material by presenting the content in new and exciting ways. Most of the research done on themed classes uses non-empirical methods and leaves many unanswered questions. The current study expands on previous research evaluating how student engagement and performance differs between multiple themed and non-themed courses using a pre- and posttest design. The survey evaluates students' perceptions of their engagement and performance based on three categories: impact on learning, effort, and engagement. We hypothesized that students will report greater engagement with the class material while also learning more for themed courses compared to non-themed courses. Currently, there are no significant findings between groups based on the pretest data, but we predict that may change once posttest data is collected. Posttest data will be collected by the time of the conference and will be included in the poster along with the pretest student survey data for themed and non-themed courses. A potential explanation for these findings can be that students won't report higher engagement or impact on learning before they take the class because they can't predict how influential the themed content will be towards their learning, engagement, and effort. But we predict that students will report higher levels of engagement and impact on learning in the posttest data for themed courses compared to non-themed because they will be more engaged in the themed class due to the content being something they can more easily relate to and take interest in.

Abstract Name: Creative Writing in the K-12 Curriculum

Creative writing pedagogy describes the methods by which educators teach creative writing. In this sense, creative writing refers to works of fiction, non-fiction, and other forms of writing that may not adhere to a standard academic and business structure. Creative writing pedagogy can include providing tips for writing, exploring different forms and genres of creative writing, and how to utilize the time and space to actively practice writing. Although studies on creative writing show that there are major academic and personal benefits, it is an underused and underserved discipline in the K-12 classroom. The goals of this study are to increase awareness around the importance of creative writing pedagogy in the K-12 classroom, to identify the barriers that prevent the full benefits creative writing can provide, and to provide policy recommendations for how to increase creative writing in the K-12 ELA curriculum in the United States. This research uses a historical literature-based analysis to examine the evolution of the academic discipline of creative writing in the K-12 classroom from the 1950s to today. Additionally, this study reveals the barriers K-12 teachers face when integrating creative writing pedagogies into the English Language Arts (ELA) curriculum in the United States and assesses their impact on the K-12 classroom from 2000 to 2020. The research identifies three main barriers educators experienced to integrating creative writing pedagogies including funding, curriculum structure, and cultural context.Keywords: Creative Writing Pedagogy, K-12 Curriculum Policy, English Language Arts (ELA) Common Core, STEM, STEAM, English Education, Hip Hop Pedagogy

Abstract Name: Impaired motor learning in Rett syndrome mice with MECP2 deletion in purkinje cells of the cerebellum

Autism is a neurodevelopmental disability that manifests cognitive and behavioral impairments. These dysfunctionalities include repetitive behaviors, motor inabilities, and decreased social skills. Rett syndrome (RTT) is one severe autistic disorder that primarily occurs in females. RTT is caused by mutations in the MECP2 gene, which is situated on the X chromosome. RTT individuals demonstrate abnormal motor function traits. Considering the role of the cerebellum in motor coordination and learning, we hypothesize that Purkinje cells, the principal neuron type in the cerebellum, are linked to motor dysfunction in mice with the absence of MECP2. Our hypothesis was tested by creating mice with this conditional MECP2 deficiency. In this study, we compared two mice groups: MECP2 knockouts and controls. These two groups were first confirmed using the immunofluorescence assay. We further examined motor learning by investigating classical eyeblink conditioning in which a signal light is paired with air puff to generate a conditioned response. Our data show that mice with MECP2 deletion in Purkinje cells exhibit impaired conditioned response, suggesting deficits of motor learning. Altogether, this study clearly reveals the significance of impaired cerebellar function in RTT, which contributes to various neurological and neuropsychological aspects of this neurological brain dysfunction.

Abstract Name: Determining The Impact of Tumor Location on Brain Atrophy in Varying Regions of the Brain in Patients with Low-Grade Gliomas

Introduction: Approximately one-third of all brain tumors are gliomas, which are tumors arising from the brain's support cells called glial cells. These can result in cerebral atrophy (brain shrinkage); while atrophy is common due to aging, severe forms are fatal. We hypothesized that shrinkage of non-tumor brain regions-of-interest (ROI) will be greater for low-grade glioma patients who have tumors in areas with more white matter pathways connected to the ROI. Thus, we aimed to examine the varying levels of interconnection between specific regions of the brain and their effects of brain atrophy. Methods: 174 patients with glioma diagnoses out of 8,310 scan sequences were considered. Information including tumor laterality/lobe, focality, size, pretreatment scan availability, and sequence type were compiled onto a masterlist. After obtaining T1 non-contrast MRI sequences, 3D Slicer/SynthSeg applications were used to analyze patient segmentations. All errors were examined for these patient scans, with most contributed to imaging issues. The independent variable for our study was the interconnection level between certain brain regions. The dependent variable was atrophy level.Results: Out of approximately thirty patients who experienced a decrease in hippocampal volume from years 1 to 2, the majority had tumors located in the frontal/temporal lobes, with fewer located in the parietal lobe and almost none in the occipital lobe.Conclusions: As the hippocampus is based in the temporal lobe, and the frontal lobe is instrumental in memory retrieval, these two lobes have a greater impact on total hippocampal atrophy as compared to the other lobes.

Abstract Name: Hurricane exposure and sociocognitive health in a nonhuman primate

Hurricane-induced environmental instability increases the risk of mortality in animal populations, including humans. Although this suggests hurricanes are significant modifiers of health trajectories, the link between hurricane exposure and individual health remains unknown. Here, we evaluated the role of hurricanes as drivers of health by characterizing sociocognitive health in a cross-sectional sample of rhesus macaques (Macaca mulatta) at Cayo Santiago, Puerto Rico exposed to a major hurricane at different life stages and contrasted these patterns with known developmental shifts in social cognition in stable environments. We experimentally measured sociocognitive health of males and females by recording their looking time toward a sequence of varying expressions of conspecific photographs (i.e., neutral, threat), and tested whether mean

looking time changed after the hurricane event. Individuals attended less to faces of conspecifics overall after the hurricane. After controlling for age and experimental variables, mean looking time to a female conspecific photograph significantly decreased after a hurricane ($b = -0.51$, $t = 3.08$, $p = 0.002$). Similarly, mean looking time to a male conspecific significantly decreased after a hurricane ($b = -0.81$, $t = 2.59$, $p = 0.01$). Notably, individuals were similarly sensitive to emotional threat faces before and after the hurricane. These findings suggest that hurricane-induced environmental instability may promote a decrease in social attention which is important toward understanding which factors are influenced by the environment and how they impact social health.

Abstract Name: Re-examining Resiliency, Mindfulness, and Seasonal Affective Disorder Related to Stress

Stress is a common experience for all individuals, especially college students. College students experience stressors including: high tuition rates, outrageous academic standards, and worry for grades (Etherton et al., 2022). Hudd et al. (2000) suggests that this stress negatively impacts college students. Stress in college students has been shown to increase: low self-esteem, difficulty sleeping, lack of energy, and poor health (Hudd et al., 2000). Taken together, these negative effects of stress impact college students' ability to be successful individuals and academics. Therefore, the present study examines the impact of stress on academic performance and well-being. Here we explore how aspects of positive psychology moderate stress among college students. Further, we explore how seasonal affective disorder (SAD) may play a role in student success and stress. Previously, we found that students who reported lower levels of stress also reported increased resiliency and mindfulness behaviors. Further, we found a significant gender effect. The present study further examines and investigates the variables of stress, mindfulness, and resilience, as well as including SAD and how it may impact student stress levels. Here we continue our survey on behaviors related to college students' academic and everyday lives with a goal of obtaining at least 100 new responses across different school levels and demographic characteristics. Original data was collected Fall and Spring semester 2022-2023. We intend to continue data collection through Spring semester 2024. This continuation study will contribute to knowledge about the overall mental health impact of stress and the moderators of resiliency and mindfulness. We hypothesize that the college students who have higher levels of resilience and mindfulness will also report lower stress, SAD, and higher achievement in academics. The overall analysis will aid in better understanding the relationship between stress and resilience in current students at our university.

Abstract Name: Turkish Feminist Challenging the Competing Images of the Ottoman Harem

Throughout history, the idea of the harem has existed in societies globally. These harems consisted of women who resided in imperial or wealthy households that afforded separate private and public domestic spaces. In each case, at some point, the society questioned the objectification, exploitation, and patriarchal nature of these harems. This research focuses on the Turkish harem during the last four decades of the Ottoman Empire during which multiple social reforms occurred, generating various social movements, including feminism. I argue that during this period, Turkish feminism, supported by the government, challenged the patriarchal treatment and subjugation of women as exemplified by the Ottoman harem, but also collaborated with the harem by exploiting the immunity of harem women to enhance their movement. During the various reform periods, Turkish feminism drew on Western feminist ideology but also challenged the growing European interest in purporting a false narrative of harems by Western orientalist artists. This narrative was due to a fetish for the "exotic" and ethnocentrism, combined with European patriarchal practices of objectifying women. This research is based on the formal and iconographical examination of depictions of harems by Osman Hamdi Bey, Fabio Fabbi, and Müfide Kadri, within the framework of scholarly art historical and historical research on the harem, Turkish feminist movement, and Orientalism. The study, therefore, contributes to research of the Ottoman harem and Orientalism by examining the concepts of the feminist movement in Turkey.

Abstract Name: Artistic National Identity Rhetorics in Post-Colonial Morocco and India

Between 1912 and 1956, Morocco served as a protectorate of both France and Spain. Whereas India has faced colonization by Britain since the 18th century. As colonial societies, Europeans romanticized both Morocco and India in their art by way of fetishization and idealization of the "exotic." Significantly, both Morocco and India were decolonized in the mid-1900s, and artists, respective to their countries, participated in the formation of new national identities. This comparative research argues that both Morocco and India experienced a negotiation between the Populists, Nativists, and Bipictorialists. During Morocco's protectorate, which occurred simultaneously with Modernism, three groups of artists were identified in Moroccan art by how they approached nationalism in their work: the Populists, Nativists, and Bipictorialists. These three national identity rhetorics continue to be relevant after decolonization and were carried on by post-colonial artists establishing new national identities. In Morocco, the notion of the Populist, drawing almost explicitly on Western aesthetics, is exemplified by Hassan El Glaoui. Fatima El-Farouj and Ahmed Cherkaoui advocate the Nativists by leaving behind Western art influences. Finally, Farid Belkania, the father figure of the reinvention of the Casablanca Art School, explores Bipictorialists that combine Moroccan and Western (specifically French) artistic cultural production. Similarly in India, artists such as Francis Newton Souza, Jamini Roy, and Nalini Malani advocated the populist, nativist, and Bipictorialists notion of Indian identity in their artwork. The study utilizes semiotic examination of artwork and scholarly research on national identity formation and decolonization to contribute to the limited research of comparative studies on post-colonial societies between Morocco and India.

Abstract Name: Best Practices for Language Acquisition

This thesis examines dominant language acquisition and implications for “best practices” in two contexts – Italy and the United States. This study has implications for improving language learning for learners in multicultural contexts. For the purposes of this study, dominant language acquisition refers to children learning a language other than their home language that is primarily spoken in their schools. The study was conducted through cross cultural comparison of curriculum and instruction, as well a review of United States ELL policies and practices in comparison to Italian Language acquisition policies and practices. Data collection included school observations in Italy, interviews of Italian school personnel, and curriculum and related document review in Reggio Emilia, Italy. Data analysis was conducted using recommendations established by Saldaña (2022). Findings and implications relate to best practices for dominant language learning for multilingual children.

Abstract Name: Developing A Lewis Acidity Scale For Redox-Inert Metal Salts

In this work, we determined the ability of different Lewis acidic salts of alkaline, alkaline earth, and redox-inert transition metals to form complexes with ammonia and fluoride ions. To achieve this, we utilized modern density functional theory (DFT) techniques. The energies resulting from the complexation studies were used to generate two Lewis acidity scales, namely the fluoride ion affinity and ammonia affinity for these salts. These scales will serve as a tool to evaluate each Lewis acid's effectiveness in extracting fluorides from organofluorides and promoting the coupling of the organofluoride to amines to form nitrogen-rich compounds.

Abstract Name: The association between cause-specific mortality in people with diabetes and the social determinants of health: A county-level analysis of US data

Through this research, an attempt has been made to explore the correlation between different factors for

mortality among people aged 25 or older with diabetes and the social causes impacting human lives. By making an analysis of the primary available data, reports and research articles concerning the United States. Through this study, we tried to identify how social determinants fluctuate mortality rates for individuals suffering from diabetes. Moreover, this study finds a major connection between cause-specific mortality and social determinants. The findings of the research underline the significance of addressing the prevailing economic, societal, and environmental factors to elevate health standards and their results for people suffering from diabetes.

Abstract Name: A Three-Dimensional in vitro Model of Disease That Improves Preclinical Research by Incorporating Genetic Diversity and Increasing Physiological Accuracy

Biomedical research is essential for the discovery of new medications and treatments, and is built upon the cooperation of preclinical (in vitro/vivo) research and clinical trials. However, 85% of treatments successful in vitro/vivo fail in clinical trials, suggesting that in vitro models are poor indicators of clinical success. The issue lies in conventional “two-dimensional” in vitro models containing genetically identical cells grown on a flat plate, which lack the variety of cell types and cooperation/structure found in real tissue. Moreover, 2D in vitro models do not simulate humans’ genotypic variability, which affects both pathophysiology and treatment effectiveness. In contrast, 3D in vitro disease models (e.g. organoids/spheroids) contain the extracellular components, structures, cell-cell interactions, and microenvironment observed in human tissue, resulting in more physiologically accurate disease models. This paper consolidates current research of 3D in vitro models of varying complexities for different diseases to propose an effective and efficient solution for creating 3D in vitro models. Organoids should be the model of interest for organ/tissue-specific diseases and tumors, while patient-derived xenografts formed by implanting organoids into humanized mouse models should be used for studying body-wide disease/treatment effects. Growing organoids in prepared hydrogels allows them to mimic a human extracellular matrix and microenvironment, and adjusting the hydrogel’s characteristics allows control over organoid growth/differentiation. Sourcing undifferentiated stem cells from patients of different ethnicities, ages, and socioeconomic statuses allows representation of diverse populations and corresponding epigenetics. Adipose stem cells are abundant and easily accessible with minimally invasive procedures.

Abstract Name: Healing Ethnic Divides: The Promises and Limitations of Consociational Government in Bosnia-Herzegovina

Bosnia-Herzegovina was entrenched in civil warfare between the years of 1992-1995. The establishment of

the Dayton Accords in 1995 was intended to transform Bosnia-Herzegovina into a livable functioning Democracy. With help from the international community, the Dayton Accords presented Bosnia with the opportunity to develop a government that would effectively address the country's ethnic tensions. While there have presently been no outbreaks of a second civil war ethnic tensions within Bosnia are still causing immense polarization, impeding the government from creating necessary symbolic legislation, and furthering discrimination against ethnic minorities. Ethnic conflict literature has found that strong governmental foundations and cultural alignment help to resolve conflict among groups. The consociational government that was established in the Accords was intended to guarantee the inclusion of all ethnic groups into the political process and prevent one group from becoming the majority. Why has the consociation of the political system set up after the Dayton Accords in Bosnia not resolved ethnic tensions in the country? Using the case study method this thesis will analyze the government structure and policy making process in Bosnia-Herzegovina to understand why the framework established by the Dayton Accords has not lessened ethnic tensions, has not advanced the passage of legislation important to certain ethnic groups, or prevented further social divide in the country.

Abstract Name: Robust Design and Optimization of Turbomachine Compressors

This research is dedicated to advancing gas turbine technology for a greener and more cost-effective commercial air transportation. Our focus lies in optimizing the High Pressure Compressor (HPC) component of NASA’s Energy Efficient Engine (EEE) which compresses air prior to entering the combustion chamber. Our goal for the research project was to improve the compressor’s pressure ratio from inlet to outlet to enhance the efficiency of the combustion process. Factors affecting compressor performance, such as blade twist angle, blade geometry, and shroud and hub tip clearance, are analyzed and optimized to improve efficiency and overall performance. We created Computational Fluid Dynamics (CFD) models within the Ansys software suite and successfully optimized the model of the HPC by leveraging the San Diego Supercomputer Center. This research achieved a pressure ratio increase across the first four stages of a ten-stage compressor, surpassing NASA's 1980s model. This paper outlines the methodology, including geometry generation using Ansys BladeModeler, blade row meshing with TurboGrid, and CFX simulations. The optimization process involved multiple design iterations and a response surface method to attain the highest pressure ratio. Our multidisciplinary approach underscores the potential of leveraging emerging technologies of CFD, and High Performance Computing to significantly improve the efficiency of existing models, as exemplified by the successful optimization of the EEE’s HPC.

Abstract Name: Retrieval Augmentation Generation (RAG): Advancing Analytical Precision in Multimodal Data.

In the face of escalating data volumes and computational constraints, this research introduces the sophisticated Retrieval Augmentation Generation (RAG) methodology. Tailored to the intricate challenge of analyzing heterogeneous data sources, RAG utilizes an Extract, Transform, Load (ETL) process to systematically structure data. Advanced Machine Learning techniques, encompassing Dimensionality Reduction, Feature Engineering, and Clustering, construct a comprehensive data source. Visualization techniques, coupled with Tableau integration, facilitate nuanced pattern exploration. Fine-tuning a Large Language Model ensures precise inferences, minimizing hallucinatory outcomes. Additionally, RAG extends its purview to extract information from PDF documents, contributing substantially to a more exhaustive analysis of data.This research presents a technically sophisticated and holistic approach to analyzing and visualizing data from disparate sources. The convergence of clustering visualization, chatbot interaction, and Tableau integration underscores the adaptability of the proposed methodology. Despite achieving a commendable 98% accuracy rate, user evaluations identified areas for improvement, emphasizing the need for continuous enhancement to address diverse user queries. Expert opinions were consulted to validate results, providing valuable insights for future refinements. Notably, the chatbot has actively engaged with thousands of queries, revealing that while the model has successfully addressed the majority of questions, ten specific inquiries yielded unsatisfactory results, highlighting opportunities for targeted improvement.This research introduces a comprehensive technical solution for assessment reports and identifies opportunities for future enhancements. Validated by expert opinions, incorporating user feedback serves as a roadmap for continuous improvement. As the technological landscape evolves, the iterative refinement of the RAG methodology will ensure its adaptability and effectiveness in extracting meaningful insights from heterogeneous data sources, contributing to the advancement of analytical precision in technology assessment reports.

Abstract Name: Significance of m6A mRNA Methylation in CNS Demyelination and Inflammation

This research explores the role of the METTL14 gene in oligodendrocytes, the cells responsible for myelin production in the central nervous system (CNS). Myelin is very important in nerve conduction and has a strong correlation with demyelinating diseases such as multiple sclerosis (MS), the study aims to unravel the impact of METTL14 on oligodendrocyte function and survival.Using mouse models, MS-like symptoms were induced through Experimental Autoimmune Encephalomyelitis (EAE) and cuprizone models, representing autoimmune and toxic demyelination, respectively. Through tamoxifen inducible Cre recombinase, METTL14 was selectively ablated in oligodendrocyte precursor cells (OPCs) and mature oligodendrocytes.Results revealed distinct outcomes in both models. In the EAE study, METTL14 ablation in mature oligodendrocytes led to reduced T-cell infiltration and tissue damage at post-induction day 30, suggesting a protective effect. Additionally, at the peak of the disease, METTL14 ablation resulted in increased proliferation of OPCs. In the cuprizone study, METTL14 ablation in OPCs led to a reduction in OPCs during the peak of the disease at two weeks.The research incorporated advanced techniques, such as Tamoxifen IP Injection, immunohistochemistry, and HALO software for quantitative analysis. Some of the key markers include PDGFRa for OPCs identification, Ki67 for cell proliferation, CC1 for mature oligodendrocytes identification, MBP for myelin staining, and TPPP for myelinating oligodendrocytes identification. They were employed to assess the effects of METTL14 ablation in immunohistochemistry staining.In conclusion, this study provides several insights into the epigenetic regulation of the myelination process and the impact of METTL14 on oligodendrocyte survival and functionality. The findings suggest a potential therapeutic avenue for demyelinating diseases by targeting METTL14. Further research will investigate the effects of METTL14 in the brain, specifically the corpus callosum due to its high density of oligodendrocytes.

Abstract Name: Engineering Useful Gene Therapy Vector Properties in the Baculovirus

Viral methods are commonly used for the delivery of gene therapies. Current common viral delivery methods include lentivirus and adeno-associated virus. These can efficiently deliver DNA into living systems, but have small packaging capacities, unable to hold larger constructs created to deliver more complex, nuanced therapies. This research aims to use baculovirus, an insect-virus with a comparatively large carrying capacity, to deliver inducible, targeted gene therapies to mammalian systems. This work focuses on the process of producing pseudotyped baculovirus containing proteins to enhance transduction, immune protection, and

targeting. Genes for the pseudotyped proteins were placed downstream of the p10 insect promoter in the baculovirus genome using standard molecular cloning techniques. Baculovirus was then produced, purified, then tested in vitro on various cell lines using GFP as a reporter for transduction, as well as in vivo in C57BI6 mice using a firefly luciferase reporter. Both in vitro and in vivo, vesicular stomatitis virus protein-G (VSV-G) has been determined to improve transduction efficiency. With VSV-G, a three-fold increase in transduction was observed in HEK293T and C2C12 cells, and a 30-fold increase was seen in HEPA-1,6 cells. Decay accelerating factor (DAF) also appears to provide protection from the complement portion of the immune system. In vivo, while pseudotyping with VSV-G and DAF independently increased baculovirus transduction, adding both proteins to baculovirus together led to the highest transduction and expression that persisted for a month. Ongoing efforts are focused on the engineering and production of pseudotyped baculovirus containing proteins to enhance targeting and transduction in primary T-cells. The level of control afforded to clinicians and researchers by the large DNA capacity of baculovirus can be used to implement small-molecule inducible systems for temporal control of therapeutic gene expression, or autonomous cell-state sensing mechanisms to monitor and respond to CAR T-cell activity in vivo.

Abstract Name: Validating methods of diagnosing urinary tract Infections in rats post spinal cord injury

Spinal cord injury (SCI) results in paralysis of extremities and can have a significant impact on bladder function, thus diminishing quality of life. Current treatments, including intermittent catheterization to empty the bladder, provide symptomatic relief but carry notable side effects, including urinary tract infections with a 15% mortality rate, emphasizing the need for innovative approaches. The rat is one of the most used animal models to investigate novel treatments. However urological procedures including intermittent transurethral catheterization can result in bacteriuria. It is difficult to determine if the observed bacteriuria represents a urinary tract infection (UTI) because there are no rapid and validated tools to screen for UTIs in rats. The objective of this study is to identify a rapid and reliable method for diagnosing UTIs in rats, ensuring diagnostic accuracy and eliminating false positives. Urine samples were collected through sterile transurethral catheterization in rats and tested with two methodologies: 1) UTI home test strips and 2) urine culture as a control. The UTI test strips allow quantification of leukocyte concentrations and pH levels, common indicators of UTIs. Concurrently, urine culture via CHROMagar Orientation provides preliminary species identification in these samples. Results showed that samples with higher pH levels and increased leukocyte concentrations exhibited more bacterial colony forming units on CHROMagar. We found a 100% accuracy using the leukocyte indicator and an 89% accuracy with the pH. The leukocyte indicator showed a 100% diagnostic sensitivity, indicating a high probability to detect an UTI if it is present. The pH indicator showed an 11% incidence of false positives. These results support the use of the leukocyte indicator in UTI home test strips for rapid screening in rats. This research is a critical step towards developing rigorous workflows for diagnosing UTIs in rats and facilitating the optimization of urological procedures in post-SCI rats.

Abstract Name: Phenylboronic Acid Nitrogen Mustards induce P53 Upregulation Inhibiting Cell Migration and Invasion in Breast Cancers

Breast cancers are renowned for their heterogeneity and aggressive nature. The limited treatment options and less favorable prognosis, particularly in Triple-negative breast cancers, position them as the most aggressive among various cancer types. The Peng group has pioneered the development of FAN-NM-CH3, a ROS-activated prodrug that surpasses others in its category, including the FDA-approved chlorambucil and melphalan, by multiple folds. This prodrug exhibits selectivity for H2O2, upon encountering it, activation occurs. The potent activated drug then proceeds to Alkylate DNA strands, hindering cancer cell replication and leading to their death. Gene expression evaluation revealed an upregulation of the tumor suppressor gene P53, supporting a transcriptional mechanism that induces tumor shrinkage. The tumor suppressor P53 protein plays a crucial role in maintaining genomic stability and regulating cell division, preventing uncontrolled and rapid proliferation. The observed increase in P53 expression in cancer cells treated with the prodrug suggests its role as an upregulator of the P53 protein, which, in turn, suppresses tumors. These findings provide valuable insights into the prodrug's function within cellular pathways, shedding light on its regulatory role over other genes that contribute to tumor suppression.

Abstract Name: TEG-working Principle and TEG Performance Analysis

Critical problems currently facing the world include global warming, rising power costs, and population growth. Scientists are working to increase the effectiveness of energy harvesting in this regard. The improvement of the power generation industry is concentrated on waste heat recovery systems using thermoelectric generators (TEGs), which have proven to be capable of converting thermal energy directly into electric energy through the Seebeck effect. TEG is regarded as an environmentally benign power source because it utilizes the existing waste heat sources in a variety of applications to generate electricity. The integration of thermoelectric systems with other technologies for the generation of green energy is introduced in the current study. This paper presents an in-depth analysis of thermoelectric generators (TEGs). Specifically, a comprehensive overview of their working principles from, such as the Seebeck effect, the Peltier effect, the Thomson effect, materials used, Figure of Merit, improvement techniques including different thermoelectric material arrangements and technologies used, and substrate types is provided. Additionally, potential applications of TEGs and their current status and future prospects are discussed. Finally, the importance of predicting the output of thermoelectric devices is highlighted. Moreover, The performance of a combined solar photovoltaic (PV) and thermoelectric generator (TEG) system is examined. Further research should be conducted to investigate potential ways of improving the output of thermoelectric

systems, as well as to explore different methodologies for utilizing them in various settings. It is essential to underline the importance of predicting the output of thermoelectric devices, as it will help determine the future use of this new technology as well as select the most suitable design parameters for thermoelectric generators and systems.

Abstract Name: Examining the Virulence of Candida Albicans

The CDC is aware of at least 25,000 candidemia which is a fungal bloodstream infection occurs each year. Candida albicans was the focus of this lab over the summer, it is an organism that is famously known to cause severe infection by building off of microbial surfaces known as biofilms. Biofilms form when yeast cells attach to a surface and then later fungal cells spread, beginning the change from yeast to a filamentous cell. After the final step of maturation, any cell that is not attached to the matrix are then released into the surrounding environment. This is precisely what causes the infections we see. What this summers research was focused upon was understanding the how, what, and why of the attachment and if there could be any way we could target a drug to resolve this issue. We looked for defects in the attachments by completing a virulence assay and using many strains from a mutant library, a positive and negative control was used alongside it as well. What was found of interest particularly was the Cht2 gene because of its enhanced virulence .

Abstract Name: Understanding Healthcare Experiences

Disparities in health between Black people and white people are signs of a systematic and serious public health crisis that needs extensive attention to understand causes and find solutions. Understanding the overall experience of Black patients when seeking medical treatment is a necessary part of this research, because it has been shown that poor treatment by doctors leads people to avoid the healthcare system entirely, leading to worse health outcomes. The research I conducted compared the personal experiences of young Black people who sought medical treatment to those of White people. Using the prolific recruitment website I surveyed 125 Black participants and 103 White participants about their most recent experience with the medical system, and explored any disparities that emerged. Results showed few disparities in reported treatment by healthcare providers. Black patients waited significantly longer to see their doctors than White patients, $t(221) = 2.125$, $p < .035$. However, providers spent more time with Black patients than White patients,

t(226) - 3.64, p < .001, and Black patients and White patients did not differ in how warm or competent they felt their provider was. This was fewer disparities than I expected based on the literature, but I noticed the following unusual features of the participants, which may explain this. First, a third of the Black patients saw a Black doctor, which is much higher than the national average (6%), and 54.4% of Black participants had seen their provider at least once before, which might suggest they liked the provider's care at least somewhat, or they would not have chosen to see them again.

Abstract Name: Public Perception of AI Integration in Healthcare: A Survey Study on US Citizens

In recent years, the revolution of artificial intelligence (AI) has taken the world by storm. From education to entertainment, the integration of AI has had many benefits on how we live our day-to-day lives, the potential to lower costs being the most prominent. Healthcare is a sector in which AI has not had much entry due to its dependency on human-to-human interaction, and it is imperative to understand how and why this will change as this determines the future for all patients and healthcare workers. To analyze US citizens' opinions on the integration of AI in healthcare settings, I designed an 18-question survey that was sent to various US citizens on Amazon Mechanical Turk. This resulted in 189 complete surveys. Important revelations have been revealed from this survey that could predict a promising future for AI in healthcare. From surgery to radiology, US citizens are hesitant to let AI alone fully control their medical procedures but are increasingly open to AI's involvement in addition to a human. The less invasive the procedures, the more open people were to AI's involvement. Surprisingly, the older the respondents were, the more open they were to AI being integrated into their healthcare. These results are essential for future healthcare workers looking into studying one of the various fields of medicine as their prospective field may soon be obsolete. Radiology, for example, has become a field of medicine that US citizens have been far more amenable to with the use of AI. In order to better understand the future of AI, we need to understand how comfortable people are with AI in healthcare settings, and this study provides a basis for that understanding.

Abstract Name: Development of a Novel Microgel Containing CXCL12 and Fas-ligand to Enable Allo-islet Transplantation Without Systemic Immune Suppression for Type 1 Diabetes

Type 1 diabetes (T1D) is an incurable disease caused by autoimmune destruction of pancreatic islet cells. Islet transplantation has proven to be successful in curing T1D, but the requirement for chronic systemic immunosuppression and the scarcity of donor islets are barriers to its implementation. The objective of our

research is to combine the immune-modulatory proteins, CXCL12 and Fas-Ligand (Fas-L), with allogenic donor murine alloislets to enable immunoprotection and support of beta-cell function without the need for systemic immune suppressionAs a first step towards this objective, we have constructed a streptavidin (SA) fusion protein with the immunomodulatory proteins FasL and CXCL12 that self-assemble with and then release from biotinylated microgels. We are currently studying how these immune modulatory proteins are released from the microgel in vitro. To this end, we are developing a novel HABA (4'-hydroxyazobenzene-2-carboxylic-acid) based assay to quantitate this. The ratio of unbound HABA to HABA bound to free biotin or SA-CXCL12 protein can be read by measuring light absorbance at 500nm. In this way, we have begun to determine the kinetics of the release of SA-CXCL12 and SA-FasL from biotinylated microgels. After conducting HABA assay, a western blot was done which showed biotin release from microgel in our initial experiments. These initial studies reveal a potentially complex pattern of release of SA-CXCL12 from the biotinylated microgel in vitro that demands further exploration.

Abstract Name: Potential Meditators of PTOA

Post traumatic osteoarthritis (PTOA) develops as a result of injury to the joint. This process involves progressive joint damage and chronic low-grade inflammation that leads to PTOA pain. This summer, I focused on damaging joint calcification and a serum macrophage-related inflammatory biomarker as potential mediators of PTOA pain. Progressive joint calcification is associated with sensory nerve growth, and soluble CD-14 is an activated macrophage biomarker associated with OA severity. Given that PTOA pain is related to both peripheral and central changes in the nervous system, we hypothesized that PTOA pain is more strongly correlated with circulating CD14 levels compared to joint calcification. We tested this hypothesis in lean and obese adult mice. 16-week-old male and female mice were fed either a high fat or control fat diet. At 36 weeks of age, mice were anesthetized and had a non-injury sham load or rapid compressive load applied to the knee to cause PTOA. Von Frey filament and Dynamic weight bearing tests were used to evaluate mechanical pain sensitivity before injury (baseline), and two- and four-weeks post injury. At 40 weeks of age, the mice were euthanized, and we collected knee joints and serum. We used micro-computed tomography to quantify joint calcification, and we quantified serum CD14 using an enzyme linked immunosorbent assay. At baseline, diet did not alter pain sensitivity. Pain sensitivity increased two weeks after both compression injury and sham loading to a similar level in lean and obese mice. We are completing the four-week post injury data analysis, and we have collected all samples to measure serum CD-14 and joint calcification. We will compare the increase in pain sensitivity to serum CD-14 concentration and joint calcification volume to test our hypothesis.

Abstract Name: Prediction of Loan Defaultation by using IBM Watson Based Machine Learning Techniques

This research pertains to the utilization of artificial intelligence/machine learning to predict loan defaults. The outcome of this research will aid banks in preventing credit losses. Our hypothesis is that the personal and social standing of the subject has the greatest impact on whether a loan will be defaulted. For this research, a dataset from Kaggle was gathered from Coursera's Loan Default Prediction Challenge. The data took in multiple categories to predict loan defaults, ranging from income to education. The aim of the study was to develop algorithm based predictive models that can predict the outcome with a high accuracy, and pinpoint significant factors. IBM Watson Cloud based platform was used to conduct this investigation, considering its capability to select high-performance algorithms to generate models such as ROC curves, while also using enhancements. For the current data, the most prominent models were XGB Classifiers and Snap Random Forest Classifiers. The XGB Classifier models performed slightly better, having an accuracy of 88.6% with and without enhancements, while the Snap Random Forest Classifier models had an accuracy of 88.5%. The ROC curves for all models differed slightly. XGB Classifier models with enhancements demonstrated higher values for sensitivity and specificity, but it is important to note the higher specificity rates in every model, signifying its benefits for identifying loans without a default. When evaluating the different features affecting the predictions, Age exhibited the highest feature importance of 100%. However, the two XGB Classifier models had a feature/product (Age,Income) which also scored a 100% feature importance. These models provided a significant insight into how machine learning could successfully detect loans that would not have defaults. Nonetheless, further research should be conducted in identifying ways to advance them to be more successful in identifying loans that will be defaulted.

Abstract Name: Analyzing GPT-4's Predictive Power in Stock Market: A Comparative Study of individual Technical, Fundamental, and Sentimental and multi-modal Analyses Across Diverse Financial Data Sets

The integration of artificial intelligence (AI) into financial domains has become a focal point of interest, particularly with the recent advancements in large language models. Our study explores the predictive capabilities of GPT-4 in stock market analysis, using results of few-shots (pre-trained) and zero-shot analysis by employing different indicators and datasets from technical, fundamental, and sentimental analyses, as well as a multi-modal approach to the stock market. Building on existing research, our study addresses the gaps in empirical validation, especially in substantiating GPT-4's predictive prowess. Notably, we draw inspiration from successful endeavors using sentimental analysis, adapting the variable StockTwits for our research. Additionally, we refine multi-modal analysis based on lessons learned from failures in the Wall Street Neophyte study, incorporating additional indicators as well as data using prompt engineering and prompt tuning.To investigate GPT-4's potential to outperform traditional methods individually and in combination, a variety of variables, including historical patterns for technical analysis, financial data for fundamental analysis, and media and social media for Sentimental Analysis, will be fed to GPT-4 through carefully crafted prompts. Anticipated outputs include predictions of price lows and highs, accompanied by Standard Deviation and efficient explanations for the predictions made, facilitated through Chain-of-thought prompts. Furthermore, we also describe the strengths and limitations of GPT-4 by comparing its results, using a few statistical measures, with current leading domain-specific fine-tuned models, namely AltIndex, Danelfin, Candlestick.ai, EquBot, including the state-of-the-art model FinBERT (for sentimental analysis), with the real stock market prices/data. The aim is to provide a comprehensive understanding of GPT-4's rationale in

forming predictions, ensuring transparency and reliability in its analytical capabilities. This research holds practical significance and explores how AI, in general, can help both novice and experienced traders, offering a potential breakthrough in financial market trading strategies and AI's predictive abilities.

Abstract Name: Navigating a Fragmented Landscape: Insights from Civil Society Actors in Lebanon

In the contemporary era, civil society has become an essential component for addressing the political liberalization and democratization of Middle Eastern regimes. This study concentrates on civil society in Lebanon, a small democratic nation in the Levant. Lebanon's government is a consociational system characterized by dysfunctional power-sharing among sectarian parties. Comprehending the factors in Lebanon that influence civil society's ability to function and serve its purpose is essential. This understanding can assist in gaining insights into how civil society activists in the Middle East may mobilize to contribute to purposeful political and social evolutions.This exploratory study seeks to gain a better understanding of how Lebanese civil society functions and the factors that contribute to its capacity (or incapacity) to resolve societal challenges in the context of the Lebanese state's frailty. This study seeks to analyze the impact of multiple contemporary stressors on the fragile state infrastructure, namely the over a decade-long hosting of Syrian refugees and the country's recent political and economic collapse. It also aims to examine how these particular challenges have affected the function of civil society, as well as the intricate dynamics between various organizations at the national and international levels.The gathered evidence supports the conclusion that civil society organizations (CSOs) in Lebanon struggle to navigate a landscape characterized by multiple crises and a faltering public sector. As local CSOs devote a significant portion of their attention to humanitarian aid and external funding, their interactions with international NGOs and Syrian refugee populations contends with complex challenges. Ultimately, this reality has revealed the diminished capacity of CSOs to contribute to meaningful and lasting change in the country.

Abstract Name: Expression of myoneurin in the green anole lizard (Anolis carolinensis)

The green anole lizard (Anolis carolinensis) is seasonally breeding such that this lizard displays major differences in physiology, morphology, and behavior between the breeding and non-breeding seasons. During the non-breeding season, the lizard will have smaller gonads, lower sex hormone levels, and a decrease in

reproductive behaviors compared to breeding lizards. In this study, we are examining myoneurin (MYNN) mRNA expression to determine whether this gene is involved in mediating seasonal changes in the green anole. MYNN is known to regulate transcription and control the expression of genes; our group predicted that MYNN will be more present in the non-breeding season. To do this, we first designed several primers sets that amplify the anole MYNN gene and used PCR and gel electrophoresis to confirm the quality of our primers. We verified that only one of our primers sets amplified MYNN through DNA sequencing. We then isolated mRNA from the hypothalamus of breeding and non-breeding male and female lizards ($n = 6$), performed cDNA synthesis, and set up standard curves. Our group ran standard curves for the MYNN gene and received inadequate results. The efficiency value equated to zero for each of these runs. We think it is likely that our primers may have been contaminated, resulting in the failed standard curve. Finally, we were able to perform a full run on our control gene, Beta-actin, and we found no differences between sex and season ($p \geq 0.377$). Future research will involve continuing to trouble shoot our qPCR conditions to successfully amplify MYNN. This work will help us determine if MYNN is involved in regulating seasonal changes in the brain that correspond to reproduction.

Abstract Name: Tulsi as a Natural Remedy for Type II Diabetes

Type II Diabetes is caused by the lack of insulin receptor signaling present in beta cells, which inhibits the absorption of glucose. Human Islet Amyloid Polypeptide (hIAPP) is co-expressed with insulin, however, the aggregation of the hIAPP creates amyloid fibrils which cause beta cell death. Tulsi extract has been shown to naturally and effectively reduce hypoglycemia in rats. It is also thought to have anti-diabetic and antioxidant properties. The objective of this work is to determine the effect of Tulsi on the viability of beta cells and observe its effect on hIAPP toxicity levels. Tulsi was extracted with ethyl acetate and its effects on cell viability were tested using MTT Assay. After determining the optimal concentration of the Tulsi extract, the cells and extract were tested against hIAPP. High concentrations of Tulsi extract decreased cell viability, but the 1:5 dilution of the extract did not drastically reduce viability. HIAPP in all concentrations decreased cell viability and proved to be toxic to RIN-m cells. HIAPP combined with low concentrations of the Tulsi extract did not decrease cell viability. Higher concentrations of the Tulsi extracts had the ability to save the cells from the toxic hIAPP. In the future, even higher concentrations of Tulsi can be tested against hIAPP to further determine its effects on beta cells and the molecular processes involved.

Abstract Name: Using Confocal Microscopy to visualize the interaction between SERCA2A and phospholamban in cardiomyocytes to demonstrate that Ca2+-dependent PLB deinhibition of SERCA2A is a viable approach to improve cardiac contractility

Heart Failure with Reduced Ejection Fraction (HFrEF) is characterized by the inability of the heart to pump blood efficiently due to left ventricular (LV) enlargement. HFrEF accounts for approximately half of the 23 million heart failure cases annually. Impaired calcium uptake into the sarcoplasmic reticulum (SR) is a key abnormality in failing hearts. The regulation of SR calcium uptake is mediated by a Ca(2+)-ATPase known as SERCA2, and its activity is controlled by a protein called phospholamban (PLB). The inhibitory interaction of SERCA2a and PLB is the main regulator of cardiac contractility. The Meyer lab developed a construct utilizing a green fluorescent protein (cpGFP) inserted between SERCA2 and PLB. This construct allowed for the selective interference study of the recombinant protein SERCA2a-cpGFP-PLB. By using a Nikon A1R FLIM Confocal Microscope, we will be able to visualize the interaction between SERCA2A and PLB in rat cardiac myocytes during contraction and relaxation and demonstrate that Ca2+-dependent PLB disinhibition of SERCA2A through an increase in stimulation rate is a viable approach to improve contractility. In patients with heart failure with reduced ejection fraction (HFrEF), there is a decrease in the levels of SERCA2a and an increase in the inhibition of phospholamban (PLB). This alteration makes the SERCA2a-PLB complex a potential target for drug therapy, as it plays a central role in regulating the contractility of the heart. Visualization of the temporal interaction between these proteins in a single heartbeat will allow us to determine how to best interfere with this mechanism. This would also allow researchers to understand better and predict how pharmacological drugs could alter the protein kinase A pathway and alter calcium cycling in the cell.

Abstract Name: From Sub-Saharan Struggles to Caribbean Crisis: Tackling Child Soldiering Globally with U.S. Intervention

The phenomenon of child soldiers, once primarily associated with Sub-Saharan Africa—home to approximately 40% of the world's child soldier population—has expanded geographically. According to the United Nations, from 2005 to 2022, over 105,000 children were confirmed recruited by armed groups worldwide, with the actual number likely surpassing that figure. This disheartening reality has also reached the shores of the Caribbean, especially Haiti. Child soldiers, by definition, constitute a group of children—boys and girls from all over the world—engaged in roles such as armed soldiers, spies, chefs, porters, messengers, or, alarmingly, sex slaves. The use of child soldiers reflects a complex and deeply rooted set of issues often arising from socioeconomic challenges, political instability, and armed conflicts. Our initial research, conducted in the spring of 2022, and supported by existing literature, consolidated our findings on child soldiers in selective regions of Sub-Saharan Africa. These regions included Liberia, Sierra Leone, Somalia, Burundi, Rwanda, Sudan, Ivory Coast, Congo- Brazzaville, and Congo-Kinshasa. As we expanded our work beyond Sub-Saharan Africa, we were able to substantially assess the global involvement of international organizations such as Human Rights Watch, Save the Children, and the Coalition to Stop the Use of Child Soldiers. The aim of our current paper is three-fold: firstly, we will contextualize our data-informed definition of the child soldier phenomenon within Sub-Saharan Africa. Secondly, as we revisit key postures of local governments and the U.S. foreign policy landscape, our analysis will unveil a comparative study of the said phenomenon from Sub-Saharan Africa to Haiti. Thirdly, we will share potential solutions and strategies that could be conducive to sustainable positive changes in fighting the phenomenon. It is our hope that such a comprehensive approach could ensure a thorough understanding of the multifaceted reality of a child soldier, both regionally and globally.

Abstract Name: Quantification of Lactic and Acetic Acid Concentrations in Silage

Silage is an integral source of feed for livestock who depend on farmers to provide the proper nutrition to ensure their health and wellbeing. Fermenting plant materials such as corn and alfalfa extends the bunk life of the feed and makes the feed more palatable to farm animals. To determine the quality of the fermentation, it is necessary to quantify the lactic and acetic acids in the silage as their respective quantities are key indicators of proper fermentation. Lactic acid, primarily generated as a byproduct of lactic acid bacteria (LAB) fermenting sugars, is the major acid in fermentation. Through microbial and enzymatic oxidation, a portion of lactic acid is converted into acetic acid, while acetic acid is also produced by other microorganisms. High concentrations of acetic acid often lead to a prolonged fermentation period, while low concentration of lactic acid is an indicator of restricted fermentation. Consequently, quantitative analysis of these acids is a useful metric for ensuring proper silage fermentation. This study, will determine if lactic and acetic acids can be quantified through titration and develop a method to quantitatively analyze the acid concentrations through proton nuclear magnetic resonance (1H NMR) spectroscopy. Although lactic and acetic acids can be quantified using enzymatic methods and by high performance liquid chromatography (HPLC), NMR allows the analyst to measure the concentrations of both acids using a single spectrum taken in a matter of minutes. This study investigates the use of 1H NMR as an alternative method of quantitative analysis that is economical, requires minimal sample preparation, and does not require toxic reagents as opposed to previously mentioned methods. Overall, the application of NMR spectroscopy in this context holds promise as an advantageous approach to lactic and acetic acid quantification.

Abstract Name: Investigating Missense Variants in Cleavage Sites of Alzheimer’s–related Amyloid Precursor Protein

Alzheimer’s Disease is the most common neurodegenerative disorder in the world and can be caused by aggregations of amyloid beta protein in the brain. Amyloid beta is a derivative of amyloid precursor protein, which is coded for by the APP gene. When APP is atypically expressed, amyloid beta can be aggregated into longer chains, forming plaques. The oligomers and polymers that make up these plaques are toxic and illicit cascading reactions, causing neurotransmitter interruption and cell death. This study investigates 10 missense amino acid swaps in APP cleavage sites using homology modeling and data gathered from pathogenicity predicting software. It is expected that missense variants in APP cleavage sites may be pathogenic to protein structure and function.

Abstract Name: Participants' Experiences with a Telerehabilitation Behavioral Intervention to Improve Physical Function and Physical Activity After Lung Transplantation: A Mixed-Methods Study

Health intervention studies increasingly leverage telehealth, therefore assessments of patient experience during an intervention are critical to determine reception and the extent to which the intervention met their needs. The study's purpose was describing the experiences of lung transplant recipients (LTRs) randomized to the telerehabilitation behavioral intervention of Lung Transplant Go (LTGo), a clinical trial assessing the efficacy of a supervised exercise training and behavioral coaching via a video conference platform, compared to enhanced usual care with self-directed activity tracking and monthly newsletters. Data collected at 3 months and 6 months included semi structured interviews (SSI), telehealth usability questionnaires (TUQ), and adherence patterns (number of phase 1 exercise sessions completed and phase 2 phone calls). The sample was comprised of 38/44 (86%) of LTRs who completed at least one SSI. Throughout the study, interviews collected open-ended comments which were mostly positive at 3 and 6 months post-intervention. Negative comments about technology only occurred at 3 months; all 6-month comments were positive. Participants completed a mean of 9.35/12 weekly Phase 1 sessions, 7.45/8 behavioral topics, and 2.23/3 monthly Phase 2 phone calls. Average scores for the TUQ were 6.43/7 (the higher the score the greater usability). TUQ scores and adherence remained high throughout the study and feedback from the SSIs was predominantly positive. The few negative comments were related to intervention feedback about the intervention progression and time commitment. As TUQ scores and adherence rates remained high, it is unlikely that the uses of telehealth systems was a significant barrier to accessibility and reception by LTRs. The participant feedback suggests that participants view telerehabilitation as an acceptable approach to rehabilitation. But further research at a larger scale is necessary to determine if telerehabilitation is an acceptable and sustainable method for self-management beyond the active intervention period.

Abstract Name: Changes in Quality, and Bioavailability of Dissolved Organic Matter in a Semiarid Intermittent Stream Network as a Result of Seasonal Drying and Rewetting

Dissolved organic matter (DOM) serves as a significant source of energy and carbon in stream ecosystems. The quality and bioavailability of DOM can strongly influence the transfer of energy and carbon to higher trophic levels facilitated by stream microbes. (Fellman et al,. 2008). In intermittent stream networks, seasonal drying and rewetting has been shown to affect the quality of DOM, although it remains unclear how the

correlation between bioavailability and quality of DOM varies with seasonal drying and rewetting. We measured quality and estimated bioavailability of DOM using bottle incubations from seven locations in the Gibson Jack watershed in Southeastern Idaho. We hypothesized that bioavailability of DOM would decrease with seasonal drying, and with that change, the quality of DOM would be more aquatic and microbial in character, showing a higher biological index (BIX). Our results showed that BIX, as measured by fluorescence spectroscopic techniques, increased during drydown suggesting the DOM was from autochthonous origin. Contrary to our hypothesis, we found that the bioavailability of DOM decreased with dry down by approximately 2% throughout the watershed whereas it increased by 2% during re-wet. Our findings suggest that the percent bioavailability of DOM decreases as the quality of DOM becomes more humic, or terrestrial like in character, during rewet, while the percent bioavailability during dry down increases as the quality becomes more humic. These findings contribute valuable insights into understanding the intricate relationships within intermittent stream networks during seasonal changes and have implications for broader ecological and biogeochemical processes.

Abstract Name: Colson Whitehead’s Martyr for Racial Acceptance in

Throughout history, racism has been at a constant high, only finding suppression through the appearances of martyrs. Colson Whitehead’s The Nickel Boys portrays the young Elwood Curtis as a martyr for a new wave of racial acceptance among America’s youth. Exploring the short life of Elwood as a Black teenager growing up in 1960s Tallahassee, readers find an experience that is all too common for the minority youth of this time. From racism and discrimination to mutilation, Elwood experiences a cruel, unfair reality that is defined by his false sentence to Nickel Academy. Elwood’s life is ultimately cut short when he is executed by the administrators of the prison masquerading as a reformatory school. Pushing past the harshness brought on by the racism dwelling in the hearts of those around him, Elwood finds motivation through the words of Martin Luther King Jr. and friendship through another African American teenager who shares the same fate as him. Elwood meets Turner after arriving at Nickel Academy. Turner stays by his side until Elwood is executed by the Nickel staff. Turner pushes forward and continues his life in New York City, burdened by the trauma he suffered at Nickel Academy. Turner chooses to lead his life following Elwood’s ideals and beliefs, paralleling the dynamic of Jesus Christ and his apostles. Turner does not completely escape due to the past trauma and guilt holding him back. As Martin Luther King Jr. became a martyr and Jesse Jackson pushed forward, Elwood becomes a martyr and Turner becomes his follower, tougher and militant, driven by the death of his guide.

Abstract Name: Geometric Distribution of Order r

Individuals have attempted to describe the patterns and movement of the stock market using Normal Distribution. The normal distribution, considered a thin-tailed distribution, does not properly convey the probability of unlikely events. Due to its thin-tailed nature, the probability of a rare event occurring is found to be a very small probability, so small it can be considered zero. Should Normal distribution be the correct distribution to model stock market, then events such as “Black Swan” events, events that are random and highly unexpected, would not occur (Taleb, Chandler, 2007). A few examples of “Black Swan” events include: the financial crisis of 2008, the COVID-19 global pandemic in 2020, and the volatility of stocks of 2020. The application of Geometric distribution of order r could more accurately describe the patterns within these rare events. The theoretical properties of Geometric distribution of order r will be applied to real data from selected “Black Swan” events to show consecutive successes of observed drastic changes in the data. A financial recession and a global pandemic both qualify as unexpected events with minimal probability of occurrence. COVID-19 cases grew exponentially in 2020 throughout the nation and the stock market took a huge hit in 2020 concurrent with the increasing pandemic crisis effecting a majority of Americans. In 2020, the stock market, experienced severe volatility that supposedly had a probability of near zero. The drop in stocks blindsided many individuals and impacted many more. Finding the distribution that works best for such cases would provide more accurate description of real-life data. The growth of understanding within this area of statistics will only continue benefit those impacted by such unexpected events.

Abstract Name: Turning-Up the Volume of Knowledge on Fam107a: A Novel Cochlea Expressed Gene

Insufficient thyroid hormone levels during critical windows of development result in hearing loss. Understanding how thyroid hormone mediates cochlear development is a critical step in understanding thyroid hormone-linked deafness. Recently, our lab identified Fam107a as a potential thyroid hormone regulated gene in the developing cochlea. The function of Fam107a is largely unknown, although several reports suggest it is a tumor suppressor. Furthermore, Fam107a expression in the cochlea has not been described. We hypothesize that Fam107a is a thyroid hormone-regulated gene and that its cochlear expression is disrupted following developmental hypothyroidism. To test this, timed-pregnant mice will be separated into two different experimental groups: euthyroid (control) provided with normal drinking water and hypothyroid (experimental) provided with water containing the thyroid gland inhibitor methimazole. The hypothyroidism inducing treatment will be administered from gestation day 13 (G13) until pup sacrifice during the perinatal period. The spatial and temporal pattern of Fam107a mRNA in the developing euthyroid and hypothyroid cochlea will be visualized using in situ hybridization (ISH). ISH will utilize a Fam107a cRNA successfully generated during academic year 2022-2023. Additionally, quantitative changes in Fam107a mRNA will be measured using real-time PCR. Our initial results suggest that Fam107a mRNA has regional specificity in the developing cochlea. Specifically, we note expression in certain epithelial cells of the cochlear duct. Overall, our goal is to understand Fam107a mRNA expression levels between hypothyroid and euthyroid (normal/control) mice. If Fam107a mRNA levels are impacted by developmental hypothyroidism, we propose that Fam107a might ultimately help understand deafness associated with low thyroid hormone in development.

Abstract Name: Characterization of disease progression in amyloid- and tau-based mouse models of Alzheimer's Disease

Astrocytes have a crucial function in regulating neuronal synapse formation, function, and elimination. One important mechanism to modulate neuronal synapses is by releasing a variety of secreted proteins that act at the synapse. In Alzheimer's Disease (AD), neurodegeneration may be perpetuated or triggered by astrocyte dysfunction that contributes to the progressive synapse loss and memory impairments characteristic of the disease. The astrocytes in AD transition to a reactive proinflammatory state, which involves morphological rearrangement of the intermediate filament protein, glial fibrillary acidic protein (GFAP), in astrocyte processes. These reactive astrocytes are less supportive of neuronal synaptic function. Therefore, we hypothesize that targeting astrocytes will attenuate disease progression. In order to test this hypothesis, we want to pinpoint the time point at which astrocytes are transitioning to a reactive state and use this time point for our interventions. We characterized the onset and progression of astrocyte reactivity, plaque burden and hyperphosphorylated Tau in two commonly used AD mouse models, APP/PS1 and Tau*P301S. Each mouse line was crossed into the Aldh1L1-Cre line to allow for Cre-dependent targeting of astrocytes in future intervention studies. Three different time points (4, 6 and 9 months) were analyzed to pinpoint the onset of astrocyte reactivity, plaque deposition and accumulation of hyperphosphorylated tau. We are using immunohistochemistry to quantify GFAP immunoreactivity, plaque density, and hyperphosphorylated tau area. Based on these findings, future intervention studies will be performed prior to the onset of astrocyte reactivity in an attempt to ameliorate astrocyte reactivity and slow disease progression.

Abstract Name: Physical properties of electrospun Zinc Oxide and Titania-based nanofibers

By making polymer solutions containing metal precursors, nanofibers with various properties can be made utilizing electrospinning. The desired properties of these nanomaterials depend greatly on the conditions in which they are made, ranging from solution composition ratios to ambient humidity during the electrospinning process. These nanofibers have a wide variety of potential applications, from photocatalysts to medical applications for advanced drug delivery. The process of electrospinning composite nanofibers pose a challenge, especially when it comes to achieving production of structures with reproducible properties. The created nanofibers are analyzed using SEM (Scanning Electron Microscope), BET (Brunauer-Emmett-Teller) instrument, XRD (X-Ray Diffraction) system, and Ultraviolet-Visible spectrometer.

Abstract Name: Atheist Influencer's Perceptions of the Atheist Community

The internet has played an increasing role in our society, and many people have begun to find and form communities online. These communities can be especially important to people who are geographically isolated or socially isolated from others with similar views. One example is atheists. In this context, atheists can be defined as those who lack a belief in a higher power or any religion. On digital platforms, some people may become social media influencers, defined as people who have roughly 1,000 followers or more. This poster examines answers from fifteen qualitative interviews conducted by a research team in order to illustrate common narratives about how atheist influencers view themselves as being in a digital community, and how the influencers view their own roles and content in such a community. It also examines the role online platforms play in community building and if atheist influencers participate in more traditional, in-person communities as well. Findings suggest that atheists predominantly do not consider atheism to be a religion, but that they do perceive themselves as being in a community, albeit a loose one. Most do not consider themselves leaders or influencers, but many express a desire to create a small community with their own content by providing a safe space and setting an example for how people should act through their own content. While this study focuses specifically on atheists, aspects of this project can be applied more generally to the shifting of in-person communities to online communities and the increasing role of online spaces and interactions in everyday life.

Abstract Name: A targeted immunotherapy against aggressive ovarian cancer

Background: Ovarian cancer (OC) is a prominent cause of cancer-mediated mortality in women worldwide due to its aggressive and metastatic features. Current therapies extend survival of patients with OC; however, acquired resistance and a suppressive tumor microenvironment still remain issues. Moving toward a clinically relevant therapy, we validated the antitumor effects of combinatorial treatment using two immunomodulators, interleukins (IL)-7 and 12, enhancing potent inflammatory immune responses against various cancers.

Approaches: OCs contain high levels of exposed collagen types I and III. To achieve superior tumor-directed delivery while minimizing systemic adverse effects on the host, both IL-7 and IL-12 were fused to collagen-binding domain (CBD); CBD-IL-7 and CBD-IL-12, respectively. Antitumor responses were validated in vivo with a humanized mouse model. Female humanized mice were orthotopically xenografted with human OC cell line, SKOV3 (104 cells), to the left ovary. SKOV3 cells were genetically labeled with firefly luciferase and mCherry fluorescent protein for in vivo detection. Antitumor efficacy was determined via weekly bioluminescent imaging (BLI) and survival. Residual tumors that were undetected by BLI were confirmed via histology. Results: Tumor growth was confirmed via BLI weekly post-xenograft. Mice that received a one-time combinatorial treatment of CBD-IL-7 (125 pmol) and CBD-IL-12 (330 pmol) exhibited potent antitumor efficacy with no detectable toxicity. Tumor suppression was confirmed in 4/4 mice within four weeks of treatment. Survival analysis revealed a three-fold increase compared to the control group over four months. This model also supported the establishment of antitumor immune memory in 2/3 mice due to an evoked antitumor memory response against a second xenograft of SKOV3 cells subcutaneously. Conclusion: Our findings indicate that this tumor-targeted immunomodulatory approach against OC has increased potential to induce durable antitumor effects and immune memory responses without mediating severe toxicity to the host.

Abstract Name: Persistence and cross-contamination of Listeria monocytogenes on avocadoes in the food environment

Listeria monocytogenes is a Gram-positive foodborne bacterial pathogen. Outbreaks linked to avocadoes and packaged fresh produce need to be prevented. Therefore, factors that enhance its ability to survive, adhere, and transfer to fresh produce need to be investigated. There is potential for contaminated surfaces to cross-contaminate fresh produce in the packing houses. The combined factors of low temperature, high humidity, and dust particulates that trap bacteria are crucial in dry environments for the survival of L. monocytogenes and its ability to transfer to fresh produce. Therefore, the main objectives of this research were to (1) Determine the survival of L. monocytogenes serotype 4b on avocado skins over 2 weeks at room temperature and at refrigeration (4oC) at high humidity conditions (76% relative humidity (RH); and (2) Determine the transfer of L. monocytogenes serotype 4b from a contaminated surface (stainless-steel) to avocados at room temperature. Our results showed that L. monocytogenes could persist on avocadoes under both temperature and humidity conditions for 2 weeks. Our cross-contamination studies showed that contaminated stainless-steel surfaces could transfer bacteria to avocadoes, and vice-versa from contaminated avocadoes to stainless-steel surfaces. This data is useful for risk-assessment analysis and implementation of appropriate control practices.

Abstract Name: Development of MATLAB Programs Addressing Heterogeneity for Meta-Analysis of Multiple Types of Research Data

In the field of medical research, meta-analysis plays a vital role in combining the results of multiple studies to comprehend its impact on subsequent decisions which are based on final research outcomes. We identified the need for developing open-source MATLAB programs that can be used to perform meta-analyses on correlational, binary and continuous medical data using the fixed-effects and random-effects models. The continuous fixed-effect model used the mean, standard deviation, and sample size to estimate the bias-corrected standardized mean difference (Hedges' g). For binary data, events and non-events in two independent groups were used to compute the Odds Ratio as the effect size measure, while in correlational data, the r value was used as the effect size. Subsequently, 95% confidence interval, z-value and p-values, along with the variance of the true standardized mean difference were calculated. The MATLAB programs were then validated by applying them to various examples of medical data. In the second part of the code, heterogeneity in the effect sizes was addressed using MATLAB. Our aim was to quantify this heterogeneity, separating the true variation and random error, there is a need to isolate true variance and then use it to identify various perspectives on the dispersion. To achieve this goal, the MATLAB model was further developed and determined the Q statistics (a measure of weighted square deviations), the results of a statistical based on Q (i.e., P), the between-studies variance (T2), the between-studies standard deviation (T), and the ratio of true heterogeneity to total observed variation (I2). This analysis provides evidence of heterogeneity in the true effect size. The open-source MATLAB code presented at this conference is available for any user to use. Each model presented will show validation results for various studies, ensuring the code's robustness and its potential for broader implementation.

Abstract Name: Analysis of Cervical Cancer Predictions Using AI/Machine Learning Techniques

Cervical cancer continues to be a major public health concern, highlighting the critical importance of early detection. Leveraging advanced artificial intelligence and machine learning, like IBM Watson, facilitates timely diagnosis. Utilizing data from the UCI Repository, this study focused on identifying risk factors leading to cervical cancer biopsies. Annually, the U.S. reports approximately 11,000 new cases of invasive cervical cancer, resulting in 4,000 deaths, with a global toll of 300,000 women. Human Papillomavirus (HPV) is the primary risk factor, potentially compounded by Chlamydia infection. Family history of cervical cancer and long-term oral contraceptive use increase risks, likely due to reduced protective methods and hormonal impacts on HPV. Childbirth, especially with HPV, is associated with elevated risk. Smoking contributes to precancerous changes and invasive cervical cancer, particularly in HPV-infected women. Immunosuppressed individuals are more vulnerable to HPV and rapid cancer progression. The study's supervised models were enhanced with feature engineering techniques, achieving a remarkable 99.7% accuracy using the XGB Classifier and Decision Tree Classifier. Factors such as HPV infection diagnosis at 100%, CIN infection diagnosis at 47%, IUD at 18%, Age at 5%, Number of Sexual partners at 4%, Hormonal Contraceptives at 3%, Smokes (years) at 3%, first sexual intercourse at 10%, and number of pregnancies at 2% were assessed as potential risk factors. This high accuracy rate suggests that the models were successful in accurately predicting whether patients were at risk of cervical cancer. The presentation will discuss the

applied algorithms and the effect of split ratios on the model's outcomes. It will include the relative importance of how artificial intelligence can be used to help further advance the health environment.

Abstract Name: Investigating the Roles of Telomerase RNA (TR) Structural Domains on TR Structure and Telomerase Activity in the Parasitic Protozoan, Trypanosoma brucei

Each time eukaryotic cells divide a small amount of DNA is lost from the chromosomal ends. This occurs because DNA polymerase is unable to perfectly replicate the chromosome ends, a phenomenon known as the end replication problem. As telomeres shorten, genes are damaged, leading to cell death. To prevent the degradation of genes, cells have caps of non-coding, repetitive DNA called telomeres at the chromosome ends to serve as a buffer. Telomeres are added to chromosomes by the ribonucleoprotein (RNP) complex, telomerase. Telomerase consists of telomerase RNA (TR) and the telomerase reverse transcriptase (TERT) enzyme, which maintain telomere length and genome stability. The TR provides a template for the addition of telomeric repeats to the chromosome ends while the TERT catalyzes the addition of repeats, thereby extending the proliferative capacity of cells. When either component is missing or mutated, telomerase function is compromised.Rapidly dividing cells rely on telomerase to extend their telomeres and support indefinite proliferation. Dysfunction of the telomerase complex has been linked to diseases including cancer, age-related disorders, and genetic syndromes. Understanding the role of telomerase RNA is crucial for developing new therapies to prevent or treat these conditions.Our research works to better understand the functions of discrete TR structural domains and their impacts on TR structure and telomerase activity in the parasite Trypanosoma brucei. We examine the impact of distinct TR domains on telomerase function. This work, along with planned studies will aid in understanding the telomerase RNA structure, and its distinct functions.

Abstract Name: Membrane Potential Dynamics During Bacteriophage Infection

Bacteriophages are viruses that infect and replicate within bacteria with the help of their host cellular machinery. They typically utilize a tail apparatus to establish a passage across the entire bacterial cell envelope, enabling the transfer of the viral genome into the host cell cytoplasm and initiating the infection process. It has previously been shown that membrane potential (MP) in bacteria plays an important role in cell-cell communication and metabolic coordination within bacterial biofilms. Studying the dynamics of MP during a single bacteriophage infection event can help us understand the propagation of phages in a

population, especially in the presence of anti-phage defense systems of different kinds. Bacteria have an abortive infection defense system that induces death or dormancy upon infection; providing community-level defense by preventing phage propagation within the population. It might be particularly interesting to observe the dynamics of MP during infection when the defense systems that induce bacterial dormancy are present.Here we us voltage-sensitive dyes (VSD) that rely on intamolecular photoinduced electron transfer to measure the MP dynamics. The dye molecule inserts into the lipid bilayer of the bacterial cell membrane. Any changes in the MP induce a change in the fluorescence quantum yield and excited state lifetime of the dye. Preliminary intensity-based widefield fluorescence measurements have been performed over long periods to record MP fluctuations in a single cell infected with phages in cell cultures of Bacillus subtilis (B. subtilis). Further experiments utilizing the dye's excited-state lifetime as an MP readout are currently being performed using (i) a commercial confocal FLIM and (ii) a home-built wide-field FLIM set-up that utilizes a time-gated SPAD camera and a phasor-based analysis to quantitively capture small changes in resting MP during the cell cycle.

Abstract Name: Diffusion Models: Exploring Methods for Inverse Problems

Denoising diffusion models are known for their ability to generate diverse types of data that are not present in the original input. These models can handle various forms of data such as images, videos, and figures. The denoising process involves removing the predicted noise, obtained from a trained noise predictor, from a noisy image to align it with the user's desired outcome. In addition to advancements in diffusion models, significant progress has been made in solving inverse problems. These problems involve deducing or restoring missing or damaged parts of visual input data based on available observations. This research aims to investigate the potential of denoising diffusion models in addressing inverse problems, following two proposed paradigms presented at CVPR 2023: the replacement-based method and the reconstruction-based method. By exploring these approaches, we aim to uncover new possibilities for the application of denoising diffusion models in the field of inverse problems.

Abstract Name: Effects of Antioxidant-coating for Microelectrode Arrays for Preserving Inhibitory and Excitatory Neuronal Populations

Intracortical microelectrode arrays (MEAs) are important for neuronal interfaces and are used in neuroscience research. These devices can record neural activity at single-neuron resolution (single-unit

activity). However, the recording performance of MEAs diminishes over time, at least in part due to neuroinflammation and associated oxidative stress. Moreover, prior literature suggests that inhibitory neurons are more susceptible to oxidative stress and physical trauma than excitatory neurons. Our previously published research has shown that coating MEAs with the antioxidant Mn(II)tetrakis(4-benzoic acid)porphyrin (MnTBAP) mitigates the loss of single-unit activity and improves chronic recording performances of MEAs. In addition, MnTBAP-coated devices demonstrated a decrease in genetic markers for inflammation and oxidative stress in tissue surrounding the implanted probe. In this study, we further investigate the effects of MnTBAP coatings on the recording performance of inhibitory and excitatory neurons. Single-unit activity can be classified into two subtypes of neurons based on the duration of their spiking activity: fast-repolarizing (putative inhibitory) and regular-repolarizing (putative excitatory). Using this classification, we will determine if the MnTBAP coating affects the recording of these putative inhibitory and excitatory neurons differently. From our previous study, we know that the MnTBAP coating results in a greater number of neural signals surviving at chronic time points. Here, we hypothesize that this effect is predominantly due to the protection of inhibitory neurons through the mitigation of oxidative stress. We expect to see more inhibitory neural signals for MnTBAP-coated devices than for uncoated devices, while uncoated devices should have mostly excitatory neural signals at chronic time points. Our findings will advance our understanding of how specific neuron subtypes respond to intracortical arrays and how MnTBAP improves chronic recording performance. This study will shed light on strategies to optimize long-term neural recordings.

Abstract Name: Variation of Dopamine Concentration in Dorsal Striatum During Locomotor Initiation and Termination

Significant evidence shows that dopamine (DA) is responsible for task learning by encoding reward prediction errors (actual reward - expected reward). Although we consider DA as an important factor in reward signals, the death of dopaminergic neurons can cause problems in movement which is considered to play a role in Parkinson’s. Previous work demonstrated an increase in DA release within the dorsomedial striatum (DMS) during the initiation of a locomotor bout, and higher DA release in the dorsolateral striatum (DLS) during the termination of the locomotor bout. However, the cellular and behavioral mechanisms for these dynamics remain unclear. Here, we set out to study the effect of DA stimulation within the DMS and DLS in animals using optogenetic stimulation protocol to examine how learning to run on a wheel changes. The experimental setup consists of a training wheel which was set up along with a rotary encoder to record the linear distance traversed by the mouse and a reward dispenser. The mouse will be exposed to an LCD screen projecting a virtual corridor controlled via LABVIEW behavioral software.We will be analyzing mouse vigor to run on a wheel in different task sessions with varying levels of agency. The mouse displays higher vigor to run on the wheel when they can detect progress toward getting a reward.They become less invigorated to run when they cannot detect progress. Therefore we hypothesize that when DMS is stimulated, there will be more vigor observed from the mouse, causing them to increase their velocity on the wheel to get the reward. In contrast, we expect the DLS stimulation to decrease their vigor which will be reflected as a reduction in their velocity. When completed, our studies will illuminate how dopamine changes in the dorsal striatum regulate locomotor initiation and termination.

Abstract Name: Negotiating Ownership and Management of Public Green Space: How the TEP Ménilmontant Community Challenges Paris' Top-Down Urbanism

Paris has increasingly sacrificed public open spaces in lower-income areas for social housing construction. For example, the municipality has largely restricted community gardens to sites slated for development. Open spaces that remain consist of traditionally manicured, municipality-managed, tourist-centric parks and gardens with strict norms and few allowed activities. However, on one site the city targeted for development, the TEP Ménilmontant, a community mobilized to resist the municipality's forced competition between social housing and public green space. Thus, this paper asks how the community occupation, management, and use of the TEP challenge Paris' current top-down approach to planning public space. Through participant observation and interviews with the TEP's main volunteers and community members, I have found that the TEP is combatting this approach through its claim for permanence, collective decision-making, resource leveraging, mutual aid, and flexible land uses. Though municipal officials in support of the TEP cite the surrounding area's density and the ecological need for green space as reasons against municipal development, I argue that the robust social infrastructure of the TEP asserts a more radical reason: the benefits of community self-management and shaping of public space, namely the TEP's resulting uniquely high social diversity and strong network of community care and commitment. As seen in the trajectory of community gardens in New York City, and within Paris itself, much is lost from the elimination or co-optation of community-managed spaces. Accordingly, Paris must adapt its planning framework to grant permanence and maintain the self-management of community-claimed public spaces.

Abstract Name: Effects of astrocyte silencing in the amygdala on pain behaviors in a pre-clinical neuropathic pain model

Chronic and persistent pain imposes a significant burden on healthcare systems, necessitating the exploration of innovative analgesic strategies. The amygdala, a key player in the emotional-affective component of pain and pain modulation, exhibits hyperactivity in various pain models, but underlying mechanisms are not fully understood, and recent evidence suggests that they cannot be explained solely by neural factors. Despite this, the involvement of neuroimmune signaling, a crucial element in maintaining neuronal functions, in amygdala-related processes remains largely unexplored. Astrocytes, constituting a substantial portion of glial cells in the central nervous system, undergo reactive changes in pathological conditions, yet their role in pain-related amygdala neuroplasticity is largely unknown. This study aims to elucidate the impact of astrocytic signaling on amygdala functions in a neuropathic pain model. Our approach integrates pharmacology with behavioral and immunohistochemical analyses to examine the role of amygdala astrocytes in neuropathic

pain. We administered fluorocitric acid (FCA), a selective inhibitor of astrocytic metabolism, stereotaxically into the amygdala of adult male rats four weeks after neuropathic pain induction (spinal nerve ligation, SNL). Pain-related behaviors, including mechanical withdrawal thresholds, evoked audible and ultrasonic vocalizations, spontaneous behaviors (rodent grimace score, RGS), and anxiety-like behaviors (open field test, OFT), were assessed within 24 hours post-FCA or vehicle microinjection in SNL rats. Unexpectedly, FCA increased mechanical hypersensitivity on both injured and uninjured paws, increased vocalizations, and had facilitatory effects in OFT and RGS. Immunohistochemistry confirmed astrocytic inhibition by FCA, as indicated by decreased astrocytic GFAP marker in FCA-injected animals compared to vehicle group. This study implicates amygdala astrocytes in the modulation of pain-related behaviors in neuropathic conditions. The somewhat surprising results suggest that astrocytes may serve compensatory protective functions and could be a potential target for therapeutic interventions in chronic pain conditions.

Abstract Name: North Korean Religion: Kim Il-Sung’s Persecution of Christian Ideals and the Transfer of Secular Power

This review analyzes recent research to gain a deeper understanding of how Kim Il-Sung rose to power and used his agenda to create a state ideology, persecute religion, and elevate his status throughout the North Korean state. The analysis begins with an introduction to the background of the Korean peninsula starting with the liberation of the territory due to the end of World War II in 1945 by the Soviet Union military along with Korean forces. Christianity is closely tied to Western culture, so the Communist Party refuted this religion by persecuting Christian believers. Kim Il-Sung wanted the citizens of North Korea to follow the ideology he set in place, Juche, rather than believing in separate religions with the goal of unifying the state under a collective regime. This review analyzes primary and secondary sources from North Korea, the United States, the Soviet Union, and South Korea to determine how citizens reacted to changing agendas. This paper synthesizes these ideas and applies them to how the public reacted to the changing agenda of the North Korean regime. This research analyzes literature on Kim Il-Sung’s actions, agenda, and propaganda tactics in the context of his leadership of the North Korean government and how he wanted to be seen as an all-powerful ruler through these various approaches. Kim’s power is highlighted not only as a leader but also as a divine individual as discussed throughout the work. Finally, this paper discusses how evolution required the North Korean government to adapt to change despite Kim Il-Sung’s agenda by amending the North Korean Constitution to allow for the practice of religion under strict supervision.

Abstract Name: The Noah Project

The Noah Project is a collaborative and interdisciplinary effort pioneering a pathway to directly influence those impacted by ASXL. There are three rare genetic disorders that our team is focused on: Bohring-Opitz Syndrome (ASXL1), Shashi-Pena Syndrome (ASXL2), and Bainbridge-Ropers Syndrome (ASXL3). Due to its rarity, healthcare professionals know very little about the disorder or how to treat it. Furthermore, only a small number of ASXL-related websites are available to the public. After conducting a SWOT analysis on these websites, our team decided that each of them had room for improvement, and making revisions to the most outstanding website would be more beneficial. In order to effectively decide which elements to add or remove, we created a survey that would be given to the families who have an impact. The team has begun the process of fundraising for the 2024 ASXL Family Conference and the Miracle League. Currently, the team is in the early stages of brainstorming community events, which include but are not limited to interactions with campus-based programming and non-profits within the greater Birmingham area. Additionally, our team will begin a protocol to screen cell lines that will be used to test drugs in the ASXL mutation and wild type.

Abstract Name: A Fully Explicit Integrator for Modeling Astrophysical Reactive Flows

Simulating complex astrophysical reacting flows is computationally expensive, reactions are stiff and typically require implicit integration methods. The reaction update is often the most expensive part of a simulation, which motivates the exploration of more economical methods. In this study, I investigate how the explicit Runge-Kutta-Chebyshev (RKC) method performs compared to an implicit method when applied to astrophysical reactive flows. These integrators are applied to simulations of X-ray bursts arising from unstable thermonuclear burning of accreted fuel on the surface of neutron stars. They were also applied to the double detonation sub-Chandrasekhar model for type Ia supernovae, occurring when a carbon-oxygen white dwarf accumulates sufficient helium to ignite at the surface. The code framework for these problems is contained within Castro and are ran at the National Energy Research Scientific Computing Center. This study shows the RKC method performs with similar accuracy to our traditional implicit integrator, but is more computationally efficient when run on CPUs.

Abstract Name: The Bright Side and the Right Side: Optimism and Moral Self-Image as Antecedents of Organizational Citizenship Behavior

Organizational citizenship behavior (OCB) is action taken by an employee to benefit an organization that is not formally required by their job or that exceeds formal requirements, without the expectation of reward or affirmation. OCB is essential to fostering a positive work environment, yet its origins are difficult to predict. Optimism can be both dispositional and state-driven, described as a positive outlook. Optimism and morality both fall under the “Big 5” Personality Trait umbrella. Moral Self-Image (MSI) is a recently introduced construct describing how one perceives their own morality. The Broaden-and-Build Theory of Positive Psychology supports our first hypothesis; high scorers of optimism will be more likely to engage in OCB. Based on theories of moral compensation, we hypothesize that low scorers on the Moral Self-Image scale are more likely to engage in OCB. Based on a survey of Likert-type scale questions, we expect to find a negative correlation between Moral Self-Image and OCB. Furthermore, we expect to find a positive correlation between optimism and OCB.

Abstract Name: Assessing the Fidelity of Illuminating Engineering Society (IES) Profiles in Architectural Lighting Simulations: A Comparative Analysis

The purpose of this study is to compare how Enscape 3d and Lumion simulate IES lights for non-VR applications. Enscape 3d and Lumion are two AEC industry-standard architectural visualization software programs that allow users to upload Illuminating Engineering Society (IES) light profile data to simulate the precise characteristics—color temperature, luminous intensity, distribution, and beam spread—of light sources specified for an architectural project. In practice, the accuracy of these simulations is crucial, as they impact decision making and final design outcomes. However, existing research on architectural lighting simulation primarily centers on the rendering fidelity of light sources for use in virtual reality (VR) applications, and moreover, is often limited to the analysis of a single software. The study design consists of thirty 8’ x 8’ x 8’ boxes modeled in Autodesk Revit, with each assigned a material to the floor, ceiling, and four wall surfaces. One of three lighting types, each with a unique IES profile, were placed in the center of the ceiling of each box: an omni, area, and spotlight. Each box was rendered first in Enscape 3d, then in Lumion. All rendered images were then organized within a grid for comparison. Three measures were assessed: interface design—the ease with which users can operate the software controls; lighting fidelity—the accuracy with which each program simulates lighting distribution, beam spread, and luminous intensity; and material fidelity—the accuracy with which each program simulates the reflectivity, roughness, and color value of the materials on which the lighting is cast. Differences observed among these three measures in between each program will be discussed. Understanding the abilities and limitations of each software program will allow more effective adjustments to lighting schemes during the design process to prevent costly change orders later on.

Abstract Name: Analyzing the Nexus: Political Infrastructure and Communication Strategies in Shaping Public Response to London's Ultra Low Emission Zone

In 2015, along with 195 other states, the United Kingdom committed to the vital carbon emission reduction goals of the Paris Agreement. Now, more than halfway to the 2030 deadline, London and cities worldwide are struggling to implement sustainable transportation solutions in order to meet their carbon neutrality goals. As a global city, London has been wrestling with finding the balance between effective policy and community buy-in regarding the rollout of new vehicle regulations and recent expansion of the contested Ultra Low Emission Zone (ULEZ). This transdisciplinary qualitative case study examines how the policy communication strategy to promote the ULEZ used by The Greater London Authority over the last four years has influenced the current relationship between policymakers and the impacted community in the Greater London area. The data was collected over a three-month period between September and November 2023 from participant observations on existing public modes of transport in London, interviews with policy, electric vehicle and sustainability experts, a survey targeted towards uncovering Londoners' perceptions of the ULEZ, public consultation and political polls, and archival research in the Transport for London (TfL) database. The main finding of this research is that environmental policies are never purely environmental, but rather complex and political, and thus can easily be disrupted and exploited for political gain by manipulating public opinion. Furthermore, while public support may not be a prerequisite for an environmental policy to be initiated, it may be necessary to sustain the political infrastructure that the policy relies on. The significance and purpose of this research is to remind future policymakers of the importance of well-tailored communication strategies to gain public support when implementing green policies.

Abstract Name: Leadership in Energy and Environmental Design: Cases of LEED Certifications for Fulton County School Buildings in GA

The Research Center for Sustainable Communities (RCSC) at Kennesaw State University (KSU) has been conducting analytical studies on how to enhance sustainability and reduce the carbon footprints of school infrastructures statewide in GA. The RCSC seeks ways in which the state could advance healthier and more sustainable, equitable, and cost-effective learning environments. Rooted in this initiative and funded by the KSU Office of Undergraduate Research, this research aims to examine the employment of Leadership in Energy and Environmental Design (LEED) certification as an outline for promoting the existing operation of school buildings. LEED is a globally recognized rating system with a set of rigorous standards developed by the U.S. Green Building Council (USGBC). There are 808 high schools in Georgia, 18 of which are LEED-certified. Centered on Fulton County, the team will inquire about what measures were taken by these certificated high schools in the County that were not implemented in the rest of the County. The research will encompass a multi-faceted methodology, including a literature review, interviews (i.e., with county officials), and analysis of building certificate data. The findings will provide insights into the economic and environmental aspects of such certificates and the role of county decision-makers and stakeholders. Ultimately, the research will underline sustainability through environmental stewardship, economic prosperity, and social responsibility.

Abstract Name: A Quantitative Analysis of a Pre-College Support Program

The focus of this research project is on the emotional and behavioral well-being of youth enrolled in an Upward Bound program in the midwestern region of the United States. Upward Bound is a federally funded program that provides academic and social support to high school students who are traditionally underrepresented in post-secondary education.The research team utilized a quantitative approach to data collection. The research was longitudinal, and data was collected from four different cohorts at time of entrance into the Upward Bound program: Summer 2018 (n=18), Summer 2019 (n=17), Summer 2022 (n=24), and Summer 2023 (n=16). Participants were asked to complete a modified version of the Strengths and Difficulties Questionnaire (SDQ) which is a twenty-five item measure that contains four different subscales: emotional problems, conduct problems, hyperactivity, and peer problems. Higher scores on the measure and corresponding subscales indicated a lower level of functioning in that area. A fifth subscale, entitled pro-social skills, was scored differently meaning a higher score indicated a higher level of functioning.Data analysis indicated that the 2018 and 2019 cohorts reported fewer concerns related to emotional problems, conduct problems, hyperactivity, and peer problems when compared to the 2022 and 2023 cohorts. In addition, the 2018 and 2019 cohorts scored higher on pro-social skills than the 2022 and 2023 cohorts. One interpretation of the data is that the COVID-19 pandemic negatively impacted the social and emotional well-being of the youth who participated in this research.

Abstract Name: Making a Safe Home for People with Blunt Eye Trauma

The purpose of the project is to create a home that is functional for someone with blunt eye trauma and its potential long-term effects. Blunt eye trauma can cause a series of symptoms such as blurry vision, double vision, and blindness. In addition, it can lead to various intrinsic eye injuries, such as a globe rupture, whose symptoms include eye deformity, eye pain, and vision loss. Therefore, the home must have a natural process of way-finding to accommodate the navigation of the new space. Through case studies and literature review, the information outlines inclusive design features that are or are not appropriate in this application. For example, creating a distinctive feature for each room enables the user to be able to decipher where they are located. Having bold, contrasting elements allows them to be identifiable from one another opposed to having no variation. Adequate lighting is crucial when trying to navigate and perform tasks within each room. The orientation of the home must be positioned in such a way to optimize daylighting. In addition, the implication

of cove lighting provides indirect light that illuminates the space whilst avoiding any harmful glare. Every individual has unique vision capabilities and personal tolerances, therefore flexibility in controlling environmental quality is very important. Incorporating technology that allows the space to be easily controlled by the user is another layer of design that can aid visual impairment. Overall, the considerate implication of lighting, color, finishes, and other signifying elements, would effectuate an optimal home environment for a user with blunt eye trauma.

Abstract Name: A cross-sectional study of public superfund information: Implications for public health risks from air pollution exposure

Millions of people around the world are affected by the release of hazardous substances that impact air quality and contribute to a decrease in life expectancy. In the United States, about 21 million people live within a one-mile radius of a superfund site, exposing them to harmful chemicals from vapor intrusion and air pollution; however, residents of affected communities are often not informed about the toxic substances to which they are exposed, largely because information available to the public is not easily understood. In this cross-sectional study, we assess the readability of environmental health data obtained from 282 superfund sites in the tri-state area of New York, Connecticut and New Jersey. Descriptive statistics for the distribution of readability scores from the Gunning Fog, SMOG, and Flesch-Kincaid tests were used to assess the metric of publicly available superfund information on the U.S. Environmental Protection Agency (EPA) website. In our comparison between resolved and unresolved cases as indicators of readability scores; unresolved cases showed statistically higher readability levels than resolved cases. The mean readability, 14.19 (Range: 10.37-19.18; SD = 1.30, N = 282) was attained with statistically significant difference at p<.05, (t (280) = 4.105, p <.001). This high mean readability score revealed unfamiliarity with published superfund information in the communities and demonstrated the need for simpler language to reduce complexity, and improve comprehension of public health risks by superfund sites to enable residents to protect themselves. This study can contribute to the advancement of environmental justice, critical for the successful management of superfund sites across the US. Addressing this challenge is paramount to an understanding of how to detect, report and remediate the release of toxic substances, and to prevent unwanted human exposures to air pollution.

Abstract Name: Compassion Fatigue Within Pre-Service Teachers

With growing signs of burnout along with increased compassion fatigue reported in teachers, we were interested in studying whether this burnout and compassion fatigue begins to show during the student teaching semester. This semester occurs during the last semester of the pre-service teacher's undergraduate studies. This semester should align with the "real world of teaching", and set up individuals to get ready to enter the field.Current research shows a correlation between teacher burnout symptoms to teaching enthusiasm levels. Analysis of previous research proved that gender, seniority, and the teacher burnout symptoms of emotional exhaustion and a decreasing sense of personal accomplishment were significant predictors of both teaching and subject enthusiasm (Dağyar & Kasalak, 2022). Additionally, research by King and Wheeler (2019) explores the "dark side" of interpersonal communication allowing students to open up about traumatic personal experiences and the stress that can lead to compassion fatigue in teachers. Furthermore, Ziaian-Gafari and Berg's (2019) qualitative research explored compassion fatigue and burnout, which both appeared when general education teachers worked with students with exceptionalities or those students with trauma. Compassion fatigue has been shown to affect one's health-related quality of life negatively (Jackson et al., 2021). Looking at this previous research, we were interested in exploring when this compassion fatigue begins to show during teaching. Specifically, our research questions are: (1) Do pre-service teachers show signs of compassion fatigue during the student teaching semester? (2) Do pre-service teachers report needing additional assistance (such as mentorship or counseling) during the student teaching semester? To explore these questions, we gave the standardized survey, The Professional Quality of Life Scale (ProQLS) to 55 pre-service student teachers in Spring 2022. Our poster will dive into the qualitative results.

Abstract Name: The Relativity of Reality in Revolution: Woolf's Attention to Astronomy in TO THE LIGHTHOUSE

Virginia Woolf was a writer not only heavily involved with literature, philosophy, and history, but also with the early 20th century developments in the physical sciences, especially with topics related to astronomy. Woolf was writing in the wake of Einstein's theory of relativity as well as Hubble's discovery of the expansion of the universe. Indeed, many critics, such as Holly Henry, see the influence of astronomy in her works and laced throughout her diaries. However, despite this attention, most critics curiously fail to consider how astronomy was woven into Woolf's masterpiece, To the Lighthouse. In viewing this novel through the lens of astronomy, not only are we able to see the constellation of connections and understand an essential analogy, but we can also identify the design of relativity permeating To the Lighthouse. As Woolf was influenced by astronomical discoveries, she designed characters to be similar to objects in outer space to display the relationships between them and to articulate how relativity influences one's experience with reality. Specifically, Woolf designed her characters to represent physical bodies in a solar system, where Mrs. Ramsay is encapsulated in the brightness and energy-creating nature of a star and Mr. Ramsay is the alienation of a distant planet in the same solar system. By constructing her characters in a solar system, she gave attention to each perspective by using relativity to describe the space and time they occupy and how this influences their interaction with reality and the world around them.

Abstract Name: Preimplantation Genetic Testing and the Future of Public Health

Preimplantation genetic testing (PGT) has emerged as a new form of assisted reproductive technology (ART) in recent years. Although it was initially used as a method used to prevent the transmission of genetic diseases, PGT has evolved to encompass a wider range of applications by spearheading new innovative methods in stem cell research, gene editing methods, and genetic disease therapies. This has the potential to significantly impact public health and expand the use of reproductive technology in healthcare systems.This poster presentation aims to analyze the current and possible future applications of PGT in the field of public health while sparking a discussion about PGT's continued growth and future role as a biotechnology in said field. The presentation will also delve into its principles and techniques, while also examining the ethical implications of PGT and what it means in the field of public health. The methodology used will utilize studies done by public health professionals and other healthcare experts. This includes ethical analyses, literature reviews, case studies, statistics, and consultations that highlight the application of PGT.The results show that PGT plays a significant role in public health by decreasing the risk of genetic disorders in offspring by offering expecting parents an insight to the health of their future children and future generations. It is also reliable and contributes to reduced costs in healthcare and improved pregnancy outcomes. PGT has revolutionized personalized medicine by screening embryos for specific traits which offers new solutions to preventing genetic disorders.However, the usage of PGT raises ethical concerns as genetic profiling raises concerns about societal values, eugenics, healthcare equity, and biotechnology regulations. Preimplantation Genetic Testing holds significant potential for shaping public health and biotechnology, but responsible use and ethical standards play a crucial role for its full potential.

Abstract Name: Effectiveness of Mobile Clinic in Improving Access to Mental Health Services for Those Experiencing Health Disparities in Rural East Tennessee

Health disparities, specifically those with mental health, are experienced by people living in rural communities. Data has shown that telehealth and mobile health clinics have improved access to care for those living in rural areas. However, in many rural counties individuals do not have access to internet and transportation limiting the availability of telehealth. The purpose of the study is to determine if the use of a mobile van providing internet services will increase utilization of health care. Secondarily, the number of clients seen will be determined to evaluate usage of the service. A grant has been received to utilize a mobile van in Hamblen, McMinn, Morgan, Monroe, and Sevier counties, and will operate five days a week for 50 weeks. A descriptive, non-experimental design will be used to survey a minimum of 50 clients using a self-developed questionnaire. Data analysis and conclusions/recommendations are to be determined as this study has not reached completion.

Abstract Name: Teacher and Speech-Language Pathologist (SLP) Use and Perspectives on Telegraphic Speech with Children who are Deaf and Hard of Hearing

Simplified speech is often used by adults when speaking with young children, especially children with language delay. However, there is research that has shown that there is controversy surrounding whether this simplified speech should be telegraphic (e.g., Doggie go, more toy) or grammatical (e.g., Go, Doggie! More toys) (Venker, Yasick, McDaniel, 2019). Use of telegraphic input has been studied regarding children with language delay, but there is limited information on use of telegraphic input with other populations, such as children who are deaf and hard of hearing. The purpose of this study is to expand on prior research regarding use of telegraphic input with children with language delay titled, “When Is Simplified too… Simple?” (Venker & Stronach 2017) and examine parent, teacher, and Speech-Language Pathologist (SLP) perspectives on and use of telegraphic input when speaking/working with children who are deaf and hard of hearing at the prelinguistic, one-word, two-word, and telegraphic stages of spoken language acquisition, through a set of survey questions. These survey questions come from a research study titled “Saying too Little Can Make a Big Impact: Graduate Student Knowledge and Use of Telegraphic Input” (Schaar & Stronach 2021), with modifications made to focus on children who are deaf and hard of hearing. This research study will present new perspectives on use of telegraphic speech and its perceived importance by caregivers for use with children who are deaf and hard of hearing.

Abstract Name: How Self-talk is Used by College Students to Improve Cognitive Functions Related to Learning

The role of language and self-talk in cognitive psychology is becoming a bigger area of research for both linguists and psychologists. However, much of the research only focuses on how athletes use self-talk to improve sports performance and does not look at people’s daily lives or how it can be used in academic environments. There is also a tendency to group audible verbalizations directed toward oneself (private speech) and internalized language used to guide mental processes (inner dialogue) together or to just focus on one with no comparison of the two methods. This proposed study is a phenomenological analysis that aims to examine how self-talk is used by college students to enhance aspects of cognition, such as memory, attention, motivation, and abstract thinking, as well as the differences between speaking out loud and in one’s head. Another goal of this research is to examine the benefits of both private speech and inner dialogue to explore the different outcomes of these two models of self-talk. This proposed study will consist of transcribing and

coding interviews with 16 participants and looking for themes related to the type, form, and content of self-talk used by college students. It is expected that college students use private speech and inner speech for different functions, and that self-talk is used more frequently in academic contexts than in everyday activities. This proposed study benefits education, mental health counseling, and personal development by providing data on what kinds of methods are more heavily utilized for learning and personal goal achievement.

Abstract Name: Ribosome Biogenesis in Cancer Cachexia

Cancer cachexia is a wasting syndrome characterized by the loss of skeletal muscle mass, which in turn is a predictor of poor prognosis and mortality in cancer patients. Maintaining skeletal muscle mass during cancer is also associated with longevity in this population. The synthesis of ribosomes, known as ribosome biogenesis, is a central mechanism regulating cell mass, including muscle cells. This investigation aims to determine whether ribosome biogenesis and ribosomal abundance in skeletal muscle is impaired during cancer cachexia in a genetically modified mice model of pancreatic adenocarcinoma (the KPP mice) that resembles muscle wasting in humans due to cancer cachexia. The KPP mice will be used to test the hypothesis on whether ribosomal abundance is affected in cancer cachexia and whether lower ribosome synthesis precedes the onset of cancer cachexia. Understanding the molecular mechanism of muscle wasting in cancer cachexia will allow us to design better therapeutic approaches.

Abstract Name: The Impact of Postpartum Depression on African American Fathers In The United States

Postpartum depression (PPD) is a widely used terminology, however it does not currently reflect a unique clinical diagnostic label. The guidance as defined by the DSM-5-TR is best classified as Peripartum Depression, or Major Depressive Disorder with peripartum onset defined as a subtype of depression that occurs during pregnancy or in the first four weeks after delivery. Approximately, one in eight women experience symptoms of PPD in the United States, and 50% of men whose partners are diagnosed with PPD go on to develop depression themselves. To assess the impact of PPD [as experienced by women] on African American fathers in the U.S., a literature review process was conducted. The search strategy was limited to peer reviewed publications within the last ten years, and focused on the U.S. population. Based on the limitations and three key terms, postpartum depression, women, and fathers, 4,683 studies were identified from databases and registers. Seven articles were included in the final extraction. The majority of current studies centered on data from White, or European ethnic groups and out of the seven, one article provided

data on African American fathers. Guidance for fathers who experienced the effects of their partner's PPD and how to receive support is also very minimal. Fathers possessing current knowledge or a better understanding of PPD, stressors, available social support, and perspective on treatment could decrease depressive symptomatology for both parents while simultaneously improving the bond between father and infant and the quality of the partnership or relationship between the parents.

Abstract Name: A Novel Model Investigating the Genetic Mechanisms of Plasma Cell Differentiation

B lymphocytes are one of the key immune subsets that participate in the adaptive immune response. Antibody secreting cells (ASCs) are terminally differentiated from mature B cells, mediating their protective function by secreting antibodies against infectious agents. Epigenetic control of ASC differentiation by histone modifying enzyme EZH2 contributes towards the survival and function of these cells. Upon antigenic exposure, EZH2 expression is upregulated in differentiating B cells with levels peaking within ASCs. As the role of this enzyme in ASC differentiation from the memory compartment is not fully understood, exploring further will identify novel mechanisms controlling this differentiation.We are developing a mouse model targeting EZH2 in B cells to determine its role in ASC differentiation. CRISPR technology within Sca1 and cKit expressing hematopoietic stem cells (LSK cells) will be utilized followed by a B cell-specific deletion induced by tamoxifen in vivo. Our initial approaches have identified these LSK cells and achieved a purity of above 99% upon isolation from the bone marrow. We were able to maintain and expand LSK cells in culture, allowing for maintenance of the stem cell population for a month, and then transfer cells into irradiated recipients to detect engraftment within four weeks. Generated lentivirus was able to transduce these LSK cells, demonstrating over 50% efficiency. We will be investigating the ability of this lentivirus to knock out genes in Cas9 expressing B cells. Our approaches will ultimately contribute to the development of a mouse model that can be exploited to study the biology of ASC differentiation.

Abstract Name: A nonpathogenic signal peptidase mutant of the maize anthracnose fungus Colletotrichum graminicola secretes cell wall degrading enzymes normally

Colletotrichum graminicola is an economically devastating fungus that causes anthracnose leaf blight, stalk rot, and top die-back in maize. As a hemibiotrophic pathogen, C. graminicola uses two methods of nutrient acquisition. The fungus first invades living cells biotrophically and later switches to necrotrophy. This transition from biotrophy to necrotrophy is attributed to the up regulation of genes encoding cell wall degrading enzymes (CWDEs). CWDEs also play roles in host-pathogen communication and are critical to promoting disease susceptibility. A mutant strain of C. graminicola (MT) lacks pathogenicity to maize leaves and stalks due to a mutation in the 3'UTR of a gene (Cpr1) encoding a homolog of the SPC22/23 subunit of the signal peptidase complex. Despite being able to germinate and penetrate host cells, the MT is interrupted early in infection, so it never shifts to necrotrophy, produces lesions, or sporulates. To investigate the mechanism behind the non-pathogenicity of the MT, it was hypothesized that the MT is deficient in its ability to secrete CWDEs in planta during the transition to necrotrophy. Hydrolase activity against plant cell wall polymers in culture was quantified and compared via reducing-sugar assays and utilization of chromogenic substrates. Individual CWDEs, such as pectate lyase, were also visualized as fluorescent fusions and quantified in the wild type (WT), MT, and complemented MT (C-MT) strains in living or killed maize leaf sheaths, and in culture. Pectate lyase plays a critical role in pectin degradation and was selected due to its high expression in transcriptome studies. Results indicated that hydrolase activity and enzyme secretion by the MT were equivalent to those of the WT and C-MT, suggesting that the lack of pathogenicity in the MT is not due to an inability to secrete CWDEs. Understanding fungal pathogenicity mechanisms is crucial to develop plant resistance to fungal pathogens.

Abstract Name: Leveraging Machine Learning in the Design of Novel Ionic Liquids

Ionic Liquids (ILs), recognized for their versatile applications across various domains, have stirred considerable interest. However, the traditional experimental approach to discover unique ILs is resource intensive and time consuming. To address this, our study introduces a contemporary method for generating unique ILs, leveraging machine learning to ensure desired chemical properties and novelty in the resulting ILs. While many neural network architectures have attempted to tackle similar problems related to chemical generation, our research uniquely employs the Generative Chemical Transformer (GCT) model for IL generation. Integrating the proven Transformer and Conditional Variational Autoencoder (CVAE) architectures, the GCT model can generate novel ILs with specified properties. We utilized the National Institute of Standards and Technology database to obtain properties of 450 ILs at varied temperatures and atmospheric pressure, amassing 3315 data points. Each data point was tailored to include the IL depicted as a standard SMILES string, alongside the recorded temperature, pressure, and IL properties such as density, viscosity, and electrical conductivity. The GCT model, trained on this data, generated 30000 ILs for model testing. By facilitating the creation of valid and innovative ILs with predefined attributes, our research streamlines and expedites generation of efficacious ILs.

Abstract Name: Self-efficacy for Food Security and Intention to Increase Fruit and Vegetable Intake among Hispanics/Latinos in U.S

Background: Studies demonstrate self-efficacy is often related to eating habits. However, given the disproportionate rates of food insecurity among Hispanics/Latinos and the serious consequences it has on people's health and well-being, this research aimed to examine the association between self-efficacy for food security and intention to increase the number of servings of fruits and vegetables. Methods: A cross-sectional study of 750 Latino/Hispanic adults was conducted. Participants were asked to report on self-efficacy for food security using a six-item scale with response options of 1=not at all confident to 4= very confident. Participant average responses were recoded to be dichotomous: low self-efficacy or high self-efficacy. Intention was measured by asking, "How sure are you that you can increase the number of servings of fruit that you eat daily?". A similar question was asked for vegetable intake with a 4-point Likert scale. Chi-square tests for independence were used to examine associations between self-efficacy and intention. Results: Among the 750 participants, the mean age was 48.4 years old (range 18-93). Less than half (44%) of the participants classified as having low self-efficacy. There was a significant relationship between self-efficacy for food security and intention. Participants with high self-efficacy were more likely than those with low self-efficacy to have higher intention to increase their daily intake of fruits X2 (3, N = 750) = 123.5, p < .001 and vegetables X2 (3, N = 750) = 116.2, p < .001. Conclusion: The results are in alignment with current literature on low self-efficacy's correlation to less healthy eating habits. Food security risk factors such as low-income status and environmental factors such as accessibility to grocery stores with healthier food options could be driving factors. Public health efforts are needed to address food insecurity.

Abstract Name: Ink & Design: The Connection Between Graphic Design and Tattoos

This paper explores the world of tattoos, aiming to shed light on the intricacies behind why people have been getting tattoos for centuries. It touches on the meanings behind tattoos, such as cultural or religious reasons. It also connects the process of being a Graphic Designer with being a Tattoo Artist and how both professions go through very similar processes to create their final product. This paper expresses how tattoos use all parts of design as well as shed light on the influence of art movements in both tattoos and design, and the symbolism that often occurs in both fields. I aimed to uncover the importance of human expression and how tattoos are an important part of design and should not be easily overlooked by diving into the connections between the two. This reveals a profound aspect of showing how our creativity and identity intersect in these two distinct art forms.

Abstract Name: Re-Traditionalism, Sexology, and Art: Competing Narratives of Gender and Sexuality in Socialist Poland

Most scholars of the Polish People's Republic focus on gender roles concerning the socialist government and its ideals. Many scholars contrast this socialist gender ideal with the gender concepts of post-socialist, capitalist Poland. This study argues that, in socialist Poland, there were four competing narratives of gender roles, including the narratives of the Polish state, the Polish Catholic Church, sexology advocates, and artists. The following findings were established based on this research. First, as the de-Stalinization process progressed between the 1950s and 1980s, the government promoted the re-traditionalization of gender roles, which pushed women back into the domestic sphere, heavily regulating but liberating birth control through the network of public well-woman clinics. Similarly, the Catholic Church advocated traditional gender roles but critiqued the adverse effects of abortions and contraceptives since abstinence was the foundation of the Catholic Notion of family planning. At the same time, society engaged in sexology learning, which was a rapidly growing scientific field that demystified sexual life but also promoted traditional sexual relations as the only way to be sexually satisfied. Women artists, on the other hand, engaged in this negotiation of gender roles by challenging the state, Church, and sexologists' re-traditionalization of gender in society. This research is supported by a semiotic examination of artwork by Krystyna Wrobleska, Natalie LL, and Ewa Partum, utilizing studies on the Polish socialist reforms, constitution and laws regarding marriage, and the combative but collaborative relationship between the Church and state.

Abstract Name: Stamps as Messengers of Socialist National Identity in The People’s Republic of Congo (1969-1991)

Since the nineteenth century, political entities have used stamps as one of the many elements of national and political identity formation and projected that identity to a global audience. This study examines how the People's Republic of Congo utilized stamps following the political coup of 1969 until the regime's fall in 1991. Through the formal and iconographical examination of monthly stamps issued during this period and scholarly stamp studies, this research argues that in the People's Republic of Congo, stamps with socialist, nationalist, cultural, religious, and global imageries and symbols were a primary element in the creation of a socialist national identity. First, stamps were introduced as a reflection of political change and the establishment of the People's Republic of Congo. Three major trends are identified in the following examination of the stamps of the People's Republic of Congo. Stamps with socialist and communist leaders, revolutionary heroes, and national symbols supported socialist ideology. Stamps with national flora and fauna enhanced the national image by promoting tourism and displaying the country's natural environment. The most significant number of stamps contained images that targeted Western audiences as they depicted imagery of Christianity, celebrities, musicians, and international holidays and events and promoted the

country's openness to the Western world. This study is significant as the socialist period of The People's Republic of Congo is often neglected in discussions about socialism and art.

Abstract Name: Understanding Religion and Spirituality in Social Work

This research study examines the topics of religion and spirituality in the social work profession. Social workers are often nervous when discussing religion and spitituality due to concerns over crossing personal boundaries or ethical violations, or solely because the social worker themselves may not feel adequately educated or hold strong religious and/or spiritual beliefs. Following IRB approval, electronic surveys were sent to social work students (from religion and non-religious schools) and practicing social workers in order to learn more about their attitudes and behaviors when it comes to the topics of religion and spirituality in their practice. Data analysis demonstrated a significant difference between students who declared social work as a major compared to those in other majors in the following areas: attending religious meeting as a child and the belief that everyone needs to find their own religion and beliefs, A significant difference between social work major from a religious school compared to those in a non-religious school in the following areas: attending a mission trip and ideas of God or a transcendent Spirit are irrelevant in the world today. Of note, there was also a significant different related to race and having “strong faith”. Other qualitative results supported the researchers initial hypothesis that many social work students and social work practitioners do not have high levels of confidence when discussing faith or spirituality with clients. The researcher is currently exploring these topics by conducting a series of qualitative interviews with practicing professionals to better understand the role of religion and spirituality in a day to day setting. Initial results of these findings will be shared.

Abstract Name: Therapeutic Communication Training: Teaching Nursing Students Empathy

The Jeffries/National League for Nursing Advancing Care Excellence (ACE) framework is a listening and communication skills scaffolding program that can be used to improve measures of therapeutic communication. The ACE framework has been shown to increase measures of empathy, self-awareness, active listening skills, and PCC orientation in student nurses through randomized controlled trials. PCC has been consistently shown to improve patient outcomes. Nursing programs strive to prepare students for entry into professional practice through cognitive, affective, and psychomotor skills. Teaching therapeutic communication skills is a priority to ensure student competency during clinical experience and after entry into practice. The project will evaluate the efficacy of utilizing the Jeffries/National League for Nursing Advancing Care Excellence (ACE) framework on the development of active listening skills and patient-

centered care orientation among a convenience sample of undergraduate nursing students at the University of Central Oklahoma. Undergraduate students enrolled in the University of Central Oklahoma nursing program will be exposed to the ACE framework. Two core variables will be tracked, and data from pre/post conditions analyzed along with demographic data, employment, and pre-exposure to active listening skills training. PCC orientation will be measured with the use of the Patient-Provider Orientation Scale. Active listening will be measured with the Active-Empathetic Listening Scale. This quality improvement project will determine if use of the ACE framework will enhance performance, thereby producing students that are better equipped to improve patient outcomes.

Abstract Name: Testing the Moderating Effect of Burnout on the Relationship between Anxiety and Sleep Quality

Several studies strongly indicate a connection between the quality of sleep and students' learning abilities and academic success. Thus, understanding the factors that disrupt one’s sleep quality is important. One potent factor that can disrupt sleep is mental health, particularly anxiety. Although anxiety is a natural process to try to keep a person safe by alerting them to potential dangers, this has a downside by increasing psychological and physiological arousal that can disrupt how well one sleeps. Previous research has found strong correlations between sleep quality and anxiety; however, some people may be more vulnerable than others to the negative association of anxiety and sleep. Notably, those experiencing burnout may be psychologically depleted from their workplaces and have fewer resources to cope with anxious states. Therefore, this study will investigate how anxiety predicts sleep quality (Research Question 1), and how anxiety and burnout both relate to each other in their relationship to affect sleep quality (Research Question 2). Online surveys were completed by non-faculty employees (n = 140) from the University of California, Merced participants. These measures included the Generalized Anxiety Disorder-7 Scale, the Pittsburgh Sleep Quality Index, and the Bergen Burnout Inventory. Data analyses are ongoing. We expect to find a strong positive correlation between anxiety and sleep quality. In addition, we expect a significant interaction of anxiety and burnout, such that burnout amplifies the effects anxiety has on participants’ sleep quality. The findings are expected to offer valuable insights into the role of anxiety and burnout in influencing sleep quality, shedding light on potential interventions to cultivate more sustainable and healthy work environments and mitigate the risk of burnout and anxiety.

Abstract Name: Antioxidant properties of a zinc complex with a macrocyclic redox-active ligand

Recently, a Zn(II) complex with a polydentate quinol-containing ligand was found to be a functional mimic of superoxide dismutase. In order to establish structure-function relationships for this new class of antioxidant, we prepared a Zn(II) complex with 1,8-bis(2,5-dihydroxybenzyl)-1,4,8,11-tetraazacyclotetradecane, which consists of two quinols covalently tethered to a cyclam macrocycle. The ligand differs from other frameworks that we have investigated in that it prevents exogenous ligands from coordinating cis to the bound quinols. We have characterized the antioxidant properties of the isolated Zn(II) complex using common assays.

Abstract Name: Factors Associated with Changes in Oral Microbiota

Previous research has shown that changes in physical and psychological stressors can affect the biodiversity of the oral microbiome. Disruption of homeostasis in the oral microbiome has been known to increase the risk of developing dental caries, periodontitis, and other oral health concerns. This study aims to investigate possible correlations between college student lifestyle habits and these health challenges. After receiving IRB approval, students from a variety of academic disciplines and class status at a small, private university in the Pacific Northwest were invited to participate in this study. Participants signed informed consent documents and their data will be collected during finals week of the Fall, 2023, semester. The following data will be collected: survey responses that are designed to measure self-perceived stress, nutritional habits, dental hygiene practices, and other lifestyle factors; responses to the Penn College Perceived Stress Scale, saliva samples, and basic vital signs, which include blood pressure and heart rate. The saliva samples will be analyzed using a salivary cortisol ELISA to measure the amount of cortisol present. In accordance with previous research, it is hypothesized that the amount of cortisol will positively correlate with the amount of stress revealed in the Penn College Perceived Stress Scale. The bacterial species present in the saliva samples will also be identified through gene sequencing. Previous research leads to the hypothesis that Fusobacterium, Corynebacterium, Eikenella, Leptotrichia, and Tannerella will be upregulated when stress is high. Statistical analysis will be performed to confirm if there is any significant correlation between lifestyle habits, vitals, and the composition of the oral microbiota. It is expected that results will show a correlation between student stress and lifestyle habits and the diversity and composition of the oral microbiota.

Abstract Name: The Detriment of Bruxism on Longevity of Dental Veneers in Middle-Aged Adults with

Anxiety: Materials, Lifespan, Treatment Plan

The problem with bruxism patients struggling with fixing and avoiding lasting negative deterioration of teeth along with other sensitive dental procedure structures such as veneers due to their stress and anxiety levels which may be leading to sleep hindrance needs to be addressed in future works of dentistry by creating durable veneers with different material combinations to satisfy both resistance needs from grinding teeth through the day and/or night and reaching aesthetic expectations of the patient(s). Studies of both bruxism connections to anxiety, along with physical and mental health/fatigue, paired with veneer compositions and fracture patterns, emphasizing the significance of factors like color perception in shade selection due to its connection with an individual's confidence based on their front teeth appearance were gathered for future dental advancements to consider in order to reduce stress levels of patients which may decline bruxism and build tooth coverings able to resist the repetitive action of teeth grinding. This may create a pathway for new innovative dental treatment strategies through material changes that can revolutionize dentistry, especially the specialties dealing with sleep disorders and mental issues. Results showed patients diagnosed with sleep bruxism (SB) reported 22% in respective to their own group suffering from depression compared to the control variable group at 11.1%. The majority of sleep bruxism participants voted their most common level of depression to be "severe" (48%) versus the undiagnosed group selecting "normal" (38.77%). Participants with any type of bruxism showed significantly higher levels of dental anxiety and emotional stress compared to those that responded "no" to grinding teeth (sleep bruxism: dental anxiety: 13.47, emotional stress: 27.16; without sleep bruxism: dental anxiety: 9.93, emotional stress: 24.49). Bruxism had underlying factors to anxiety (genetic probability: 0.428, p-value: 8.34*10^-05).

Abstract Name: How Gaming Affects Novice Pilots

The aviation industry is anticipating a pilot shortage of 600,000 by the year 2040. Methods for improving pilot training are needed to combat this shortage. Research has shown that gaming can enhance hand-eye coordination and cognitive skills related to visually tracking objects. This study investigates the flight performance and gaze patterns of gamers in comparison to non-gamers. The research utilized an FAA certified flight simulator, eye-tracking glasses, and a video camera. Two groups were selected based on their gaming experience: non-gamers, and gamers. Both groups received basic flight training and completed a short practice flight. During data collection, participants were instructed to maintain a straight and level flight path. Eye-tracking glasses monitored where participants directed their gaze, whether at the cockpit window screens or individual gauges. Recorded gaze footage was processed using iMotions software. The initial data obtained from the iMotions analysis, revealed that experienced gamers spent more time on average looking at the window screens than the non-gamers and both groups minimized their interactions with the airspeed and compass gauges. Flight performance was rated based on the pilot's ability to maintain the straight and level flight mission. In addition, we measured inter-rater reliability for data generated from the rubric. Based on a review of the two groups' flight performance metrics, the gamers demonstrated superior flight performance on average, while novice gamers tend to exhibit lower performance levels.

Abstract Name: Ave Maria: Analyzing Gender Inequality in Latin America through the Lenses of Marianismo and Machismo

Gender inequality is oftentimes viewed as evidence of a society's lack of progression: despite that, gender inequality is rampant throughout all regions. In recent years, there has been an emphasis on gender inequality throughout Latin America, such as the rise of femicide, or the murder of women. Throughout Latin America, gender inequality can be rooted to Spanish and Portuguese colonial concepts of marianismo and machismo.Marianismo refers to glorification of the Virgin Mary and the ideology that Latina women should embody the values of Mary, whereas machismo refers to the masculinization of men with distinct aggressive characteristics. Machismo culture emulates traditional patriarchal values, such as the domination of women, which in turn leads to violence towards women. These attitudes are then upheld by marianismo culture: women are expected to remain chaste, to be homemakers, and ultimately both accept and become perpetrators of the very status quo that ensnares them. Gender inequity through marianismo and machismo exists in a dual role: to ensure women disappear both into the homes and into their "proper place," and to ensure that men remain emotionless, aggressive, and "stereotypically" masculine beings. These systems of oppression then form societal expectations regarding gender, and when these systems are broken, violence can and has occurred, such as the rise of femicide in the region.The research aims to answer the question "In the modern age, how have marianismo and machismo gender stereotypes formed a system that operates on ensuring gender inequality?" The expected conclusions are that both marianismo and machismo delved from both colonial and Christian ideology that blended together to form a detrimental social system that continues to operate in Latin America.

Abstract Name: Agent Behavior Modeling and the Interactions with Surroundings in Data-driven 3D Digital Twin Environments

Digital twin models build on real-world data-driven situation awareness and data streams, enhancing our capabilities to better understand the interactions and operations of real-life objects, systems, and processes. Most of the current civil infrastructure simulation tools are specialized to a single type of urban mobility (e.g., motorized vehicles), failing to incorporate the social science components and human interactions with surroundings into reflecting the functioning of city dynamics.This research project aims to develop the 3D digital twin simulation environment of the city of West Palm Beach, Florida. The objectives of this research include (1) building streetscape infrastructure based on real 3D building inventory data and (2) integrating human behaviors and their interactions with streetscape into the simulation environment. Unity and C# programming languages were used to develop the digital twin environments and to model agent behaviors and interactions.In this research work, multiple agents were integrated into the digital twin environment by defining their human behaviors and interactions with the streetscape infrastructure. First, the pathfinding behavior of the agents was developed to enable multiple agents to find a way to get to their destinations in the

streetscape. Moreover, their travel behaviors (e.g., walking speed and social distancing to nearby agents) were modeled to represent human-to-human interactions. Last, the interactions between agents and surroundings (e.g., stopping at an intersection and checking whether an intersection is free of vehicles before crossing) were added to the digital twin model. The performance of the agent behavior and their interaction models were tested and validated in the simulation environments. The potential growth of this research project is exceptional as researchers continue to improve its design and simulate more streetscape interactions, furthering the goal of making streetscapes safer, more efficient, and more accessible to all.

Abstract Name: Fear and warming in California: How do heat waves and predation risk impact resource dynamics in female crickets?

The effects of climate change are ever-expanding as human populations continue to impact our planet's ecosystems. Extreme changes in temperature due to climate change are no longer isolated events, as demonstrated by the growing prevalence of heat waves globally. Heat waves often place organisms in vulnerable situations, forcing them to find the means to regulate body temperature, conserve energy, and find resources to fuel reproduction. In addition to heat wave exposure, animals regularly encounter threats from other organisms in their environments, such as predation risk. The combination of these two factors introduces a conflict between survival and investment into fitness-related traits; food is required to withstand a heat wave and to invest in reproduction and self-maintenance, but foraging in the presence of predators increases the threat of mortality. Thus, we used female variable field cricket (Gryllus lineaticeps) to investigate the effects of heat waves in conjunction with predation risk (exposed food and water sources, and exposure to scent from black widow spiders, Latrodectus hesperus) on resource acquisition (food intake) and allocation (investment into ovarian and somatic tissues). A simulated heat wave increased food intake and the allocation of resources to reproductive investment. Crickets exposed to high predation risk reduced food intake, but were able to maintain their reproductive investment at the expense of investment into somatic tissue. Thus, exposure to both heat waves and predation risk deprioritized investment into self-maintenance, which may impair key physiological processes (e.g., immunity or stress tolerance). This study was the first to integrate the effects of heat waves and predation risk on resource acquisition and allocation, and it can help us understand how multiple covarying stressors alter important decisions by animals in a changing world.

Abstract Name: Evaluating the Dot Survey Method as an HIV/AIDS Community Health Approach in Rural Dominican Republic

Despite advances in the clinical treatment and prevention of the human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS), HIV/AIDS remains an epidemic in developing regions due to a lack of health system infrastructure, low education and literacy levels, poverty, and other socioeconomic drivers of the disease. In the context of limited healthcare and educational resources, it is imperative that novel community health tools are developed to build HIV/AIDS health literacy and promote sustainable wellness in underserved communities. In this program evaluation, the dot survey methodology was tested within a community health initiative (CHI) in the Northern Dominican Republic in May 2023. Adapted for use from open markets, the dot survey incorporates direct participant engagement into traditional data collection by soliciting responses through placement of dot stickers on a poster. In total, 92 adult participants were recruited during pop-up clinics in four rural communities, with an average age of 44 years and 25:67 male to female gender ratio. In their responses, participants indicated strong knowledge of the basics of HIV transmission and management, but their knowledge of more complex methods of transmission varied, as did their perceptions of people living with HIV. Almost all participants indicated they were comfortable sharing their opinion through the dot survey and that they liked the dot survey more than other survey methods (97%). Overall, the dot survey method was proven to be feasible in low-resource settings, as well as a powerful tool for shared learning and the creation of rapport between patients and CHI providers.

Abstract Name: Liver transplant with a cold ischemic time less than 3h with or without normothermic machine perfusion: a comparison

Background: Recent U.S. data on normothermic machine perfusion (NMP) in orthotopic liver transplantation (OLT) has shown 93-94% 12-month patient survival and 97-99% graft survival. NMP trial patients had a MELD of 19 to 28 and a DCD use rate of 16% to 19%. Their actual cold ischemia time (CIT) ranged between 2.3h and 2.9h. We thought to analyze UNOS data to see if those outcomes are comparable to donors with very a CIT <3h. Methods: Deceased donor OLT performed between 2018 to 2020 were recorded. CIT was stratified into four categories: <3h, 3-6h, 6-9h, and >9h. Kaplan-Meier and Cox regression analyses were used. Results: 20,590 recipients were analyzed. We found that CIT 3-6h, 6-9h, and >9h groups had 40%, 60%, and 110% higher chance of graft failure rates compared to the CIT <3h group (all $p \leq 0.05$), respectively. Recipients falling within the <3h CIT represented a smaller subset (n=660) and had 93% 12-month patient survival and 94% graft survival (Figure). The average CIT was 2.7±0.3h, the mean MELD was 22.3±10.3, and there were 5.2% DCDs in the <3h CIT group. Reasons for graft failure were PNF, HAT, infection, rejection, GVH, and biliary issues. There was no statistical difference in patient and graft survival between DCDs and DBDs within the <3h CIT group (p>0.2). Conclusions: Liver transplants from deceased donors with <3h CIT have similar patient and graft survival rates compared to those with <3h CIT pumped with NMP. Using deceased donor livers with a projected CIT<3h might be a complementary option to NMP when the situation allows.

Abstract Name: Fear of Mass Shootings: Mass Media, Myths, and Trust in Government

As shootings keep increasing throughout the years, so does the fear of falling victim to one. In 2023, there have been more mass shootings than days, with over 565 occurring across America. The increase of fear of mass shootings has increased based on the effects of mass media, myths, and the trust we have in government officials that occurs after the shooting. Due to these effects and media coverage portrayal of mass shootings, the fear keeps increasing. Relying on the Chapman Survey of American Fears, a representative national sample of U.S adults, I found that the more one watches or listens to mass media, the more likely one is to believe myths about mass shootings. Using the survey, I found a high fear level among those who identify as a woman, people of color, and are 35 and younger. These discoveries correlate with the way that shootings are portrayed in the media. Mass media will often portray victims of shootings to be women and young adults as it calls the attention of consumers and what type of shootings are shown. They will portray mass shooting perpetrators as young, white adults but turn it into an issue of mental health rather than guns which thus furthers the misinformation about gun control and shootings. As our digital era expands and we seek our news through media, we need to recognize what is the truth and what is misinformation. Media coverage plays into the increase of fear of mass shootings as they contribute to the problem by providing notoriety to the perpetrator rather than assisting in news coverage of governmental policies and change.

Abstract Name: One Size Does Not Fit All: Creating Educational Equity for Later Diagnosed Autistic Women

Autism research focuses on the externalized behaviors usually associated with the male phenotype of autism with little representation of the internalized behaviors associated with the female phenotype of autism. Even more so, there is little research involving later diagnosed autistic women — especially women of color. Beyond this, non-white individuals have been marginalized within the sphere of education, and their marginalization is exacerbated by an autism diagnosis.In the realm of schooling, the relationship between race, gender, and disability lacks investigation. In this exploratory study, I draw upon qualitative data from interviews of 18 racially diverse autistic women ages ranging from 18-52. In these interviews, I investigate the questions (1) “What are the behaviors, attitudes during and towards schooling, and self-perceptions of late-diagnosed women with autism across different racial demographics?” and (2) “How do these attitudes and behaviors correlate to their GPAs?” Since the current literature addresses the issues autistic individuals have with camouflaging their autistic traits because of the toll it takes on their mental state, this can be further analyzed in a school setting. This daily environment forces autistic individuals to exercise their camouflaging

abilities while experiencing many changes and social interactions. I am conducting a thematic analysis across the experiences of these women and comparing their experiences to their past and/or current GPAs. So far, these interviews have exposed a pattern that autistic women are consistently not believed and lack the resources they need to succeed in a formal classroom setting and school environment. As data continues to be collected from this study, women with ability and racial and ethnic minority status will gain the opportunity to add their own voices to conversations they have historically been left out of.

Abstract Name: Photothermally driven assembly and shape transition of giant amphiphilic microstructures

Amphiphilic molecules are known to self-assemble into diverse morphologies to form micelles, vesicles, lamellar, hexagonal, and cubic phases. We developed a new experimental platform to realize light-driven self-assembly of an ionic amphiphile (Cetyltrimethylammonium bromide, CTAB) and gold nanoparticles into structures with a size of a few micrometers. The self-assembly is driven by a convective flow arising from the photothermal heating of gold nanoparticles in suspension. We synthesized the gold nanoparticles using a seed-mediated growth method. The seed solution was prepared by mixing a CTAB aqueous solution with tetrachlorauric acid (HAuCl4) and sodium borohydride. We prepared a separate growth solution by adding ascorbic acid to a mixture of HAuCl4 and CTAB, and then mixed it with a 2-hour aged seed solution. After stirring for 10-15 minutes at 28°C, the solution produced a purple-magenta color. We measured the absorption spectrum of the synthesized gold nanoparticles using UV-vis spectroscopy and found two dominant peaks – one at 540 nm (the surface plasmon resonance peak of the gold nanoparticles) and another at 268 nm (likely arising from the excess CTAB present in the solution). Using an inverted optical microscope, we illuminated the gold nanoparticle/CTAB solution with high intensity LED light. We observed a flow of nanoparticles towards the center of illumination and the formation of microscale structures with a variety of shapes. At low nanoparticle concentration and low light intensity, the formed structures were large plates and rod networks. At high concentration and high light intensity, the structures transitioned into small circular disks and hexagonal crystals. We studied the sample at different temperature (25°C-80°C) and confirmed that the convective flow is essential for the formation of these structures. This work is the first demonstration using photothermal convection to drive rapid supramolecular self-assembly, and thereby holds promise in the field of nanotechnology and nanocomposites.

Abstract Name: Rational targeting of candidate transcription factors in a neurodevelopmental disorder model.

Chromatin is the physiological substrate of all genetic processes in eukaryotic cells. Histone proteins represent a major constituent of chromatin. Their post-translational modifications have long been recognized among major regulators of gene expression in eukaryotic cells. Mutations in the proteins involved in establishment and interpretation of histone modifications are frequent in many diseases, including cancer and developmental disorders. Recently, histone genes were implicated in several neurodevelopmental phenotypes, including intellectual disability (ID) and autism spectrum disorders (ASD). Despite significant progress in topic, molecular mechanisms underlying these diseases remain largely unknown, and etiological treatments are lacking.A heterozygous germline mutation in linker histone H1.4 was identified in many patients with childhood overgrowth, ID and ASD. All H1.4 mutations are short indels that result in a stereotypical frameshift that replaces wild-type, lysine-rich C-terminal tail of H1.4 with a glutamic acid-rich de novo peptide, identical in all patients. Despite the dramatic change in charge, levels of H1.4 remain unchanged, and mutant resembles the wild-type linker histone in biochemical assays. However, RNA-Seq and ATAC-Seq analysis identified aberrant activation of neurodevelopmental programs coincident with a focal increase of accessibility at a subset of approximately 2000 genomic sites associated with a class of basic leucine zipper (bZIP) transcription factors.Seven paralogous bZIP transcription factors were identified as ectopic interactors with H1.4 mutants in pulldown and mass-spectrometry assays. Genomic and imaging data demonstrate that accumulation of mutant H1.4 drives aberrant retention of bZIP factors in chromatin. These present a potential target to alleviate cellular phenotypes driven by H1.4 mutation. Experiments are underway to establish a genetic rescue using an inducible CRISPRi system. These studies will determine whether manipulating downstream transcription factor targets would rescue histone mutant phenotype, providing first clues to rational therapies in an incurable neurodevelopmental disorder.

Abstract Name: Survey of Clinical Trial Data of Immune Checkpoint Inhibitors – Avelumab and Cemiplimab

Immune checkpoint inhibitors, specifically PD1/PDL1 inhibitors, have revolutionized cancer immunotherapy by empowering the patient's immune system to combat cancer cells. Nevertheless, their efficacy exhibits significant variation across different cancer types and even within the same type. The research focused on assessing clinical paradigms of the four drugs and identifying novel biomsarkers predictive of response to these drugs in various cancer types of avelumab and cemiplimab. The analysis encompassed 392 publicly accessible clinical trials spanning phases I to III. The study's foundation rests on two primary databases: ClinicalTrials.gov for clinical trial information and Drugs@FDA.com (as of June 20, 2023) for drug approval data. The core assessment criteria comprised the present development status, approval timelines, and recognized indications, encompassing combined therapies. Clinical trials underwent systematic categorization based on factors such as conditions, sponsoring entities, study types, initiation dates, and posted dates. Furthermore, the research delved into indications currently in development, showcasing potential for future FDA approval based on observable trends. In the case of avelumab, indications with the most promise for approval include colorectal and breast cancer, in addition to ovarian cancer. These indications stand out due to the extensive volume of related clinical trials and the high degree of collaborative engagement in their exploration. For cemiplimab, breast cancer, head and neck cancer, and melanoma demonstrate substantial potential for FDA approval, evident through the significant number of trials. Additionally, cemiplimab's distinctive characteristic of receiving higher sponsorship involvement from diverse categories in approved drugs opens the door to potential approval for prostate cancer and lymphoma indications. Avelumab and cemiplimab’s similarities were comparable development times of 1491.5 and 1303 days. Some differences were seen in the indication development as avelumab had more involvement of the collaborator and others while cemiplimab had more trials by sponsor and others.

Abstract Name: Comparative Genomic Analysis of Colorectal Cancer Microbiome Bacteria to Discover Novel Relationships

Colorectal cancer (CRC) is uncontrolled tumor growth that starts in the rectum or colon (Park E. et al., 2022). Many factors affect the development of cancer, including daily habits, environments, and genetics. Our research focuses on analyzing the differences in pathways/enzymes between cancerous and non-cancerous associated bacteria in the gut microbiome outlined by a recent cancer microbiome review (Park E. et al., 2022). By utilizing the Bacterial and Viral Bioinformatics Resource Center (BV-BRC), we compiled our bacteria's genetic information into genome groups and used the comparative systems service to identify target pathways and construct phylogenetic trees. After focusing on genomes, we delved deeper into the enzymes. The programming language R was used to narrow down four specific enzymes from the set of genomes: two from the pathways only in non-cancerous bacteria and two in cancerous-associated bacteria. A Multiple Sequence Alignment (MSA) run at the genome level identified the range of lowest entropy among the genes in the four enzymes - one of which had the lowest range of 30-40. We are using NCBI Blast and other bioinformatics methods to characterize/validate the four enzymes in our respective target bacteria. Our end goal is to target/screen the unique pathways and enzymes (like the enzyme with EC number 5.4.3.2) of the cancer-associated bacteria and non-cancerous associated bacteria to decrease the metastasis of CRC tumors (Park E. et al., 2022). These genes, which code for the enzymes, can be manipulated in the wet lab as shown by the cited paper

Abstract Name: Galactic Supernova Neutrino Burst Signals with PUSH and SNEWPY

The overarching goal of our project is to generate artificial supernova neutrino signals using a combination of two codes called PUSH and SNEWPY. PUSH is a 1D supernova simulation code that simulates the supernova explosions and generates unoscillated neutrino spectra. SNEWPY is software written for the SuperNova Early Warning System collaboration which combines the data from supernova simulation with a prescription for the flavor transformation and then computes the neutrino event rates in terrestrial detectors. Together, they form a pipeline that allows us to simulate the neutrino signal from a nearby supernova and design protocols for extracting the information we seek from a signal. To develop this pipeline we created a PUSH supernova model class using Python to be inserted into the current SNEWPY software. We then extracted and read data from PUSH to form correlations between neutrino data and supernova events.The PUSH model class extracts, reads and handles data for us to model the relationship between different variables, including luminosity, flux, time, neutrino flavor/type, and energy.Then after running SNEWPY flavor transformations, we determine the neutrino fluxes that reach the Earth. With nine different models and different mass orders, we can create multiple models that correlate the flavor and flux of neutrinos seen on Earth.From there, a part of SNEWPY called SNOwGLoBES provides functions to format the data files run through a chosen set of neutrino detectors and output the final result of data we speculate to see on Earth at the next captured CCSN event. From the output we expect our generated data and models will capture distinct differences in resulted neutrino emission, hence relating back to the type of model and creating a distinct connection between neutrino data detection and types of supernovas.

Abstract Name: Determination of the Conformation of AfeETF for Further Biochemical Experimentation

The electron transport flavoprotein (ETF) found in mitochondria mediates transfer of electrons during respiration. However anaerobic bacteria such as Acidaminococcus fermentans possess a different type of ETF, which can execute electron transfer bifurcation. A. fermentans ETF (AfeETF) couples two electron transfer reactions, producing a more energetic product than the starting material. This is a newly recognized mechanism that naturally conserves energy at the level of electron flow. Thus, the ETF protein is a valuable source of insight for creating novel materials and devices to capture and store energy. The knowledge of how ETF conformational (open or closed) changes are coupled to the reactivity of its cofactor flavin is essential for understanding how to make the electron flow of such reactions more energy efficient. This project will test small extensions to the ETF proteins, that will act as steric doorstops, to hold the protein in its closed or open conformation. These extensions are small polypeptide chains that will be attached to the N terminus or C terminus subunit of the AfeETF. The recombinant protein subunits will be expressed in bacteria, purified, and observed using polyacrylamide gel electrophoresis. Improper folding of the recombinant subunits is expected to result in diminished protein yield or fractionation to the insoluble phase during purification. Functional integrity of the protein subunits will be assessed by examining the stoichiometry of bound flavin using spectroscopy. The proposed experiments will enable testing of other reaction variables for energy efficiency while retaining AfeETF in constant open or closed conformation states. Thus, this project will provide key biochemical knowledge to harness biological reactions for sustainable energy solutions.

Abstract Name: Social Media Use and Pretrial Publicity Effects

Much research has been done on pretrial publicity but virtually all of it has been done with traditional social media, and there is very limited information on the amount of pretrial exposure and pretrial judgments of guilt. This study seeks to obtain information about cases that have recently appeared in the media to determine levels of coverage that are likely to result in widespread attention. It will further identify, for each of those cases, the source of information, and the extent to which crime coverage is received via new media. Finally, it will seek to correlate exposure levels with prejudgment of guilt. This information is directed at the fundamental question about the rate of exposure and its connection to pretrial judgements, which is at present a connection lacking a scientific consensus. In addition, it will speak to questions that courts must address, which is not typically whether publicity can influence the outcome of a trial but the amount and types of exposure that require judicial remedy. Through a Qualtrics survey, survey research will ask 200 respondents to indicate their familiarity with each of nine different contemporary court cases. The survey will further query the source of information about each case, include objective questions about each case to assess the accuracy of beliefs about the case, and assess prejudgment levels. Finally, the RAND (2019) instrument will be modified for the present study. The scale includes consumption measures for both traditional and social media news sources. Together these measures will assess traditional and social media news consumption and will separately query media exposure about particular defendants and news consumption overall.

Abstract Name: Nuclear Power as a Future Main Source of Electricity

AbstractThe use of nuclear power to produce electricity is a promising source of safe, clean, and reliable energy. Though in the past public opinion has inhibited the growth and success of this electricity source; today, with the pressure of climate change forcing the world to make a lasting change in the way our society generates electricity, nuclear power is the most prominent source for a clean energy future. The first main goal of our research is to gain knowledge to further understand Montana’s public opinion and knowledge of nuclear power and, more importantly, the foundation and reasoning for their views. We have conducted a survey that asks whether the respondent is favorable or unfavorable and why they hold that opinion, then whether they feel knowledgeable or unknowledgeable about nuclear power to produce electricity. We have surveyed students at the end of two Montana State University energy and sustainability courses, and in the next semester, we will conduct the survey in the beginning and end of courses from the science and business backgrounds. The second main goal of our research is to gain an understanding of why nuclear power has such a high price tag associated with it. We are researching the costs through summaries of techno-economic analyses of the construction and operation of previous nuclear power plants. To achieve this goal, we have been in contact with Northwestern Energy, Idaho National Laboratory, NuScale Power, and other sources from the internet. These sources have been gracious enough to share abundant information and data regarding their economic and financial knowledge and research into the field. With this information, a further goal is to identify where nuclear power can decrease costs to make it more economically viable and competitive.

Abstract Name: Identifying New Small Proteins in a Molecular Biology CURE Class

Small proteins, defined as those containing 50 or fewer amino acids, are difficult to identify and characterize using standard bioinformatic and biochemical techniques. The process of identifying new small proteins, however, is an ideal project for a hypothesis-driven Course-based Undergraduate Research Experience (CURE) laboratory class. Working in groups of two, undergraduate students use basic DNA and protein sequence characteristics to identify a short open reading frame (sORF) in the Escherichia coli genome that they predict most likely encodes an expressed protein. The hypothesis for their semester-long research project becomes “We hypothesize that this sORF encodes a small protein.” Students then use molecular biology techniques such as polymerase chain reaction, DNA purification, cell transformation, and homologous recombination to create bacteria strains required to test their hypothesis. Finally, at the end of the semester they perform western blots to determine if their candidate small protein is synthesized. Over the past eleven years more than 400 students have tested over 200 sORFs for synthesis, identifying at least 58 new small proteins. Most recently, nineteen students in the Spring 2023 class identified three new small proteins out of nine sORFs tested. Altogether, students in the small protein CURE class learn valuable molecular techniques while making publishable contributions to our understanding of the E. coli small proteome.

Abstract Name: The Impact on Children Coping with the Loss of Fathers to Suicide

Suicide in men has become increasingly common in the last decade. Often, these men do not have known mental health conditions and do not seek external support. Many factors contribute to this issue such as gender stereotypes, stigma, limited access to services, and unsupportive environments. Losing a parent in childhood can be traumatic and lead to long-term consequences. Some challenges these bereaved children face include emotional-social delays, disruptive behaviors, and mental health struggles. These children must receive adequate support to grieve in their families, communities, and schools. Interventions can be implemented to lessen the impact on these families, reducing confusion, anger, and loneliness. Previous literature has demonstrated how the loss of a parent can result in issues such as incomplete education, depression, and various mental health conditions, including alcohol and substance abuse, along with the absence of known mental health conditions in men who commit suicide. To better understand the determinants of suicide and its impact on their bereaved children, a literature review was conducted. This

information can be utilized to work towards increased prevention of male suicide in our society, ultimately reducing the impact on survivors, such as intergenerational trauma, continuing stigma, and the significance of fathers. The insights gained from this literature review can inform various professional settings, including counseling and mental health, as well as direct areas surrounding these families in schools and communities. By working towards a decrease in suicide among fathers, we can minimize the loss of children and loved ones. The findings of this literature review will help elucidate themes related to how children of fathers who committed suicide describe their own experiences with mental health and the barriers to support they encounter.

Abstract Name: Development of a low-cost portable Multispectral Camera for Bovid Teeth Examination

Bovid teeth are among the most commonly found fossils in South Africa, and the accurate identification of such is vital for paleoenvironmental reconstructions as they reflect ecological adaptations. Currently, methods to test species identification of Bovid teeth involve manually tracing and binarizing images of the occlusal surface with an image manipulator software, which can be time-consuming and inaccurate depending on the tooth's condition and image quality. Previous studies on human dentition have found that multispectral imaging at the Near-Infrared wavelength (NIR) can acquire high-contrast images of enamel and enamel demineralization. The images showed cross-polarized reflectance, interproximal reflectance, and occlusal transillumination. Post-processing techniques have proven effective, including isolating the occlusal surface and quantitative analysis of pixel mean light intensity.This study aims to develop a low-cost multispectral camera with macro-imaging capabilities tailored to examine bovid teeth closely. The study will also investigate the utility of reflectance values from the occlusal surface of the teeth for more accurate species identification. The initial study will test the reflectance differences between local extant bovid species, Bos taurus and Capra aegagrus hircus, domestic cattle and goat. The difference in reflectance values between species will then be compared to the difference from the Elliptical Fourier Analysis (EPA) from binarized images of the teeth. It is hypothesized that there will be a significant difference in reflectance values of the occlusal surface of the teeth due to differences in diet and water consumption habits. Further research can then be done to determine the accuracy on fossilized species.

Abstract Name: Ethics of Web3 and Decentralized Internet

For this presentation, I will present a care ethics analysis of Web3 and decentralized internet, with a specific focus on privacy concerns and the increase of internet scams due to the lack of regulation and accountability. Ethics of care argues that there is moral importance in promoting the well-being of caregivers and receivers

in a network of social relations, recognizing that all human life is co-dependent. It is important to note that care ethics was not designed to engage with such large networks of relationships, I will be expanding it to apply to the situation, so it gives us just one new way of viewing it. I will expand on this ethical lens by including points from care ethics, specifically points from Joan Tronto, such as the empathy in the design of Web3, and responsibility for online communities. My research explores the intricate web of relationships and responsibilities in the decentralized environment, aiming to shed light on the vulnerabilities within internet scams in contrast to the benefits of cryptocurrency. I examine here the moral dimensions of these scams, considering the impact on individuals and the broader digital community. The emphasis on care ethics demonstrates the interconnectedness of actors within Web3, as well as the need for a collective commitment to certain forms of innovation.

Abstract Name: Extending the Olive Branch of Rhetoric to Everyone

Rhetoric is a field that pervades every facet of human life. This field of language is important in understanding how society and the individuals within it interact within the scope of persuasion. With this discipline I will be analyzing the process of book bannings in the US through the lens of queerness. In order to do this I will be utilizing and rhetorically analyzing texts from a trans scholar by the name of Jack Halberstam such as Gaga Feminism, as well as reframing Kate Crawford's idea of the Atlas of AI to create my own rhetorical theory of a metaphorical Atlas of rhetoric. Through my own rhetorical theory I will analyze censorship, the accessibility of rhetoric, and exclusionary power structures that control texts as if they were natural resources. The study of rhetoric helps people understand the choices other people as well as themselves make when formulating arguments, which can lead to a closer understanding of both sides. Since it gives people the tools to analyze other people's use of rhetoric, it then helps to examine systems of power in our world that are used to hold marginalized members of society back. Because of the important job rhetoric serves, it is crucial that we view it critically, since it is not immune to the woes of exclusionary practices. The point of my analysis on book bannings is to model what I wish for the future of rhetoric; I am working to allow everyone to participate in rhetoric as a wide net community, so that no identity is left out. In the case that there is a perspective that does not appear within this community I hope to build, it would simply be because they have not heard of the movement, but the olive branch is in constant extension to everyone.

Abstract Name: MEAM: A novel, low-cost algorithm utilizing ensemble learning with Audio, Visual, and Text-based applications to generate an overall human emotion

In the era of pervasive digital communication, understanding human emotions is a paramount challenge with profound implications for various domains, including healthcare, education, and human-computer interaction. This research presents a cutting-edge Multimodal Emotional Analysis Model (MEAM) designed to offer a comprehensive and context-rich assessment of human emotions by simultaneously analyzing audio, video, and text-based inputs. This model's applications are far-reaching. In healthcare, MEAM can aid in early detection and monitoring of mental health disorders by analyzing patient interviews and expressions. In education, it can enhance personalized learning experiences by gauging student engagement and emotional responses during online lessons. Human-computer interaction benefits from MEAM by creating empathetic AI interfaces that adapt to users' emotions, offering more tailored and supportive interactions. The Multimodal Emotional Analysis Model represents a pivotal advancement in emotion analysis technology, paving the way for deeper insights into the human psyche. By fusing audio, video, and text-based inputs, MEAM provides a greater context for understanding emotions, opening doors to more empathetic and responsive systems across various sectors. MEAM was able to achieve a high accuracy reaching 70% accuracy on facial emotion recognition, 95% accuracy on Audio Emotional Classification, and 96% accuracy on Text Emotion Recognition with each of these models being tested across 8 classes of emotion.

Abstract Name: AI/Machine Learning Techniques to Predict the Presence of Hazardous Superfund Sites Using Socioeconomic Data

Superfund sites are contaminated sites caused by the mismanagement of hazardous waste dumping adversely affecting human health. As a result, they pose important questions regarding their locations, given that research has shown that poorer communities tend to have disproportionally higher levels of hazardous waste sites. With this in mind, we aim to determine the validity of our hypothesis of lower socioeconomics positively correlating to the presence of a superfund site. Using socioeconomic data from the 2010 US Census and superfund data from the National Priorities List, we try to discern whether there is environmental discrimination surrounding superfund sites. The selected data had 344 input parameters like land area, education levels, and demographics. To validate the proposed hypothetical correlation, the IBM Watson platform was used to model machine learning algorithms optimized for accuracy. The models selected were the LGBM Classifier and the Decision Tree algorithm. The original prediction model utilized unbalanced data, resulting in the model having a high specificity and a low sensitivity. To balance the data, attempts were made to undersample the negative cases, which helped the best-performing model, the LGBM Classifier. The LGBM Classifier achieved higher accuracies in predictions of both (65.4%-positive and 71.2%-negative), got an F1 score of 0.669, and scored 0.732 under the ROC curve. After running the experiment, it was found that the most influential parameters on the prediction were land area, census mail return rate, and number of people with a bachelor’s degree or higher. The proposed hypothesis was found accurate as a strong correlation was found between lower socioeconomics and the presence of superfund sites. Using these results, we anticipate that this research can be used to launch the public debate over superfunds to give more understanding of how socioeconomics can affect the location of superfund sites.

Abstract Name: From Clowns to Crowds: History of the Culture Change of Competitive Eating

Greatness comes in many shapes and sizes. Some search far and wild to achieve greatness, while others look within themselves to find self-fulfillment. The most prominent way to become great as a competitive eater is to eat the most hotdogs on the Fourth of July. At one time competitive eating was looked at as a carnival attraction or some kind of gimmick. What events caused the shift from carnival culture to the competitive sport it is today? Drawing from news articles, interviews, and scholarly-primary works, this paper demonstrates that the sport went through three stages of transformation. Competitive eating originated in the early 1600s, when it was seen as more of a sideshow attraction. The initial shift of carnival to competitive culture began to appear in the first Nathan's Hotdog Eating Contest on July 4, 1916. More eating events began to pop up and stars of the sport started to emerge. In the second phase of development, in 1997, these breakout athletes organized into the International Federation of Competitive Eating, today's Major League Eating. The sport now had sanctioned events under its own organization. The final stage was a time of cultural unease and the emergence of an eating legend, as the clashing tensions between American and Japanese athletes created the most notable eater of today, Joey Chestnut. The competition between nations put competitive eating in the spotlight and made it must-watch television, pushing it toward where we are today. The world of competitive eating is mostly untouched by scholarly sources. This research allows for the hunger of this cultural history to be fulfilled.

Abstract Name: Endothelin Receptor B Blockade in a Model of Salt-Sensitive Hypertension

Hypertension is one of the most common health conditions worldwide. Although the causes of hypertension are varied and incompletely understood, individuals with salt-sensitive hypertension have a greater risk for cardiovascular diseases. Dysfunction of the endothelin B receptor (ETB-R) is known to cause salt-sensitive hypertension. Therefore, we hypothesized that blockade of the ETB-R increases kidney expression of factors involved in salt-sensitive hypertension. Rat models of ETB-R deficiency (ETB-def) and Transgenic (TG) controls were given a high salt diet (4% NaCl) and either vehicle or A192621. A192621 is a selective antagonist for ETB-R. We extracted RNA and performed RT-qPCR from kidney cortex samples. A192621-treated ETB-def rats displayed higher expression of endothelin-1 (2.23 ± 0.67; $n = 3$) when compared to TG rats (1.35 ± 0.15; $n = 4$; $p = 0.0978$). Endothelin-1 was similar in both vehicle-treated ETB-def and TG (1.28 ± 0.12 vs 1.01 ± 0.10; $n = 2/3$ respectively; $p = 0.6416$). Endothelin-3 expression was similar in A192621-treated ETB-def rats (1.40 ± 0.51; $n = 3$) compared to A192621-treated WT rats (1.11 ± 0.15; $n = 4$; $p = 0.4738$). Endothelin A receptor expression was higher in ETB-def than TG rats regardless of A192621 or vehicle treatment (2-way ANOVA group effect of genotype $p = 0.0778$). Additional targets including the angiotensin II receptor 1a were not different across genotypes or treatment. Overall, we observed changes in components of the endothelin system in both TG and ETB-def rats following high salt diet and ETB-R blockade methods.

Abstract Name: Designing Strategies That Emphasize Mentorship Within a Center for Student Research at a Public Regional Minority-serving Institution

The Center for Student Research (CSR) at California State University, East Bay supports students performing independent research with faculty. Since its founding in 2012 with 28 students, the CSR has expanded the number of engaged students and faculty with a maximum of 235 students and 80 faculty mentors in 2019 and offers programming related to professional development and funding for research and travel. A primary focus of the CSR is to ensure that students benefit from one-on-one faculty mentorship. Here, we describe implemented strategies to empower students through student-faculty mentorship. The CSR has implemented three practices: 1) Engaging faculty and students in an advisory board to restructure the center; 2) Requiring an application from both faculty and student to set mentoring goals and expectations; and 3) Using a badging system to ensure that both faculty and students are tracking the progression of students. First, engaging both faculty and students on our advisory board allows both groups to work together to contribute to the development of programming of the CSR. Second, requiring faculty to describe their approach to mentoring when nominating students ensures that mentors have a structured and tailored approach to ensure an effective working relationship. Lastly, our badging system asks faculty and students to identify at least 3 skills that the student must accomplish over the course of the term. Once accomplished, the students receive a digital badge that can be shared widely such as on social media platforms. Our 2023 mid-year progress reports indicate that badging serves as a very effective tool for tracking both faculty and student progress, as it has resulted in several students and faculty working together to submit abstracts, publications, and increased competency within the discipline. Future programs within the CSR will continue to emphasize mentorship and documentation of resulting short- and long-term products.

Abstract Name: The contribution of tourism to community recovery after natural disasters

In a world where natural disasters increase in frequency and intensity, local tourism businesses have become more vulnerable than ever before. Although the destination community requires an extensive amount of time, the perspectives of the local businesses have been relatively neglected. Despite the extant body of literature regarding crisis management policies and tourists' visitation intentions, there is a severe scarcity of scholarly inquiries that analyze the operational guidelines and strategies of tourism destination management. Therefore,

this paper aims to balance the viewpoints of the stakeholders in tourism and hospitality businesses. Drawing the Tourism Recovery Scorecard (TOURS) model, multidimensional insights will be provided by spotlighting the major contributors to the local economy, Small- and Medium-sized Enterprises (SMEs). For an in-depth analysis, this research will conduct thematic analyses through NVivo. As Hawaiians are currently preoccupied with restoring tourism after a wildfire, the sample will be the Hawaiians who have lived in Hawaii for five years and are engaged in SMEs. Random sampling will be adopted for the data collection through the Native Hawaiian Businesses and Organizations. The projected number of sample size will be 30, and two independent researchers will analyze the narrative. The findings will be demonstrated in accordance with the significance of the theme and the narrative disclosed pertaining to the subject matter. The anticipated theoretical implication of this research is supplementing the viewpoints of destination residents to the TOURS model. The provision of a comprehensive perspective on the TOURS model is anticipated to enhance the model's reliability. Additionally, policymakers and the disaster-affected local community will gain from this research. This research increases the likelihood that the viewpoints of the local community will be considered in the restoration of the destination, as their input will provide regional policymakers with vital information that enables them to allocate resources effectively.

Abstract Name: Machine Learning versus Kinematic Variables in Collider Physics

The calculation of the W boson mass (W-mass) is a benchmark and testament to the usefulness of kinematic variables in experimental particle physics. More complex particle physics processes demand the use of more complicated kinematic variables and, correspondingly, more computational power. This project is developing a neural network that aims to reduce the required computational power of these kinematic variables while still maintaining their predictive power. The network was given either a distribution of transverse masses of the decay products or an incomplete distribution of 4-momenta (to simulate real collider data). The project also experimented with training the neural network on normalized data, different training data sizes, and different learning rates. Overall, the best architecture for this problem cannot be generalized for all W-mass calculations, but there are some patterns that emerge. For example, normalizing the training data from 0 to 1 improves network results. In addition, a network learning rate of around 0.001 seems to provide the most accurate results. Finally, increasing training data sizes corresponds to smaller errors until the error plateaus at roughly 600 training points. This work will be the foundation of a future project that utilizes Lorentz Boost Networks in conjunction with our network in a way that identifies the optimal distribution of kinematic variables to learn the mass of intermediate particles in more complicated decay processes.

Abstract Name: Region-Specific Economic Impacts of Extreme Weather Events

The research investigates the economic repercussions of climate change on various sectors in British Columbia. The central research purpose of our project is: Investigating the economic factors influenced by climate change and developing a machine learning-based forecasting model specifically for industries affected by climate change. By exploring the distribution of productivity in each sector in British Columbia, we can determine the relationship between dominant industry productivity and factors affecting climate change. The study promotes the need for improved data collection and the incorporation of climate considerations into economic forecasting and planning processes. The results from analysis will enhance the accuracy of economic impact assessment related to climate change for the next five years, which will be a novel contribution to the field. We will demonstrate the correlation between temperature variations and productivity with the help of linear regression model, and also use a Long Short-Term Memory (LSTM) machine-learning model to predict productivity trends, incorporating the temperature variables from the past 20 years of data. The evaluation of the Normal Q-Q plot in our preliminary analysis reveals the existence of heavy tails in the distribution, potentially due to Heteroscedasticity implying that the presence of variability may result in unusually high or low differences in residuals, impacting the overall distribution. We delve into a heteroscedasticity analysis that helps identify different levels of residual variability across predictor values, which can potentially impact coefficient precision in climate models. The findings suggest a significant decline in productivity for British Columbia's Agriculture and Mining sectors due to climate change. This research enhances understanding of the intricate interplay between climate change and productivity, providing actionable insights for stakeholders. We aim to present a comprehensive analysis so that we are able to contribute to the broader discourse on climate-related economic impacts.

Abstract Name: White Knight or Mere Bystander? Examining the Complex Role of Benevolent Sexism on Bystander Intervention in Workplace Sexual Harassment

Although workshops addressing sexual harassment (SH) in the workplace have focused on helping bystanders find ways to intervene in SH situations, attitudes and beliefs about gender and harassment may pose a barrier to various stages in the bystander intervention (BI) process. A cross-sectional study of 451 academic and professional scientists demonstrated that regardless of noticing the event and knowing how to help, participants were more likely to interpret a SH event as an emergency and accept responsibility to help when endorsement of SH myths was low and benevolent sexism was high. Interestingly, willingness to implement help increased as SH myth endorsement and benevolent sexism decreased, which may indicate that the chivalrous and paternalistic veneer of benevolent sexism extends to recognizing issues of SH but ultimately prevents taking critical action. Other common measures of gendered and societal attitudes (i.e., social dominance orientation, hostile sexism) were also negatively related to various stages of the BI process, indicating that attitudes about gender equality must be addressed and changed in order to address SH in the workplace.

Abstract Name: Explore undergraduate baccalaureate nursing students' sleep quality during their clinical experience

BACKGROUND: Good sleep quality ensures personal physical and mental health of an individual. For undergraduate baccalaureate nursing students, who are in a very rigorous academic program as well as clinical practice, sleep health becomes even more crucial. Poor sleep quality can affect cognitive functions, decision-making skills, and overall clinical performance. The purpose of this study is to explore the sleep quality of undergraduate baccalaureate nursing students in different academic years during their clinical experience.METHODS: The objective population for this cross-sectional survey was Bachelor of Science in Nursing (BSN) students who are enrolled in clinical courses at three universities. The survey consisted of demographics, sleep quality, and clinical performance. The Pittsburgh Sleep Quality Index (PSQI) was used to measure sleep quality and the Self Efficacy in Clinical Performance (SECP) scale was used to evaluate clinical performance. SPSS software was used to analyze the data.RESULTS: There were 124 nursing students participating in this study. The mean age was 20.87 years and 88.9% was female. 30.65% of the nursing students reported good sleep quality (PSQI < 5) and 69.35% of them reported poor sleep quality (PSQI > 5). Among the nursing students with poor sleep quality, sophomores had the highest percentage (78.57%), followed by seniors (71.87%), and then juniors (63.64%). Results of this study indicated that nursing students' clinical performance self-efficacy scores increased with their academic year. Sophomores had the lowest clinical performance self-efficacy score (67.25%), followed by juniors (72.52%), and seniors (74.40%).CONCLUSIONS: This study revealed that sophomores had the poorest sleep quality and the lowest confidence in clinical performance during their clinical experience. These results should raise nursing educators' awareness by implementing educational strategies earlier in the curriculum to improve nursing students' sleep health and confidence in their clinical performance.

Abstract Name: Revealing the processes behind decision making in high stress situations

The Prefrontal Cortex (PFC) and hippocampus are some of the most critical regions of the human brain that influence decision making. There are four steps in the decision making process. To understand what happens, comparisons of brain activity during decision making during high stress versus low stress situations were made. By examining relevant data and literature, it was found that stress exposure affects the neural circuits and increases the likelihood of us engaging in risk-taking behaviors. Stress is associated with the sympathetic adrenal medullary (SAM) axis and the hypothalamic pituitary adrenal (HPA) axis. It has been shown that the prefrontal cortex is involved in activating the HPA in response to stress. This study will examine the neuroscience behind decision making and how we can improve decision making in high stress situations. Stress is multifaceted and thus needs to be examined in the context of decision making.

Abstract Name: From Mary Kay and Johnny to The Mary Tyler Moore Show: How Television Sitcoms Shaped Our Perspective on Dating and Sex for Single Women.

Mary Kay and Johnny was the first sitcom broadcast on national television in the United States. It starred a married couple and was the first program to show a couple sharing a bed. Mary Kay and Johnny paved the way for later sitcoms, such as The Mary Tyler Moore Show, to challenge societal norms regarding sex and romantic relationships. Today's depiction of single women in television sitcoms is a reflection of the progress that America has made due to the waves of feminism and the sexual liberation movement. However, there remains a double standard within society and television between men and women in romantic relationships. According to studies on the sexual double standard, the social consequences between men and women engaging in sexual activity differ substantially. Men are held to fewer standards and even praised for sexual behavior. Conversely, women are governed by purity culture and judged for their number of sexual partners and when it is socially acceptable for her to have sex (first date, long-term relationship, marriage.) The purpose of this paper is to analyze how specific television sitcoms between the 1950-1970's contributed to the sexual liberation movement, women's rights, and societies' current attitude regarding sex and romantic relationships for single women. I explored this question by analyzing texts on feminist theory, text on American television, and primary television sitcom sources. Television sitcoms grew from avoiding even the suggestion of a sexual relationship for single women to actively discussing contraceptives and a single woman's sex life. Representation in television sitcoms regarding the double standard between single men dating and single woman dating is still necessary today. By reflecting on the growth of television sitcoms and its influence on society, we can address current gender norms for sexual conduct and liberate women from societal pressure surrounding sex and dating.

Abstract Name: Understanding the Overexpression of TATA box-binding protein-associated factor 13 (TAF13) in Eukaryotic Cells

TATA-binding protein (TBP) and TATA box-binding protein-associated factors (TAFs) comprise RNA Polymerase II (RNA Pol II) pre-initiation complex, a universal component that carefully controls the transcriptional initiation process. One of the TAFs, TAF13, also plays an important role in the regulation of RNA Pol II transcription initiation which is evolutionarily conserved from yeast to humans. It is found that TAF13 is overexpressed in thyroid carcinoma (TC) cells, while the exact mechanism that is responsible for this overexpression is unclear. Our hypothesis suggests that targeted degradation by the 26S proteasome via ubiquitylation (UPS) may be the mechanism that regulates the stability of TAF13. To test this possibility, we evaluated the role of UPS on the stability of TAF13 in yeast (Saccharomyces cerevisiae). Importantly for the first time, we found that TAF13 undergoes polyubiquitylation and have yet to find if it is regulated by the 26S proteasome. In the case of our hypothesis being supported by experimental results, therapeutic intervention could be possible for future patients of thyroid cancer.

Abstract Name: Extending Moral Foundations Theory: Unraveling the Foundation of fairness in Political Decision-Making

We propose that the two independent foundations of equality and proportionality make up the foundation of fairness to address gaps in differing stances on what fair means, particularly among policy issues. This paper explores gaps in Moral Foundations Theory (MFT), a framework for understanding the moral underpinnings that shape decision-making processes. MFT identifies five fundamental moral foundations: care, fairness, loyalty, authority, and sanctity. The study aims to investigate how politicians engage with these foundations with respect to political ideology. We compiled SCOTUS opinions from all cases deliberated during the 2022-2023 term, collected congressional tweets from both Democrat and Republican House members, and utilized a modified MFT dictionary to quantify the presence and frequency of moral foundations. Preliminary findings suggest that there is a significant correlation among Martin-Quinn scores of SCOTUS justices and

usage of equality over proportionality. The Twitter dataset further supports this correlation, suggesting that liberals emphasize equality in their decision making more than proportionality, while conservatives tend to do the opposite. We also find that moral words are expressed more frequently in appealing to the shared ideological backgrounds of constituents than the creation of political stances. These computationally driven results support an extension to MFT, with respect to how different foundations inform on political stance and ideology.

Abstract Name: Environmental Neurotoxins Effects on Neuronal Networks and Synaptic Mechanisms

Endocrine-disrupting chemicals (EDC) disrupt activity-dependent signaling necessary for immediate early gene (IEG) transcription in developing neurons. Here we show that 6OH-BDE-47(a hydroxylated metabolite of PBDE-47; a commercially used flame retardant) and BPA (a ubiquitous plasticizer) disrupt activity-dependent Arc (model IEG) transcription. The toxins were administered to primary cortical neuronal cultures at different doses and developmental ages with either bicuculline - to measure synaptic signaling, or Tetrodotoxin (TTX) and phorbol myristate acetate (PMA) in tandem - to induce MAPK intracellularly through PKC. Arc pre-mRNA levels were then amplified by one-step RT-PCR using intron-spanning primers and quantified by qPCR. Data demonstrates a dose-dependent attenuation in Arc induction in both MAPK activation models. This finding brings into question how MAPK- which is necessary and sufficient to rIEG induction - is attenuated by such toxins. We believe this attenuation in Arc transcription may be explained by the structurally unhindered OH groups in these compounds, which may potentially disrupt phase-separating behaviors at the synapse and/ or nucleus. IEGs are significant because they rapidly activate in response to environmental changes and exposure to these environmental toxins may disrupt synaptic plasticity. The mechanisms which these toxins may disrupt are elusive and begs for further investigation.

Abstract Name: Viral Communities in the Human Gut from Ancient to Modern Epochs

The human gut microbiome is central to health, digestion, and immune response. Gut viruses also contribute to human health, but their response to changing human diets from pre-historic to modern timescales has not

been thoroughly examined. To address this, we extracted and analyzed viral sequences from publicly available gut microbiome data, including samples from modern-industrial populations, modern-pre-industrial populations, and fossilized feces, known as coprolites. Lifestyle predictions of identified phages revealed modern samples exhibit higher proportions of temperate viruses than paleofaecal samples. This correlated with an increase in genetic hallmarkers of pathogenicity and a decline in frequencies of oxidoreductase genes involved in metabolism of toxins in gut virus communities from antiguity to modern times. Finally, clustering of viral metabolic gene composition revealed industrial samples exhibited higher homogeneity than pre-industrial and paleofaecal samples. Altogether, this shows that the modern human gut virome has lost metabolic diversity, is likely less resistant to toxic secondary metabolites, and is more temperate than pre-historic and pre-industrial populations, to deleterious effect on modern health.

Abstract Name: Simulation-Based Optimization of IceCube-Gen2 Modules for Enhanced Sensitivity to Neutrinos from Galactic Core-Collapse Supernovae

The IceCube Neutrino Observatory is capable of detecting high-energy astrophysical neutrinos from unknown sources as well as bursts of MeV neutrinos produced by galactic core-collapse supernovae (CCSNe). Propelling this capability forward, the upcoming IceCube-Gen2 telescope will encompass nearly tenfold the volume of its predecessor, incorporating cutting-edge multi-photomultiplier-tube Digital Optical Modules (mDOMs) and Wavelength-shifting Optical Modules (WOMs) presently undergoing development and testing. The design of the new modules will have a significant impact on the sensitivity of IceCube-Gen2 to supernova neutrinos. To gauge sensitivity and refine sensor design, we devised a high-fidelity simulation based in GEANT4, focusing on mDOMs and WOMs, accounting for depth-dependent ice properties enveloping the modules. The simulation allows for the direct injection of signal events, encompassing supernova neutrino flux with varying progenitor masses, as well as background events stemming from the radioactive decay of trace elements within the detector. Leveraging the mDOM simulation, we conducted an analysis of local coincidence in detected neutrinos and investigated a novel methodology termed "coincidence cuts" to attenuate background events and minimize the false detection rate of galactic CCSNe. Additionally, the WOM simulation yielded promising outcomes by shifting Cherenkov radiation—produced by the charged particles generated through neutrino-nuclear interactions in ice—from the ultraviolet wavelength to the visible range, where the detectors exhibit peak sensitivity. Consequently, we anticipate WOMs to exhibit heightened sensitivity to supernova neutrinos compared to existing detectors in IceCube. These simulations play a pivotal role in the optimization of neutrino detectors in IceCube-Gen2, enhancing their sensitivity to MeV neutrino bursts from CCSNe. Given the rarity of core-collapse supernovae occurrences in our galaxy, transpiring approximately once a century, it is imperative to maximize detector sensitivity to capture this singular astronomical event.

Abstract Name: Patriarchy, Economy, and Puritanism: Slavery's Development in Colonial Massachusetts

Though slavery had a crucial role in the socioeconomic development of the United States, its influence in the North gradually decreased relative to the South. This paper, through a focus on Massachusetts from 1700 to 1754, takes an encompassing inspection into the factors catalyzing that divergence. First, the colony's rocky soil, short growing season, and high fertility rate reduced plantation size and owners' purchasing power. Planters often bought slaves in the spring and sold them in the winter, not having the resources to keep them for the entire year. This economic system prevented the accumulation of a stable slave labor force, exacerbated by constant fluctuations in the Atlantic trade markets. Second, many citizens of Massachusetts exerted constant political pressure against introducing more Africans to protect domestic labor. Numerous damaging public depictions of African Americans- such as semi-prominent merchant John Saffin labeling them "cowardly and cruel… libidinous, deceitful, false and rude"- illustrated an increasingly galvanized public opinion against slave importation. Finally, the majority of Massachusetts' citizens adhered to Puritanism, with its obsessive adherence to the Bible and constant discussion of religious scripture. Although not all spiritual leaders opposed slavery, the egalitarian Puritan ideology catalyzed public debate over its legitimacy. This paper examines why arguably the driving institution for the first two centuries of American history bifurcated between the North and South. Rather than augmenting the widespread notion that the Northern colonies dramatically abolished slavery because of their moral superiority, it recognizes that economic and political calculations were equally responsible for its steady, almost imperceptible erosion.

Abstract Name: Identification of novel ACSS2 inhibitors in regulating breast cancer brain metastatic growth

Triple negative breast cancer accounts for about 15% of all breast cancers. The overall survival rate of these patients is 77% but drops to 12% once tumors metastasize to the brain which equates to less than 6 months. There are currently no effective drug treatments for patients with brain metastasis, thus there is an urgent need to develop novel treatment strategies. Breast cancer cells that have metastasized to the brain depend on acetate for growth and survival rather than glucose. The acetyl CoA synthetase 2 (ACSS2) enzyme converts acetate to acetyl CoA which is critical for the fatty acid production and gene regulation in tumors in the brain. Our lab has previously shown that genetically targeting ACSS2 can reduce the growth and survival of breast cancer brain metastasis cells in the brain. Further, we have identified novel ACSS2 inhibitor analogs that can cross the blood brain barrier to treat breast cancer brain metastasis. Here, we tested novel secondary analogs of ACSS2 inhibitors for anti-cancer effects using breast cancer brain metastatic (BCBM) cells in vitro and whether they blocked downstream targets of the ACSS2 metabolic pathway. Here, we show that treating BCBM cells with inhibitors 2749, 7033 and 4855 was able to block cell growth measured by crystal violet staining with 4855 having similar effect as first-generation analog 8007. These novel inhibitors were tested further through western blotting and show that novel ACSS2 inhibitor 4855 lead to a reduction in E2F1: a downstream protein of the ACSS2 metabolic pathway. These results suggest a crucial role for ACSS2 in the regulation of breast cancer brain metastasis and identifies ACSS2 inhibitor 4855 as a potent novel ACSS2

inhibitor of BCBM cell growth and supports further testing of these drugs as novel therapeutic agents for the treatment of breast cancer brain metastatic growth.

Abstract Name: Battery Discharge Tests Using Real Load Profiles for off-Grid Power Systems

Over 100,000 people in the U.S. lack access to grid electricity, most of whom live on Native American reservations or other Tribal Lands such as the Navajo Nation. Off-Grid renewable energy solutions using photovoltaic modules and battery banks can be used as an alternative to grid electricity. Off-grid systems can suffer outages not because the equipment has failed or the system was installed incorrectly, but because the batteries are unable to adequately serve the load. Selecting the appropriate size of battery for an off-grid system can be challenging. One reason is that the capacity of a battery is rated assuming it delivers a constant load current, which rarely happens in actual electrical systems. A battery's performance can be greatly influenced by fluctuations in load, which can lead to unexpected performance, reduced lifespan, and even safety concerns. This research aims to comprehensively investigate and analyze the performance of lead acid batteries by discharging them according to actual load profiles from residential off-grid systems on the Navajo Nation. A 183Ah gel lead acid battery is discharged using a programmable DC load to investigate how varying discharge currents affect the capacity of the battery. A better understanding of how battery capacity is affected by varying loads can improve the design of battery banks in off-grid systems. The work is part of a multi-year National Science Foundation-funded collaborative project between Seattle University (SU) and Navajo Technical University (NTU), in partnership with the Navajo Tribal Utility Authority.

Abstract Name: Measuring and Analyzing the Retention of Entrepreneurship Education at Musashino EMC: Through AI analysis and Measurement of the Global Entrepreneurship Monitor

In today's uncertain world, we are developing an entrepreneurship education program that takes into account the current social conditions represented by VUCA (Volatility, Uncertainty, Complexity, Ambiguity). Musashino EMC will open in April 2021 as the first four-year university entrepreneurship department in Japan. This study included all videos recorded of online-type 1-on-1 meetings between faculty and students that were conducted in April for all second-year students of Musashino EMC.Meetings were recorded using the ZOOM functionality, and AI analysis by I'mbesideyou was performed. in I'mbesideyou's AI analysis, based on emotion indices such as Happy, Angry, Neutral, Sad, Fear, and Surprise, "percentage of statements", " The mental health index was calculated based on the emotional indices of Happy, Angry, Normal, Sad, Fear, and Surprise, with three additional analysis items: "percentage of comments," "negatives and positives

of comments," and "speaking speed. By comparing these results with the Global Entrepreneurship Monitor (GEM), a representative survey of entrepreneurship, 20 participants were selected as those with large and small changes in the mental health index.In addition, the GEM model's entrepreneurial activities have a significant impact on a nation's economic growth, and are composed of "Attitude," "Activity," and "Aspiration. Questionnaires were created to check the degree of achievement of these three items from the Musashino EMC curriculum, and a questionnaire survey was conducted on 20 selected students. The survey was conducted on 20 participants to measure the effectiveness of Musashino EMC's education and to evaluate the effectiveness of Japan's first entrepreneurship department in the world. In a recent survey conducted to measure the level of achievement at Musashino EMC, more than half of the students subjectively indicated that they were able to retain their skills, but we intend to further deepen our understanding by extracting the population based on the results of AI analysis.

Abstract Name: Evaluating Blood Biomarkers to Predict Surgical Success in Patients with Degenerative Cervical Myelopathy

Degenerative Cervical Myelopathy (DCM) is defined as age-related osteoarthritis that results in the narrowing of the cervical spinal canal, leading to chronic spinal cord compression and neurological disability. The most common treatment for DCM is decompression surgery. Currently, there is no predictive measure to assess the chances of surgical success in patients before surgery. The disparity between patients who achieve surgical success and those who don’t remains unknown. In medicine, blood biomarkers have become an incredible tool to help identify disease presence, disease severity, and surgical success. Current literature has found a strong correlation between several biomarkers and common neurological and spinal cord diseases. Currently, no such biomarker exists for DCM. In this study, the pre-operative and post-operative blood work of 15 patients has been evaluated to assess the levels of GFAP, AB42, AB40, APOE, and NeFL as potential biomarkers for DCM. Through a preliminary ELISA screening, followed by a secondary Simoa assay, APOE was the most relevant and identifiable biomarker in patients with DCM. Pre-operative blood work displayed elevated levels of APOE in patients with DCM compared to baseline levels. Post-operative blood work revealed that surgery resulted in a statistically significant decrease in APOE in patients. Patient recovery was assessed utilizing the mJOA scoring system which evaluates sensory and motor health before and after surgery. Patients with greater levels of APOE achieved greater “percent recovery” than their counterparts. The current data supports the potential use of APOE as a viable biomarker to evaluate surgical success.

Abstract Name: Data Analysis on EdTech Investments in Private Equity via Pitch

Affordability, accessibility, and relevancy remain pressing concerns within higher education. The integration of technology into educational practices presents a promising avenue for addressing these challenges. Venture Capital firms increasingly support educational technology (EdTech) companies, signaling potential shifts and innovations in higher education. Investigating these investments offers insights into forthcoming solutions within the educational sphere.This study delves into the landscape of Private Equity Funds investing in Education Technology using comprehensive data from Pitchbook. By leveraging this directory, we construct a robust database encompassing crucial metrics such as the Internal Rate of Return (IRR), Liquid Cash (Dry Powder), Fund Size, the ratio of EdTech to non-EdTech investments, alongside detailed information about investees, including funding amounts. Our analysis focuses on discerning patterns, including the average investment received by EdTech companies and disparities in capital allocation between funds solely dedicated to EdTech versus those with partial investments.Unveiling these investment trends not only sheds light on financial aspects but also facilitates strategic matchmaking between aspiring EdTech entrepreneurs and Private Equity firms inclined towards investing in this domain. Furthermore, this comprehensive dataset enriches our comprehension of the EdTech landscape, potentially guiding future innovations and policy decisions in higher education.This research aims to contribute significantly to understanding the dynamics of EdTech investments in Private Equity, offering actionable insights and fostering collaborations that drive positive transformations in the education sector. The utilization of Pitchbook data enables a nuanced exploration, opening avenues for informed decision-making and fostering a more conducive environment for EdTech advancement within the educational landscape.

Abstract Name: De novo Identification of Flagellar Microtubule Doublet Proteins in Trichomonas Vaginalis Using Cryo-Electron Microscopy

Trichomonas vaginalis (Tv), the flagellated extracellular protist and causative agent of the sexually transmitted infection, Trichomoniasis, is implicated in many perinatal complications, male and female UTIs, and increased rates of HIV transmission. The Tv flagella, composed of an arrangement of outer microtubule doublets (OMDs) forming a ring around a central pair of microtubules, produces a unique undulating motility that facilitates locomotion and host cell adherence. Currently, the lack of a high-resolution structure for the Tv OMDs presents a gap in our understanding of integral proteins for flagellar assembly and their potential applications in drug development. To address this, we utilized cryo-electron microscopy (cryo-EM) to image the OMDs of Tv flagella. Using single particle analysis, we successfully resolved a high resolution 3.65 Å (.37 nanometer) reconstruction of the OMDs from around 83,000 particles. We identified ~35 distinct internal and external proteins by fitting atomic models of proteins from our mass spectrometry data into our reconstruction. We designated two previously uncharacterized proteins, CCDC_347810 and CCDC_165330, at the junction where the α and β tubule converge, forming the doublet. Based on homologous comparison with sea urchin and bovine sperm microtubule proteins, we suspect these two unidentified proteins are

involved in junctional stabilization of the OMDs and outer radial spoke association, supporting Tv's flagellar beating. This work elucidates the structures which contribute to the stability of the OMDs and the OMD's connection with other flagellar proteins. More broadly, this research unveils novel protein densities that provides a molecular basis for targeted therapies against Tv.

Abstract Name: Enhancing 3D Molecular Visualization in College-Level Chemistry Education

The ongoing research initiative is a comprehensive response to the imperative need for elevated understanding of three-dimensional (3D) molecular structures within higher education. The inadequacy of conventional teaching approaches reliant on two-dimensional (2D) diagrams and physical models has catalyzed the exploration of innovative methodologies to address this educational gap. Within the expansive landscape of higher education, this project sets forth overarching goals aimed at the enrichment of chemistry education and the fostering of inclusivity through the strategic utilization of virtual reality (VR) technology. The multifaceted objectives encompass not only enhancing student comprehension of complex 3D molecular structures but also amplifying engagement, elevating academic performance, and ensuring equitable access to cutting-edge technology, particularly among underrepresented groups. The implementation of this ambitious project involves a nuanced set of key methodologies, including the meticulous development of pre and post-VR exposure assessments, the creation of VR-enhanced educational games, and the orchestration of pilot programs accompanied by comprehensive student assessments. The significance of this endeavor transcends institutional boundaries, resonating on local and regional levels by contributing to the enhancement of chemistry education quality and actively addressing educational disparities. By deliberately extending access to state-of-the-art technology to underrepresented groups, the project acts as a catalyst for nurturing a more educated, skilled, and diverse workforce—a testament to the broader societal impact of integrating advanced technology into education.

Abstract Name: Touch Dynamics: A Biometric Authentication Method for Mobile Devices

The widespread adoption of smartphones has led to a growing demand for secure and convenient identity authentication methods. Touch dynamics, which analyzes the unique characteristics of an individual's touch behavior, has emerged as a promising biometric modality for mobile devices. This paper provides a comprehensive overview of touch dynamics-based authentication, covering its underlying principles, system architectures, feature extraction techniques, classification algorithms, and performance evaluation metrics.

Additionally, the paper discusses the advantages and limitations of touch dynamics compared to traditional biometric methods, such as fingerprint and facial recognition. Furthermore, the paper explores the potential applications of touch dynamics beyond authentication, such as user profiling and affective computing.Despite its promising potential, touch dynamics-based authentication faces challenges that warrant further exploration. Enhancing robustness against environmental factors, mitigating the impact of device variations, and addressing concerns regarding privacy and security are crucial areas for future research. By addressing these challenges, touch dynamics can become a ubiquitous and trusted biometric modality for mobile devices, revolutionizing the way we interact with technology. The research anticipates that touch dynamics will demonstrate promising results in terms of authentication accuracy, robustness, and user acceptability. The discussion will address the implications of the research findings for the future of biometric authentication and mobile security.

Abstract Name: Global Sustainable Stock Portfolios From an Investor’s Perspective

Sustainability is an increasingly important aspect of our world. Yet many stock investors are unfamiliar with sustainable investments and, therefore, do not consider them a relevant alternative to traditional investments. Our goal is to compare sustainable investments to traditional investments and propose sustainable investment strategies. We used B-Lab certification as a sustainability benchmark. B-Lab certification is obtained by companies that work rigorously to maintain high scores on the globally used environmental, social, and governance scale (ESG). B-lab certification is challenging to attain and maintain, so it has become a critical standard to identify sustainable investments. To show investors how sustainable stock investments compare to traditional alternatives, we plan to compare stock portfolios of publicly traded B-Lab certified companies to the S&P 500. Our team also plans to conduct event analyses to measure the effects of particular global events on the performance of sustainable portfolios. We will consider events such as statements made by Elon Musk on social media regarding sustainability. Lastly, we are interested in analyzing sustainable investments according to traditional portfolio management strategies such as small companies vs large companies, domestic vs international, and per-industry performance. We hope to share valuable knowledge about sustainable investment alternatives and propose potential investment strategies. We are convinced our findings could potentially draw the attention of more investors to many overlooked investment opportunities.

Abstract Name: Recreation Centers and Youth Mental Health: A Dual Theoretical Exploration

In this presentation, I will present a conceptual framework to study the role that recreation centers play in enhancing the mental health among youth. Amidst the growing concern of mental health disorders among youth, specifically within low socioeconomic groups, these community centers can offer vital support. The presentation underscores the unique position of recreation centers as accessible and inclusive spaces that provide a range of activities to foster mental well-being and social interaction.Opportunity theory and social capital theory are employed to understand the impact of recreation centers. Opportunity theory suggests that the activities and programs available at these centers provide young people with positive experiences and skill-building opportunities, which are crucial for their psychological development. Meanwhile, social capital theory emphasizes how these centers build community bonds and a sense of belonging that lead to a social network and can buffer negative mental health outcomes.Empirical data is reviewed to demonstrate how regular engagement in recreation center activities correlates with improved mental health outcomes. These include reduced symptoms of depression and anxiety, improved self-esteem, and better social skills. This suggests that recreation centers serve not only as spaces for physical activities but also as safe environments for emotional and social development. It also sheds light on the potential of these centers in reducing the demand for formal mental health services by providing a supportive and engaging community environment.The presentation concludes by emphasizing the need for further empirical research to strengthen the evidence base for the role of recreation centers in mental health promotion. It advocates for policy changes that recognize and support these centers as vital assets in public health strategies, particularly for youth mental health.

Abstract Name: Dynamic shape changing terrain for robotics locomotion

The indoor construction of terrains is a preferred approach to robotic locomotion verification due to its convenient access to various monitoring and computing equipment that is typically hard to deploy outdoors. Some standard practices include a human arrangement of bricks, boxes, and panels, and a more uniform composition with wooden blocks. Nevertheless, robotic experiments may require different terrestrial features and it is tedious and challenging to manually reconstruct various empirical environments in a timely manner.The above issue can be overcome by automating the terrain reconstruction and the literature suggests that such automation can be achieved through shape-changing interfaces concentrating more on user haptic interaction. As an adaptation to more aggressive actions, the Walkable Pin-Array target on larger scales and heavier surface payload, yet still coerces the actuator quantity agreeing with the terrain width and the pin-locking mechanism in a row-consistent manner. To this end, we propose a scalable dynamically-reconstructable terrain that is inspired by the Pin-Array but has few limits on the actuation and the pin-locking mechanism. The terrain prototype enables an independent self-locking-unlocking mechanism for each pin without compromising the pin payload. It also features a coreXY gantry that allows rapid relocating of at minimum one linear actuator to maneuver pins' height. Online planning and control are applied to locally realize the target terrain morphology in almost real time, followed by adaptation to any global scale. In this way, the proposed terrain platform can approximate more dynamically varying environments at different scales.

Abstract Name: Computational investigation of ortho toludinium carboxylate ionic liquids to increase antimicrobial activity against fungi and bacteria

Bacillus cereus, Escherichia coli, and Aspergillus niger are some of the most common bacteria and fungi which people get infected with every year. Approximately there are 63,400 cases of Bacillus cereus, 95,000 cases of Escherichia coli, and 4.8 million cases of Aspergillus niger. Ionic liquids (ILs) are a commonly used substance with unique and versatile properties, allowing them to be used in a wide range of applications due to their distinctive properties. They're commonly used in fields such as electrochemistry and energy, recently they've been rising in popularity in the medical field as they demonstrate strong antimicrobial activity. This research aims to test if ILs, specifically ortho toluidiniummethanoate, ortho toluidiniumacetate, ortho toluidiniumpropanoate, ortho toluidiniumbutanoate, and ortho toluidiniumtrifluroaccetate can be used with a range of different proteins such as Bacillus cereus, Escherichia coli, and Aspergillus niger. Optimizations of IL ligands using the Density Functional Theory and B3LYP/6-31+G(d,p) basis sets were done in Gaussian 16. Mathematica was then used to complete calculations to find LUMO, HOMO, HOMO LUMO gap, ionization potential, electron affinity, chemical hardness, chemical softness, electronegativity, chemical potential, and electrophilicity index. VINA was then implemented last to create docking poses between the substrate and the IL ligands, which allowed for the testing of binding affinities. Our results indicate strong affinity between these ligands and proteins found in these bacteria and fungi.

Abstract Name: Investigating ASXL Variation in Leukemic Cell Lines

Addition sex combs-like 1 (ASXL1) is a protein involved in cellular differentiation, epigenetic modification, and transcriptional regulation. The gene that codes for ASXL1 consists of 13 exons and 12 introns. In acute myeloid leukemia (AML), as well as many other myeloid malignancies, ASXL1 is frequently mutated. These mutations have been observed in approximately 20% of patients with myelodysplastic syndrome and in individuals diagnosed with AML. ASXL mutations have also been found in lymphoid leukemias, but at a much less frequent rate (~2%). These mutations can result in abnormal splicing, termination, or missense mutations. Abnormal splicing can result in a mutated protein that is larger or smaller than normal, while a termination mutation results in proteins that are smaller than normal. Protein size can be detected through gel electrophoresis and western blot analysis, using specific antibodies that bind to ASXL. The most common splice variant of ASXL1 is 166 kDa in size. This study aims to compare the size of ASXL1 in two different leukemia cell lines. Using an ASXL1 Monoclonal Antibody (11I4), we were able to compare ASXL1 in HL60 (AML) to ASXL1 in Jurkat (acute t-cell lymphocytic leukemia). We were able to confirm the presence of alternative forms of ASXL1 in both HL60 and Jurkat. In both cell lines ASXL1 was smaller than normal. In Jurkat cells ASXL1 was approximately 45 kD, while in HL60 cells the protein was 34 kDA. This difference in size could be a result of normal alternative splicing, abnormal splice mutations, or termination mutations which result in truncated, and therefore smaller, proteins. Further research should be done to sequence the genes to determine whether these leukemic cell lines carry mutations (splice-site or termination)

or whether they are normal splice variants and whether these abnormal proteins contribute to the uncontrolled, leukemic, growth in these cells.

Abstract Name: The Construction of a Cross-Disciplinary Space for Creative Interaction: The Gertrude Stein Salon during the formation of Modernism

This study explores the historical precedent of interdisciplinary collaborative spaces within the Parisian Salon system of early Modernist 20th Century France using the Gertrude Stein Salon as a case study. The model of the multi-disciplinary higher education makerspace and its role within the creation of student collaborative relationships in university contexts may be identified as a contemporary version of the Parisian Salon system. To understand the development of the interdisciplinary collaborative space and the dynamic relationship that such spaces create, a literature review was conducted of articles from 1958 - 2022. The primary research focuses were the Modernist Gertrude Stein Salon, the formation of relationships between artists such as Picasso and Matisse, the precedent of the contemporary collegiate makerspace, and the importance of collaborative dynamics and relationships within higher education campuses. Two major differences between the historical Paris Salons and its contemporary counterpart of the interdisciplinary makerspace were identified; The Paris Salons were characterized by a comparatively informal and personal collaborative nature while the contemporary makerspace offers technical and non-technical equipment and support that were not present in the Paris Salon system. Injecting the informal, personalized, and discussion-based nature of the 20th Century Parisian Salon into the contemporary interdisciplinary collegiate makerspace will create a space within university campuses in which students are supported and encouraged to collaborate and form interdisciplinary relationships that further foundational knowledge, form industry connections, and create career-long interdisciplinary interactions.

Abstract Name: Evaluating the role of glycoprotein LRG-1 on delayed neurological deficits after a subarachnoid hemorrhage

Subarachnoid hemorrhage (SAH) is a highly serious condition where blood vessels in the brain burst and can cause bleeding in the space surrounding the brain. This condition has a 40-50% mortality rate and annually affects 30,000 people in the United States alone. Additionally, 20-30% of SAH survivors experience further neurological decline, the most common being delayed cerebral ischemia, and these symptoms have been identified as the leading cause of mortality for SAH survivors. It is crucial to understand why these deficits occur and how patient outcomes after a subarachnoid hemorrhage can be improved by specifically targeting

these conditions. Leucine-rich alpha-2 glycoprotein, or LRG-1, is known to cause disease progression and promote angiogenesis, and studies have shown that LRG-1 can promote apoptosis through the TGFβ signaling pathway, causing ischemic effects to be more aggressive. However, if LRG-1 is silenced, the signaling pathway is inhibited and this can lead to less inflammation. In autoimmune and cardiovascular diseases especially, the elevation of LRG-1 has directly led to disease progression, which indicates that it can be a possible biomarker and target for certain conditions. Currently, detection methods are lacking to screen patients for complications directly after SAH, which raises the questions of if LRG-1 contributes to cellular damage following SAH for patients who experience ischemic defects. Previous research has shown a correlation between increased LRG-1 levels after SAH in mice, but this study aims to evaluate and understand specific LRG-1 expression patterns after a subarachnoid hemorrhage. This will be accomplished by using cell culture models with LRG-1 and hemoglobin, immunofluorescence assays, and endoglin-specific assays with plasma and mice brains. For future outlook, the takeaways of this project will be used towards implementing LRG-1 inhibition after a subarachnoid hemorrhage to test its therapeutic potential as a biomarker.

Abstract Name: Metabolic Rewiring Elucidates Metastatic Behavior in Non-Small Cell Lung Cancer

During metastasis, cancer cells detach from the primary tumor and migrate through the circulatory system. Most cancer cells die from oxidative stress during this process. How the remaining cells adapt to survive this stress is largely unknown, but a key hypothesis is that circulating tumor cells (CTCs) rewire metabolic programs to adapt to these stresses. In this work, we investigated the metabolic differences between anchorage-dependent and anchorage-independent growth in non-small cell lung cancer (NSCLC). A key limitation in this area is that standard cell culture conditions do not accurately recapitulate the in vivo environment. To more accurately model the in vivo environment, we cultured NSCLC cells in human plasma-like media (HPLM), which better recapitulates the physiological nutrient concentrations of the blood. To investigate differences in metabolic activity between anchorage-dependent and independent growth, we cultured cells under standard or physiologically relevant conditions. We performed stable isotope labeling with key nutrients (glucose, lactate, glutamine, etc.), and preliminary results indicate key metabolic and proliferative differences across these conditions. Cells cultured in HPLM use less glucose and glutamine to fuel the TCA cycle compared to standard culture conditions, and non-adherent cells are primarily using glutamine to fuel TCA intermediates. We are currently leveraging these metabolic differences to identify novel therapeutic strategies to target CTCs. These assays are a starting point for ongoing in vivo models of circulating tumor cells, allowing for investigation of the metabolic phenotypes of CTCs from novel patient-derived xenografts.

Abstract Name: Unlocking the Seasonal Secret: How Season of Birth Shapes Adult Mental Health Outcomes

The season of birth serves as a useful proxy or indicator of the various environmental conditions throughout the perinatal period. The season of birth has been largely studied in the context of severe neuropsychiatric disorders, particularly schizophrenia. However, research pertaining to common mental health disorders remains limited. Depression and anxiety continue to be leading causes of global disability and premature mortality, significantly contributing to the large and increasing health burden worldwide. Therefore, this study sought to fill the existing knowledge gap by investigating the association between the season of birth and symptoms of depression and anxiety among adults using a survey-based cross-sectional research design. Primary data was collected using a comprehensive questionnaire developed to encompass demographics, health behaviours, health outcomes, as well as birth, early life, and family history information. Depressive symptoms were assessed with the Patient Health Questionnaire (PHQ-9) and symptoms of anxiety with General Anxiety Disorder 7-Item (GAD-7) scale. A mixture of descriptive and inferential statistics was used to analyze the data. Generalized Linear Mixed Model (GLMM) analysis was performed to determine any observed associations between season of birth, life history traits, depression and anxiety. Understanding this relationship could potentially help characterize the season of birth as an additional risk factor that influences susceptibility to certain mental health conditions in one's lifetime. Gaining insight into this association is critical for planning prevention efforts, assessing susceptibility, and providing targeted interventions for at higher-risk individuals. This presentation will present the main findings of this survey and provide insights into how the environment and genetics can influence mental health.

Abstract Name: Electrostatic Properties of Alpha-Crystallin Domain of HSPB5 and its Effect on Chaperone Activity

When a cell undergoes stress conditions, such as oxidation or ageing, an increase in protein instability can occur and prevent proper cell functions. Small Heat Shock Proteins (sHSPs) are molecular chaperones that work to maintain a healthy proteome by associating with misfolded "client" proteins to delay aggregation under such conditions. HSPB5, a human sHSP, is ubiquitously expressed throughout the body. HSPB5's disease mutant, R120G, is a defective chaperone associated with cataracts and desmin-related myopathy. It is still unknown how this mutation is detrimental despite many years of research. My research aims to understand how this mutation retunes the electrostatic properties of HSPB5, affecting its chaperone activity. Residue R120 is part of an electrostatic network that helps create an important structural feature in the folded region of HSPB5, the alpha-crystallin domain (ACD). In the unmutated (WT) protein, the ACD surface is overall positively charged. Substitution of the positive R120 to glycine alters both ACD's structure and electrostatics. I generated two mutants, R120K (retaining positive charge) and R120D (switching to negative charge) to investigate how R120 plays a role in ACD's conformation. Using a negatively-charged molecule, ATP, as an "electrostatic" probe in 2D NMR, I observed differences between its binding affinity to my R120

variants. I found that only R120K ACD behaves similarly to WT ACD, suggesting a possible correlation between charge potential and ACD's interactions with ATP. Currently, I am investigating if charge potential affects chaperone activity through aggregation assays with a client protein, human γD-crystallin, found in the lens and implicated in cataracts. I predict that WT and R120K, with similar electrostatic properties, will have similar chaperone activity. R120G and R120D, prevalently in an "active" state, will have higher chaperone activity. Understanding how such mutations affect HSPB5's conformations and chaperone activity is a step forward in understanding sHSPs' chaperone mechanism.

Abstract Name: Fun with Fractran

Fractran is an esoteric programming language developed by a renowned mathematician, John Conway. In contrast to traditional programming languages, Fractran operates in the realm of pure mathematics, using fractions to represent the algorithm and its execution. The essence of Fractran lies in its minimalist approach to computation. Programs in Fractran consist of a sequence of fractions, each representing a transformation rule. These rules dictate how the program evolves, with the computation progressing through a series of multiplications and divisions involving rational numbers. The elegance of Fractran lies in its ability to harness the simplicity of fractions to express complex computational processes. Despite its simplicity, it is Turing-complete and has the important advantage that the Godel number can be explicitly computed for any program. This poster delves into the essentials of Fractran, the advancements made in the previously designed code– PIGAME, and a newly designed code– SQRT2GAME, together with the necessary proofs.

Abstract Name: Psychological Mechanisms of Epistemological Processes: A Spinozan Model of Belief Acquisition

The questions of how and when individuals believe or disbelieve a novel proposition following mental representation have remained unresolved within epistemological discourse. Contemporary research testing belief-fixation has focused on memory activation during veridical judgements. Support for the Spinozan or "ballistic" model represents the growing challenge to the widely accepted Cartesian or "static" model. However, criticism of the ballistic model has framed its necessary assumptions inaccurately. This warrants reiterating its basic assertions, as many of these dissenting findings suggest support for the model with proper consideration. We used evidence from three experiments testing declarative memory errors to argue for the core principle of the Spinozan view: simultaneous to comprehension of novel information is initially regarding it as true. Each experiment used variations on the Dispositional Judgement Task; participants were

presented statements labeled as true or false followed by a memory recognition test consisting of half novel and half old statements. Statements were rated for similarity and mutual exclusivity relative to those initially seen initially in a pretest. These categories were then compared for differences in belief bias. Results from each experiment found greater instances of false-errors than true-errors, an imbalance in “falsification bias” that aligns with predictions following from the core features of the ballistic model, while still upholding its compatibility with features of belief previously alleged as inconsistencies. The current article aims to establish these core features, isolating them from unsupported additions and revising the original discussion of our findings using a mixed-effects model to show their true potential. An adapted version of Cook & O'Brien’s activation pattern as passive, dumb, and “smart” was incorporated to describe the relationship between propositions and extant memories. This reframing explains spontaneous disbelief and the observed falsification bias as a result of comprehension requiring propositions to be initially believed prior to being judged.

Abstract Name: Memory and Identity in Julia's Alvarez How the Garcia Girl's Lost Their Accent

The life of an immigrant can be one of ambiguity, two languages, two faces, two identities. Trapped between two worlds, an individual often finds it difficult to discover their true self. Memories of the past surround all aspects of their lives, creating a conflict between the old and the new. An identity not yet formed faces assault from both directions, leaving an individual alone and isolated from both cultures. This clash is discussed in Julia Alvarez’s novel How the Garcia Girls Lost Their Accents (1991) through the lives of the four Garcia sisters who immigrated to the United States from the Dominican Republic as a family in order to escape political persecution under the Trujillo regime. Together they have difficulty assimilating to the culture of the United States. The parents desire the idea of the old country, but the girls crave new freedoms and experiences in New York. Yolanda, the primary perspective, struggles with this question of identity throughout her life, returning at the beginning of the book to the Dominican Republic in an attempt to understand herself. From that moment against the clock, the story is told backwards, retelling the story of the Garcia family as it was. The Garcia family is not alone in their experience. Starting in the 1950s, thousands of Dominicans immigrated to the United States in order to escape the tyranny of Rafael Trujillo. This work analyzes the effect of memory experienced by the character Yolanda in the novel, How the Garcia Girls Lost Their Accents in order to explore the multi-faces and challenges of identity often encountered and negotiated by those navigating biculturalism.

Abstract Name: Impact of Immigration Policies on National Economies: A Global Analysis

Exploring the intricate relationship between immigration policies, political dynamics, and the economic well-being of nations, this study leverages data from The World Bank, a global institution representing member nations. Focusing on the influence of open border policies on a country's economy, my research investigates the changes in immigration policies that occur during political transitions and their consequential impact on both the influx of immigrants and the overall economic state. Using the data from member nations, I explored the correlation between a nation's acceptance of immigrants and its economic performance. The comprehensive dataset employed in this study provides a rich source of information, enabling me to analyze trends and draw meaningful connections between immigration policies and economic indicators. My findings reveal a strong correlation between countries with open immigration policies and those boasting higher GDP per capita and standards of living.This research contributes to the understanding of the global economic impact of immigration policies, shedding light on how political decisions shape a nation's openness to immigrants and, consequently, its economic prosperity. The implications of this research extend beyond individual nations, offering insights into the broader discourse on the economic consequences of immigration policies. My study aims to inform policymakers, researchers, and the general public, fostering a more informed and evidence-based discussion on the interplay between immigration, politics, and national economies.

Abstract Name: Exploring the Spectrum of Non-Invasive Blood Glucose Monitoring: Wavelength and Physical Factors

Diabetes and metabolic diseases are among the most pressing health concerns of our time. Currently, monitoring blood glucose, a pivotal indicator of these conditions, involves the cumbersome process of frequent blood drawing or subcutaneous needle injections. Fortunately, the drive for precise, non-invasive glucose monitoring methods has intensified, leveraging technological advancements in diverse wavelength multispectral imaging. These devices adopt lasers with photodiodes or cameras to correlate blood glucose with imaging data, building safer, cheaper, and more reusable procedures for measuring blood glucose. Nonetheless, numerous facets of this process remain unexplored. Light wavelength substantially influences estimations' accuracy due to the diverse interactions between wavelengths and skin. Additionally, several patient-related physical factors, including skin color, temperature, humidity, and skin texture, that further impact the light’s transmittance and absorption. To examine these variables, we engineered a device that harnesses a range of light wavelengths, from 650nm to 980nm, to gather data from human subjects. Concurrently, we measured physical factors, including skin temperature, humidity, skin color, and skin texture. Our methodology starts with the collection of physical factors, followed by blood glucose measurement with traditional glucometers, and ends with capturing image data from all wavelengths. Then, we construct estimation models for each wavelength. Performance is compared through three distinct methodologies and metrics: statistical accuracy with Mean Absolute Error, clinical accuracy through correlation with Clarke Error Grids, and clinical accuracy through agreement with Bland-Altman Plots. Subsequently, we extend this evaluation across all physical factors, exploring their impact on overall model performance across our chosen metrics. After reviewing recent literature, we anticipate a weak, positive relationship between wavelength and the accuracy and precision of models. Moreover, we anticipate skin color and humidity to influence performance the most with a negative relationship between wavelength and the influence of factors.

Abstract Name: Students Academic Success Prediction Using AI/Machine-Learning Models

This study delves into the complex relationship between students' mental health, social behaviors, and academic success. Utilizing a robust dataset from Kaggle, originally collected by Dartmouth University, we explore how factors such as depression, stress, loneliness, and everyday social and personal behaviors influence students' academic performance. Standardized questionnaires adhering to international standards, including PHQ-9, PSS, Vr_12, PSQI, Panas, Flourishing Scale, Loneliness Scale, and Big Five, were distributed among students to gather comprehensive data. Our analysis employs advanced machine learning algorithms, including LGBM Classifier, Snap Boosting Machine Classifier, and Snap Forest Random Classifier, on the IBM Watson platform. This approach builds on our previous investigation, where academic stress was linked to students' GPA. The current study's models demonstrate accuracies ranging from 70%-80%, varying based on algorithmic adjustments and enhancements like HPO-1/HPO-2/FE. This paper presents detailed project summaries, ROC Curves, and Confusion Matrices for each model, offering a comparative analysis to our previous work. The initial results indicate a significant impact of stress, depression, and loneliness on academic performance, highlighting the importance of mental health in educational settings. This study underscores the importance of holistic education, recognizing that students' well-being is intrinsically linked to their academic success. The findings of this study not only reinforce the need for holistic educational strategies but also open new avenues for utilizing machine learning in understanding and enhancing student success. This research provides valuable insights that can guide educational institutions in creating and improving student wellness programs, while also enabling the development of personalized support systems through the use of advanced machine-learning algorithms, tailored specifically to meet individual student needs. A full analysis and implications of these results will be elaborately discussed at the conference, with an anticipation that this methodology could be extended to future studies on student stress and academic achievement.

Abstract Name: Groundwater Contamination and Property Values: A Hedonic Price Analysis

About 15% of the United States population (~43 million people) rely on private wells for their source of

drinking water. This water is not regulated by the Environmental Protection Agency, and as a result, the water in these wells can contain harmful contaminants (e.g., arsenic, nitrates, and nitrites) that go undetected by homeowners unless otherwise tested. Using a dataset of housing transactions (n=3,908) in the Orlando, Florida Metropolitan Statistical Area, I examine the impact of testing well water on the property value at time of sale. In Florida, not all homes with wells are tested before sale. I address the possibility of selection bias by using a subsample of homes from this dataset (n=1566) that had all tested their well water before being sold.Using a hedonic pricing model, I test the impact of a well water test finding a contaminant above the detectable limit on sales price, controlling for housing characteristics, geospatial characteristics, and the date of sale. My results indicate a 10% decrease in property value when a well test revealed a contaminant to be above the detectable limit, relative to properties with well tests that did not reveal any contaminant above the detectable limit. The most robust, significant effects are found when homes were tested within a 3-year window prior to transaction. This has implications for the public health and financial stability of homeowners using private well water, particularly in areas that are more susceptible to extreme weather events.

Abstract Name: Cultural Learning Strategies in Ethiopia and the United States Experienced by International Students at a Mid-size Midwestern University

Cultural learning strategies refer to the methods and processes by which individuals acquire knowledge, skills, beliefs, and behaviors that are specific to a particular culture or social group. This research responded to an interest in how cultural learning strategies in Ethiopia compare to those in the United States. Ethiopian students experience cognitive dissonance, because their previous educational experiences were so different from the United States. This research will provide suggestions for current and future Ethiopians who are adapting to college in the United States. The university's international faculty interviewed current students from Ethiopia who were studying computer sciences. Open-ended interview questions will generate understandings of differences in cultural learning and how university students overcame those challenges. The outcomes of this project will guide educational policies, curricula for international student orientation, and faculty professional development.

Abstract Name: Binding studies of Methylene Blue, Pyronin Y, and Acridine Orange with Cucurbit[7]uril and Cucurbit[8]uril using Constant Constraint Analysis

Hypothesis: The "container molecule" Cucurbit[8]uril will bind similarly to tricyclic dyes (Methylene Blue, Pyronin Y, and Acridine Orange) that have very similar structures. This study will allow a better

understanding of the binding properties of these molecules, for potential future use in reactions and medicine.The size-dependent properties of cucurbit[n]urils (abbreviated as CB[n]) as hosts for tricyclic cationic dyes (Methylene Blue and Pyronin Y) are of considerable current interest. Previous work on UV-visible spectra of host-guest complexes, using Job's plots, has shown a 3:1 ratio for Pyronin Y: CB[8] and 2:1 for Methylene Blue: CB[8]. The binding stoichiometry is generally accepted as 1:1 for the smaller CB[7] and both of these dyes. We report here on a new method to determine the stoichiometry of host-guest complexation. Applying the method of Constant Constraint Analysis (CCA), an approach previously developed to deconvolute circular dichroism spectra for the secondary structural analysis of proteins, we are able to deconvolute spectral components arising from associated and unassociated dyes. We arrived with a guest:host ratio of 2:1 for both Pyronin Y and Methylene Blue and CB[8]. Preliminary results show little or no binding with CB[7] for both of these dyes. We have also extended these studies to Acridine Orange, and preliminary data show binding patterns that are similar to those of Methylene Blue and Pyronin Y.

Abstract Name: Drought and Disparities in Spain

The ever-growing threat of climate change presents increasing hazards to Spain's water supply due to its historic susceptibility to drought. This difficulty is amplified with the regional division of 17 autonomous communities, zones of Spain with their own economic organization, climates and water conservation policies. This study requires a literature review and examination of relevant government documents and secondary sources. I examine the history, climate patterns and water policy of Spain to show how Andalucía, a southern autonomous community, is unequipped to handle the impacts of climate change. The social and economic divide between the North and South of Spain stemming from the Middle Ages has created economic marginalization amid the autonomous communities. These disparities leave the South at an economic disadvantage while combatting drought related disaster. Consequences of climate change in Spain such as rising temperatures and records of drought and rainfall show that the South is at a higher risk of prolonged droughts caused by little rainfall. Furthermore, an examination of existing water policy in the South reveals archaic policies with a need for legislation reform. Overall, the North is economically secure and less prone to drought due to higher levels of rainfall. The South faces more severe impacts and has fewer resources for mitigation. The Andalucía is the agricultural epicenter of Spain, so the lack of water in this region has serious implications not only for the autonomous community but for the entire economy of Spain. This study is meant to analyze the reasons why Andalucía suffers from drought related issues. More investigation is needed to evaluate how to properly integrate changes and solutions to help assist Southern Spain with the social and economic impacts of drought.

Abstract Name: Seizure Mortality in Mice Lacking the Bmal1 Gene in Relation to Circadian Rhythm and Time-of-Day

Epilepsy is very common as 1 in 26 Americans will develop it within their lifetime. Seizures can result in death which is termed Sudden Unexpected Death in Epilepsy (SUDEP), which is more common during the night. SUDEP has the second highest years of potential life lost across all neurological diseases. Mouse models of seizure-associated death are also more likely to die during the night. The suprachiasmatic nucleus is the central circadian pacemaker. Circadian rhythms are maintained through a self-regulating transcription-translation feedback loop involving clock genes, such as Mop3/Bmal1. We hypothesized that when there is disruption of the molecular clock the time-of-day-dependent seizure-mortality will be eliminated. The first experiment was investigating mortality, seizure severity, and duration regarding time of day. Using heterozygote Mop3/Bmal1 mice we induced full hindlimb extension seizures with 50 milliamp shocks. The second experiment was investigating locomotor activity in a light dark cycle then transitioned to constant darkness. Using Mop3/Bmal1 wildtype and Mop3/Bmal1 knockout mice we measured location with actograms. Heterozygote Mop3/Bmal1 mice have low seizure mortality regardless of time of day. Seizure severity and duration were not dependent on the time of day or sex. The C57BL6J background strain did not exhibit the same low mortality. A younger cohort of the heterozygote Mop3/Bmal1 mice had similarly low mortality regardless of time of day. Mop3/Bmal1 knockout mice do not have time-of-day dependent locomotor rhythms when in constant darkness. Identifying the mechanism controlling the molecular clock could set the stage for chronotherapeutic strategies to reduce the nighttime risk of death for people living with epilepsy.

Abstract Name: Student’s Access and Agency: How are College Students Taking Control of Their Own Sex Life?

This project-oriented research thesis focuses on the importance of having contraceptvies available and accessible on college campuses, toward the goal of offering practical resources and tools to students and student groups seeking to be leaders initiating positive sexual health changes at their university. This project uses a mixed-methods approach for its research: first, I will document disparities in access that are common across campuses, using surveys and informal interviews with students and analysis of campus health websites, supplemented with phone inquiries. Second, I will be conducting informal interviews with Wayne State University's peer universities and some in-state colleges for a total of 11 universities in the participant pool. These informal interviews will be conducted with student organizations from universities across the country on changes they've been able to make for the accessibility of contraceptvies to diversify my final resource. Third, I will use my praxis-oriented activist/advocacy methodology to produce a practical online resource from my informal interviews and personal experience that outlines student organizations' possible responses to gather their data and make their own cases for reforming contraceptive access on their campuses. Interviews and gathering information from the campus health employees as well as student groups will enhance my understanding of the relationship and climate between university administration and their students, which will help me create a robust instrument students can use as a contraceptive campaign.From previous experience with this topic, the results of my research should conclude that student groups across the U.S. will have to create vigorous campaigns in addition to building coalitions with other student organizations to be able to diminish the barriers many students face when attempting to get contraceptives on

their campus. Because I am expecting this result, I intend to create a campaign plan to help students advocate for access to contraceptives.

Abstract Name: Insider/Outsider Perspectives of Civil Conflict in Music and Education

In 2022 and 2023, I conducted two critical analyses. The purpose of my 2022 study was to dive deeper into music education curricula in the United States and find places where exposure to BIPOC and/or different cultures is lacking and/or not given proper representation. The purpose of my 2023 study was to explore the relationship between music, peace, and conflict in Northern Ireland. While both studies examined songs, albeit in different regions, I found several consistencies among the studies that may help to inform both the role of reflexivity in the insider/outsider perspective of musical analysis and the continuous conflicts and violence that have permeated within music teaching and learning across time. Therefore, with the intent of developing an over-arching theory of insider-outsider perspectives on music and conflict, the purpose of synthesizing these two studies was to offer a reflexive analysis of the impact that music has in civil conflict across space and time from an insider and outsider point of view. Overarching themes from my synthesis include musical “othering,” implicit and explicit violences, and representation through signs and symbols.

Abstract Name: Accessibility and Recyclability for a Circular Economy

With the rapid growth of modern technology and declining focus on designing for longevity, electronics have been going to landfills more rapidly than ever. Electronic waste includes anything with electronic components in it, like cell phones, microwaves, coffee makers, washing machines, refrigerators, etc. The focus of research in circular economy is to study the ways in which we can reduce the number of electronic devices that end up in landfills and ultimately result in toxic waste. One aspect of the problem is how cultural views on recycling can be improved, and reasons why the average person would choose to partake or not in repair/recycling of the unit. However, the aspect that is being focused on in this research is from the perspective of the designers and manufacturers of the products. This research uses numerical values and procedures to assess the accessibility of recycling common household electronics. An increased amount of time and effort that goes into disassembling the product into recyclable parts could result in lowered initiative to participate in a circular economy. This issue can ultimately be addressed by things like improving material usage in the components and making the products easier to take apart, as well as building for longevity instead of planned obsolescence. With this research we begin by taking the unit apart to its most basic components, figuring out which materials it is composed of, and finding out where and how to recycle them.

While we are mainly focused on recycling, the accessibility of disassembly also has a large impact on repair culture. If the inside mechanisms are easier to reach and identify, it is likely that more people will feel that it is worth it to repair instead of replacing.

Abstract Name: Human vs. Animal Bone: Less-destructive Identification using Scanning Electron Microscope and Artificial Intelligence

In the medico-legal field of forensic anthropology, correctly determining whether a bone came from a human or an animal is a vital step in any case. If an animal bone is misidentified as human, resources may be wasted on an unwarranted forensic case. If the reverse occurs, the deceased may never be identified or recovered. Current best practices to differentiate human from animal on non-morphologically distinct bone fragments are destructive, requiring cross-sections or for the bone to be ground into a powder. In an effort to create a less destructive procedure for bone fragment differentiation, I have been developing a method of bone cell analysis that utilizes a scanning electron microscope (SEM) to take images of the bone cell structures. Human bone cells are typically laid out in what looks like concentric circles, called Haversian systems, while animal bones are typically laid in flat, more elongated layers called Plexiform systems. Manual classification of these images, however, proves challenging to replicate or regulate. We developed a machine learning algorithm to do this differentiation for us, based solely on observable characteristics in SEM images. Preliminary results show up to an 88% accuracy rate for differentiation. Using an SEM, samples can be directly placed inside the microscope for imaging and do not necessarily need to be thin or severely altered in order to image, thus leading to a less destructive (and often non-destructive) method of bone cell analysis. Destructive analytical techniques halt further analysis of a sample, which can run a case dry or impede the investigation process. As scientists and forensic anthropologists, we have an ethical duty to maintain the integrity of the remains we are working on out of respect for the individual and their culture and kin.

Abstract Name: Experimental Ekphrasis: Frankenstein's Exploration of the Limits of Representation

This paper explores scenes of experimentation in Mary Shelley's Frankenstein guided by the literary term ekphrasis—the verbal representation of the visual. Shelley's linguistic descriptions of the perception and appearance of the creature communicates a paradoxically unimaginable image. Specifically, through her emphasis on light and color, Shelley's scenes of experimentation assume a painterly effect, reminiscent of historically artistic practices. As Alexandra Neel suggests, Shelley's "undeading" of her creature follows the

practices displayed in still life, but also figuratively “stills life” to fasten the creature to not only a linguistic, but also a visual medium of perception. Though Shelley’s portraits of Caroline and William are most often referred to in ekphrastic analyses of her text, I argue that Shelley’s attempts at rendering the creature in her scenes of experimentation are examples of Neel’s stilled life, and therefore, ekphrastic moments. As a result, I am able to apply a visual, artistically driven analysis of the elements in Shelley’s descriptions to reveal that in her attempts to represent the creature, she inevitably fails to represent him. Consequently, I use the broader scope of aesthetic theory as a backdrop for the issues concerning judgement and representation. Both Kant and Burke provide the foundation to analyze Frankenstein ekphrastically and aesthetically, revealing how the employment of ekphrasis itself is a limit of representation. Ultimately, the examination of the creature’s overall unrepresentability allows for the more extensive questioning of the limits of art and literature.

Abstract Name: A Study on Feminism in Ancient Greek Theatre

As a woman who has primarily studied music and is now studying theatre as well, I have really started to wonder and consider where the women are in the creation and beginning of these art forms? For music, I had that mostly explained to me in the majority of my studies over the years. However, I have become increasingly interested in theatre and am almost baffled by how theatre was even possible without women. When looking back at the start of theatre it is impossible to notice the lack of women playwrights, actors, critics, and more. Even further, it begs the specific question of how there were women’s roles with no women? If there were men playing these roles, how did they do that and adapt? What did critics think of this at the time? Were there laws or societal standards that gatekept women from the stage? Did the lack of women impact the emotional and physical variability in these famous works when first performed? For me personally, it is a constant badgering of never ending questions of what happened here and then wondering how it evolved from there to what we have today. Using sources from William J. O’Neal, Jeffrey Henderson, Froma I. Zietlin, Sue-Ellen Case, and David Cohen I intend to discuss what a woman’s role was in society outside of theatre in ancient Greece, how that societal role specifically impacted theatre, what theatre critics’ thought of women in that time and why that was important to women’s theatre, the women’s role and stereotype itself, and the great debate on whether women were even allowed to attend theatrical festivals or other theatrical works.

Abstract Name: Acoustical Measurements of NASA's Space Launch System Artemis-I mission

As the global space industry expands, impacts from super heavy-lift launch vehicle noise on payloads, communities, and natural habitats are better understood with improved source models. In support of model development, this paper discusses ongoing analyses of far-field acoustical measurements made of the NASA Space Launch System (SLS) Artemis-I mission. A group of students and professors from Rollins College and Brigham Young University deployed fifteen acoustical measurement stations prior to the launch, including ten autonomous stations within Kennedy Space Center and seven manned stations off-Center, ranging from 1.4 to 50 km from Launch Complex 39B. In this paper, a brief overview of initial analyses from all fifteen stations is discussed, including sound pressure levels, waveform characteristics, and frequency spectra. Additionally, an explanation of sound power calculations is included to understand the source characteristics and compare SLS to other rockets through acoustic efficiency. Both source and propagation analysis are presented in conjunction to understand acoustic phenomena during the Artemis-I launch and prepare for Artemis-II, scheduled to launch in 2025.

Abstract Name: TikTok, Trauma, and the Possibilities for Peace and Justice: The Impact of Trauma Language Misuse on Social Media

Trauma is a theory that explores the experiences of humans when they reach a point of such overwhelm that their higher brain function shuts down, allowing their brains to be led solely by the deep, lower brain, fight-or-flight instinct. Traumatic experiences and events are frequently mass-shared through various social media platforms that provide many with important sources of information and human connection. In this thesis, I explore the connections between trauma and social media, specifically the incorrect uses of trauma language on the social media platform TikTok, and relate my findings back to the ongoing work of the field of Peace and Justice Studies, as well as broader social justice work. As my research will show, the pervasive misuse of trauma language on social media risks obscuring the technical meaning of a theory that is being widely recognized as increasingly important for promoting peace and justice.I begin with an exploration into the literature behind trauma theory, working closely with the work of Resmaa Menakem and Carolyn Yoder, whose trauma-based approaches play into the ongoing conversations and work surrounding peacebuilding. Then I will explore the applications of trauma-informed approaches to the Peace and Justice field and evaluate the relationship between social media and trauma. Drawing on these pieces of literature, I then construct a new typology of misuse of trauma language on TikTok and analyze trauma-related content on the platform using the Categories of Misuse developed through my research and evolving social science methods. The project concludes with a summary of my findings and a discussion of the implications of misuse of trauma language on the broader field of Peace and Justice.

Abstract Name: Efficacy of Skin Protection Education on the Habits of Undergraduate Students and Coaches

The purpose of this study is to evaluate the effectiveness of sun protection education in leading to incorporation of more sun protective habits into the daily routine of study participants. The participants will be undergraduate students, faculty, staff, and student athletes on Lubbock Christian University's campus that are between the ages 18 and 64 years old. This study is primarily observing if sun protection education among undergraduate students, athletes and coaches of outdoor sports lead to a significant increase or change of the usage of sun protection methods in their normal routine. Improving the rates at which students utilize sun protection methods and avoid sun exposure, when possible, may reduce the incidence of skin tumors later in life. The study is currently taking place. The expected results are that a total number of participants, ranging from 100 to 200, would increase their daily habits of protecting their skin from sun exposure. Participants will be given an explanation of the study and informed consent. After an Initial Sun Prevention Attitudes and Behaviors Survey an investigator will give an explanation of the dangers of sun exposure as well as the various methods one can use to prevent sun damage. Use of sun damage prevention will be encouraged and samples of sunscreen will be given to the participants. The educational session will then conclude with a reminder of the final step of participant enrollment the Follow-Up Sun Prevention Attitudes and Behaviors Survey approximately 3 months after the date of the educational session. The data will be deidentified before being sent to the research committee. We hope to show that if undergraduate students were a target audience of educational materials, they may practice daily routines that could reduce the incidence of skin diseases later in life.

Abstract Name: Empowering a Just Transition: Integrating Climate Workforce Opportunities in Philadelphia

This research project focuses on community-based climate transition workforce opportunities as catalysts for a Just Transition. Unlike traditional employment paths, these opportunities do not require a college degree and can be a pathway for progressive employment opportunities and degrees. Further, escalating demand for skilled green workers versus traditionally educated workers is creating change in employment practices. Notably, the Shapiro administration in Pennsylvania eliminated the 4-year degree requirement for 92 percent of state government positions, reflecting the increasing preference for green skills over formal education, a sentiment echoed by Biden’s Council of Economic Advisers.This research, centered in Philadelphia, assesses the alignment of climate transition workforce opportunities with workforce development organizations, private companies, and universities. Initial findings identify key opportunities for growing Philadelphia’s green economy and establishing foundations for strategic partnerships. Valuable recommendations and insights emerged from consultations with stakeholders, including the ideas to create apprenticeships, additional skills certification, programs for training trainers, and continuing education certificates for green jobs.The future phases of this project aim to implement identified recommendations by evaluating potential collaborative mechanisms among universities, workforce development organizations, and private companies. A stakeholder-suggested convening by Drexel University will seek to unite stakeholders to collectively explore and leverage potential workforce development avenues. This inclusive approach strives to create accessible, sustainable employment pathways into climate transition job opportunities for Philadelphia residents. The initial goal is to determine how best to strengthen and supplement workforce development programs. Thus far, the collaborative strategy utilized throughout this project has begun to successfully

address challenges and capitalize on opportunities at the nexus of natural infrastructure, climate resilience, and workforce development, contributing to a more equitable and sustainable future.

Abstract Name: Reflection in Action: Exploring Differences between Self-Perception and Clinical Perception of Social Communication Skills in Young Adults with Autism Spectrum Disorder Through Reflective Practices

Though there are existing programs to aid the college transition, students with autism spectrum disorder (ASD) demonstrate a need for additional support for their pragmatic deficits. This study sought to investigate the potential of reflection in increasing the accuracy of perceptions of college students with ASD on their pragmatic skills. The investigator hypothesized that the accuracy of self-perceptions would increase after watching a video of their performance. All participants were students from the Students with Autism Transitional Education Program (STEP) at Eastern Illinois University (N=8, 7 males and 1 female). Each participant held a 3-minute conversation with the principal investigator and self-rated their pragmatic performance both immediately after the conversation and after watching a video of the conversation. The principal investigator also completed a rating for each participant. Ratings were completed using a rating scale designed by the investigator that assesses verbal and nonverbal pragmatic skills, as well as social cognition. Results revealed a lack of a significant difference between the immediate participant self-rating and that of the researcher, and a lack of a significant difference between the immediate and delayed participant self-rating. There was a high, significant correlation between the delayed participant self-rating and that of the researcher. A highly significant correlation between the immediate and delayed participant self-rating was found as well. These findings confirm that due to the inherit deficiencies of autism spectrum disorder, individuals with ASD need additional support in building a sense of self-awareness as they learn social skills essential for success in a college environment. Further implications for the use of reflection in building these awareness skills in students with autism will be presented.

Abstract Name: Identifying a minimally destructive method for detecting enamel defects in human teeth

This study explores the detection of enamel developmental defects, focusing on the manifestation of Wilson Bands or accentuated Striae of Retzius —a microscopic disturbance caused by external stressors during amelogenesis. Some of the stressors that may lead to the development of Wilson Bands are low birth weight, malnutrition, and vitamin deficiencies.. The goal of this study is to test the feasibility of using tooth crown surface morphology as a minimally destructive alternative to dental histology for the detection of Wilson

Bands. Four teeth were collected from a population in Northern Jordan who lived during the Roman Period. The crowns of these teeth were (1) 3D scanned using a Faro Design ScanArm, (2) photographed using a Leica M125C microscope, (3) and molded using dental putty. This process was repeated after the surface of the crown was etched using phosphoric acid for 20 seconds. Each tooth was thin sectioned and micrographs of the enamel were taken. The 3D scans and micrographs were compared to identify changes in surface morphology at the locations of a known Wilson Band. Using molds of the surfaces of tooth crowns from specific individuals known to have experienced childhood stress, the method was tested to see if tooth surface variation could be detected on molds. By correlating disruptions evident on and beneath the crown's surface, this study pioneers a noninvasive method for diagnosing and analyzing disruptions in dental development while remaining minimally destructive to the samples.

Abstract Name: Learning Outside the Classroom

Research shows positive correlations between students' academic success and their involvement in co-curricular activities, however, there is limited knowledge about the accessibility of such co-curricular activities and those actively offered in public schools. This research is a pilot study looking across four different counties in North Carolina at 20 public high schools regarding the options of co-curricular activities and the barriers to access them, while comparing it to the overall school standard. This research addresses the gap in literature by obtaining first-hand accounts through interviews with senior administrators in public high schools, who actively engage in both the academic and co-curricular aspects of their schools, to look at the barriers of access to co-curricular activities and the percentage of students who participate in these activities. This study was conducted using a mixed methods approach through interviews with Assistant Principals at schools as well as quantitative research about each public school that was assessed. Within the research, the main barrier to co-curricular activities was transportation access. This barrier has caused an impact to limit the involvement from students who are in a lower-income bracket, whose parents are more often unable to drive them to and from the different co-curricular activities. There was a strong correlation ($R = 0.78$) between the schools' NC report card grade and amount of co-curricular opportunities offered.

Abstract Name: Evaluating the Impact of Food and Nutrition Security Support Groups in Kamuli, Uganda

The Iowa State-Uganda Program (ISU-UP) established the Food and Nutrition Security Support Groups (FNSSGs) in 2019 to address sustainable food and nutrition security for mothers and children who previously experienced malnutrition in Kamuli, Uganda. FNSSG members make nutrient-dense porridge, participate in income-generating activities, contribute to group financial savings, and participate in skills development. Since the establishment of the FNSSG program, no formal evaluation of the program had been completed before this project. The primary objective of this project is to better understand the impact that the FNSSGs have had on members and their communities. Sub-objectives were to understand the program's impact on food and nutrition security, how FNSSGs contribute to ISU-UP's strategic plan, and identify any unexpected impacts of FNSSGs. To achieve these objectives, six focus groups were conducted in July 2023 with FNSSG members to record their perceptions of the FNSSGs and the impact of FNSSGS. Key informant interviews were conducted with program staff to gather background information on the FNSSG program implementation and groups. Information received through these interviews and focus groups resulted in qualitative and quantitative data, which was analyzed using thematic analysis and descriptive statistics, respectively. From this, increases in the number of meals eaten per day and the variety of foods eaten at these meals increased across all six focus groups, demonstrating maintained food and nutrition security. Additionally, every focus group reported that all household members continue their consumption of nutrient-dense porridge as the program intends, indicating that the program is achieving its primary goals. Beyond this, members reported various social capital increases within their communities due to their FNSSG participation, highlighting the unexpected benefits reported. With these reported benefits, clear ties were found to five of ISU-UP's six strategic goals, indicating the FNSSG program is providing food and nutrition security for mothers and children.

Abstract Name: Effect on Food Storage on Vitamin C Content of A Spinach

Effect on food storage on Vitamin C of a Spinach will focus on the amount of Vitamin C that is in the vegetable. In this experiment, we explore the effect of the different sample preparation and storage methods on the vitamin c content in spinach. We have 4 samples that contained different manipulations of the forms of the spinach, including cooked spinach, cooked fresh spinach, uncooked and frozen. Our methodology investigated whether there was any effect on the percentage level of ascorbic acid in each of these samples.

Abstract Name: Education without Barriers: Strategies for Supporting the Academic Success and Inclusion of Children who are Deaf, DeafBlind, and Deaf Disabled in the Classroom

Throughout the world, children with disabilities are being denied their right to quality education and are facing constant barriers even when enrolled in school. The purpose of this transdisciplinary qualitative case study is to explore how a school for the Deaf in New York City works to create an environment designed for inclusion and enable all of its students to achieve academic success, regardless of their disability (or multiple disabilities). The research was conducted via a three-month internship from September to November 2023 at a school for the Deaf, a school which values inclusivity and provides education for Deaf, DeafBlind, and Deaf Disabled students from birth to 8th grade. Data was collected through participant observation within classrooms at the school, semi-structured interviews with two classroom teachers, and a survey of teachers, teaching assistants, paraprofessionals, and other staff members at the school. The outcomes of this study highlight that staff preparedness, communication modes, and connection with students are key factors that impact the academic performance and inclusion of students at the school. This research adds to the limited literature on education of Deaf Disabled students by providing insights into specific inclusive teaching practices and educational methods used at a school that utilizes the best practices from current research in Deaf Education.

Abstract Name: Assessing Protist Diversity in Ephemeral Ponds of New Jersey Pinelands using DNA Metabarcoding

Ephemeral ponds are unique and ecologically valuable ecosystems that support a variety of organisms including protists. These microorganisms have important roles in nutrient cycling, primary production, and trophic interactions. However, the biodiversity and distribution of protists in these habitats is poorly studied. This study used 18S DNA metabarcoding to explore the protist communities in ephemeral ponds in New Jersey Pinelands, with a focus on comparing the abundance of species between sampling types. Samples were collected from 30 ponds in 2020-2023, from natural and artificial substrates. 4022 unique 18S DNA sequences were found reflecting the rich biodiversity within ponds. The most diverse and abundant prostan groups were ciliates, cercozoans, excavates, amoebozoa, peronosporomycetes, green algae, apicomplexans, and dinoflagellates. Multivariate analyses showed that protists communities are strongly impacted by water chemistry, including nutrient and road salt pollution estimated by measuring chloride concentrations. We also revealed significant differences in composition of protistan assemblages inhabiting different microhabitats. These findings provide novel insights into the understanding of biological diversity of ponds and underscore the value of modern molecular approaches to characterize microbial community composition. This study is the first step towards obtaining an accurate picture of the microbial diversity in ephemeral ponds, which would eventually allow for making more informed conservation and protection decisions for these unique ecosystems.

Abstract Name: Biomolecule-binding, cytotoxicity, and cellular targets of novel dirhodium complexes

Cancer is known to be an incredibly difficult disease to treat. With every cancer stemming from its own unique origin, no one treatment is effective across the board. In this work, we explore potential metal-based therapeutics, with a specific focus on rhodium complexes and their potential to be used as cancer treatments. Our aim is to correlate chemical changes on the rhodium complex to improvements in their cellular uptake and toxicity. Cellular experiments are carried out in cervical cancer (HeLa) and triple-negative breast cancer (MDA-MB-231) cell lines. Data will be shown for binding to potential cellular targets (DNA vs. proteins), ability to enter cells (whole cell uptake), ability to kill cancer cells (cell viability MTT

assays), and possible interactions with the ubiquitin-proteasome system (UPS)-an important protein degradation pathway. Preliminary results show that all rhodium complexes bind to both DNA and protein, that all complexes bind more quickly to protein than double-stranded DNA, and that changes in the rhodium complex structure affect initial binding rates by two orders of magnitude. Our results also demonstrate that adding sugars to the rhodium complex increases its solubility, but does not increase the toxicity. We plan to present data on how addition of more greasy components on the rhodium complexes impact their cellular uptake, and affect their interaction with the ubiquitin-proteasome system.

Abstract Name: The History of Emojis and Visual Communication

The emoji is fascinating in its design it takes the core of visual communication and strips it down to its simplest form. This makes it highly recognizable in many cultures. Graphic designers use visual communication in everyday life such as graphs, packaging, and street signs. The emoji takes those and turns them into a set of symbols you can recognize and use as a form of communication. The emoji breaks the language barrier as it has symbols that span over many countries. It can be seen as its own language as well people can use the imagery to form sentences and to help with the emotion of a caption or message. The first set of emojis was created in Japan by Shigetaka Kurita an interface designer, he created it for the Japanese phone company NTT DoCoMo. The set of emoji is now in the Museum of Modern Art as it has become such a cultural icon that it is considered to be modern art. The emoji can be seen as one of the most influential designs in the last 50 years since it was created. Visual communication is one of the most important things to a graphic designer. The way the human eye perceives things is the reason visual communication is so important as it allows the viewer to feel the emotion through more than words. This is why the emoji is so effective as it allows for people to show there true feeling behind the type and text.

Abstract Name: The renaissance and the printing press

The Renaissance era was an evolution of art and design because it pushed mad production and design in many ways which allowed design to develop further. The Renaissance is the era of “rebirth”; it was the revival of the classical arts of the Greek and Roman times. The way the graphic design world is today is greatly impacted by the Renaissance era. One of the most important is the printing press. It helped bring mass production to the forefront which allowed for things such as books and typography to evolve in a way that may not have been otherwise. The printing press allowed for not only printing it also allowed for a boom in the industry as a printer which can relate back to graphic design today and now us graphic designers have to know how to print and produce work. Typography grew and people started experimenting with type and having an easier time producing and using type. Typography and people finding and creating their own fonts that could be created and fit for certain occasions. Graphic design today is quick and you need to be able to produce something in large quantities at times, may it be a book, magazine, or poster. This is what the Renaissance evolving design and its scholars let us be able to do. If it was not for the past we know we would not have been able to work with such the level of digital technology we have today.

Abstract Name: Developing a Deep-Learning Algorithm to Classify Smartwatch Data to Evaluate Manual Wheelchair Users' Pressure Relief Exercises

As wheelchair users sit for long periods of time, they are susceptible to developing pressure ulcers, which can often be painful and even deadly, accounting for 60,000 deaths in the U.S. each year. Clinical Practice Guidelines (CPGs) outline a set of exercises for manual wheelchair users and how often to perform them. However, although researchers have proven the effectiveness of these guidelines in preventing pressure ulcers, the number of cases has not decreased since their introduction into the standard. This project aims to answer why and, in the process, provide manual wheelchair users and their healthcare providers a practical method to assess whether they are following the CPGs correctly.Previous research that has used sensor data to evaluate movements of wheelchair users often depended on clunky and expensive sensors that require extra effort to install and maintain. Our project aims to overcome this issue by collecting data with a smartwatch, which takes comparatively little effort on the part of the user to install and maintain, especially if they are already accustomed to wearing and using one.We have designed and implemented a machine-learning algorithm, which employs a deep Convolutional Neural Network (CNN) to process the watch sensor data such that we will be able to classify the CPG-recommended exercises. Currently, we are collecting data and training the model. We are experimenting between fine-grained classifications with higher numbers of classes and coarse-grained classifications with lower numbers of classes to see which can achieve a higher accuracy. As sensors are subject to noise, we will implement an advanced differentiation approach that finds the difference between each adjacent measurement to negate most of the noise. The success of this project will advance research in pressure ulcer prevention and equip wheelchair users with the ability to self-assess their adherence to CPGs.

Abstract Name: The Silk Battalion: Sexual Violence during the 1998-1999 Kosovo War

This study addresses the causes for the immense brutality of sexual violence during the 1998-1999 Kosovo War. Employing content analysis of hundreds of international news articles, memoirs, UN reports, and HRW documents published between 1998-2000, this study applies coding for levels of brutality and common themes among accounts of sexual violence during the war to test two hypotheses: 1). that an extreme ethnonationalist agenda will result in a greater endorsement of a strategic widespread rape campaign toward Kosovar Albanians residing in Serbia and 2). that an extreme commitment to power-seeking goals will result in a greater endorsement of a strategic widespread rape campaign toward Kosovar Albanians residing in Serbia. Data supported both hypotheses, in line with the Preference-Based Theory of Wartime Rape (PTWR), which explains wartime sexual violence through an analysis of in-group mechanisms and the armed group leader's leadership ideology, or "preferences," existing as two dimensions: nationalism and power-seeking. Therefore, this study confirms the validity of the PTWR applied to the Kosovo War, finding Yugoslavian president Slobodan Milosevic's "extreme" values for both dimensions to have contributed to the higher incidence and severe brutality of wartime rape. Finally, this study also confirmed the PTWR's findings that wartime rape is unique from other human rights violations because of its gendered nature and that the ethnic component of the Kosovo War was significant to the incidence of rape, given its employment as a genocidal strategy based on its inherent reproductive function. Through corroborating the PTWR's applicability to the Kosovo War, this study challenges research by other scholars who suggest older theories of strategic wartime rape are to blame for the extreme brutality of sexual violence seen during war.

Abstract Name: Travel Posters and the Romanticization of Destinations in Graphic Design

Travel posters are a unique art form that has evolved throughout the history of graphic design. Since the Industrial Revolution and the “Golden Age of Travel” in the 1920’s and 1930’s, travel posters have been romanticizing destinations. They use imagery and typography to sell the idea of a destination to audiences and create a sense of romance and allure for the places they are advertising. Travel posters have evolved throughout the history of graphic design alongside design movements and trends as a whole, and have even developed their own recognizable style. Examples of travel posters that have been extremely successful are the WPA’s national parks travel poster series, which revived the United States national parks and made them a point of interest. Travel posters are not only an art form, but they tell a story and sell the idea of beauty and adventure by romanticizing destinations.

Abstract Name: The Impact of Victorian Graphic Design on Typography and Advertising

The Victorian era was a time of technological advancements that paved the way for a more modern and advanced society. New improvements to printing technology allowed for more never before used type printing and design techniques, such as woodcut type. These advancements led to a more detailed type called display type, as well as new product packaging and other new advertisement options commonly seen in Victorian era circus posters. All of these designs focused on dramatic, bold, and expressive typography to catch the attention of the viewer. Because of these new technologies and techniques the world of graphic design was forever changed and helped it evolve into what we see and use in modern graphic design today.

Abstract Name: Modelling seiche waves in Yellowstone Lake towards understanding lake volcanic interactions

Yellowstone Lake straddles the edge of the volcanically active Yellowstone Caldera. Volcanic activity, in the form of surface deformation or hydrothermal venting in the bed of the lake can produce measurable lake level changes. Changes in water level, associated with seasonal movement of water, ice, and waves on the lake surface can in turn create deformation in the nearby land. A clear understanding of how lake water loads change over space and time is an important step toward quantifying the multiple interactions between Yellowstone Lake and the underlying volcano. Here, we analyze observations of lake bottom pressure and temperature collected at 12 stations around Yellowstone Lake from July 2016 to July 2017 to determine lake level. In particular, standing waves of water, known as seiches, are representative of periodic shifts in the amount of water distributed across the lake, with dominant periods of 51 and 78 minutes. These seiche waves are present year-round, even when the lake is covered by ice, and though they are small (typical seiche amplitude was about 1-10 cm) they represent large movements of water mass. By measuring the changing amplitude and phase of these seiches at each station throughout the year, and comparing with theoretical model predictions of relative seiche amplitude and phase, we can create a 4-D synthetic model representation of water load changes during the year of observation. We find that using only

two seiche modes we can adequately reproduce the observations. The resulting model of seiche waves in Yellowstone Lake is an integral part of our further studies hydrothermal activity and caldera properties in the region.

Abstract Name: The Roles of Sex and Androgen Receptor in Object Recognition in Mice

The current study is using the novel object recognition test, commonly used for the investigation of learning and memory, with an automated animal tracking system in the male mice that lack functional androgen receptors (AR) due to testicular feminization mutation (Tfm) to test if androgens activate AR to masculinize mouse cognitive function. The behavioral assay has been conducted as follows: After habituation in an open arena (W: 30cm x L: 49cm), a subject mouse is first presented with two similar objects for 10 min or the time when the two objects are investigated for 30 sec each (familiarization). After a break of 5 min, the subject continues the test during a second session during which one of the two objects is replaced by a new object and is evaluated for the time spent on a familiar and a novel object (novel object recognition). So far, we have completed the behavioral tests of 4 wild-type (WT) female, 3 WT male, and 3 Tfm male mice. Our preliminary data show that during familiarization, both WT and Tfm males completed the 30-sec exploration of the two identical objects within 10 min while none of the four WT females finished the same task within the time limitation (18 ± sec). For novel object recognition, no effect of sex or mutation on the time spent on investigating the novel or the familiar objects was observed. However, among the three groups, the total time spent on investigating both objects were the longest in Tfm mice, the shortest in WT females, and the middle in WT males (p<0.05). Both WT and Tfm males also visited the objects more frequently than WT females (p<0.05). Our preliminary data demonstrate the uncharacterized roles of sex and AR in object exploratory behavior.

Abstract Name: Snail Behaviroral Response to Heatwaves with Local and Nonlocal Predators

Extreme weather due to climate change can threaten marine biodiversity, putting them at risk. Heat waves produced by climate change are particularly threatening because they can cause mass mortalities and alter species interactions. In addition to the threats of heat waves, longer term changes in climate have led to coastal species migrating to new regions, and exposing prey to novel predators. It is thus important to understand how native species respond to non native predators as extreme weather events increase. Much organisms use behavioral thermoregulation to avoid extreme temperatures. However, little is known about how behavioral thermoregulation affects their ability to avoid other risks like predators. In particular prey response to local and nonlocal predators. In this study, response behaviors of the common periwinkle (Littoraria irrorata) in the presence of local blue crab (Callinectes sapidus) and nonlocal predator, Florida Crown Conch (Melongena corona) was studied. Using a combination of outdoor and indoor laboratory experiments, we studied the behavior of these snails.Snail height and body temperatures were measured during the outdeoor mesocosm experiment. Snails were placed in buckets in pools that contained either blue crabs, conch, or no predators. Half treatments were ambient outdoor temperature and half received a heat wave treatment. The indoor laboratory experiment focused on snail speed and direction of their behavior response when exposed to a nearby predator. The snails were placed in tanks with each of the different predator in the water. Snails show a strong response to these predators, but behavior differed depending on the predators. Heat waves

also influenced the retort to antipredator response. Findings from these experiments have important implications for species responses to local and non-local predators in future conditions.

Abstract Name: The Misinformed Globe: A Review of the Spread of Intentional and Unintentional Online Misinformation

Due to the speed at which information is given to consumers, very few people care to check the accuracy of information. This research study aims to discover what is currently known about how the circulation of misinformation affects individuals' information consumption habits so effective methods can be created to decrease the amount of misinformation online. I surveyed scholarly journal articles within the field of media studies to examine how consumers interact with online data and how media is tailored to provide information. While some social media sites attempt to combat misinformation, most prioritize consumers' engagement with little regard for information accuracy. The main goal for online sites is reported to be increasing viewership (Luo et al., 2021). Also, the declining accuracy of political news has resulted in the public losing trust in all types of online information. In conclusion, current consumer habits are emotionally driven, allowing social media to manipulate users to gain viewership. All parties lack concern for accuracy which is how misinformation is being spread so rapidly in the digital age. To improve the accuracy of virtual information, consumers must be more vigilant and self-aware when reposting and interacting with information online as small actions can further the spread of misinformation for years and generations to come. Keywords: misinformation, media interactions, misleading, consumers, promoting, and reputational.

Abstract Name: Investigating the Effects of Trichoderma on Brachypodium Plants at Different pH Levels

Soil pH is an essential factor in plant growth, and depends on environmental conditions and irrigation practices; both of which have contributed to acidity damage in plants. In recent years, it has been discovered that Trichoderma harzianum fungi have beneficial effects on plant growth and pathogen resistance. To test whether T. harzianum can protect plants against acidity damage, brachypodium plants (stiff bromes) were grown in Ecofab chambers with varying pH conditions, in the presence or absence of T. harzianum. Root length and plant stalk length measurements were recorded for four weeks. It was found that the microbes have a positive effect on the plant stalk height, while root lengths on average either remained the same or shrank. While the microbes may promote growth in the plant stem itself despite an acidic environment, it is unclear whether the roots themselves were damaged or protected from the acidity. The results may be interpreted that the roots themselves were made more efficient, discarding the need to grow larger, or imply a more parasitic relationship where t.harzianum takes from the roots composition in order to provide the growth-promoting products on the plants themselves. With this study as a baseline, future research direction encourages looking at possibly using trichoderma in soil with low pH, and looking at possible partner microorganisms that work with Trichoderma to improve plant growth.

Abstract Name: Effect of Kidney Resident Macrophage-derived C1q during Acute Kidney Injury

Kidney resident macrophages (KRMs) play an important role in kidney function and the response to acute kidney injury (AKI). We have found complement protein C1q to be uniquely expressed in KRMs but not infiltrating macrophages (IMs). Here, we studied the immune response in a cisplatin-induced model of AKI in order to test the hypothesis that C1q modulates the response of KRMs to AKI.Cx3cr1CreC1qfl/fl (n=15) and C1qfl/fl control (n=6) mice were injected with 20 mg/kg cisplatin to induce AKI. 3 days post-injury, serum was collected for serum creatinine measurements by mass spectrometry. Right kidneys were harvested for histology and left kidneys were digested to a single cell suspension and immune cell populations were assessed using flow cytometry.There was no difference in serum creatinine between Cx3cr1CreC1qfl/fl and C1qfl/fl control mice (mean 0.84 vs 0.78 md/dL, SEM ±0.2946, p-value = 0.8221) 3-days post injury. The number of KRMs remained the same among both populations. There was no difference in the number of neutrophils and IMs infiltrating the kidney 3-days after injury. KRM-derived C1q does not have an effect on kidney function and the immune response in a cisplatin-induced model of AKI. Additional studies using other models of AKI such as bilateral ischemia reperfusion injury will be needed to fully evaluate the role of C1q in AKI.

Abstract Name: Empathetic Autonomy: Locus of Control's Resonance in Human Connection

This study explores the intricate relationships between locus of control (LOC), empathy, and personality traits, examining their influence on individual identities and societal dynamics. LOC represents individuals' beliefs regarding control over life events, varying from internal attributions to external factors. Empathy involves understanding others' emotions, while the Big Five traits characterize distinct individual dispositions.The study aims to contribute significantly to theoretical frameworks of identity cultivation and personality development by investigating how these constructs influence one another. The project anticipates offering a nuanced perspective on the often dichotomous views of internal versus external LOC orientations and seeks to challenge the hegemony of internal LOC superiority in various contexts. Moreover, understanding this relationship can deepen conflict resolution strategies by recognizing societal structures and biases' influence on contemporary challenges. The study envisions fostering a paradigm shift towards acknowledging both internal and external factors, motivating proactive steps for societal evolution and democratic community building.The hypotheses propound multifaceted relationships between LOC orientations and empathy. The hypotheses suggest diverse connections between LOC orientations and empathy. Internally-oriented individuals may show heightened empathy, leveraging personal agency for strong connections. Conversely, they may lack sensitivity to external influences, demonstrating lowered empathy. Meanwhile, externally-oriented individuals may exhibit elevated empathy due to increased sensitivity to external circumstances, yet might paradoxically display reduced empathy by attributing blame to external factors, impacting their sense of agency.A comprehensive online survey deployed via Microsoft Forms and accessible through the SONA research pool at Old Westbury collected data from 75 respondents to date. This survey assessed demographic information, Rotter's LOC Scale, the Interpersonal Reactivity Index (IRI) for empathy, and the Ten-Item Personality Inventory (TIPI) for personality traits. Statistical analyses using SPSS will explore relationships among variables. The proposed procedure will be done by the time of the conference.

Abstract Name: State Responses to Covid: Cataloguing Changes to Experience Rating

In the face of massive layoffs during the early days of COVID-19, several states decided to suspend experience rating—the practice by which states penalize firms for layoffs in the form of higher payroll taxes. In this study, I do independent research to catalog which states suspended experience ratings, when they announced the suspension, and when, if at all, each state resumed the practice of experience rating. I find that about half of states suspended experience ratings and that the decision to suspend experience ratings was not apparently correlated with a state's political leaning or eventual COVID-19 death rate. The data collection effort paves the way for future analyses on the effect of experience rating on workers and the labor market more broadly.

Abstract Name: Establishing Linkages between Nutrients, Nitrogen-fixation, and Microcystin Production by Phytoplankton Communities in Hypereutrophic Taylorsville Lake

Multiple public health advisories have been issued at lakes and reservoirs throughout the nation, due to the occurrence of harmful algal blooms (HABs) and the resulting release of toxic microcystin into the water by Cyanobacteria/“blue-green algae”. Microcystin describes a class of >200 organic compounds, which are all cyclic heptapeptide toxins. Humans, pets and even wildlife could experience rashes, hives blisters, liver necrosis, or even death after drinking or coming into contact with microcystin-contaminated lake water. These HAB events, which are more common in eutrophic and hypereutrophic environments, can be disruptive and dangerous, posing a serious risk to local ecology, public health and drinking water infrastructure. In the interest of proactive water resource management, it is vital to understand the many physiochemical and ecological variables that will influence both Cyanobacterial growth, and their production of microcystin. The main objective of this research project was to elucidate the linkage and possible correlation between nutrient amendments, nitrogen fixation, and microcystin gene expression/production by phytoplankton communities in a hypereutrophic lake. The physical experiment involved installing mesocosms in hypereutrophic Taylorsville Lake, during the HAB season of Summer 2023. Some were installed as controls, while some were amended with Nitrogen and Phosphate, and all were monitored for changes in water quality parameters (pH, chlorophyll, total N, total P, microcystin concentrations), as well as N2-fixation rates, and expression of microcystin and N cycling genes by metabolically-active phytoplankton. This project will illustrate the effects, if any, of nutrient amendments on microcystin production by the Cyanobacteria population in Taylorsville Lake. Additionally, more insight on the environmental factors influencing these events will serve state and federal agencies, further informing future nutrient management decisions in the interest of preventing and managing toxic HAB events.

Abstract Name: JSR Engine

The JSR engine represents a hybrid propulsion system intended for operation across Jet/Scram/Rocket engine stages, constituting an ongoing undergraduate research project.Modeled after the Pratt & Whitney J58 engine, the JSR incorporates a variable inlet cone to manage shock positioning and angle modulation with increasing Mach numbers. Drawing inspiration from the J58's application in the SR-71, the engine aims to navigate high altitudes, achieve remarkable speeds, and endure challenging conditions characterized by elevated temperatures and substantial skin friction. These conditions closely mirror the supersonic and hypersonic environments anticipated for the JSR.To execute this undergraduate research, an array of software tools including CATIA V5, ICEM CFD, CFD ++, Tecplot, and Matlab are being employed to construct comprehensive models. Collaboration with an experienced advisor supplements the research efforts. Our current roadmap entails finalizing a conceptual model encapsulating all our research findings and efforts by December 10th, 2024.

Abstract Name: Capital Structure Implications of Options Implied Volatility

The "meme stock" mania provides an opportunity to study the relationship between implied volatility, which is used in pricing options, and securities in the capital structure of a company. Meme companies, such as GameStop and Bed Bath & Beyond, take advantage of extraordinarily high implied volatility to restructure their capital structure. The capital markets decisions taken by these firms could be studied to show that equity implied volatility is an asset for a company that is not listed in its balance sheet. However, in extreme cases the implied volatility itself is a European Put Option on the shareholder equity of the company, which creates the "meme stock" phenomenon when exercised. Through methods of Monte Carlo simulation, we can price this European Put Option and draw conclusions about the capital structure of a company.

Abstract Name: Investigating the anti-cancer effects of resveratrol in the SK-MEL-24 melanoma cell line

Cancer is a disease characterized by uncontrolled growth of abnormal cells. Resveratrol is a naturally-occurring bioactive polyphenol found in the skin of red grapes that is known to possess a number of health benefits including anti-cancer properties. One of the most common types of cancer in the U.S. is melanoma which develops from the pigment-producing cells (melanocytes) found in human skin. This study aims to investigate the effects of resveratrol on the melanoma cell line SK-MEL-24. SK-MEL-24 cells will be treated with both pharmaceutical-grade and commercially available over-the-counter resveratrol sources. The effect of resveratrol on SK-MEL-24 cell proliferation will be assessed utilizing trypan blue exclusion methods. Furthermore, to gain insight into the possible mechanism of action for resveratrol’s suspected anti-cancer properties, western blotting will be used to investigate the levels of apoptotic proteins as well as proteins involved in oncogenic cell-signaling pathways. The study hopes to expand on our current understanding of how resveratrol may or may not regulate cell-growth, specifically in skin cancer, possibly contributing to the future development of natural product-based skin-cancer therapeutics.

Abstract Name: The Vietnam War: Was it a National Security Issue?

The United States' choice to enter Vietnam was fueled by a need to demonstrate to the world that they were, in fact, the global hegemon they had presented themselves to be in the wake of World War II. In an attempt to halt the spread of communism through the utilization of containment, then détente, the US deployed forces to Vietnam in fear of the "domino effect" taking place, thereby spreading communism and creating a direct threat to democracies everywhere and threatening the national security of the United States of America if not stopped. President Eisenhower was the first president to highlight this issue, and later, President Johnson sent troops to Southeast Asia in an effort to stop the spread of communism during the height of Cold War tensions, consequently starting the years-long Vietnam War. However, despite the early confidence and desire to solidify America's power on the global scale following the foreign policy failure regarding the Bay of Pigs, US intervention in Vietnam ultimately was unsuccessful, jeopardizing the lives of hundreds of thousands while simultaneously implementing irrevocable effects on both American and Vietnamese troops and civilians alike. The Vietnam War propelled the idea of the 'Imperial Presidency' in America, hence why the war went on so many years longer than it should have. Despite the US pulling out of Vietnam five decades ago, many scholars have debated if America gained anything from it. Perhaps America did. Perhaps they did not. However, the bottom line is this: The Vietnam War wasted lives and resources in the name of protecting national security, but the ‘US national security’ that officials were so worried about was never threatened in the first place.

Abstract Name: Examining the Conflict Between Identity and Social Awareness in Zora Neale Hurston’s “How It Feels to Be Colored Me” and Barracoon

In what ways can identity in the United States be explored? Whether it is through lived experiences or heritage, the complexities of identity form an insight into an individual’s social awareness. However, identity can also serve as an epicenter for conflict. In the case of Zora Neale Hurston, the weight of identity can be a hindrance. Hurston captures these perspectives in her essay, “How It Feels To Be Colored Me” (1928), exploring her adolescent years and how she became familiar with race as a concept. Hurston holds a celebrative view of black culture, rejecting angst when discussing her experiences. This selective perspective on identity reflects a desire to detach oneself from the realities of marginalization while still embracing the beauty of one’s identity. Hurston’s controversial views on racial identity resulted in years of contention with her peers, yet opened an avenue for cross-generational insight on what defines black identity in the United States. In research conducted a year before the publication of “How It Feels To Be Colored Me” (1928), Hurston reveals that she does not regard her community’s marginalization with apathy. In 1927, Hurston orchestrated a series of interviews with Oluale Kossola, or Cudjo Lewis, one of the last remaining survivors of the Trans-Atlantic Slave Trade. Hurston’s research would later be published as Barracoon: The Story of the Last Black Cargo (2018). Having remained unpublished until ninety years after its completion, Hurston’s work made unprecedented strides through establishing an interpersonal relationship with Kossola rather than conforming to a traditional anthropological study. A close, parallel study of these two works reveals Hurston’s understanding of black identity as an interplay between individual and communal consciousness. This analysis determines whether an individual is capable of formulating social awareness by contextualizing their identity themselves or through their community, respectively.

Abstract Name: A Case for Educational Equity in Mississippi: An Analysis of Mississippi's Social Emotional Learning Standards From a Critical Lense

In 2021, the Mississippi Department of Education released Social Emotional Learning Standards. While these standards are not novel in development in other states, these standards are novel in Mississippi. Mississippi's SEL Standards are based off the CASEL-5 Framework, which is evidence-based and rooted in restorative justice practices. Both the Mississippi SEL Standards and the CASEL-5 Framework consider five essential domains: social awareness, self-management, social awareness, relationship skills and responsible decision making. These standards were developed in response to the COVID-19 pandemic and its ramifications. This study aims to address a lack of literature regarding SEL implementation in Mississippi's public elementary schools. This study considers Mississippi's SEL Standards for Kindergarten, First grade, and Second Grade. This study accounts for the impacts of the governmental action on SEL instruction. This is accomplished by utilizing the Ecological Systems Theory. This study considers how the macro-system (government and public policy) impacts SEL instruction in Mississippi's microsystem (local education agencies) and individual students' well-being. Public policy that is considered includes The War on Drugs, educational grants such as No Child Left Behind (NCLB) and Race to the Top Grants (RTTT), and juvenile justice laws in Mississippi. The purpose of this study is twofold. This study seeks to explore the intended outcomes of SEL Standards in Mississippi. In addition, this study aims to investigate how these intended outcomes inform the development of a scaffolding document for K-2 students in Mississippi. This study utilizes an inductive analysis that considers the language of each of the standards listed for kindergarten, first and second grade students. The inductive analysis will inform a culturally responsive scaffolding document. This study provides diverse, culturally responsive resources that inform a scaffolding document. The scaffolding document seeks to make SEL implementation more accessible by providing hyperlinked read-alouds, songs, lesson plans and other digital materials.

Abstract Name: Family Satisfaction of the Self-Determination Program (SDP) in California-an Exploratory Study

Background: Enacted in 2021, Self-Determination Program (SDP) provides individuals with developmental disabilities with more freedom, control, and responsibilities in choosing services than traditional regional center services. However, whether the SDP is meeting its goals and family needs is largely unknown due to the recency of the program implementation.Objectives: This study aims to examine: families' satisfaction levels of the SDP vs. traditional services, whether the SDP achieves its program goals, and explore challenges and needs to improve the SDP.Methods: Following IRB approval, 77 adults with at least 4 months of experience in both the SDP and traditional services were recruited (n=55 self-advocate and n=22 parent/legal guardian, mean age= 33.2, SD 5.3). They self-reported information about their demographics and experiences with both services via an anonymous online survey.Results: Satisfaction with the SDP and traditional services differed significantly between the self-advocate and parent/legal guardian group in the topic of community integration and study/job skills. However, the overall difference in preference and satisfaction for services was not notable. The parent/legal guardian group showed satisfaction for the SDP in four categories. The SDP positive experience data revealed five themes: social integration, self-determination, development/improvement, enhanced-quality-of-life, and job/career. Six themes identified from the data as needs to improve in the SDP include improved online materials, personalized support/feedback, enhanced-communication, collaboration/integration, community-support, and training.Conclusions: The study findings indicate that families did not show a strong preference for the SDP or traditional system and a strong satisfaction in multiple categories. However, there were differences between self-advocate and parent/legal guardian group in 4 items which highlights the importance of self-advocate participants. Also, qualitative analysis reveals the necessity of the SDP improvement and suggests potential solutions. Further research with larger sample sizes and diverse communities is needed.

Abstract Name: Is Successful College Admission in R.O.K Becoming a Privilege of the Wealthy?

In the Republic of Korea, there is a unique private education/tutoring system referred to as ‘Hagwon’, a for-profit institution that offers additional coaching for students to produce better results in college admission. Although going to Hagwon is not mandatory, there are claims that public education offered in schools is not enough for students’ success in college entrance exams, as the exams cover far more difficult questions than what students get to practice in school. With such beliefs expanding among students, every year, Hagwon thrives more than in its previous years, and now the Korean authorities, including the government are targeting Hagwon, believing it is becoming a privilege of the wealthy and the existence of it causes inequality in fair competitions for the placement in renowned colleges. The investigations conducted by the authorities after June of 2023, indicated that there indeed were certain acts behind Hagwon and its students/parents that fostered such inequalities. It is hypothesized that the special education offered by Hagwon can be challenging for families to afford based on their economic standings. To test if this hypothesis holds to be true, I approached by comparing the earnings of Korean households, in the forms of GDP, GNI, relevant government-collected data, and the monthly fees required for Hagwon, as a means to examine whether it is becoming a privilege to certain members of society. Also, by looking into previous literature and hearing the past experiences of current students who attend such renowned colleges, I examine how helpful Hagwon is to students in their successful college admission. Based on the brief review of literature and data collected for this project, the findings support the aforementioned hypothesis.

Abstract Name: Stress-Induced Changes in the 5' End Regulatory Structures of the TP53 mRNA

Tumor suppressor TP53 is responsible for multiple regulatory functions including DNA repair, apoptosis, and cell cycle control. Loss-of-function mutations of the TP53 gene have been found in about 50% of all cases of human cancer. Expression of the TP53 gene is regulated using highly diverse mechanisms resulting in 13 known isoforms. Interestingly, TP53 mRNA has been reported to use IRES-mediated translation, especially under cellular stress. Previous studies have implicated the role of structurally stable motifs in the 5’UTR region for mediating cap-independent translation. We present a secondary structure model of the regulatory region spanning 142 nucleotides upstream and 356 nucleotides downstream of the start codon for full-length TP53. The target region includes an alternate downstream start codon. Our model, based on SHAPE-MaP data from gently extracted total RNA from A549 human lung carcinoma cell line using 5-nitroisatoic anhydride (5NIA), confirms previously observed secondary structure motifs.We then apply the in-cell probing reagent 5NIA to detect changes in SHAPE reactivity in live A549 cells and compare reactivities with the cell-free model. We observe that the IRES-related motifs remain stable in unstressed live cells. Next, we treat cells with etoposide, an oncogenic stress inducer. Our initial studies detect measurable changes in SHAPE reactivity in a short hairpin motif downstream of the standard AUG start codon. Furthermore, base-pairing probabilities of this motif region drop from >80% to <30% under etoposide stress. Prior reports implicate the role of IRES-transacting factors (ITAFs) including Hdm2 interacting with this mRNA region, and in certain cases correlating with the translation of an N-terminal truncated TP53. We outline future directions investigating the TP53 mRNA structure under different stress conditions, and also aim to identify changes in ITAF-interaction sites using RNP-MaP.

Abstract Name: Inhibition of cellulase activity by liquid hydrolysates from hydrothermally pretreated soybean straw

Soybean is one of the world's staple crops largely grown as a protein-rich animal feedstock as well as for direct human consumption. According to the USDA report, annual soybean production in the U.S. was 4.44 billion bushels in 2021, which was 46% higher than those from the 2012 harvest and accounted for approximately 35% of world soybean production (https://www.nass.usda.gov). The one-pot biomass conversion process is a promising strategy to minimize potential product loss and reduce processing costs. However, this strategy has technical limitations due to the inhibitory effects of biomass components like lignin as well as the generated inhibitors during biomass processing. In this study, the inhibitory effects of liquid hydrolysates formed by hydrothermal pretreatment of soybean straw with either sodium hydroxide (NaOH) or hydrogen peroxide (H2O2) on cellulolytic activity were investigated. Hydrothermal pretreatment of soybean straw (10% w/v) was carried out with either sodium hydroxide (1% v/v) or hydrogen peroxide (1% v/v) at 121oC for 60 min to evaluate the effect of inhibitors released from soybean pretreatment on cellulolytic enzyme activity. The fraction of cellulose in pretreated solids (1% w/v) was hydrolyzed for 72 h with 45 IU/g glucan in the presence of either buffer or liquid hydrolysate generated from the pretreatments. Hydrolysis of NaOH and H2O2 pretreated solids resulted in 57% and 39% of glucose yields in buffer, respectively. With liquid hydrolysates, NaOH and H2O2 pretreated biomass showed 20% and 30% yield, respectively, indicating the enzyme suppression by inhibitors in the liquid hydrolysates. Of the enzyme activities in hydrolysates tested, NaOH hydrolysate showed a higher inhibitory effect on enzyme activities compared to H2O2 liquid, where enzyme deactivation has a first-order correlation and the way the filtered inhibitors were generated from pretreated soybean straw.

Abstract Name: Danio rerio as a model organism for real-time in vivo CaMKII activity measurement

CaMKAR (CaMKII Activity Reporter) is a fluorescent biosensor that has recently been engineered to accurately and efficiently quantify the activity of CaMKII (Ca2+/calmodulin-dependent protein kinase II), a serine/threonine kinase whose hyperactivity contributes to the progression of various types of lethal cardiac dysfunction including arrhythmias and heart failure. This biosensor was used to identify a novel CaMKII inhibitor that can be used clinically to prevent cardiac arrhythmias. The structure of CaMKAR consists of a circularly permuted green fluorescent protein (cpGFP) fused to a phosphorylated amino acid binding domain and substrate peptide from the CaMKII autophosphorylation domain. Upon a conformational change following phosphorylation of the substrate peptide by CaMKII, CaMKAR emits green fluorescence. Until now, CaMKAR has only been utilized in isolated cells and cell-free assays as limitations in exciting the cpGFP in CaMKAR with the excitation wavelengths have hindered CaMKAR from being utilized to report CaMKII activity in an intact animal model. To combat this limitation, the development of a transgenic line of Danio rerio with CaMKAR was sought as a novel model for in vivo CaMKII activity measurement. Boasting a transparent embryo allowing for non-invasive imaging methods as well as straightforward genetic manipulation techniques, Danio rerio has emerged as a vertebral model organism in the past few decades, making it an ideal model organism candidate. CaMKAR cDNA was first inserted into the founder fish's genome via genetic cloning and crossed with wild type Danio rerio to yield a transgenic line. The lines were screened for the amount of CaMKAR expression with fluorescent imaging technology and its functionality was further analyzed with calcium influx inducing drugs and confirmed with the Semi-Automated Optical Heartbeat Analysis Software. We aim to utilize these organisms in the development of a tool for novel compound screening.

Abstract Name: Fe-activated CoO catalysts for oxygen evolution reactions (OER): A Computational Investigation

The production of hydrogen through water-splitting reactions is a sustainable method for storing renewable energy. However, these reactions involve oxygen evolution reactions (OER) that suffer from slow kinetics and high thermodynamic potential. Catalysts with well-defined active sites and the ability to accelerate electron and proton transfer kinetics are needed to address these challenges. In this context, researchers have turned to transition metal oxides as potential catalysts, with cobalt oxide (CoO) emerging as a promising candidate due to its abundance, low cost, and remarkable stability. Despite its favorable characteristics, such as high abundance, low cost, and remarkable stability, the OER performance of CoO still falls short of noble metal catalysts, necessitating further optimization. In this study, we explored the OER activity of cobalt oxide (CoO) catalysts through iron (Fe) activation. We used Density Functional Theory to compute the reaction energies for non-activated CoO and Fe-activated Co, for OER performance. We also computed band structures and charge transfer characteristics to analyze the two catalysts' differences. Furthermore, we verified our computed results with experimental results. This work reveals the potential of strategic elemental activation in optimizing OER performance for CoO-based catalysts, offering valuable insights for future research in sustainable energy technologies.

Abstract Name: Sleep and Cardiovascular Risk Variables Correlate Perivascular Space Morphological Alterations in the Aging Brain

Perivascular Spaces (PVS) are fluid-filled spaces surrounding the brain blood vein as part of the glymphatic system. Morphological deformities of PVS may lead to the glymphatic malfunctions, a biomarker for subsequent development of Alzheimer’s disease. Studies point to changes of PVS caused by swelling of aquaporin-4 leading to morphological alternation which could have correlative relationship with cardiovascular disease such as cerebral small vessel disease and hypertension, a possible connection between cardiovascular health and neurodegeneration. This study aims to investigate the cardiovascular risk factors that most contribute to morphological alternation of PVS in health human subjects, establishing a preliminary connection between cardiovascular risk factors and glymphatic functions/brain aging. Using a semi-supervised U-Net deep-learning model, 394 subjects from The Human Connectome Project Aging dataset’s T1w/T2w images were auto-segmented. U-Net model learned the segmentation from expert’s annotations. After segmenting, PVSs were separated using depth-first search and skeletonizing algorithm which selected top 10 PVS from each subject for tortuosity, linearity and cross-sectional diameter. We then predicted these morphology features using risk factors including Pittsburgh sleep quality index, triglycerides, blood pressure, cholesterol, and BMI using 5-fold nested cross-validation. We used a prediction model as the bootstrap random forest regression with training parameters of number of trees = 100, number of features sampled for each split = 7, minimum number of split per tree = 10. Finally, we compared the predicted values with ground-truth PVS morphology values using Pearson correlation test. The results revealed significant associations between PVS morphology and cardiovascular risk factors. This finding well-aligns with previous research linking PVS changes to cardiovascular and sleep quality factors, suggesting cardiovascular risk factors' role in deformity of PVS. The study is novel in its investigation of causative factors for PVS morphological changes, enhancing understanding of glymphatic function and brain aging.

Abstract Name: Are anti-Müllerian hormone receptor type 2 (AMHR2)-expressing cells responsible for the adrenal gland development?

Adrenal gland diseases display a higher prevalence in women than men, and genome-wide studies reveal sexual dimorphism in adrenal gland gene expression. The underlying mechanism of this dimorphism remains unclear, but it is hypothesized to be linked to the shared origin of the adrenal gland and gonads during development. The receptor for the anti-Müllerian hormone (AMH), encoded by AMHR2, controls the differentiation of secondary sex organs. Mutations in AMH or AMHR2 result in Persistent Müllerian Duct Syndrome (PMDS), a condition in which a biological male develops female sex organs.Despite primarily expressing in sex organs, the pilot study indicates that AMHR2(+) cells contribute to adrenocortical cells. The present research project utilizes a mouse model with double genetic modifications, expressing the diptheria toxin subunit alpha gene (DTA) in AMHR2(+) cells. This causes the elimination of all AMHR2(+) cells and their descendants. A comparative analysis of adrenal glands between double mutant mice and wild-type littermates will elucidate the role of AMHR2(+) cells in adrenal gland development.Preliminary results show small testes and ovaries in double mutant mice, emphasizing the importance of AMHR2(+) cells in gonad development. However, despite AMHR(+) cells being in the adrenal gland, adrenal gland size remains unchanged. This result aligns with lineage tracing findings that the adrenal gland cortex continuously renews its cell population.While the preliminary data suggests no impact on adrenal gland size, ongoing research involves double immunostaining to assess the potential effect on adrenal cortex zonation. Marker genes like 3βHSD, β-catenin, CYP2F2, and tyrosine hydroxylase are used to identify specific cell types and zonation patterns. If AMHR2(+) cells play a crucial role, the expectation is a disorganized adrenal cortex in double mutant mice. This study contributes valuable insights into the role of AMHR2(+) cells in adrenal gland development and may uncover connections to sexual dimorphism.

Abstract Name: Does the stanol composition of animal feces impact the use of coprostanol in tracing human presence on the landscape?

Fecal stanols are a class of organic compounds that form in the digestive tracks of animals and are introduced into the environment during defecation. Soil and lake sediments can then be collected and analyzed for stanol concentrations. Coprostanol, in particular, is increasingly measured as a proxy for human presence and density in a specific region because this stanol is present in very high concentrations in human feces. However, other animals produce coprostanol, which may complicate archaeological interpretations. Ideally, a “fingerprint” of different stanols in the sediment could be used to determine if the coprostanol is from humans or other animals. We present results from a study that analyzed eight fecal stanols in thirteen wild animals that originate from Africa, North America and eastern Asia. The animals were selected based on feeding strategy-herbivore, omnivore, and carnivore- and their likely proximity to ancient humans or sediment sources. In general, herbivores produce the least amount of coprostanol, consistent with their diet. Both omnivores and carnivores produce, on average, nearly identical amounts, with chimpanzees having the overall highest amount for all animals. The relative percentage of stanols helps identify the different feeding strategies. Herbivores have the most similar data to one another with low percentages of coprostanol and cholesterol and high percentages of 24-ethylcoprostanol, a stanol derived from plants. Omnivores have more scatter in the data. They tend to have significant percentages of coprostanol and 24-ethylcoprostanol but lower percentages of cholesterol. Carnivores cluster tightly with very high percentages of cholesterol,

small percentages of coprostanol, and almost no 24-ethylcoprostanol. There are significant exceptions with some omnivores like bears plotting with carnivores, and certain wolves and African painted dogs plotting more as omnivores. Our data suggest that coprostanol values be interpreted carefully in archaeological sites.

Abstract Name: Detection of PFAS using molecularly imprinted polymers

PFOA and PFOS are two of a class of frequently used compounds called perfluoroalkyl substances (PFAS), or “forever chemicals.” These PFAS are released into the environment as a result of the use of fluoropolymers in industrial and consumer applications, such as construction, electronics, and products such as Gore-Tex® and Teflon®. In the environment, PFAS preclude degradation and resist traditional methods of water purification, gathering at increasing concentrations in groundwater sources. This leads to bioaccumulation in humans and animals, posing significant health risks such as decreased fertility and increased risk of cancer. Because of this, it is essential that an effective method be developed for the detection and extraction of these compounds from the environment. Molecularly imprinted polymers (MIP) are designed to bind to discrete molecules by the formation of highly selective non-covalent binding sites, and applications of MIPs for PFAS have been reported. The goal of this project was to create fluorinated MIPs with highly specific PFAS binding sites for use in sensors as a new method of PFAS detection that would allow quick assessment of PFAS levels in the field. Fluorinated MIPs (fMIPs) with binding sites for PFOA and PFOS were synthesized from novel crosslinking monomers containing fluorine in the main chain and/or on the periphery. In addition to the fMIP, a non-imprinted control polymer was synthesized for the comparative assessment of non-specific binding to PFOA and PFOS. The selectivity of the MIP was determined using quartz crystal microbalance and resistive platforms. Binding capacity was determined using HPLC-MS.

Abstract Name: Positive Emotion and Suicidal Tendencies: A study of daily emotional regulation use in autistic and socially anxious groups

Objective: This study examines the role of positive reframing as a strategy to mitigate suicidality and enhance positive emotions. Background: Emotional regulation difficulties have been identified in numerous psychiatric populations, potentially leading to stress, incarceration, and tragically, suicide. Amidst rising rates of suicidality among at-risk populations, this study aims to investigate the pivotal behavioral factors influencing suicidal thoughts and actions in autistic and socially anxious populations. Methods: Our investigation employed a longitudinal ecological momentary assessment study to explore the impact of various emotional regulation skills on positive emotion, negative emotion, and suicidality. We recruited 95 participants, 72 of which met criteria for inclusion, to answer daily surveys administered through a smartphone app that tracked emotional regulation use, positive emotions, negative emotions, and suicidal tendencies over time. Results: Our results indicate that for the social anxiety group, enjoying the moment affects positive emotions (E=2.14, p<.05), but this effect is not observed in the autism group. Furthermore, both groups demonstrated that accepting feelings (E=4.40, p<.001; E=2.63, p<.01) and acknowledging that feelings don’t last (E=1.69, p<.05; E=3.13, p<.001) significantly increased daily positive emotions. Conversely, hiding feelings significantly decreased daily positive emotions in the social

anxiety group (E=-1.76, p<.05). Self-blame increased negative emotions in both groups by, on average, four points. Regarding the reduction of daily average suicide composite scores, accepting feelings emerged as a significant factor for both groups (E=-1.88, p<.01; E=-2.15, p<.001). On the other hand, using self-blame significantly increased average suicide composite scores for social anxiety, mirroring its effect on negative emotions (E=1.42, p<.01). Conclusion: Positively reframing emotions is associated with increased positive feelings and reduced suicidal tendencies. This research sheds light on the complex interplay between emotional regulation strategies and their impact on mental health and emotions in these at-risk populations.

Abstract Name: Flowering of Ericamerica nauseosa

Flowering of Ericameria nauseosaChristine KingInvestigation research project on the effects of climate change on the flowering and populations of Ericamerica Nauseosa.iNaturalist and r studio software analysis of climate change and the effects of climate changes on plant life. Total records 179 observations It’s growth rate is 2 to 4 years and its common name is Rubber Rabbitbrush. This shrub thrives in dry soil in full sunlight. Drought tolerant once established in the soil. There are 33 species of Ericamerica. Annotation for flowering: numerous flowerheads- tubular disk shaped. Flowers bloom from August to September. Species prevalence for the project and workability The species blooms yearly between August and September therefore it is a ideal specimen for the research project. Phenology: “Rubber rabbitbrush is a large woody shrub covered with yellow flowers in late summer and fall. Flowers occur in clusters of 5 and are small and tubular. The many thin, upward bending shoots or branches give this a plant a broom-like appearance. Stems and leaves are covered in soft hairs that give off a gray-green cast. Leaves are spatula-shaped and long. It typically grows up to 6 ft tall and is found in grasslands, disturbed areas, and riparian areas” (budburst.org). Location: Arizona , California , Colorado , Idaho , Kansas , Montana , North Dakota , Nebraska , New Mexico , Nevada , New York , Oklahoma , Oregon , South Dakota , Texas , Utah , Washington , Wyoming Similar species commonly mistaken for Ericameria nauseosa Mistaken for sagebrush when not flowering. Abstract Name: Using terrestrial laser scanning and model optimization for characterizing urban tree structural parameters

Above-ground biomass (AGB) is an important metric used to quantify the mass of carbon storage in terrestrial ecosystems. Urban trees have long been valued for the potential to store significant AGB. However, urban environments pose various challenges for accurately recording AGB due to the plasticity of tree form, high species diversity, and heterogeneous and complex land cover. Light Detection and Ranging (LiDAR) is a state-of-the-art technology of remote sensing that offers an opportunity to assess AGB in urban trees effectively and inexpensively. Using LiDAR and geometric modeling algorithms, we can generate three-dimensional (3D) point clouds and digital tree segmentations. These 3D models can be used to estimate urban tree structural parameters such as height, diameter at breast height, volume, surface area, etc. First, we manually extract individual tree point clouds from plot-scale LiDAR data collected in an urban setting at Midwestern State University (MSU Texas). We then apply state-of-the-art digital tree segmentation and geometric modeling algorithms to estimate tree structural parameters and AGB of these urban tree species. Finally, we validate the available modeling tools by

optimizing parameters and comparing the outputs from the model simulations with extensive field measurements (harvested total biomass and branch biomass) from the campus trees. The model with optimized parameters for North Texas tree species (Red Oak and Cedar Elm) would provide a more accurate estimate of the total AGB of these urban tree species. This can offer a non-destructive approach for estimating urban tree AGB which is essential for understanding the overall atmospheric carbon sink and also has practical recommendations for sustainable urban forest management strategies.

Abstract Name: Acute Metabolic and Perceptive Responses to a Multi-Ingredient Pre-Workout Supplement and CrossFit®-Style Exercise

CrossFit® (CF) is a form of high-intensity functional training where trainees are often challenged to complete as much work as possible within a set time limit. Though multiple factors (e.g., strength, experience, skill) are relevant, being able to sustain a fast pace over time is dependent upon the continued supply and availability of energy to working muscle. Multi-ingredient pre-workout supplements often contain several substances known to alter blood flow and substrate utilization (i.e., fat instead of carbohydrates). However, no study has investigated the acute effects of such formulations on CF performance. PURPOSE: To compare the acute effects of a multi-ingredient pre-workout supplement on metabolic responses to 5- and 15-minute versions of the same-style workout. METHODS: Men and women (n=20: 29±8 years, 172±8 cm, 81±15 kg) with CF experience (≥2 years) were recruited for this crossover-designed, placebo-controlled study. Across four, weekly visits in randomized order, participants completed pre-exercise ratings of perceived exertion (RPE), subjective assessments of perceived energy, fatigue, and focus, along with objective assessments of blood flow (heart rate [HR], quadriceps cross-sectional area [CSA]), and metabolism (blood lactate, oxygen uptake [VO2], and respiratory exchange ratio [RER]) before consuming a pre-workout supplement (S) or non-caloric placebo (P). After resting 40 minutes, participants completed a 5- or 15-minute circuit of rowing (men: 9kcal; women: 7kcal), six barbell thrusters (men: 43.1kg; women: 29.5kg), and three box jumps (men: 0.6m; women: 0.5m) for as many reps as possible and then repeated all pre-exercise assessments. EXPECTED RESULTS: Due to physiological limitations and the likelihood that all efforts will be near-maximal, regardless of condition or time, no differences are expected in HR, VO2, and CSA. However, it is hypothesized that S will allow for more repetitions to be completed, greater perceived energy and focus, lower perceived fatigue, and lower post-exercise concentration of blood lactate.

Abstract Name: Impact of the Medicaid expansions on heart disease mortality in the United States: A county-level Analysis

Despite the significant changes that the Affordable Care Act (ACA) made to the US healthcare system since 2010, little statistical analysis of its impact on the deadliest chronic diseases has been made. County-level data from the United States is

used in conjunction with difference-in-difference models to isolate the effect of the Affordable Care Act on preventable deaths due to heart disease. Our national causal inference analysis found a significant decrease of preventable heart disease mortality due to the Medicaid expansions.

Abstract Name: Fabrication of Polysulfone/Sulfonated-polyether-ether-ketone Membranes for Removal of Organic Contaminants from Water

Per and Polyfluoroalkyl (PFAS) are surfactant chemicals formally or currently used in non-stick cookware, water-repellent clothing, household industrial products, etc. Recent studies have shown that PFAS constitutes a serious risk to human health. The presence of PFAS in water systems and sources has increased the demand for efficient, less harmful water treatment methods. Due to the structural complexity of PFAS, traditional water treatment technologies have proven insufficient for the removal of PFAS. Membrane technology is employed in this project as it is more adaptable, uses less energy, and has a smaller environmental footprint compared to other forms of water treatment. This research focuses on optimizing the functional properties of polysulfone (PSf)--based membranes by incorporating a negatively charged copolymer (sulfonated poly ether ether ketone (SPEEK)) during membrane synthesis. In this project, two types of membranes are being synthesized and compared. The SPEEK-PSf membrane composite was compared to the PSf membrane, and it was found that PSf membranes had a lower rejection of anions compared to that of the SPEEK-PSf membranes. The addition of SPEEK into the membrane matrix was observed to improve membrane performance via anion rejection, and permeability. Furthermore, the ability of the SPEEK-PSf membranes to adsorb the organic dye methylene blue was investigated. It was found that the introduction of a negative charge on the membrane surface via the incorporation of SPEEK polymer in the membrane matrix improved the adsorptive properties of the membrane. Characterization of the membranes was done through Scanning electron microscopy (SEM), Fourier-transform infrared spectroscopy (FTIR), X-ray photoelectron spectroscopy (XPS), and Nuclear Magnetic Resonance (NMR) spectroscopy.

Abstract Name: Optimizing Interdependent Security Decisions through Multi-agent Reinforcement Learning

This research project addresses optimizing security decisions under interdependent risks using a Multi-Agent Deep Q Networks (MADQN) reinforcement learning framework. The characteristic of the interdependent risk decision problem is that the agents' decision affects others' performance. The central question driving this research project is, "How can the security decisions of interdependent agents be optimized to achieve an overall increase in safety?" Traditional approaches for addressing the challenge of interdependent security decisions, such as Nash Equilibrium Analysis in Game Theory and Optimization Models, typically rely on obtaining the optimal decision based on predefined environmental models. However, the environmental model is not always accessible to agents when making security decisions. Our goal is to enhance security practices by considering uncertainties and unknown environmental conditions in the decision-making process. The methodology involves treating each agent in an interconnected network where the agent has their own Deep Q Network (DQN) model to support their decision. Each agent can observe their potential loss, their security investment decision, and the actions of other agents. Each agent's action is the quantifiable security investment they are willing to make. After each action, the agent receives a reward that considers the expected loss, probability of risk, and investment cost. The reward is used to train their DQN model to optimize their decision to minimize systematic risk. The expected results assess the

effectiveness of the MADQN framework and address the ability of the agent to learn from the environment by interacting with it. The capabilities of this framework will empower agents to optimize their decisions while also improving the overall security level of the system with cost efficiency.

Abstract Name: Bees of the Sonoran Desert

Tucson and the surrounding Sonoran Desert has over 800 native bees, but not all of the species present have been identified. For context, this is a grand amount of biodiversity for bees in a single region outside of the Amazon, largely due to our local Sky Islands. Very little is known about the bee diversity in the Sonoran Desert and the Arizona-Sonora Desert Museum (ASDM) is completing some initial phenology and population studies to identify what species are present during which times of year. Many bees collected by the Arizona-Sonora Desert Museum's "Bee Team" are awaiting identification, and Pima Community College (PCC) students are assisting with this backlog of bees to publish DNA sequences to the Barcode of Life Database (BOLD), an international scientific collection of DNA sequences. PCC students in partnership with Tucson Bee Collaborative, University of Arizona, and the ASDM are working to analyze and document the DNA of our diverse bee population through the use of DNA extraction, polymerase chain reaction amplification, gel electrophoresis, DNA sequencing (outsourced), and bioinformatics tools to obtain a consensus sequence for our bee specimen for publication in BOLD. As a student researcher with the Tucson Bee Collaborative, I was tasked with identifying bee #11 using DNA barcoding, employing the use of bioinformatics. When compared to bees published in BOLD, our specimen is most closely related to the Centris genus, but did not yield an exact match to published data. This means we will likely be the first to publish our specimen's DNA barcode in BOLD. When looking at the phylogenetic tree of our specimen, it may be of the Centris rhodopus species. Understanding our primary pollinators will empower us to preserve and protect our incredible biodiversity in the Sonoran Desert.

Abstract Name: Factors that Contribute to Successful Funding Applications for Wildfire prevention and Preparedness in High Risk Communities

This study takes a journey into the heart of high-risk communities on Vancouver Island, where wildfires cast a shadow of destruction every summer. As we hear the stories and witness the devastating aftermath, it becomes clear that not all communities actively participate in available programs designed to prepare and mitigate wildfire damage. In British Columbia, Canada, high-risk communities have been identified, and programs exist to aid them. This study seeks to understand the reasons behind the lack of active engagement by some communities in seeking and accessing funding opportunities for wildfire prevention and preparedness. The findings will be navigating through the challenges of communication, information flow, and the maze of funding applications. Surveys shed light on the inner workings of organizations leading wildfire initiatives, exposing possible knowledge gaps and communication blocks. In depth Interviews with funding applicants enrich the narrative, revealing a multifaceted landscape of wildfire preparedness challenges. Beyond expected barriers, the study explores application accessibility and the nuanced prioritization of prevention programs within

each community. Drawing comparisons between communities' wildfire experiences and risk perceptions differentiates success from struggle in funding status. This research serves as a beacon, not only identifying obstacles but crafting a roadmap for effective strategies. The insights garnered become a toolkit for tailoring outreach plans to each community's unique needs, fostering collaboration. Ultimately, this knowledge emerges as a catalyst, empowering at-risk communities and fortifying their resilience against the looming specter of wildfire threats. The vision extends beyond individual communities, nurturing a collaborative environment that strives collectively towards wildfire prevention and preparedness.

Abstract Name: Studying the Effects of Culture and Economic Freedom on Financial Development

While an important question, there has not been much research investigating how cultural values and economic policies work together to influence financial development globally. We think filling this gap in the literature could provide some unique insight. We will be compiling data on culture using Hofstede's framework and the Global Preferences survey, data on economic freedom from the Fraser Institute's index, plus financial and economic data from the World Bank. Then we will use some statistical analysis techniques to examine the relationships between these factors as well as how they impact things like the strength of banking systems and capital markets. Obviously, culture shapes a lot of attitudes around things like patience, risk-taking, and individualism. And those attitudes feed into financial decisions people and organizations make. Likewise, regulations and economic freedom affect how financial markets operate. However, no one has quantified exactly how those cultural perspectives and policy variables interact. This is what we are hoping to uncover. Our hypothesis based on what we know so far is that cultures with more patience, more appetite for risk, more individualism, matched up with freer, more open economies, will correlate strongly with better developed, more stable financial systems. We will empirically investigate this to test our hypothesis. The results will shed light on the financial and economic impact of culture, as well as how the economic systems and institutions of a country interact with these factors. Our work will provide suggestions on ways countries can improve their business and economic environment, given their culture, that will result in financial and economic improvement.

Abstract Name: Research Evaluating Vagal Excitation and Anatomical Linkages (REVEAL) on Vagal Nerve Stimulation

The autonomic nervous system (ANS) is responsible for maintaining homeostatic control and modulates the lymphatic, cardiovascular, metabolic, and inflammatory systems. The ANS consists of sympathetic (fight or flight) and parasympathetic system (rest and digest). The vagus nerve is involved in the parasympathetic function. The Vagus Nerve Stimulator has been approved by the FDA to treat epilepsy and depression, however the effects of VNS on peripheral organs are unclear. Increase in sympathetic nervous system throughout the body can cause adverse effects such as end organ damage hence understanding the influence of VNS on sympathetic function while learning about the correlation between SNS and VNS can lead to novel discoveries. The REVEAL study is a single blinded, multisite, crossover study, with a target sample size of 144 participants, 18 years or older. Participants will either have a previously implanted VNS or will be newly implanted prior to beginning study procedures. Six parameters of VNS are received by participants in a randomized order in acute and chronic phases. Blood pressure, heart rate and muscle sympathetic nerve activity (MSNA), the gold standard measure for sympathetic function will be measured acutely at rest and during handgrip exercise and a head up tilt test and after 12 weeks of VNS stimulation at a predetermined and randomized frequency and duty cycle. We hypothesize that VNS will lower MSNA and

blood pressure. Findings from this study will lead to therapeutic treatments and hold promise for refining VNS interventions and with a wide range of implications in various medical domains.

Abstract Name: Student Views and Practices of Sustainability: A Study at Trevecca Nazarene University

This is a foundational study answering the question: “What creates a university culture that leads to the integration of sustainable practices into campus life at Trevecca Nazarene University [TNU]?” After reviewing existing literature, the student body of TNU was surveyed about their attitudes and beliefs surrounding sustainable practice. The data indicated two clear disconnects: one between student beliefs around sustainable practice and their perception of TNU’s practices, and one between student practice on campus and off campus. The study found that 96% of the survey respondents considered sustainable practice to be broadly necessary for the thriving of the earth and human life, and 92% considered the overall health of the global environment to be deteriorating. However, when asked about the institutional behavior of TNU, only 30% of participants indicated that Trevecca practiced sustainable care for the local environment. Participants were also asked what factors informed their beliefs about sustainable practice. The most selected factor was “Educational Background,” with 46% of respondents choosing it as most influential in informing their beliefs. Of the participating students, 42% indicated involvement in sustainability efforts independent from TNU, compared to 13% indicating involvement in sustainability efforts on campus. This disparity between on and off campus involvement was deemed significant because students are able to participate in sustainable practice on campus through the Trevecca Urban Farm.This study indicated clear disconnects between TNU and its student body, though a direct cause is unclear. The results of the completed survey, combined with a review of existing literature, suggest the potential need for an increase in sustainability education opportunities at TNU. Further study is encouraged to investigate this as a potential way to bridge the ideological gap between the institution of TNU and its student body.

Abstract Name: Mental Health Access on Michigan College Campuses

Despite a decline in university enrollment across the nation, there has been an increase in college student mental health pathology (Pashak et al., 2022). The age demographic of traditional college populations coincides with the age of onset for the most common mental illnesses (El-Monshed, Fayed, & Loutfy 2021). Moreover, these students are more likely than their non-college-attending peers to experience stress due to adjustments to a new academic environment, moving away from family homes, and forming new social connections (Vargas-Huicochea et al. 2022).This study aims to examine the availability and scope of mental health resources on Michigan college campuses. This research involved a manual web scraping analysis of Michigan two-year colleges (n=23) and four-year universities (n=57). We find that 81.61% of Michigan higher-ed institutions (n = 80) offer on-campus counseling services. Twelve (13.79%) institutions supplement access by investing in third-party services (e.g. Employee Assistance Programs, BetterMynd, UWill, etc). Five schools (5.75%) have no on-campus resources but refer to third-party contractors or local resources. Eleven (12.64%) schools have no evidence on their institution website to suggest any mental health support. The proportion of public institutions offering third-party mental health resources is significantly higher (76.5%) than private institutions (17.6%).While most institutions have on-campus mental health access, colleges and universities are equipped to manage school stress. They are not well-equipped to handle mental health crises or serious mental health pathology. BetterMynd, a licensed teletherapy and medication

management provider offers pricing based on anticipated student need that rolls over to the following year. ULifeline, a virtual crisis text line is offered at no charge and is intended to support individuals through an imminent crisis. While there is extensive research on the mental health of college students, there is a notable gap in the services available to them on college campuses.

Abstract Name: Narratives of Mental Health in Professional Male Athletes as Constructed by the Media

While male athletes are often praised for being invincible, they are in no way excluded from the mental health challenges the rest of the population faces. This is especially true for those without a solid support system (Souter et al., 2018). The team developed two questions: How does the media narratively construct mental health for professional athletes? In what ways are these narratives actively resisting or reproducing the stigmas surrounding male athletes' mental health? The group first conducted initial searches in popular sports media magazines and websites. Results were limited to the top page of search finds to emulate the public attention span, and the year was limited from 2018 to the present. After initial searches were conducted, two personal athlete story articles and one media story article representing the sports' stance on mental health were chosen for football, basketball, baseball, and hockey (four sports, three stories each). After conducting narrative thematic analysis on twelve chosen articles, a dichotomy of two main narratives emerged from the data. In the redemption narrative, athletes confide in struggles they have had, but the primary focus is on the athlete's ability to overcome any struggles on their own and through their involvement in sport. In the extreme breakdown narrative, athletes get to a point where they cannot prioritize their mental health in the sporting environment and have to leave indefinitely and/or demonstrate their mental illness in extreme ways. By only showcasing these two opposing narratives, the media is constructing a narrowed version of mental health perspectives that continue to silence and stigmatize the wide variation of mental health experiences for male athletes. Despite sincere and positive messages, the underlying notion remains that male athletes must be their own mental health advocates and their stories must stay within the realms of hegemonic masculinity.

Abstract Name: Los Desaparecidos: Photographing Memory and Violence in Post-Dictatorship Argetina

From 1976-1983, the military dictatorship of Jorge Rafael Videla ravaged Argentina, creating a lengthy period of violence and discontent. Approximately thirty-thousand individuals were lost during this brutal period termed La Dictadura. Those who perished are referred to as Los Desaparecidos, the missing; they embody violence afflicted on citizens by the state. The mothers and grandmothers of the disappeared rose in protest against the Argentine government, forming a human rights coalition in 1977 called Las Madres de Plaza de Mayo. After this prolonged period of violence, much has been done nationally to recover the trust of the masses; however, the trauma of La Dictadura remains in the memory of those who experienced this military dictatorship. Through the artwork of Argentine artists and activists in the 1990's, including Marcelo Brodsky, Julio Pantoja, and Graciela Sacco, the aftermath of this period of violence was photographed, shedding light on La Dictadura and the continued impact of this dictatorship on generations of Argentine citizens. This paper will discuss the Argentine dictatorship and the artwork from the aftermath of this period as a tool of memorialization, investigating the portrayal of this dictatorship from an art historical perspective.

Abstract Name: Systemic Processes of Regulation Influencing the US Education System: Hindering Outcomes for Low-Income Students and Students of Color

Educational attainment is a mechanism for upward social and economic mobility in society. According to Morris, Conteh, and Harris-Perry (2018), this is especially true in low-income families. Higher levels of educational achievement are positively associated with higher-paying careers and more opportunities. However, experiences and opportunities within the education system are not identical for all. Research has shown that low-income students, students of color, and students with disabilities face additional inequities and barriers within their educational journeys. Prior research has addressed several of these barriers in the US education system; however, further research needs to be conducted, particularly in Missouri. According to Furtado et al. (2019), Missouri is one of nineteen states that permits corporal punishment within schools. Specifically, the St. Louis, Missouri region possesses a significantly wide racial disciplinary gap compared to state and national averages. In this research, taking into account the history of American racial discrimination, I plan to address the following question: (1) If and how does the historical legacy of legal discrimination, in terms of the racial and class composition of neighborhoods and student populations, school expectations, and the funding of schools, impact how schools have responded to formally neutral neoliberal state and federal regulations and laws. To do this, district handbooks and comprehensive school improvement plans (CSIPs) were qualitatively coded for numerous variables and analyzed for evidence of neoliberalism within school policies and practices. The results of this data collection and analysis demonstrate evidence of

neoliberal values through the increased measures of academic efficiency and achievement, increased punitive disciplinary approaches and presence of SROs, and the policing of students and families outside of school.

Abstract Name: Influence of Gender and Social Support on Suicidal Ideation in College Students

Suicide accounted for nearly 50,000 deaths last year in the United States (CDC, 2023). The Integrated Motivational Volitional Model (IMV) of suicidal behavior has indicated entrapment and social support as important components of suicidal ideation and intent. Past research shows that women tend to receive more social support than men and highlights the negative societal expectations that discourage men from reaching out for social support (Turner 1994; Bannister, 2020). Some findings suggest that social support may be more important for reducing suicide among men than women. (Šedivy, 2017). However, there is little research on the moderating effects of gender within the IMV model. The objective of this study is to test the hypothesis that gender would moderate the effect of social support on the relationship between entrapment and suicidal ideation. College students (N = 350, Mage = 18.95, SD = 1.4; 86.7% White; 71.5% Female) were recruited to complete an anonymous online survey via email invitation assessing entrapment, social support, and suicidal ideation. We ran a moderated moderation regression using the SPSS PROCESS macro. The full model was statistically significant (F (7,342) = 29.41, p < .001) accounting for 37.6% of the variance. The three-way interaction of entrapment, social support, and gender was non-significant (b = -0.03, p = 0.17; 95% CI: -0.06, 0.01). The interactions between gender and both entrapment and social support approached significance (p-values < .07). Gender also had a significant main effect on ideation (b = -4.34, p < .04, 95% CI: -8.47, -0.21). Results indicate that gender did not affect how social support influenced the relationship between entrapment and suicidal ideation, but did have a main effect, with males reporting slightly higher ideation. Additional research is needed to replicate these findings and further explore how gender impacts factors contributing to suicide risk.

Abstract Name: Modeling and Mapping of Microstructure of Powder Bed Direct Metal Laser Sintering Additive Manufacturing Hybrid Milling of Maraging Steel

Additive manufacturing (AM) has transformed conventional methods of manufacturing by enabling more intricate and customized part manufacturing. Industries including aerospace, medical, and advanced tooling utilize metal additive manufacturing (MAM) to increase component quality and performance. Although direct metal laser sintering (DMLS) has been extensively studied, a gap still exists in understanding the impact of hybrid milling on part's mechanical properties. This research aims to fill some of this gap by studying and establishing the relationship between the major process parameters and the resulting microstructure, energy density, and mechanical properties of Maraging steel parts by DMLS hybrid milling AM. A Matsuura LUMEX Avance 25 laser sintering hybrid milling machine was used to produce 27 separate ASTM standard samples of varying process parameters across three levels with three replicates. The experiments were designed using a L9 Taguchi orthogonal array design of experiments. The process parameters include laser power, print speed, hatch space, and powder layer thickness. These specimens were tested using the ASTM E8 testing standard, and microstructure evaluated using a scanning electron microscope (SEM). Analysis of Variance, (ANOVA), and Classification & Regression Trees (CART), in Minitab Statistical Software were used to analyze and model the quality characteristics. The results of this research would be the development of models of direct influence of the major process parameters on Maraging steel's microstructure development, energy density, and mechanical behavior in DMLS hybrid milling MAM. The developed process models will enhance predictions of microstructure and performance of components by the designer. The discussions will highlight the implications of these findings for industry standards and the potential shift towards wider adoption of DMLS hybrid milling as a manufacturing method for critical components in both aerospace, medical, and tooling industries. Keywords: Additive Manufacturing, Metal Additive Manufacturing, Direct Metal Laser Sintering Hybrid Milling, Maraging Steel, Mechanical Properties, Microstructure.

Abstract Name: Optimizing Muon Collisions: Tungsten Cone-Generated Magnetic Fields in the CERN Muon Collider

The CERN muon collider team in Genever Switzerland aims to collide muons and antimuons together in a detector to understand and learn more about their nature and physical properties. One major setback with this is that muons are unstable particles, meaning they have a lifetime of 2.2 microseconds, that is, 2.2 microseconds before they decay into an electron and neutrinos. Currently, there is no working muon collider, and it is because of the instability of the particles that we cannot successfully get them to interact with each other in time. One way around this setback is to supply massive amounts of energy through the form of magnetic field solenoids to accelerate the muons so that they may interact with each other and collide before decaying. The detector segment of the muon collider is equipped with a superconducting solenoid to provide a magnetic field for the muons and antimuons to accelerate. However, due to its sheer size, it cannot produce a significant magnetic field without producing too much heat loss and incurring a lot of resistance. This is where we require the help of an external magnetic field generator. There are two cones made of tungsten pointing towards the center of the detector from either side, used to shield products of muon decay from leaking into the detector to reduce background radiation. By supplying a voltage through the cones, we could theoretically strengthen the magnetic field strength felt by the muons, allowing them to accelerate faster. This could help increase the number of collisions before decay, provided the resistance of the cones is supplying an ample amount of energy and not losing too much from heat loss. Research and investigation on finding the optimal way to supply current through the tungsten cones to generate magnetic fields is currently being done.

Abstract Name: Targeting heparan sulfate proteoglycan interactions with amyloid-beta: a novel therapeutic approach for Alzheimer's disease

Over six million Americans currently live with Alzheimer's disease as of 2023 (National Institute on Aging.) It is one of the most prevalent diseases of the aging population; however, most treatment options are to mitigate the symptoms of Alzheimer's disease instead of targeting the root cause (National Institute on Aging.)Alzheimer's disease pathology is characterized by extracellular amyloid beta plaque depositions accumulating in the brain leading to cell death (Hardy & Dennis). Amyloid beta fibrils can be taken up into the neurons of the brain to cause direct cell death or can block cell-to-cell signaling to induce cell death (Lindahl et. al., Zhang et. al.). Recent data show cell surface heparan sulfate proteoglycans are receptors responsible of the fibril formation of amyloid beta by stabilizing the monomer/oligomer enough to enhance the aggregated plaque in the brain parenchyma as well as being responsible for uptake and spreading of pathogenic amyloid beta (Zhang, et. al.). The goal of this study is to develop a novel Alzheimer's Disease treatment with a glycosaminoglycan inhibiting small organic molecule. The hypothesis we propose is our compound(s) will block the interaction between the cell surface proteoglycan and amyloid beta peptides to prevent amyloid pathophysiology by amyloid-beta aggregation and endocytosis. So far, thousands of compounds have been screened through enzyme-linked immunosorbent-based assays to test the inhibition of amyloid beta binding heparan sulfate proteoglycans by each experimental compound. Lead compounds have been chosen for the next phase of trials including APP/PS1 transgenic mice and evaluate the efficacy of reducing amyloid deposition in the brain. In vivo trials are ongoing, however in vitro trials have been concluded and will be presented.

Abstract Name: STINKING THINKING: A Critical Analysis of the Influence Financial Education and Banking Tools Have on Dismantling Poverty In Black Communities

Financial illiteracy in the Black community contributes to the large wealth gap that separates White and Black households in America. The lack of financial literacy in Black households leads to having less wealth than their White counterparts, which, in turn, affects generational wealth (Aladangady & Forde, 2021) Factors that contribute to financial illiteracy are the lack of access to financial education, limited or unreliable employment, and institutionalized racism (Abdullah, 2019; Angrisani et al., 2020). Poverty is a cycle that tends to predominately impact generations of Black families and is difficult to stop. This research project aims to investigate two financial institutions, Huntington Bank and PNC, digital banking tools, and educational programs offered to their patrons. This investigation will assess if these two financial institutions assist with dismantling poverty and are easily accessible to Black people. The goal is to evaluate the gaps

between so-called financial services/education and their engagement with Black people. A way to help close the wealth gap is to educate the underserved Black communities and ensure they have the same access to financial resources and education as people of other races.References:Forde, A. Abstract Name: High-Speed X-ray Image Analysis of an Airblast Atomizer

Sprays are commonly found in many industrial applications, from fuel injection in gas turbine engines to mixing in chemical processes to water dispersion in crop growth. Characterizing sprays in the region near the nozzle exit, called the near-field region, is important because it influences the atomization and spray dispersion process. However, visualizing the near-field nozzle region using high-speed cameras is incredibly difficult because the region is optically dense, making visual access difficult. In this study, the near-field nozzle region of an airblast coaxial two-fluid atomizer is visualized using high-speed X-ray imaging methods, which are then analyzed to characterize the spray motion. Imaging was completed for different gas-liquid momentum flux ratios, gas-liquid swirl ratios, and ambient pressures. It is shown that spray flapping frequency is influenced by ambient pressure and momentum flux ratio and is very sensitive to the gas-liquid swirl ratio.

Abstract Name: Mother Computer: Thinking with Natural and Artificial Intelligences

Can "artificial" minds amplify human expression, or are they a threat to creative thinking? This large-scale project and traveling exhibition combines the art and research of Professor Dr. Nathaniel Stern, Ph.D., and world-renowned Artificial Intelligence artist and poet Sasha Stiles, towards poems, sculptures, prints,

installations, and artist books in collaboration with - and about - AI. Combining cybernetics and ecology, Stern and Stiles collaborate with Artificial Intelligences and material forms to create art and poetry that reflects on the nature of human creativity and technology, affect and interaction. The project comprises of six poems written in conjunction with AI and centered on the meaning and workings of non-human minds. The poems “Mother Computer”, “The Word After Us”, “0RAL B1NARY”, and “Feral Font” investigate what language is, the importance of language in human cultures and societies, the relevance of language(s) in the age of computing and AI, and the future of language(s) in a post-human world; “The E-Waste Land” and “Still Moving” are meditations on the relationship we have with our cybernetic systems and they give a hypothetical voice to man-made technology. Experimenting with custom-trained generative AI, natural language processing, various machine learning models, computer-aided design, blockchain, data visualization, computer vision, and text-to-image platforms reveals not only how computers and non-humans think and make, but how we process and imagine as well. These new technologies promote innovation and synthesis without replacing the human ‘touch,’ and Stern, Stiles, and their team of students exemplify this in how they materialize and substantiate various intelligences with traditional art-making methods such as printmaking, paper-making, and sculpture, all together exhibiting how creative thinking has never been solely a human pursuit.

Abstract Name: Differences in Crash Risk at Night Depending on Headlight Lightbulb Types and Auto-High-Beam Presence

Vehicle headlamps are designed to provide visibility for the driver at night while attempting to reduce glare for oncoming drivers. High- and low-beam bulbs are traditionally halogen, yet LED and HID bulbs have been used in some newer models to provide improved illumination. Additionally, some newer vehicles are outfitted with auto-high-beam (AHB) teachnologies to assist the driver. While these are all intended to assist the driver in safe driving in the dark, no studies have provided an analysis of the relationship between headlamp types, the presence of AHB, and crash risk at night.The objective of this research is to evaluate the difference in crash rates between vehicles with the different bulb types and vehicles with/without AHB at night while accounting for potential confounding factors. The central question of this research is if the more expensive LED and HID headlamps and the AHB technologies are associated with redacted crash risk. This will be evaluated using police-reported crash data from multiple states and data collected on headlamp technologies based on the vehicle Make, Model, Model Year, and Trim Level (e.g., Ford Ranger, Model Year 2021, XLT trim). These data will be analyzed using the Quasi-Induced Exposure methodology commonly used in transportation and vehicle safety research.The results of the analysis will be discussed in terms of any safety benefits provided, their role in the safety ratings provided by the Insurance Institute for Highway Safety (IIHS), and the added cost for the vehicles the different headlamp types and AHB are available on. Additionally, should the analysis results indicate significant safety benefits, the results will be discussed in terms of how the results could be considered in regulatory decisions and automotive manufacturing policy and planning.

Abstract Name: Chitosan-Glycerol Injectable Gel for Intratumoral Retention of Immunotherapeutics

Localized cancer therapeutic delivery provides several advantages over systemic delivery, including increased retention and reduction of systemic side effects. In particular, intratumoral injections are an advantageous delivery method for cancer treatment because they maximize therapeutic concentration while limiting systemic exposure. However, the dense extracellular matrix and higher pressure tumor environment severely limit injection retention, as less viscous solutions easily return via the needle track. Gel delivery systems address this limitation due to their increased viscosity and hence improved retention at the tumor site, allowing for the long-term, controlled release of therapeutics. Chitosan, a polysaccharide derived from the shells and scales of crustaceans and fish, has been used in gel creation due to its wide availability and its biocompatible nature. A novel chitosan-glycerol injectable gel was developed to improve therapeutic retention for intratumoral delivery. Different relative glycerol to chitosan volumes, ranging from 5 to 95% weight/volume glycerol, were tested to determine the optimal gelation conditions. Phosphate-buffered saline was incorporated into the solution, which was then raised to a pH of 7.8 with sodium hydroxide. After centrifugation at 10,000 rpm for 5 minutes, chitosan-glycerol gel was formed. Glycerol most significantly impacted gelation conditions independent of chitosan concentration, with gelation occurring between 70-85% relative volume glycerol. The gel was injected through a 25-gauge needle into gelatin-based tumor phantoms, and it displayed increased load retention for various molecule sizes compared to saline and chitosan-based solutions. Cytotoxicity was assessed via trypan blue staining and subsequent cell counting of 3T3 cells exposed to the chitosan–glycerol gel. After 48 hours, sustained cell counts in cases exposed to the gel via transmembrane wells indicated biocompatibility through a live:dead cell ratio within 3% of the negative control. Due to this increased retention time and biocompatibility, chitosan-glycerol gel offers a potentially effective platform for intratumoral delivery of immunotherapeutics.

Abstract Name: Synthesis and Characterization of Unnatural α,α-Disubstituted Amino Acids for Peptide Therapeutics

Peptide therapies have received a lot of interest and have been extensively studied because they are highly selective, well-tolerated, and have less adverse effects than small-molecule drugs. Due the extremely acidic environment in the stomach and the proteases of the small intestine, peptide drugs must be injected into patients to avoid destruction. To enhance the stability of peptide therapeutics in these extreme conditions, unnatural-amino acids that are not recognized by the protease are inserted, preserving the peptide containing the unnatural-amino acids from proteolysis. Unnatural -amino acids such as amino acids that contains two carbon substituents on the α-carbon that bears the amino and carboxyl groups are known as α,α-disubstituted or quaternary amino acids. The synthesis of α,α-disubstituted amino acids as unnatural -amino acids has

received a lot of attention in recent years, ranging from conformational modifiers in physiologically active peptides to pharmaceutical chemistry as they are used as building blocks for the preparation of biologically and medicinally compounds. Herein, we have synthesized two α,α-methylated unnatural-amino acids, phenylalanine and tyrosine, to incorporate into peptide therapies. We hypothesize that the α,α-methyl groups will provide additional steric hindrance in the peptide backbone and promote significant π–π stacking interactions between the two aromatic phenyl rings on the same side of the peptide, resulting in a non-covalently stapled helical peptide. Because proteases do not recognize unnatural amino acids, this peptide based on unnatural-amino acids will be highly stable in serum.

Abstract Name: Enhancing Pathogen Eradication: An Autonomous UV Robot System with Advanced Navigation and Intelligent Disinfection Techniques

UV-based mobile robots have demonstrated their efficacy in pathogen eradication, yet there is a growing demand for optimizing their performance and ensuring safety. Ultraviolet light can penetrate the cell membranes of microbes which destroy the nucleic acids and paralyze vital cellular functions preventing the reproduction of the cell. Using the Ultraviolet Germicidal Irradiation (UVGI) disinfection technique, we can implement UV-C light to limit the spread of pathogens specifically Gram Positive Cocci and Staphylococcus, which are common bacterium known for their ease of transmission through surfaces and air. Frequent sterilization of these pathogens in commonly used spaces is critical for limiting the spread of infectious diseases such as MERS, SARS, influenza, and COVID-19. Implementing advanced technologies such as robotic machines that are capable of disinfecting environments repeatedly in complex spaces plays a vital role in preventing the transmission of illnesses. Current UV robot systems are either placed in the center of the room or have rudimentary methods of mobility using RGB-D cameras and Ultrasonic sensors. In our study, we propose a cost-effective autonomous robot system that utilizes hyperspectral cameras and sensors including LIDAR for enhanced robot navigation. Additionally, through implementing image processing and object detection techniques we can create an intelligent system to determine better analysis of the environment. This will result in the robot system using different sanitizing methods, either by running the UV light for longer or by enabling disinfectant sprays in the selected area. To limit the amount of UV light with human interaction the robot system will have cameras to detect real-time interference if a human is in the room and temporarily disable the UV light. As the world grapples with ongoing health challenges, the integration of intelligent systems into UV robot technology is poised to make a significant contribution to our collective resilience against pathogenic diseases.

Abstract Name: Effects of Environmental and Economics Factors on Life Expectancy in the U.S.

U.S. governmental agencies, such as the U.S. Census, EIA, and EPA, gather voluminous data that reflect our population's statistics and the factors that impact Americans' well-being. The dataset used in this study is drawn from such sources and includes data about air and water quality, toxicity levels, solar radiation, and economic factors such as GDP per capita, unemployment rates, minimum wage, healthcare coverage, and educational attainment. This study seeks to search the mountain of data obtained during the recent U.S. Census of 2010, for all 50 states and the District of Columbia, to determine if a relationship exists between life expectancy and several environmental and economic factors. By subjecting this diverse dataset to econometric analysis, this study seeks to uncover relationships that illuminate how these factors intertwine with life expectancy and suggest policy changes to legislators, to improve longevity and health for all people. Rigorous econometric methods applied to this rich dataset aim to determine if these variables are statistically significant, elucidating the intricate relationships between these factors and life expectancy with the ultimate goal of evaluating the different governmental policies that monitor these factors. Microsoft Excel will be utilized to run an OLS linear regression to determine variables including betas, 95% confidence intervals, and standard errors. It is anticipated that the relationships determined may pinpoint key associations, demonstrating, for instance, that regions with better air quality or higher educational attainment tend to display longer life expectancies. This thorough analysis offers concrete insights into the nuanced interactions between these variables and life expectancy. By leveraging credible data and analytical methods this study will illuminate how environmental and economic factors intertwine with the length and quality of human life, potentially influencing future policy decisions within the United States and globally.

Abstract Name: The Effects of Parentification on Parental Attitudes and Beliefs

Parentification occurs when a child is placed in a parental role, forcing them to assume the duties of a parent. These duties can include contributing to family finances, caring for siblings, and/or providing emotional support to the parent(s). Parentification can be traumatic and damaging to one's sense of self, which can negatively impact one's sense of competence and security. Past literature suggests that parental competence is associated with overall self-efficacy. The experience of trauma can result in reductions in mental health which further damages interpersonal relationships. Parentification can result in a disconnect between parent and child and represent insecure attachment. This type of attachment is marked by a hesitancy to trust and rely on others, which can result in parentified children having difficulties in their interpersonal relationships as they mature. Given the established links between stressful life experiences, trauma, and parentification, the current study will try to replicate these relationships and establish further associations with attachment and attitudes related to parenting. This study will use a cross-sectional research design in which participants will fill out a series of surveys measuring their experience of parentification, beliefs, and attitudes related to parenting (e.g., appropriate responsibilities of parents, expectations related to parenting), attachment style, and adverse childhood experiences (ACEs). It is our expectation that: (1) Parentification will be associated with dysfunctional parental beliefs and (2) There will be an interaction between parentification, ACEs, and attachment on parental attitudes/beliefs, such that parentification will be more strongly related to dysfunctional parental attitudes/beliefs in participants with an insecure attachment and ACEs.

Abstract Name: Unravelling the Role of Purkinje Cells in Motor Deficits of MeCP2-Deficient Mice: Implications for Rett Syndrome and Beyond

Autism spectrum disorders (ASDs) are prevalent neurodevelopmental conditions characterized by social interaction impairments, repetitive behaviors, and motor dysfunction. Rett syndrome (RTT), an X chromosome-linked ASD, is a leading cause of severe intellectual disability in females. The majority of RTT cases result from mutations in the MECP2 gene, with symptoms including stereotypic hand movements and a decline in motor function. While the MECP2 deficiency in neurons overall is known to be the primary cause of RTT, the role of the specific neuronal type remains to be defined. Given the known link between cerebellar dysfunction and motor deficits in ASDs, we hypothesize that Purkinje cells (PCs) in the cerebellum contribute to motor impairments in mice lacking Mecp2. To test this hypothesis, we generated mice with specific methyl-CpG binding protein 2 (MECP2) deficiency in PCs. We validated our model by comparing these animals with constitutive MECP2 knockout mice using immunofluorescence. We assessed motor learning using an advanced pellet-reaching device that enables precise analysis of forelimb and digit movements. By employing the DeepLabCut software, we examined whether the two-dimensional reaching trajectory is impaired in these MECP2 conditional knockout mice. Additionally, we expressed the GCaMP6 indicator in Bergmann glia to investigate neuronal activity using fiber photometry recordings and determined whether calcium signaling during motor learning deviates from the normal pattern. Our study demonstrated the pathophysiological role of impaired PC function in cerebellar-dependent motor behavior, providing valuable insights not only for RTT but also for other brain disorders that share similar molecular and neural substrates.

Abstract Name: Drp1-Induced Mitochondrial Fission Controls Cortical Astrocyte Organization And Development

Mitochondrial homeostasis is essential to proper brain development and dysfunctional mitochondria are implicated in multiple neurodevelopmental disorders. Mitochondrial function and localization is regulated by mitochondrial fission, fusion, and trafficking, collectively referred to as mitochondrial dynamics, a process that is particularly important in highly branched cells of the brain. Astrocytes are glial cells characterized by their complex branched morphology that allows them to perform many functions such as inducing synaptogenesis in the developing cortex. Cortical astrocytes are organized in nonoverlapping territories in a phenotype described as tiling. Tiling is a hallmark of astrocyte maturity and is lost in disease, suggesting tiling is imperative to astrocyte development and function. However, the molecular mechanisms of how

astrocytes establish tiling during development are not well understood. Past research in the Eroglu Lab has shown that early postnatal knockdown of Drp1, a regulator of mitochondrial fission, in astrocytes in the mouse cortex leads to astrocyte clustering. Therefore, we hypothesized that Drp1-induced mitochondrial fission regulates astrocyte organization and tiling in the developing and mature mouse cortex. We found that sparse Drp1 KD in astrocytes induces clustering into adulthood up to 6-month-old mice, indicating Drp1 control of astrocyte organization is not a transient developmental mechanism. Furthermore, we uncovered that Drp1 KD astrocyte clusters are multinucleated and have disorganized cell somas, confirming Drp1 controls the tiling phenotype of astrocytes. Lastly, we found that astrocyte-specific conditional KO of Drp1 results in disorganization and reduced astrocyte coverage in the cortex, coupled with heterogeneous upregulation of GFAP, a marker of astrocyte dysfunction. These findings indicate that Drp1 controls astrocyte organization and identity and underscore the importance and therapeutic potential of mitochondrial fission in the proper development of astrocytes.

Abstract Name: Synaptic Lysosomal Dysfunction and the Effects of Acid Ceramidase on Synaptic Psychosine Accumulation in Krabbe Disease

Krabbe Disease (KD or Globoid Cell Leukodystrophy) is a demyelinating and neurodegenerative lysosomal storage disease (LSD) centered on a deficiency in the lysosomal enzyme galactosylceramidase (GALC). In physiological conditions, GALC removes galactose from the galactolipids galactosylceramide and galactosylsphingosine (psychosine) to produce ceramide and sphingosine, respectively. In KD, galactosylceramide is deacylated through acid ceramidase (ACD, another lysosomal enzyme), and, with GALC deficiency, there is a toxic accumulation of psychosine in both neuronal and glial cells, causing demyelination and neurodegeneration throughout the central and peripheral nervous systems. Although the mechanism of psychosine synthesis is known, the location and rate of psychosine synthesis in neurons is unclear. Due to preliminary findings showing that synapses in the “Twitcher” (TWI) mouse model of KD exhibit a noteworthy decrease in synaptic vesicles, we hypothesize that psychosine is locally accumulated and synthesized by ACD in the presynaptic compartment. To test this idea, biochemical analyses of synaptic psychosine levels and ACD activity/levels were conducted in KD-mouse, KD-dog models, and human infantile-KD samples to confirm that our observations in the “TWI” are not species-specific artifacts. The levels and subcellular distribution of ACD were analyzed through synaptic fractionation, western blot, and immunohistochemical analyses, while ACD activity was measured through an assay utilizing the fluorescent ceramide analogue Rbm14-12. Also, psychosine was extracted from each synaptic fraction and quantified using mass spectrometry. Our results showed a notable increase in psychosine accumulation specifically in the synaptic vesicles and presynaptic membranes. Additionally, alterations in ACD activity/levels in synaptic compartments were observed between KD models and control/wild-types. Interestingly, lysosomal distribution was also disturbed in TWI brains, thus providing the basis for further studies of lysosomal behavior and dysfunction in KD.

Abstract Name: Cushion Sea Stars (Oreaster reticulatus) Have the Ability to Respond to Disturbance

We were interested in the distance of movement among cushion sea stars (Oreaster reticulatus) located in Graham's Harbor, San Salvador, Bahamas. We hypothesized that there is a difference in distance moved when the starfish are under disturbed conditions as compared to undisturbed conditions. Based on our hypothesis, we predicted that the starfish move further when disturbed in comparison to when they have not been disturbed. The data was collected through six trials, over the course of three days (9-11 March, 2022). For the disturbed environment, we collected the starfish and placed them in a central location. From there, we measured the distance moved after one hour. For the undisturbed environment, we found the starfish in their original location, marked the location, and measured the distance moved after one hour. Distance moved was significantly different ($t = 3.46$, $df = 11$, $p=0.005$) between disturbed ($M = 22.89$, $SD = 24.95$) and undisturbed ($M = 0.328$, $SD = 0.979$). Statistical analysis suggests that we accept our hypothesis. These results suggest that sea stars have the ability to determine a change in their environment. Overall, this research contributes to the general knowledge regarding the behavior of cushion sea stars, as well as individual preferences of the sea stars.

Abstract Name: Beyond Obstacles: The Influence of Group Support on Physical Activity Habits

Physical activity (PA) is a vital public health approach to reduce the risk of obesity, diabetes, and other chronic diseases. African American (AA) women is one of the most affected groups due to several barriers to PA. Lack of time, motivation, social support, knowledge of PA; chronic health conditions; and neighborhood safety have been frequently reported as obstacles. Social support in addition to wearable activity monitors and a mobile application can be a favorable approach to promoting PA. PURPOSE: This study investigates the influence of social support, specifically within exercise groups, on reducing barriers to regular physical activity. METHODS: Participants are enrolled in an ongoing 24-week tiered exercise intervention that includes both in-person and virtual exercise sessions. Each participant receives a Fitbit® to self-monitor their daily PA, including the number of steps, type of PA, and sleep behaviors. An invitation only Fitbit® group was created, and intervention participants were encouraged to use. The group provided encouragement, advice, as well as PA accomplishments. A Perceived Barriers and Social Support Questionnaire was developed via Google forms for participants to complete. This 13-item questionnaire was designed to measure perceptions of social support, satisfaction with that social support and continual barriers to PA. RESULTS: The researchers anticipate that the results will reveal a positive correlation between social support and reducing barriers to physical activity among African American women. Moreover, the participants will enjoy accessing their information to stay on track of their goals. Lastly, the researchers expect that having the

ability to see others in the groups weekly step count can assist in promoting healthy competition/motivation for engagement in PA. CONCLUSION: This data will provide valuable insights into the role of social support in creating continuous exercise habits, which contributes to the development of effective interventions for promoting long-term health and well-being.

Abstract Name: Abiotic Reactions of Nitrogen Compounds on Ancient Mars

Although the modern Martian atmosphere contains little to no nitrogen, research suggests that ancient Mars was abundant in atmospheric species of nitrogen, including greenhouse gases and dinitrogen that raised both the pressure and temperature of the planet enough to maintain liquid water, a fact of interest to astrobiologists. The loss of nitrogen in the atmosphere has been attributed to many different factors, but as recent missions to Mars have found nitrites and nitrates locked in the crust, we propose that a nitrogen cycle involving surface Martian minerals might contribute to the loss of atmospheric species. It has previously been found that Martian troilite (FeS) can abiotically reduce aqueous nitrate and convert it into ammonia. Basalt, a ferrous mineral abundant on the surface of Mars, was the next ideal mineral candidate for investigation. We conducted various reactions by anaerobically stirring basalt in aqueous nitrate and nitrite solutions. Then we tested for the presence of ammonium, nitrite and nitrate using ion chromatography. The mineral was not conclusively found to reduce nitrite or nitrate species into ammonia. However, the amount of nitrite in the reaction decreased when reacted with basalt at neutral pH, suggesting the production of alternate nitrogenous products that weren't detected.

Abstract Name: Chemical Characterization of Azadirachta indica and Its Endophytic Microflora Using Metabolomic Approaches

"Azadirachta indica", also known as Neem (Neem tree), is a well-known plant valued for its medical properties and its ability to deter pests without the use of harmful chemicals. Neem is a popular remedy in both modern western medicine and traditional systems of care in India and Southeast Asia. However, there is a need of up-to-date data on the comprehensive characterisation of chemicals and the endophytes associated with it. Therefore, it is crucial to define the plant material chemical composition and guarantee conformity with particular quality standards. The objective of this study was to analyze the bioactive compounds in the leaves, bark, and fungal endophytes associated with Azadirachta indica using metabolomic approaches such as High Performance Thin- Layer Chromatography (HPTLC), High Performance Liquid Chromatography

(HPLC), Liquid Chromatography Mass Spectrometry (LCMS), and Gas Chromatography-Mass spectrometry (GCMS). The HPTLC results revealed the most suitable mobile phase for the identification of metabolites was Hexane, Ethyl acetate (70:30 v/v). The LC-MS data for neem leaves displayed the presence of Vepinin, Gedunin, Nimbolide, Salanin, and Nimbolin A. The Bark LC-MS data revealed the presence of Gedunin, Nimbin, Nimbolide, Margolone and Catechin. The fungal endophytes found on the neem bark showed the presence of catechin which was also found in the bark. Each compound found is known to be associated with Azadirachtin indica which confirms the robustness of our analytical methods. GC-MS displayed fungal endophyte isolates B from neem tree leaves contain Acetic acid, Methyl p-tert-butylphenyl acetate, 2-Imidazolidinethione, and Cyclocolrenone with bioactivity >80%. HPLC results displayed the neem leaves, bark, and bark endophytes have peaks at 220 nm wavelengths, while neem leaf endophytes have peaks at 270 nm.

Abstract Name: Evaluating the Base Editing Activity of ABE7.10

Base editors are a class of genome editing tools that have the ability to make single base variations (SNVs) in DNA without introducing deleterious double stranded breaks (DSBs). My project is focused on evaluating an existing base editor, ABE7.10, and how the mutations on its corresponding enzyme, TadA—which have arisen through generations of directed evolution processes—impact the base editing activity. A number of different generations of the mutated enzyme exist, resulting in a total of 14 distinct mutations on the TadA enzyme. By analyzing a comprehensive set of reversion mutant editors, where one or more mutations accumulated in the final ABE7.10 are reverted to their wild-type counterpart, we aim to test their individual impact on the activity of the base editor; evaluating mutations' structure/function relationships provides us with insight into the value of each mutation. By creating a library of plasmids of TadA7.10 that we've manipulated to have a single mutation reversed, we can transfect them into cells alongside a gRNA plasmid, responsible for guiding the enzyme, as well as a novel reporter plasmid, which we've designed to fluoresce in response to base editing activity. These manipulations allow us to measure the relationship between individual mutations and overall efficiency—information that is crucial to future research, since it spotlights both effective mutations and isolates mutations that decrease overall efficiency—ultimately yielding a more complete, comprehensive understanding of base editing activity.

Abstract Name: Sacred Space Design and Spiritual Experience: A Study of Latter-Day Saint Temples

Background: The apparent design shift and style of LDS temples has changed over time moving from a traditional style into a modern era. The ornamentation and architectural style of these sacred spaces play a role in shaping the user's spiritual experience by creating a profound sense of connection to religious tradition. Insights into the evolutionary link between human perception and ornamentation inform this exploration. Architecture, initially rooted in shelter and protection, has evolved into an art form, encompassing subjectivity, creativity, and aesthetics. The effects of architecture on our psychological well-being, makes it an ideal venue to understand its influence on spiritual experiences. Purpose: The purpose of this study is to investigate how the presence of ornamentation and architectural style influences the experience of sacred ordinances within LDS temples. Method: A comprehensive study method combining surveys and Visual Attention Software (VAS) to investigate the effects of temple design on user experiences. Surveys will present participants ranging in age, race, and religious beliefs with questions and visual comparisons of diverse temple styles, form, levels of ornamentation, and site design. Complementing this, VAS will offer a technological perspective by analyzing visual attention patterns. The research includes a selection of LDS temples with varying architectural styles distributed geographically to minimize regional biases. Results: The primary hypothesis is that architectural styles and factors of LDS temples impact the emotional and spiritual experiences of visitors. These results could influence and impact the process and overall thought of designing sacred spaces Conclusion: By utilizing both traditional survey methods and VAS technology, this research aims to provide an understanding of how temple architecture shapes the spiritual journey of visitors. The outcomes could have broader implications for architectural design in sacred spaces and offer valuable insights into the evolving role of architecture in spiritual well-being in a contemporary context.

Abstract Name: Targeting Mitochondrial Respiration to Overcome Therapy Resistance in Acute Myeloid Leukemia

Acute Myeloid Leukemia (AML) is a blood cancer consisting of underdeveloped white blood cells produced in the bone marrow and frequently occurs in people over 60 years. The standard care of treatment for AML is currently chemotherapy and has not changed over the past 40 years. However, chemotherapy is toxic and nonspecific, therefore there have been intensive investigations to develop new therapeutic strategies. Venetoclax, an inhibitor of anti-apoptotic BCL2 in mitochondria, has been approved by the FDA to treat AML as a targeted therapy. Despite Venetoclax leading to effective elimination of AML, patients have been shown to develop resistance to the drug. Similarly, patients treated with AC220 showed better remission rates, but not all patients responded to the treatment. The purpose of this project is to develop novel combinatorial therapeutic strategies to overcome resistance to Venetoclax or AC220. Our lab proposes a strategy to inhibit mitochondrial respiration with the use of methylating- control J protein (MCJ) mimetics to target the mitochondria. MCJ is a protein in the mitochondria that has been identified as a negative regulator of Complex I of the electron transport chain. The loss of MCJ in cancer cells leads to enhanced mitochondrial ATP production. Our lab has developed MCJ mimetics that can restore MCJ function and inhibit mitochondrial respiration. MCJ mimetics are safe since they do not affect normal cells that express endogenous MCJ. We hypothesize that the addition of MCJ mimetics will restore MCJ function, inhibit mitochondrial activity, and lead to increased efficacy of Venetoclax and AC220.

Abstract Name: The Effects on Student Mental Health based on Living On and Off Campus

While attending college can be one of the most exciting and enriching times of a person's life, it can also be mentally taxing and stressful. In fact, previous research has found that most mental health disorders first appear before or during adolescence and early adulthood (Golberstein et. Al., 2014). Adding complexity to a student's life, many students also move off campus and navigate being a renter while balancing the demands of their education. While a more holistic understanding of what effects an individual's mental health is becoming more prominent in the literature, the relationship between mental health and factors related to living off-campus have been left somewhat unexplored. To bridge this gap, I created a quantitative survey asking approximately 700 students at a regional public University in Wisconsin about the unique potential stressors related to living off-campus and being a tenant in a local community, as opposed to being a student in a dormitory on-campus. I found that there is not a significant connection between type of housing and mental health. Furthermore, I found that there is no significant relationship between number of friends and mental health, nor is there a significant relationship between mental health and rent satisfaction and mental health and utilities satisfaction. In summary, the results show that there is a no significant relationship between mental health and housing type, number of friends, rent satisfaction, and utilities satisfaction. Although these results are surprising, these findings show that these variables are not contributing to student mental health, and researchers can focus on different variables for further study.

Abstract Name: Isoprenylation Inhibition Suppresses IL-33-mediated Mast Cell Inflammatory Function

Allergic asthma is prevalent globally and has increased dramatically in the span of a generation. It is associated with systemic inflammation of the airway tract. Allergens sensitize the airway, and symptoms including coughing, wheezing, and airway hyperresponsiveness emerge chronically. It is important to understand the cellular and molecular mechanisms promoting allergic asthma to develop novel, effective therapeutics. Mast cells are a driving force in allergic asthma. These cells are activated by many stimuli, including binding of the interleukin (IL)-33 ligand to its receptor on mast cells. IL-33 is released from airway cells damaged by proteases found in many allergens. In seeking new ways to antagonize IL-33 effects on mast cells, we have investigated repurposing drugs approved by the FDA for other indications. Statins are an FDA approved class of drugs that decrease plasma cholesterol. Several studies have found that patients taking statins have a significant decrease in asthma severity, as measured by emergency room visits or hospitalization. We and others have shown that the anti-inflammatory effects of statins are due to inhibiting protein isoprenylation, a side reaction of the cholesterol synthesis cascade (Figure 1). This project determined

if inhibiting isoprenylation could decrease IL-33-mediated mast cell function. The isoprenylation enzymes farnesyl transferase (FT) and geranylgeranyl transferase (GGT) were directly targeted with the novel drugs or indirectly blocked with statins. We demonstrated that simultaneously inhibiting FT and GGT reduced IL-33-mediated inflammatory cytokine secretion by mast cells. Similar results were obtained with the use of simvastatin. In contrast, inhibiting only FT or GGT did not affect inflammatory cytokine secretion, indicating some redundancy amongst the two transferases. Our data support the conclusion that FT and GGT inhibition either indirectly via statins or directly by FGTI-2734 has potential therapeutic effects for IL-33-mediated mast cell function in allergic disease.

Abstract Name: Shred Central: Estimating the user benefits associated with large public skateparks

Skateparks, often called 'wheel parks,' are becoming increasingly common within communities worldwide. Despite this growth in parks, estimates show that the development of parks needs to catch up to users. Using a count data travel cost model, we estimate the total user benefit associated with the Lauridsen Skatepark in Des Moines, Iowa – the largest in the United States. We estimate benefits to be $61 per user per day and roughly $488,000 annually. This work contributes to the literature by being the first study to use econometric techniques to estimate skatepark user benefits. Second, we develop a simple and easy-to-apply method to assist municipalities in determining community skatepark needs. Third, our results support the notion that skateboarders are increasingly diverse.

Abstract Name: Examining a Wisconsin Farmers' Market SNAP Incentive Program - Using Administrative Data from 2018-2023

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of a variety of chronic diseases. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity among US children which have been shown to persist into adulthood. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers' markets offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at farmers' markets. We have selected one Wisconsin farmers' market that sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the market. This presentation will show that in 2020, COVID-19 increased the number of families facing food insecurity and using SNAP. Our administrative data illustrates the increases and subsequent decreases in SNAP

shoppers at the market as we moved through the pandemic. In 2023, the number of SNAP shoppers declined significantly as did the spending, but the SNAP caseload stayed constant. The remainder of this study provides more detailed results regarding the patterns in SNAP household shopping at this farmers' market using the MMP over this period. This presentation is connected to a another submission analyzing a variety of data from surveys of SNAP households shopping at this farmers' market using the MMP during these years.

Abstract Name: Autism & Employment: Challenges & Barriers in Selection for the Neurodivergent Adult

Despite anti-discrimination and employment equity legislation, adults with Autism Spectrum Disorder (ASD) face barriers to employment (Lorenz et al., 2016). and continue to experience disproportionately high and increasing unemployment rates (Wiggleton-Little & Callender, 2023). This literature review showed that negative societal perceptions of job seekers with ASD is a continued barrier to employment and that the use of two commonly used selection methods - interviews and personality tests - can result in adverse impact for individuals with autism (Wiggleton-Little & Callender, 2023). Reasons for this include vague interview questions, difficulties with episodic recall essential to behavioural interview questions, communication skills, and masking/camouflaging to display neurotypical behaviour/personality traits. Recommendations are made for more legally defensible and inclusive employee selection practices.

Abstract Name: Pollinator-Friendly Lawns and Landscaping: Bringing Nature to the City

Traditional monocultural turf grass lawns are ecological dead zones, especially for pollinators, with few to no flowering plants. Most people tend to remove these flowering plants if they have them because they are considered weeds. Besides contributing to biodiversity loss, the emphasis on lawns significantly affects pollinator survival because of habitat fragmentation. The research aims to introduce the concept of pollinator-friendly lawns and landscaping to lawn owners to incorporate greater biodiversity in the homeowner's landscape while reducing water, pesticide, and fertilizer usage. Pollinator-friendly lawns include native ground covers and other plants to provide this habitat. There are several aspects to this research: constructing a pollinator-lawn installation guide that will be published through ISU Extension, installing a demonstration plot at Reiman Gardens; and presenting at events throughout Iowa to spread the knowledge about pollinator-friendly lawns. A presentation at the Iowa Winter Gardening Fair saw great success in the attendants' interest in supporting pollinators: the seats in the room were full, and the attendants had many questions showing their consideration of installing pollinator-friendly lawns. This research will result in a practical and hands-on guide for increasing the diversity of plants and insects in urban areas.

Abstract Name: College Students and Nutrition Misinformation: Correlation Between Perceived Health and Social Media

The promotion of nutrition fraud can be driven by many forces and can impact citizens in numerous ways. For instance, the economic gain with companies marketing toward uneducated individuals makes it difficult for consumers to decipher what products, diets, supplements, etc. are harmful or potentially useless in terms of results. Additionally, the continuation of false nutrition information portrayed online contributes to the increase in mental health issues in society. Influencers promoting unrealistic diets or ineffective products can deeply alter the mental state of their viewers (Bissonnette-Maheux et. al, 2015). Lastly, misuse of dietary products can also impact the physical health of humans. If people are misguided into overconsuming foods they shouldn't indulge in, or disregarding products they shouldn't be, it can impact their nutrient retention to exert proper physical functions (Husain et. al, 2021). Overall, nutritional misinformation and lack of dietary education have impacted society due to false advertisement of products for economic gain, harming consumers' physical health, and even altering their overall mental state. This project aims to address a critical issue with implications for college students and society. The sample population for this study will be composed of undergraduate students ages 18-21 at the University of Tampa. Students who will participate in the study will range from those in a nutritional course required for allied health majors, to an entry-level class containing non-health majors. These classes were focused on in the hopes that they'll provide a good comparison of diverse nutrition knowledge in health and non-health-related majors.

Abstract Name: Reevaluating the Severity of Punishments: Do We Believe Legal Offenses Warrant Stricter Penalties than Social Norm Violations, Irrespective of Perceived Harmfulness?

The optimal functioning of society requires order—which is typically enforced either through written law with codified punishments or through unregulated social sanctions. My project examines whether we believe legal violations should be punished more harshly than social norm violations regardless of the harm attributable to the behavior. I will discuss cases, especially when social norms uphold core societal values, in which social norm violations are deemed as more punishable than legal violations regardless of the harm we attribute to the behavior. Violations of social norms have a direct influence on how we perceive legal violations themselves and impact the ways in which we interact with others. Rarely enforced laws are seen as notably more wrong when accompanied by a violation of a social norm, and may serve as codified ways to indirectly punish normative violations. Since normative violations spark the drive to punish rarely enforced laws, there likely exists at least a subset of laws which are seen as less morally wrong or harmful than

normative violations. The project will probe perceptions on how legitimate norms/laws are, whether breaking them is ever okay, how common violations are, how wrong violations are, and how harmful violations are. The data that will be analyzed for this project will come from a survey investigating people's perspectives on many different normative violations—such as putting ice in wine or yelling at a server—and many legal violations, such as jaywalking or committing murder. Finding that normative violations are seen as more harmful than legal violations has implications on our legal system; morality alongside perceived guilt are relevant in criminal contexts and must be investigated to ensure a greater level of justice in our society.

Abstract Name: Virtual Insights into Pain Management: A 3-D Computational Model of Pain-related Neurons in the Amygdala

Neuropathic pain is caused by injury to the nervous system and involves brain areas such as the central nucleus of the amygdala (CeA). Within the CeA, two populations of neurons play opposing roles in pain modulation. Neurons expressing protein kinase c-delta (PKC-δ) are pro-nociceptive (increase pain) while neurons expressing somatostatin (SST) are anti-nociceptive (decrease pain). We developed the first 3-D computational model of PKC-δ and SST neurons in the CeA and used this model to explore the role of these two neuron populations in pain regulation.Our computational model simulates the behaviors and interactions of 13000 neurons and 22000+ neural connections in a 3-D spatial domain that captures the structural properties of the CeA. Neuron-specific properties, including firing rates and connectivity parameters, are estimated from wet-lab data. During each model time step, neuron firing rates are updated based on an external stimulus, inhibitory signals are transmitted between neurons, and a measure of pain-related output from the CeA is calculated as the difference in cumulative firing rates of PKC-δ neurons and SST neurons. A sensitivity analysis of our model was performed to study the impact of select model parameters on pain-related output. Additionally, model simulations were conducted to investigate the impact of spatial heterogeneity of PKC-δ and SST neurons on model predictions of pain and the ability of spatially-targeted inhibition and activation of select neurons to reduce pain-related output.Our results show that the quantity and localization of PKC-δ and SST neurons within CeA subregions are key parameters governing pain-related output. Further, the spatial distribution of these neurons across the entire CeA is shown to greatly influence the ability of targeted neural manipulations to reduce output. These results highlight the importance of computational modeling in exploring spatial and neuron-type specific properties to inform future wet-lab experiments and aid in drug discovery.

Abstract Name: Electrochemical characterization of recast Nafion® film modified electrodes in nonaqueous systems

The behavior of recast Nafion® films on platinum working electrodes in nonaqueous solutions is characterized by cyclic voltammetry and rotating disk voltammetry. The behavior of recast Nafion® films in nonaqueous solutions has been observed to be different from the well-studied behavior in aqueous solutions. This work seeks to extensively study that behavior. The reversible redox couple tris(2,2′-bipyridine)ruthenium(II) hexafluorophosphate is studied in nonaqueous solvent acetonitrile with different electrolytes (tetrabutylammonium tetrafluoroborate, tetrabutylammonium trifluoromethanesulfonate, tetrabutylammonium hexafluorophosphate, and ammonium trifluoromethanesulfonate). The effects of the electrolytes will be compared against each other and controls (an unmodified platinum electrode and a recast Nafion® platinum electrode equilibrated in aqueous solutions of the redox couples). Electrolytes have been chosen for a variety of ion charges and ion sizes; in aqueous solutions, Nafion® is a cation exchange polymer and will exclude neutral and anionic redox molecules, however, this does not necessarily occur in nonaqueous solutions. The effects of Nafion® thickness will also be tested using control as above, and in the electrolyte tetrabutylammonium hexafluorophosphate. Additionally, there is some preliminary evidence that trifluoromethanesulfonate electrolyte may interact with the Nafion® sulfonate groups, so this will also be explored. Studies of each electrolyte variation will involve both transient cyclic voltammetry and rotating disk voltammetry; the relationship between scan rate and peak current will be explored for transient cyclic voltammograms and the relationship between rotation rate and limiting current will be explored for rotating disk voltammetry. The data from both techniques will be combined to identify the thickness of the in situ film and the diffusion coefficient for each variation.

Abstract Name: Fibrinogen Accumulates in the Spleens of Wildtype and Toll-Like Receptor 4 Deficient Mice Over the Course of Endotoxemia

Sepsis is the currently the leading cause of death within hospitals and is most often caused by a bacterial infection in the bloodstream. Due to overactivation of immune responses, this infection can rapidly becomes fatal if left untreated. In humans, sepsis first presents as fever, pain, and confusion which evolves into septic shock leading to rapid inflammation and organ failure. Fibrinogen is an acute-phase glycoprotein that contributes to fibrin-based blood clots, it is produced in the liver, then transported to other organs. Toll-like receptor 4 (TLR4) is a canonical receptor for lipopolysaccharide (LPS), the Gram-negative bacterial lipid used to induce endotoxemia and associated symptoms of septic shock. Without the presence of TLR4 physiologic symptoms of sepsis are not observed. This study investigates the accumulation of fibrinogen in the spleen of wildtype (WT) and TLR4 deficient (TLR4-/-) mice over the course of endotoxemia. Organs from WT and TLR4-/- mice were collected and lysed at 0-, 6-, 12-, and 18-hours post-induction of endotoxemia. The presence of the fibrinogen α subunit in the spleen is detected using Western Blot analysis. Results show that fibrinogen is found at higher levels in spleens of both WT and TLR4-/- mice during endotoxemia, supporting the presence of a compensatory immune mechanism outside of TLR4 that is being activated. Immunohistochemistry was performed on spleen sections to confirm the presence of fibrinogen. A

qPCR array was completed to investigate which immune pathways are activated in the TLR4-/- mice during endotoxemia. From this screen, genes associated with the complement immune pathway are found to be activated. Identifying these compensatory immune mechanisms activated in the absence of classic receptors can help develop therapeutics to result in better prognoses for immune suppressed patients in septic shock.

Abstract Name: The Relationship Between Psychological Distress and the Quality of the Relationship with the Family Caregiver After a Lung Transplant

Undergoing lung transplantation is a physically and emotionally taxing experience for patients, but having the support of a primary caregiver can mitigate psychological distress associated with managing the post-transplant medical regimen. The purpose of this study was to describe the relationship between psychological distress reported by lung transplant recipients (LTRs) and the quality of the relationship with their primary caregiver.A descriptive, correlational design was used to collect data from a sample of 88 LTRs at baseline, 3-months, and 6-months after transplant. The participants, with a mean age of 57.93 years, predominantly underwent double lung transplants (92%), were mostly white (88%), and married or living with their partner (72%). Psychological distress was measured using the SCL-90 Depression and Anxiety Subscale Scores, where higher scores indicated elevated distress. The quality of the patient-caregiver relationship was assessed using the Dyadic Adjustment Scale (DAS), with higher scores denoting better relationship quality. Spearman's rho was used to estimate correlations.Notably, anxiety scores decreased from 0.39 at baseline to 0.31 at 6 months, while depression scores decreased from 0.57 to 0.55 during the same period. DAS scores remained consistently high (65.85 at baseline to 63.49 at 6 months), indicating stable caregiver support. A small negative correlation was found between DAS and anxiety scores at baseline (rho= -0.265), and significant negative relationships were found between DAS and depression scores at all three time points (-0.289 to -0.385).Our findings revealed an inverse relationship between psychological distress and DAS meaning the quality of the caregiver relationship increases as the level of psychological distress decreases. The high and stable DAS scores reflected ongoing caregiver support, which could explain why symptoms of anxiety and depression decreased over time. This study supports the importance of promoting a strong patient-caregiver relationship to optimize levels of psychological distress.

Abstract Name: Addressing Bias in Medical Technology: Developing a Dual-Sensor System for Pulse Oximetry

Pulse oximeters are widely accessible health monitoring devices that estimate oxygen saturation non-invasively and continuously through optical measurements. However, many studies have reported biases in pulse oximetry based on numerous factors, including skin tone. In 2021, an FDA briefing warned about inaccuracies in these devices, coming after a large-scale multi-cohort study, which found that the occurrence of occult hypoxemia in darker skin patients was three times that in light-skinned patients. Occult hypoxemia refers to patients with arterial oxygen saturation below 88%, despite pulse oximetry reading between 92% and 96%. The impact of occult hypoxemia and the unreliability of pulse oximetry was especially magnified during the COVID-19 pandemic, as pulse oximeters were widely used for both at-home health monitoring and in clinical settings. In this work, we present a dual-sensor system for pulse oximetry that objectively classifies user skin tone and corrects for skin pigmentation in oxygen saturation readings. A low-cost dual-sensor system for pulse oximetry was prototyped and calibrated experimentally for skin color classification through an IRB-approved study across 20 diverse participants. Skin tone classes for device calibration were developed through K-means clustering. To account for skin pigmentation in pulse oximetry readings, Monte Carlo simulations were used to model light behavior through multilayer biological tissue with MCMATLAB. Pulse oximetry measurements were modeled across various melanin concentrations and oxygen saturations to determine calibration curves that were specific to the set melanin concentration, which were programmed into the prototype to estimate oxygen saturation based on user skin tone. Here, we present a prototyped dual-sensor system for pulse oximetry that reads user skin tone and takes skin tone into account when computing SpO2. This study demonstrates the potential for a device that provides an objective measurement of user skin tone to correct pulse oximetry readings and addresses a published unreliability in these devices.

Abstract Name: “All disease begins in the gut”: Presenting a Computational Model of the Gut-Brain Axis and Tryptophan-Serotonin Pathway

Nearly 2,500 years ago Hippocrates linked health with the gastrointestinal tract, but it was not until recently that the human gut microbiome energed as a key player in researching disease progression and regulation. It was discovered that the gut microflora's compositional diversity regulates the host's health through bidirectional communication of its genes and the release of neurotransmitters. While the majority of prior studies that seek to explore the mechanisms behind the gut-brain axis rely exclusively on animal models, recent progress has shown tremendous growth in utilizing the mathematical modeling of tissues to expand our understanding of this complex system. This project studies the link between diet and brain development and eliminates the presence of various limitations, ethical considerations, and interprecies differences from animal models in this field. We conducted a literature search for existing computational frameworks on the gut-brain axis, formed a set of equations that describe the conservation of state variable in the gut and brain, and developed the compartmental model, validating it and studying its implications. Our work highlights shifts in engineering more robust human gut-brain models and their potential to explore new therapeutic approaches to treating mental health disorders and neurodevelopmental conditions.

Abstract Name: Ojibwe Spiritual Practices from the 1930s-1978

There are few studies that discuss Native American spiritual practices during the period between John Collier's reforms of the 1930s and before the passage of the American Indian Religious Freedom Act (AIRFA) of 1978. Most studies of Native American religion during this period focus on federal policies toward Native American spirituality and Native resistance to those policies, while cultural studies that focus on how Native American people engaged in their spiritual practices during the period of study are rare. Interviews with members of the Red Cliff Band of Ojibwe reveal that during this period, some Red Cliff Band of Ojibwe members, a part of an older generation, still engaged in their spiritual practices despite the restrictions around doing Indigenous spiritual practices. Although some Red Cliff Band members still performed their Indigenous spiritual practices, many people did their practices secretly to avoid the repercussions. They avoided passing down the knowledge of their Indigenous spirituality for a variety of reasons. This resulted in the generation following these people suffering from a considerable loss of their Indigenous spirituality. In the later parts of this period, the younger generations of people began efforts to revitalize their Indigenous spirituality.

Abstract Name: The Effects of Weather Conditions on the Detection of Radon

Radon is a naturally occurring radioactive element. Elements such as uranium or thorium underground naturally decay into radon. Radon rises to the surface and into the air as a gas. This is the stage of the process we focus on because weather conditions could affect how much radon we detect. From here, radon decays quickly, releasing many radioactive particles. These particles, such as polonium, lead, and bismuth, are dangerous. If they are inhaled, they stick to the cells that line the lungs. Alpha particles released generate enough energy on impact to cause mutations in cells. These can cause physiological issues, most notably lung cancer. We are detecting radon using electronic instrumentation. There are two detectors currently in operation. These detectors take daily averages, which are monitored daily. This will give us a better understanding of radon levels locally and how they fluctuate daily. Barometric pressure, humidity, precipitation, and temperature variations may affect how much radon gas is detected in the air. Of course, we know that the amount of radon truly present is determined by the amount of uranium and polonium in the ground. Despite this, weather conditions may affect how much of this gas makes it to the surface and how much we can detect in our homes. Finding a correlation between our detected radon and weather conditions will be crucial for the future of radon detection and mitigation.

Abstract Name: Advancing Cochlear Analysis: Deep Learning Algorithms for the Segmentation and Detection of Inner and Outer Hair Cells

Hearing loss is a significant global health issue, impacting over 1.5 billion people, or roughly 20% of the world's population. Among them, 430 million suffer from disabling hearing loss, a figure projected to rise to 700 million by 2050. The repercussions of hearing loss are profound, especially in education and employment. Children with hearing impairments often receive less education than their peers, while adults face higher unemployment rates or are relegated to lower-level jobs. The World Health Organization estimates that unaddressed hearing loss incurs an annual global cost of US $980 billion. This staggering amount encompasses the expenses for hearing devices, educational support, lost productivity, and broader societal costs. In the realm of hearing health research, particularly the study of auditory hair cells (HCs) in the cochlea, traditional methods have relied on manual counting of these cells, a process that is both laborious and time-consuming. Recognizing the need for a more efficient approach, we have developed a novel deep learning-based method for the automatic detection of both inner and outer HCs along the entire length of the cochlea. This innovative technique not only expedites data collection and analysis, but also significantly reduces time, effort, and labor costs. Our approach entails using advanced deep learning algorithms to detect inner and outer HCs from mouse inner ear images and for HC segmentation. To ensure the reliability and accuracy of our method, we conducted a validation study, comparing the results with ground truth values. This new approach stands to revolutionize the study of auditory health, offering a faster, more accurate, and less labor-intensive method of data collection and analysis, which is crucial in addressing the growing global issue of hearing loss.

Abstract Name: Evaluating Effectiveness of Aging Stormwater Ponds

Stormwater ponds are designed to treat water before being released into the environment. A good quality pond will have a long enough retention time for sedimentation and for nutrient absorption in the pond’s vegetation. Moreover, permanent pond water should satisfy Environmental Protection Agency (EPA) requirements for water quality. However, as a pond ages, its pond water quality and treatment efficiency may

decrease. In this study, two ponds of different ages and surface area were selected to be evaluated for water quality. One pond was made in 2018, while the other pond was made in 2006. Water quality in this study is determined by its turbidity, density, phosphate concentration, and nitrate concentration. Turbidity is a measure of suspended particles in the water. Nitrate and phosphate are nutrients, which in excess can lead to algae blooms, which are bad for the environment. That makes it necessary to measure. Density, while not a direct measure of water quality, can give an idea of any microbiological matter suspended within the water. The water samples were taken within a grid setup one foot below the surface. Samples were also taken during each season to give a good idea of how each pond performs at various times in the year. The results showed that while both ponds are meeting MN water quality standards, the older pond consistently has equal or higher water quality compared to the younger pond. Originally, it was anticipated that the older pond would perform worse due to sedimentation and reduced water quality. However, the older pond has better vegetation growth than the younger pond, which is a result of both aging and pond size. The younger pond, being a smaller size, was much drier during the summer months, which reduces the vegetation footprint, and therefore its effectiveness.

Abstract Name: An Investigation of the Geospatial and Religious Dimensions of the Forgotten Jewish Community of Aizpute Latvia

The Jewish community of Aizpute, Latvia is one of the many undocumented tragedies of the Holocaust. Despite significant cultural and economic contributions, the Jewish community fell victim to Nazi and local antisemitic violence. After being forgotten for eight decades, the exact burial grounds of the 501 Aizpute Jews that were murdered remains unknown. A Christian Latvian, born and raised in Aizpute has placed a memorial of the twelve tribes of Israel at the potential burial site. The Aizpute community hopes to find the exact burial site in order to properly memorialize the forgotten Jewish community. The collaboration of Jewish heritage associations, anthropologists, and scientists has led to research endeavors to uncover the killing site and burial grounds of the Aizpute Jewish community. The research employs geospatial tools such as ground penetrating radar (GPR), Lidar, topographic laser leveling, alongside soil boring, historical insights, and individual testimonies. A (17X4.5M) GPR grid was collected using a pulseEKKO Pro system using a 500 MHZ antenna frequency. GPR grid was processed using EKKO_Project software. The grid was placed according to local testimonials in the forest of Aizpute. The project aims to utilize geospatial tools to generate 2D and 3D models of the potential burial site in Latvia in a non-invasive manner. Additionally, the project aims to uncover the motivations behind a Christian Latvian's determination to memorialize Jewish burial sites.

Abstract Name: Determining if Microorganisms Could Survive in Ocean World Environments

Scientists hope to find life on other planets. Research on Earth's moon, Mars, and icy moons (such as Europa and Enceladus) has begun and much has been learned. NASA has created a "Roadmap" describing characteristics necessary for life to be possible on other planets/moons and has taken particular interest in one of Saturn's icy moons, Enceladus. The Cassini satellite (created and launched by NASA) collected much information on Enceladus, by measuring the salt grains shot through hydrothermal vent plumes on the surface of the ice. With this information scientists have made many predictions on what the conditions of Enceladus are. These predictions prove favorable to the possibility of life existing on Enceladus as Cassini collected evidence of silica and phosphorus. In this research, microorganisms isolated from polar regions (an Antarctic bacterial isolate (PL17) and Psychrobacter arcticus) are grown aseptically in Enceladus-like saltwater conditions. As there is some debate about the actual concentrations of phosphorus and silica on Enceladus, these microorganisms are exposed to three different possible concentrations of each of these compounds to determine under which set of conditions life could grow. Bacterial activity is determined by the incorporation of two isotopic labels, either heavy water (D2O) amended with acetate or deuterated acetate (d-acetate). The uptake of D2O or d-acetate by individual cells is measured using Raman Spectroscopy. This research aims to provide supporting evidence that life is possible under the geochemical conditions present on Enceladus.

Abstract Name: Online Diaspora Portals and Economic Development: The Case of Bosnia-Herzegovina

Since the 1990s and the success of Taiwan's and India's Silicon Valley diasporas, diasporas have been known to be a powerful force for the economic development of home countries. As a result of these positive experiences and the connective power of the internet, many development programs are now starting to focus on using online diaspora portals for boosting economic development in target countries, and Bosnia-Herzegovina is no exception. With a large diaspora and a population that has quality access to the internet, Bosnia-Herzegovina seems like the perfect candidate to take advantage of knowledge transfers from diaspora through online diaspora portals. However, Bosnia-Herzegovina's political structure is highly hostile to business growth and innovation, a hostility that could render the power of diaspora knowledge transfer for economic growth completely worthless. Thus, this research focuses on the following question: what effect do online diaspora portals have on the Bosnian economy, given the difficult political conditions in the country? To answer this question, I interviewed diaspora and local, active and non-active members of a currently running online diaspora platform, as well as representatives of the platform. Questions covered members' motivations for joining the platform, activities and projects in which they were involved, the impact of these

projects and activities on local citizens, and personal experinces with the political environment in Bosnia-Herzegovina. While research is still ongoing, preliminary data point to online diaspora portals as having the potential to have small-scale, positive impacts on the economy; nevertheless, major institutional changes must occur before any large-scale impact can be had. These findings suggest that online diaspora portals are not a cure-all for economic stagnation. Consequently, development programs should take care to analyze country political conditions to ensure that these are receptive enough for online diasporaa portals to have a strong impact.

Abstract Name: The Role of Myeloid Derived Suppressor Cells in Radiation Resistance in Head and Neck Cancer

HPV-Negative Head and Neck Cancer (HNC) is known for high rates of radiation therapy (RT) resistance and disease recurrence when compared to other cancers. This likely contributes to the five-year survival rate for patients suffering from locoregionally advanced disease remaining below 50%. In order to address this grim prognostic outlook, the role of Myeloid Derived Suppressor Cells (MDSCs) as a contributing factor to RT resistance has become a point of interest for researchers in recent years. MDSCs are a population of immature myeloid cells that are interrupted during the early phases of differentiation and have been shown to be present in greater amounts in samples from treatment resistant tumors versus naïve samples. MDSCs have also been linked to increased cancer cell proliferation through secretion of immunosuppressive cytokines. The secretion of these cytokines then serves to recruit more MDSCs to the tumor site, increasing resistance to RT and likelihood of disease recurrence. To investigate this, an experiment was devised using an IRB-approved protocol through partnership with surgical oncologist, Dr. Zenga, to obtain primary patient tumor samples following surgical resection. Patient samples were then processed accordingly and maintained in culture in order to isolate patient-derived fibroblast and malignant cell lines. Eight pairs of patient-matched fibroblast and malignant lines were plated and exposed to one dose of 8 Gy irradiation, along with healthy oral epithelial cells and lymphatic cells. Treated samples were then collected either one day or one-week post-radiation respectively, and an untreated control sample was collected at the seven-day mark alongside the treatment group. Following collection, samples were analyzed via RT-PCR for acute changes in the tumor microenvironment following RT. While data analysis is ongoing, results indicate several MDSC recruitment factors of interest that will be investigated further upon conclusion of this study.

Abstract Name: Investigating the Effects of DNA Damage on mRNA Decay in Human Cells Using Long-Read Sequencing

Senescence is a state of virtually permanent cell cycle arrest that occurs in response to sublethal genomic damage. Senescent cells accumulate with age, where they cause several aging-related diseases through hypersecretory phenotypes. Several open questions remain regarding how cells commit to senescence as opposed to apoptosis upon DNA damage and what changes accompany this decision, particularly in response to acute DNA damage. Recent studies have shown that acute stress can result in immediate changes in mRNA metabolism and the induction of novel mRNA decay pathways to quickly remodel the transcriptome. In this study, we examined whether treatment of cells with the senescence-inducing drug Etoposide would induce immediate changes in mRNA stability that would be predictive of commitment to senescence. To accomplish this, we used long-read direct-RNA sequencing to authentically monitor changes in mRNA metabolism and capture mRNA decay intermediates after Etoposide treatment. We found that long-read sequencing detected evidence of two mRNA decay processes after Etoposide treatment: 5' mRNA shortening and decreased poly-A tails, both globally and for specific genes known to decrease with senescence. Furthermore, we found that cell cycle and DNA metabolism genes were enriched among those with evidence of decay, suggesting that there is a period of transcriptome remodeling after DNA damage.

Abstract Name: Application of the Global Observatory for Healthy and Sustainable Cities Urban Policy Indicators to Austin, Texas

Urban policies are crucial in establishing and regulating built environments, which can shape citizens' health behaviors. This study aims to assess the urban planning policies of the metropolitan area of Austin, TX, USA as part of the Global Observatory of Healthy and Sustainable Cities (GOHSC) 1000 Cities challenge. Urban planning policy documents of relevance for assessing the city's commitments and investments to healthy and sustainable lifestyles through urban planning and transportation for the metropolitan area of Austin were identified through a desk review. This included reviewing official government websites and NGOs. Using the policy checklist tool of the Global Observatory of Healthy and Sustainable Cities' 1000 Cities Challenge, the presence, government sectors and levels involved, alignment with health and sustainability promotion principles, and the existence of measurable targets are evaluated. Next, twenty-four urban policy indicators from eight categories will be generated. GOHSC indicators open source software are being used to conduct the analysis. Data collection is still underway, current findings suggest that Austin has a demonstrated interest in healthy and sustainable policies. Policies that regulate components of sustainability and health such as transportation, air pollution, parking management, etc. have been found. Many policies exist to satisfy different aspects of health and sustainability, but they do not consistently feature measurable goals or strive towards evidence-based standards. As data collection continues, more accurate information about the strength of Austin's policymaking will emerge. Ultimately, this study can help set a precedent for streamlining how governmental structures monitor health indicators in the city, informing policymakers about necessary changes, and setting the foundation for Austin's long-term sustainability.

Abstract Name: Drive, Desire and the Political Subject: the Import of Lacanian Psychoanalysis to Materialist Political Analysis

In a Lacanian account of subjectivity, desire plays a foundational role in the constitution of the subject, who is structurally undermined and symbolically alienated by the "constellation of signifiers" that situates it. An important move here is away from the Cartesian subject for whom the extension of their thought is what secures the consistency of their being, to what Lacan describes as the "sexed" subject, the subject that is mediated by their embodiment in language (the negation of the supposed totality of this certain mind-subject) and conditioned by it. This mediation through the signifier is what constitutes the subject as desirous, with the gap in totality as the point from which the unconscious originates. In this paper, I will argue that a key import of psychoanalysis is to move from a traditional theory of ontology to a theory of the drive, which to locate subjectivity not in some essential kernel of being, but in the structure of failure (and repetition of said failure) in the constitution of subjectivity as lacking. This structure of desire entails an ideological fantasy that facilitates both this relationship to the "lost object" of desire, and the undermining of said relationship through the drive, which secures a psychic enjoyment in the frustration of desire. I will further argue that this theorization provides a unique import for a materialist theory of politics. Psychoanalytic theorization of the social field, language, and the role of the subject's unconscious desire allows us to theorize complex social and political dynamics (i.e. why would someone vote against their interests?) where, contrary to the rationalist schema of homo economicus, pleasure is sacrificed for psychical enjoyment. The focus on the role of the drive highlights the tension between conscious belief and unconscious desire, which is useful for understanding investments conditioned by capitalist subjectivity.

Abstract Name: Examining Predation Damage in Shells of Chione to Assess Marine Biotic Interactions During Environmental Changes in the Late Cenozoic of Southern California

During the geologic time interval of ca. 5-0.13 Ma, much of coastal Southern California was underwater and was rich in invertebrate life, including marine bivalves and gastropods. Many environmental changes, due to the changes in climate, occurred in that interval. However, according to previous studies, even with that environmental change, the predator-prey relationships between drilling gastropods and shelled bivalves appeared stable throughout. This study aims to shed light into these biotic interactions and the impact of the environmental change in the ancient Southern California marine ecosystems, to compare them to those of modern ecosystems and their reaction to current day environmental change. We searched the Los Angeles Natural History Museum's database of invertebrate fossils for occurrences and stratigraphic information to find specimens to study. To measure drilling predation, we used LANHM specimens of the bivalve genus Chione and did point counts of drilled vs non-drilled fossil specimens. We sampled geologic formations ranging from the late Pliocene to Pleistocene from the San Diego, Los Angeles and Ventura Basins, in order to get latitudinal and water depth gradients. Additionally, we visited field localities to look for new exposures revealed by erosion during winter storms and collect more samples. Results indicate that, within the genus Chione, there appears to be an increase in the frequency of drilled shells from the mid to late Pleistocene and predation appears to vary with changes in latitude.

Abstract Name: Potential factors of non-flight thermogenesis variation in Bombus impatiens

Bumble bees (Bombus spp.) face diverse environmental conditions, making thermoregulation an essential adaptation for foraging and nest construction. Despite their critical role in commercial food production and ecosystem stability, there is insufficient information on how thermal physiology may vary between both groups and individuals. With climatic conditions changing at an unprecedented rate, this variation in thermal physiology may be key to understanding how populations will react. Recent research has begun exploring how non-flight thermogenesis differs between species, however, numerous other potential factors require investigation.This study aims to acquire a deeper insight into whether physiological differences such as caste (queens, workers, and drones), mass, and seasonality (fall and spring) may influence non-flight thermogenesis to determine its role in the varying rates of decline across populations. Using Bombus impatiens as a model generalist species, we collected specimens from Central Iowa, USA, which were then subjected to a 20-minute cold-induced “coma”. Subsequently, thoracic temperature was measured during rewarming using non-destructive infrared thermal imaging to compare the rate of change and final

temperature. Thus far, the data suggest that final temperature is not influenced by caste or seasonality, but size may influence this trait in males.Analysis of rewarming rates is ongoing. Current investigation shows that warm-up rates are not constant over the trial period. To reflect this, a new multipoint model would be beneficial in distinguishing the newly found phases in the rate of change. These data will be valuable in unraveling the intricacies of non-flight thermogenesis, shedding light on how its variability influences bumble bee populations, and aiding in conservation strategies.

Abstract Name: A Collaborative Student-Faculty Model for Introducing and Developing Research Skills in a First Year Seminar Course

In an increasing effort to, among other objectives, increase retention and five-year graduation rates by emphasizing high-impact practices (HIPs), our university submitted an ultimately successful proposal for United States Department of Education “Title III Strengthening Institutions” funding. Not surprisingly, the grant’s overarching goals correspond to well documented outcomes of Undergraduate Research (UG), namely supporting student success and boosting academic excellence. While a majority of faculty members acknowledge advantages of HIPs and involving undergraduates in research, a far smaller percentage, many of whom teach First Year Seminar (FYS) courses, think about embedding research practices in these required, and academically early, general education settings. This presentation—a collaborative faculty and first-year student effort—presents a curricular model for introducing and developing research skills from as early as the first semester and with an emphasis on appealing to a broad cross-section of students. The model supports the principle that, as our students’ needs, areas of expertise, and levels of previously acquired research training change, so should course-embedded research components evolve and adapt. Setting this model apart is the fact that the faculty member created the pedagogical plan and products in close cooperation with first-year students. The presentation consists of two parts. First, the presenters share a field-tested modifiable curricular structure for encouraging UG in general education courses (and especially FYS) across institution types and with a specialization for diverse student populations. Second, FYS student researchers will offer their observations on their research processes and present versions of their original projects that emerged from the scaffolded research model. The aim is that the student voices can help convince general education, and especially (often reluctant) FYS instructors dedicated to student success and academic excellence, to not only adopt and adapt similar models for use in their classrooms, but also to share with colleagues on their home campuses.

Abstract Name: "Homegoing": Death and Dying in the Rural South and Urban North

The way different cultures relate to death and dying not only impacts individuals' perceptions of death, but it also impacts end-of-life (EOL) care for specific marginalized groups. The underrepresented experiences are constructed because of individualistic, Eurocentric views that govern services and support. Macro-level regional socio-political-cultural differences in end-of-life culture between the urban North and rural South are a testament to the diverse tapestry of customs and values that shape how individuals and communities approach the end of life. These findings contribute to a gap in understanding of how regions in the United States differ in community support and cultural perceptions of death and dying. The aim of this poster presentation is to discuss these differences in the urban, Northeastern region and the rural, Southeastern region of the United States. The data is collected through narrative interviews from New Jersey and North Carolina. Participants from each region include hospice personnel and members of the regional communities. Utilizing qualitative research software ensures a rigorous and systematic examination of the qualitative data, allowing us to draw meaningful conclusions from the rich narratives the study participants share. The data suggests that both regions demonstrate themes of avoidance and racial/ethnic inequities in EOL care. There is different spiritual/religious significance and community support in the rural Southeast than the urban Northeast. This analysis is also demonstrating variation in post-death rituals and grieving processes between the two regions. Through this interactive poster presentation, the recognition, respect, and sovereignty of these regional distinctions will be given voice. Participants will explore how the regional differences are woven into the fabric of end-of-life care and can lead to more culturally sensitive and personalized approaches to supporting communities during this profoundly significant life transition.

Abstract Name: An Examination of the Mediating Role of Emotional Impulsivity in the Relationship Between Attention-Deficit/Hyperactivity Disorder Symptoms and Nicotine Consumption in College Students

This study aims to examine the role of emotional impulsivity in the relationship between Attention-Deficit/Hyperactivity Disorder (ADHD) and nicotine consumption (via vaping) among college students. Previous research has demonstrated a strong relationship between ADHD and nicotine consumption, including both combustible and electronic cigarettes. Due to the high levels of use of electronic cigarettes among young adults, especially those with ADHD, and the negative health-related consequences associated with vaping, it is important to examine the mechanisms that may mediate the relationship between ADHD and nicotine consumption to better inform intervention strategies. One such mechanism is emotional impulsivity (acting impulsively when in a positive or negative mood state) which has been previously associated with both ADHD and Substance Use Disorders and has been demonstrated to mediate the relationship between ADHD and problematic alcohol use. Participants will be recruited from an undergraduate sample and will be remunerated $10 for their time. Following informed consent, participants will complete a series of questionnaires (demographics, emotional impulsivity, ADHD symptoms, attention/concentration) and an affective Flanker Task that will include viewing images that are positively, negatively, and neutrally valenced. It is hypothesized that: a) ADHD symptoms will predict greater nicotine consumption and emotional impulsivity, b) emotional impulsivity will at least partially mediate the ADHD-nicotine consumption relationship, c) Flanker Task performance in each affective condition will be correlated with the matching emotional impulsivity domain (negative, positive), d) ADHD symptoms will predict poorer performance on the Flanker Task, and e) performance on the affective blocks of the Flanker Task will

at least partially mediate the ADHD-nicotine consumption relationship. A better understanding of the mechanisms, such as emotional impulsivity, that contribute to the use of e-cigarettes among individuals with ADHD can lead to improved treatment and prevention efforts.

Abstract Name: North Korean Science Fiction: Marine Resources and Futurity of a Nation

This paper examines three North Korean science fiction: Green Seedlings (P'urŭn isak, 1988), Two Arrows (Tugae ŭi hwasal, 1989), and “Make the Ocean Blue” (“Padarŭl p'urŭge hara”, 2004). These three texts express the necessity of advancement in medical technology, active international relations, and the restoration of the environment by involving marine resources. North Korean literature is often viewed as propaganda due to its ties to the party’s ideals and national campaigns. However, by examining North Korean science fiction that deal with marine settings, I argue that some writers commonly challenge the idea of collectivism and emphasize the significance of women’s role upon further development of marine industries. In Green Seedlings, scientists try to cultivate rice plants to treat and prevent cancer. In Two Arrows, specialists from North Korea are working in South Africa to develop useful marine resources that could boost the country. In “Make the Ocean Blue,” different ways seaweed can benefit the country are specified: as reagent energy for factories and as a method to rehabilitate the polluted environment. I propose that these three examples of North Korean science fiction texts address contemporary issues while expressing apprehensions about the future. Providing subjectivity and agency throughout the narrative, the authors challenge and complicate party ideals. Moreover, the significance of the marine setting in North Korean science fiction is to point out the ongoing scientific and environmental problems of the nation the readers should be aware of as well as the key roles the ocean can play in North Korea.

Abstract Name: Krüppel-like factor 4 plays a role in regulating ferroptosis-related genes

Krüppel-like factor 4 (KLF4) is a zinc-finger transcription involved in regulation of a wide range of cellular processes including proliferation, differentiation, apoptosis, autophagy, and genomic stability. Previous research has suggested that Klf4 could either act as a tumor suppressor gene or an oncogene in context-dependent manner. Ferroptosis is a newly discovered form of iron-dependent, programmed cell death as a result of intracellular iron accumulation, excess reactive oxygen species and lipid peroxides. In recent studies, Klf4, has been hypothesized to regulate ferroptosis-related genes. However, the molecular mechanism of how Klf4 regulates ferroptosis is yet unknown. Therefore, we sought to characterize the expression of genes involved in ferroptosis in Klf4-deficient cells as compared with cells that expressed Klf4. In order to

determine the levels of glutathione dependent pathway, xCT/SLC7A11 and GPX4, primary mouse embryonic fibroblasts null and wild type for Klf4 were treated for 72 hours with erastin, a drug that induced ferroptosis. DMSO was used as a control. We found that ferroptosis inhibitor genes such as xCT/SLC7A1 were up-regulated in cells that lacked functional Klf4. In addition, immunostaining analysis revealed that cells lacking Klf4 exhibited higher levels of xCT/SLC7A11. Furthermore, the human colorectal cancer line (RKOs) treated with PonA to induce KLF4 expression showed lower levels of xCT/SLC7A11 than DMSO treated RKO cells. Taken together our data suggests that KLF4 functions as a positive regulator of ferroptosis and offers a possible mechanism for how Klf4 maintains genomic stability. Thus, understanding the molecular mechanisms of Klf4 and how it regulates ferroptosis may illuminate possible targets for directed or combination therapy for cancer treatments.

Abstract Name: Using 4-in cubes to determine compressive strength of concrete

Concrete strength is mainly defined by its compressive strength for design purposes. Construction industry in the Unites States uses cylinders, 4 inches in diameter and 8 inches tall, to determine concrete compressive strength. The cylinders are axially loaded in compression until failure and the strength is calculated as the peak load divided by the cross-sectional area (i.e., $\pi \times r2$, where r is the radius). Size and shape of test specimens are not constant historically and geographically. 6-inch-diameter and 8-inch-long specimens used to be the industry standard. Considering a 6-inch concrete cylinder weighs about 30 lb. whereas a 4-inch concrete cylinder weighs only 9 lb., it was a matter of practicality to research if 4-in cylinder could replace 6-in ones. Furthermore, the construction industry in Europe uses 6-inch (i.e., 150 mm) cubes to determine concrete compressive strength. In this experimental study, 4-inch cubes were used to determine concrete compressive strength and the relationship to 4-inch cylinder strength is established. . A 4-in cube uses ~35% less concrete than a 4-in standard cylinder. This could amount to a significant reduction in material use, hence, less environmental effect. Three different concrete mixes having different binder types were produced in the laboratory. Cube and cylinder specimens were cast and tested at the ages of 2, 7, and 14 days. The results showed a high correlation between the cube and cylinder strengths. A conversion factor of 0.90, from cube strength to cylinder strength, is recommended.

Abstract Name: Identifying macrochelid mites of Tampa Bay and determining their relationship with Drosophila spp. hosts using scanning electron microscopy (SEM)

In nature, many organisms develop symbiotic relationships, such as mutualism, and parasitism, with other organisms. Mite species are commonly involved in symbioses but are understudied, likely due to their small size. Macrocheles spp. mites attach to flies for transportation. However, whether the mites damage the fly while attached is unknown. The purpose of this research was to culture and identify Macrochelid mites in Tampa Bay and find evidence for whether they are harming fly hosts using scanning electron microscopy (SEM). Mites were collected from the wild and four populations were generated in the Durkin Lab. Mites from two of the populations were exposed to fly hosts. Those that are attached were used for SEM imaging. Through trial and error, I determined the best SEM protocol for imaging using a Jeol JSM-6010 LA analytical SEM. While imaging, we found that fly and mite appendages were obstructing the view of the mite's mouthparts. Thus, whether Macrocheles spp. mites damage fly hosts remains unknown. We plan to continue modifying SEM protocols for better images and try other methods, such as bio-staining fly hosts, to determine the exact nature of the relationship between these mites and fly hosts.

Abstract Name: Life's Not Black-and-White: Identity Expression and Race in Invisible Man

Throughout Ralph Ellison's Invisible Man, an unnamed narrator partakes in a journey of self-discovery, coming to terms with the effect that race has on his identity and role in society. While some argue that the narrator's invisibility refers to how white society perceives him, I argue that this invisibility is three-fold: black America is invisible to themselves, to each other, and to white society. Furthermore, this invisibility is not the cause but is a symptom of an "identity expression discrepancy." While white Americans can choose who they are, what they do, and how they are perceived, black Americans' identities are limited to the perceptions of their race, and these limitations are assumed within oneself, between members of the same race, and by white society. Ultimately, despite Ellison's criticism of the polarization of race, he does not advocate for a colorblind society. For Ellison, the ideal society is one in which the identity expression discrepancy within black Americans is eliminated, meaning that black Americans would have the freedom to express themselves by their own individual identities, not by the color of their skin. In this way, black Americans could even choose to define themselves outside of the black historical experience. This balance is one that 21st century America has yet to perfect, but should continue to strive toward.

Abstract Name: Navigating Uncertainty: Examining the Impact of COVID-19 on Undergraduate Student Flourishing and Resilience

This study explores the multifaceted effects of the COVID-19 pandemic on the flourishing and resilience of undergraduate students. In the years following unprecedented disruptions to all realms of life, this project explores the factors related to the psychological well-being of students, in particular, concerning their experiences with the pandemic. Employing a quantitative approach, data was gathered through survey measures from a diverse sample of undergraduate students participating in the MI-Louis Stokes Alliance Minority Program. The findings reveal that the higher the level of COVID-related stress that students experience, the less likely they are to exhibit both flourishing and resilience. The continuing decreased levels of both resilience and flourishing highlight the importance of mental health support services for students and the need for flexibility in academia. These results may inform further research in the discipline of positive psychology within academia and the effects of the 2020 Pandemic. In a prolonged era of uncertainty, these findings contribute valuable insights to guide institutions and students in promoting positive undergraduate mental health and well-being.

Abstract Name: Navigating Media Overload: Exploring Social Media Consumption, its impact on consumers' mood, and adherence toward social scripts

Recent studies have shown that social media is increasingly becoming the medium by which individuals receive news and information on recent events. As the number of people receiving their news from social media increases further focus and study on the risks of political polarization, and the risks of mis and dis-information should be pursued. This study uses the many insights obtained from social research to explore the types of relationships individuals have with social media and content creators. Using survey research this study seeks to determine how social media consumers conceive of their engagement with social media, along with how social scripts and methods of socialization impact social media use. Also, of focus is determining how social media impacts the mood of the consumer. Employing the sociological theories and concepts of Mills, Durkheim, and Goffman, this study aims to investigate and explore the many ways social media operates as a social institution impacting behavior, mood, and social relationships. As time spent on social media increases, alongside the number of individuals using it for information on important life-decisions, it is more critical now than ever to enquire into the impact of these interactions both online and offline. By measuring these interactions this study can better inform the way social media impacts and is itself impacted by the social interactions it hosts, and how these interactions fit within broader social-psychological frameworks.

Abstract Name: Synergistic Effect via Combinational Therapy of Native Chumash Plants in Southern California

Antibiotic resistance is a prevalent global health threat. Due to the progressive ineffectiveness of antimicrobial drug treatments, there is a need for discovery of new antibiotics while also testing combinational therapy. In combination therapy, multiple drugs are tested as a combination to see if their combined effect is more effective or synergistic than their individual outcome. Preliminary work shows that some native California plants used by the Chumash Native Americans have antimicrobial activity. Therefore, the aim of this research is to determine the synergistic effect of six plant extracts of indigenous plants (Lemonade Berry, White Sage, Manzanita, Coastal Sage, Yarrow, Rue). The plant extracts were tested for synergistic antimicrobial activity by combining two extracts using a 1:1 ratio. The susceptibility of Bacillus subtilis, Pseudomonas fluorescens, Escherichia coli to the plant extracts was tested using the Kirby-Bauer disk diffusion method. The zones of inhibition were examined by performing a needle inoculation to test for bactericidal/bacteriostatic properties. B. subtilis and P. fluorescens displayed higher susceptibility compared to the E.coli plates. Lemonade Berry mixed with White Sage and Coastal Sage displayed higher zones of inhibition (greater susceptibility) compared to individual plant extracts tested against B. subtilis. The combination of Manzanita and Yarrow produced a greater antimicrobial effect on P. fluorescence. Yarrow mixed with Rue indicated higher antimicrobial effects compared to when individually tested against E.coli. Further investigation needs to be done to understand the potential in drug treatment of the synergistic combinations identified in this study.

Abstract Name: Characterizing the Role of MsDNA in Bacterial Retron Ec48 Antiphage Defense System

Bacteria have developed several defense mechanisms to fight phage infections. Retron systems are a type of bacterial antiphage defense system composed of a reverse transcriptase (RT) protein, a non-coding RNA called msr-msd RNA, and a transmembrane effector protein. The RT uses msr-msd RNA to synthesize msDNA, an RNA-DNA hybrid and a central regulator of retron-mediated defense. My research aims to understand the specific role of msDNA in the Ec48 retron system. The Ec48 retron system protects E. coli against phages that inhibit RecBCD, a cellular nuclease and first-line defense mechanism. Inactivation of RecBCD by phage proteins triggers the activation of the retron system. Our central hypothesis is that phage proteins inactivate RecBCD, preventing msDNA degradation and allowing msDNA to accumulate, which activates the effector protein, causing cell death. I have tested the effects of cellular nucleases RNase H and RecBCD on msDNA degradation, both in the presence and absence of RT. My results have shown that msDNA is protected from degradation by cellular nucleases in the presence of high concentrations of RT. These results suggest a model, which we are currently testing, in which RT protects msDNA when RecBCD is inhibited during phage infection, allowing activation of the retron effector protein. My research contributes to the broader understanding of bacterial defense systems, which is fundamental for potential applications in phage therapy.

Abstract Name: Using Machine Learning to Classify Autism from Oculomotor Features

Quantifying gaze behavior through eye tracking has unveiled distinct patterns in autism, offering potential for screening and diagnosis. However, it has been difficult to identify reliable visual features that can be used to distinguish autism across different studies. This project investigates whether autism can be classified using oculomotor features obtained over a sufficiently long and diverse set of stimuli, without needing to

decompose the stimuli into specific objects such as faces. Participants with autism (N = 13) and control participants (N = 19) completed a series of tasks using a Tobii eye tracker. These tasks consisted of well-validated measures to prompt specific eye movements, as well as naturalistic viewing of images and movies. We established an optimal method for characterizing oculomotor events (e.g., fixations, saccades, and smooth pursuit) through the application of a machine learning-based algorithm. We then compared properties of those events, such as duration, velocity, and acceleration, between the autism and control groups. Preliminary results show that autism participants exhibit greater randomness in the lengths of their fixation periods than control participants ($t(30) = 2.75$, $p = 0.009$). They also demonstrate that control participants exhibit a higher number of fixations per image than autism participants ($t(30) = -2.86$, $p = 0.008$). We expect to identify additional key differences in oculomotor features between participants with and without autism, and the findings will advance our understanding of oculomotor signatures in autism. This research has the potential to enhance early detection of autism, which can increase opportunities for early support and intervention.

Abstract Name: The Gender-Affirming Care for Children Controversy

Should children have access to gender-affirming care? This is a complex and controversial topic with no straightforward resolution in sight, especially now that this issue of identity has been converted into a politicized moral dilemma. Twenty-two states in America currently have bans prohibiting minors from accessing gender-affirming care, and nineteen of them have legislation that penalizes medical professionals and/or parents who try to assist minors in accessing this care. I have conducted exploratory research on stakeholders' varying opinions on whether or not children should have access to gender-affirming care. The first group is primarily conservatives who believe that children should not have access to gender-affirming care unless they are intersex infants for whom this group advocates gender reassignment surgeries. The second group is primarily progressives who believe gender-affirming care should be accessible to children, especially in the form of puberty blockers and hormone therapy. The final third group consists of intersex advocates who call for regulation in the accessibility of gender-affirming care for children. In my work, I provide relevant context and go in-depth on each group's respective reasoning, supplemented by scholarly sources and popular sources within various databases. My research will also include my personal interviews with a sampling of the stakeholders (e.g., conservative and progressive political figures, intersex advocates, gender-diverse individuals, and allies) within this dispute. From this exploratory research, I have concluded that many bans on gender-affirming care for children with the underlying theme of "protecting minors" are hypocritical and potentially life-threatening to children with gender dysphoria who have a much higher rate of suicides and attempts when they cannot access care and support. The legislation only further proves the idea that these minorities have become pawns in the never-ending political chess game powered by fear-mongering, Christian nationalism, and propaganda.

Abstract Name: If you can’t empathize, at least sympathize: Webcomic fans with endometriosis confronting non-support

When studying non-apparent chronic pain, research has shown that it affects all aspects of an individual’s life, including impaired interpersonal and psychological functioning. Research highlights the juxtaposition of maintaining a personal and social life while struggling with constant pain (Grogan et al., 2018; Roomaney & Kagee, 2016; Schwab et al., 2021). Utilizing Kafer’s (2013) political and relational model of disability, this study examines the webcomic series Chronic Pain is a Party through the author’s struggles with her disability, endometriosis. This study interprets 16 analyzed webcomics and 99 fans’ comments from Facebook and Instagram between March 3rd, 2019 to March 4th, 2020. Our aim is to spread the knowledge of individuals with endometriosis. The analysis represents an asset and strength-based system on the barriers encountered by chronically pained individuals, including social isolation and inequality. Individuals with chronic pain face new demands that affect the wellbeing of relationships including lack of acceptance in interpersonal connections, isolation, and indifference from others. These individuals reflect on their experiences of non-support by having a critical lens on society, coping with the complexities of relationships, and fostering personal development as well as community growth. Turning a critical lens on society means challenging and redefining social and cultural norms such as undermining gender constructs and defying societal expectations. The lack of support that these individuals experience can be an attributing factor to the tension of forming and maintaining meaningful personal relationships. Being chronically pained leads to the development of new coping mechanisms, medical interventions, and healing through shared experiences. This webcomic had a profound impact in which the fans and the creator expressed their frustration concerning their endometriosis symptoms and indignation against ableist social settings. When facing non-support with their in-person relationships, fans of this webcomic built a platform that represented self-empowerment, advocacy, and community.

Abstract Name: LGBTQ+ Undergraduate: Resilience, Trauma, and Success

In recent LGBTQ+ history, research has evaluated the affects of trauma and academic achievement which suggests resilience may have influence over queer-student performance. Across the literature, there are increasing numbers of all students seeking psychological assistance from their universities so it’s becoming more feasible to understand resilience than to eliminate risk. This inquiry examined the relationship between resilience, childhood adversity and academic success of LGBTQ+ undergraduate students in their ability to predict academic success based off university data. In efforts to better support undergraduate students, highlighting the strengths of marginalized populations is just as important as finding out in which area they need greater support and access to resources. It is hypothesized that Lesbian/Gay/Bisexual undergraduate students will have similar experiences and scores of heterosexual/cisgender undergraduate students leveraging greater academic success by comparison of those that identify as Transgender, Queer or other fluid identity. Data will be collected from participants via participant pool at a public university, using the 25-item

Connor-Davidson Resilience Scale (CDRS-25); Early Trauma Inventory Self Report-Short Form (ETISR-SF) and self reported demographic information which includes undergraduate GPA. Data collection is currently in progress and expected to be completed by October 2023. This study has great implications on the avenues universities can pursue for further research. Understanding which populations are succeeding despite life-setbacks and which ones need more support gives schools information to create stronger networks for supporting their student populations.

Abstract Name: The Potential of Birds as Indicators of Microplastic Pollution in the Terrestrial Environment

Plastics are ubiquitous in the marine and terrestrial environment and pose a threat to ecosystem health. Microplastics, plastics under 5mm in size, are an emergent area of concern in ecology. While marine environments have received significant attention, terrestrial microplastic research remains limited, despite the abundant levels of microplastics found in terrestrial environments. Marine birds have been studied extensively in regard to microplastic ingestion while terrestrial birds have been largely ignored. The few prior studies on terrestrial birds have primarily attributed differences in microplastic ingestion to dietary variances, overlooking the potential impacts of water intake strategy and foraging methods, crucial avenues of ingestion worth exploring. Thus, I conducted a study to examine the abundance, type, and size of microplastics in the GI tracts of various terrestrial birds to gain a better understanding of local terrestrial microplastic pollution and the transfer of microplastics from environment to bird. I isolated and identified the microplastics in the GI tract of terrestrial birds, starting with a dissection of the bird to remove the GI tract, then a chemical digestion to isolate the inorganic material, a filtering, and finally an examination of particles of interest under a microscope. Over 400 microplastics of varying color and type have been found in the 10 birds dissected thus far. Within the next 3 months, I will complete an analysis of 20 more birds that use multiple foraging strategies. I will present data from 30 birds total of differing species, diet, foraging strategy, and habitat to gain a more expansive understanding of terrestrial microplastic pollution. Birds have direct interaction with the terrestrial environment through ways of diet, foraging strategy, and water intake, ways that have extensive variation. The prevalence and diversity of birds within terrestrial ecosystems render them excellent candidates for the study of microplastic pollution.

Abstract Name: Toxicant Sensitivities Among Closely Related Strains of the zooplankter rotifer Brachionus plicatilis

This research compares differences in toxicity sensitivity within and among eight strains/species within the Brachionus plicatilis species complex. Due to its importance in aquaculture, this species complex is the most extensively studied rotifer group. However, a study to directly compare ingestion toxicity sensitivities within this species complex has not been completed. Therefore, we proposed to use a simple ingestion assay to investigate the differences in toxicant sensitivities. The ingestion assay is a sub-lethal test that can quickly evaluate toxicity. The following toxicants were picked to be analyzed: cadmium, chromium (VI), mercury, and carbofuran. The closely related species include B. rotundiformis (Hawaii, USA), B. manjavacas (Azov Sea, Russia), B plicatilis (Salebrejo, Spain), B. rotundiformis (Adriatic, Italy), B. manjavacas (Pettaquamscutt, RI, USA), B. manjavacas (Manjavacas, Spain), B. species (Almenara, Lost Lake, USA), B. plicatilis (Tiajin, China). Results demonstrate there are significant differences between the species in all four toxicants. Despite the results not corresponding with the three named species groups, namely, B. plicatilis, B. manjavacas, and B. rotundiformis, the data does reveal differences among these species. Further research into the differential toxicity sensitivities is warranted.

Abstract Name: The Double Penalty: Examining how the Vienna Family Network Assists Immigrant Mothers in Vienna, Austria

At some point in their lives, many women will encounter social, familial, and career disadvantages due to being working mothers, or the so-called ‘motherhood penalty.’ In Vienna, Austria, a city where 34.2% of the population are foreign nationals and 44.4% were born abroad, additional challenges such as language barriers and legal complexities impede the accessibility of employment and social benefits (Stadt Wien, 2023; Reeger & Josipovic, 2020). The Vienna Family Network (VFN) is a Vienna-based non-profit organization that provides support services specifically tailored to immigrant mothers living in Vienna. This transdisciplinary qualitative case study explores immigrant mothers’ unique experiences of the motherhood penalty while living in Vienna, as well as the ways in which the VFN aids in the mitigation of its effects. Research was conducted in Vienna over a three-month period from September to November 2023 via a feminist and decolonial framework, utilizing a series of semi-structured interviews with both leaders and members of the VFN, a survey of the members, and field observations of VFN groups and events. The study demonstrates that working immigrant mothers living in Vienna use the VFN because it helps them overcome challenges within their social, work, and family lives by serving as a community building and information hub. The findings thus identify the VFN as a significant contributor to enhancing the overall well being of working immigrant mothers. Shedding light on the unique challenges faced by working immigrant mothers and highlighting the role of community-based organizations in mitigating the motherhood penalty, this research contributes valuable insight for the development of supportive family and immigration policies and practices.

Abstract Name: Analyzing Light Curve of Wasp-59b using EXOTIC

In this project we are presenting our work on exoplanet Wasp-59b based on data by ground-based robotic telescopes. We are using NASA's official data reduction software for exoplanet watch, EXOTIC (EXOplanet Transit Interpretation Code), to analyze the raw data in the form of FITS images. EXOTIC selects the best configuration of comparison stars, aperture, and sky annulus and then fits the observed transit with a model light curve. Based on the light curve graph, we found significant detection rating of 0.0225 (+- 0.0057) and a mid-transit time of 2459497.726 (+- 0.034) BJD. Using this information, we are able to calculate the exoplanets mass: 0.863 (+- 0.045) MJ, orbital period: 7.919585 (+- 1e-05) day, eccentricity: 0.1 (+- 0.042), angular velocity: 74.0 (+-15.0) degree, radius: 0.775 (+- 0.068) RJ, and its temperature: 670.0 (+- 35.0) K. Studying exoplanets is important as it helps us to understand other solar systems as well as our own. This study will aid in the more accurate big ground-based or space-based observatories, help monitor the variation in brightness of stars, as well as identifying and confirming any new exoplanets that are orbiting in our solar system. Ultimately, this research allows us to comprehend more fully whether there are other planets where the requirements needed for life might exist.

Abstract Name: Erased: The Hidden Stories of Queer People in the Civil Rights Movement

"Erased" is a thirty-minute six part mini series biographical digital story series that profiles the lives and contributions of four Black LGBTQIA civil rights activists: Pauli Murray, Bayard Rustin, James Baldwin, and Audre Lorde. The screening of this 6 episode biographical narrative will serve as a call to action, for viewers to educate themselves on both Black and Queer history. The history that is currently being erased through the silencing of "Critical Race Theory" and the passing of the "Don't Say Gay Bill". The social identities of being Black or Queer deviates from cultural demands and social norms, causing social marginalization and silencing. The first episode will serve as an introductory episode leading the viewers into the next four episodes. The Cass Identity model is the guiding framework for this project. This model serves as a lens from which to gain understanding about the experiences of the Black sexual minority. The final episode will lead to a call to action for the viewers. Historically marginalized Queer and gender non-conforming individuals whose stories have been intentionally excluded; this project aims to give them back their voices. The current socio-political trends are actively working to diminish the experience and existence of Black Queer individuals. In doing so, this will cause Black Queer individuals to ask questions such as where is my role model in the fight for equity & will my freedom ever ring?! The lack of visibility and representation of Black Queer social justice in these social movements has erased their impact on society. This project aims to pay homage through storytelling and right the wrongs of history by highlighting the contributions of historical Black Queer activists while simultaneously inspiring the next generation of Black Queer social change makers.

Abstract Name: Low Dimensional Materials as additives to High Density Polyethylene for Space Applications: First Computational Investigation

Advanced Space suit materials are composed of synthetic plastic, polymers like nylon and spandex, that shield astronauts from the harsh lunar environment. Protecting astronauts from radiation and severe temperatures, conserves a material that needs to be lightweight, flexible and holding tensile strength over a cycle of long missions. High density polyethylene introduces resistance of secondary radiation, thermal and mechanical properties due to their rich hydrogen and carbon atoms. However, to enhance HDPE properties low dimensional materials like graphene, graphene oxide and boron oxide have been a popular additive to HDPE to increase the materials tensile strength and conserve important properties. Density Functional Theory (DFT) computations are carried out to investigate the adsorption energy dependence of HDPE angle. Molecular Dynamics (MD), were used to inspect the new material system for thermal and electrostatic properties.

Abstract Name: Investigating Transcriptional Changes in the Absence of PCM During Stationary Phase in Escherichia coli.

Over the lifespan of an organism, proteins in its cells will become damaged either from unfolding or misfolding or from chemical damage. This can lead to a loss of function of a protein necessary for an organism's survival. Our laboratory studies isoaspartyl protein damage, which occurs from the spontaneous isomerization of aspartate amino acids in proteins. Damaged proteins have been linked to Alzheimer's, aging, and various autoimmune diseases. The enzyme PCM can reverse the isomerization and repair the protein. This method of "recycling" molecules can improve the longevity of a protein and potentially an organism. The survival of mutant Escherichia coli lacking pcm is affected by protein unfolding stressors such as oxidation, osmosis, or heat stress. We hypothesize that PCM increases long-term survival of E. coli by maintaining protein folding. We examined E. coli's response to the lack of repair at the level of gene expression by sequencing total mRNA from normal and pcm mutant cells. The bioinformatic analysis from the RNA sequencing of pcm+ and Dpcm strains revealed gene insH1 that was overexpressed by 5-fold and genes cysD and csrC that were under expressed by at least 6-fold. Of particular interest, we found that ibpA, encoding a heat-shock chaperone which prevents protein unfolding under heat stress, was overexpressed by 7-fold in a Dpcm strain, supporting our hypothesis. Testing of double knockout mutants lacking pcm and ibpA will be done under protein-unfolding stress conditions to further examine the gene's role in E. coli.

Abstract Name: Archaeological Analysis of the Burns Spoke Burial Mound (8BR58) at Cape Canaveral Space Force Station and the State of Florida

At Cape Canaveral, Florida, the Burns Site (8BR85) is a burial mound consisting of various active phases starting in the Late Archaic through the Malabar II period. The mound displays a Native American mortuary practice called ‘radial burials.' Radial mounds are a type of burial pattern that contain indigenous human remains oriented in a spoke wheel pattern, the heads of the individuals pointed toward the center of the mound and the feet pointing outward. Some researchers credit it as a response to deaths of the indigenous peoples following European contact. Other evidence suggests it is a custom that predates colonialism. Using quantitative and qualitative data collection, an ‘Attributes Table’ was formulated to help determine if there are any anomalies associated with the radial burial pattern and other Native American burial mounds.

Abstract Name: Undergraduate Students' Opinions of Exercise as an Alternative Mental Health Treatment on US College Campuses

Since COVID-19, college student mental health is significantly declining. University counseling services are understaffed relative to the increasing numbers of students seeking care, and many are experiencing increased counselor turnover. Colleges are in need of accessible strategies for maintaining student mental health. Exercise is proven to be an effective mental health treatment, with recent work suggesting equivalent efficacy to pharmaceutical interventions and cognitive behavioral therapy. Exercise significantly reduces depression and anxiety and negative affect. However, college students encounter barriers that inhibit exercise.The present study aims to explore undergraduate students’ knowledge, attitudes, and opinions about exercise as an alternative mental health treatment on United States college campuses. Following recruitment via SONA, student participants will complete a baseline demographics questionnaire, and measures of depression, anxiety, stress, and self-care behaviors. Focus groups of 4-5 students will be conducted to explore students’ experiences with campus mental health resources, their mental health and physical activity habits, and campus barriers inhibiting physical activity and access to mental health care services. Focus groups will be recorded and transcribed verbatim, and transcripts will be coded by a team of 3 researchers, with coding disparities discussed until consensus. Findings will be compared between upperclassmen and underclassmen, athletes and non-athletes, and higher and lower mental health levels (median split), to see if there are common themes among these groups.We expect to find students will know the mental benefits of physical activity and will be accepting of it as a treatment. However, students will express difficulty with finding time for exercise and self care in their schedules, due to other commitments. The conclusions from this study will be brought to the College administration, counseling center, and recreation services to emphasize the need for accessible exercise options to support mental health on college campuses.

Abstract Name: Impact of Salinity and Burial on Morella cerifera seedlings

On Virginia barrier islands shrubs have encroached into grasslands due to warmer winter temperatures; however, it is unknown if they will continue to grow when hurricane frequency increases. Encroaching native shrub, Morella cerifera (hereafter Morella) is protected by high dunes but when dunes are destroyed, the habitat of salt and burial sensitive species is disturbed. The goal of this study was to examine the independent influences of salinity, burial, and the combination of both on the growth of Morella. The experiment took place in a light and temperature controlled environment. A single pot contained one Morella seedling and three grasses to simulate the natural microhabitat. There was one control and three treatments, water only, no burial (control), salinity only, burial only, and salinity and burial. Seedlings that were subjected to salinity were treated with 35 ppm salinity and seedlings under the burial treatment were buried to 75% of their height. There were seven replicates of each group. The growth metrics were height and canopy growth. After seven weeks, the average height growth of Morella seedlings in the control group was 7.93 (±1.65cm) and the average for the burial only group was 4.74 (±1.60cm). Similarly, the average canopy growth of Morella seedlings in the control group was 482.83 (±88.52cm) and the average for the burial only group was 254.20 (±91.75cm). The treatments that contained salinity only or salinity and burial showed no appreciable growth for height or canopy. The average height and canopy growth for the control group was significantly greater than the salinity only group (p<0.01) and the salinity and burial group (p<0.01) but was not significantly different from the burial only treatment group. Salinity appears to be the primary factor that deters the growth of Morella.

Abstract Name: Spotlight on Female Leadership: How a College Education at the College of Saint Benedict Can Foster Female Leadership

For many years the U.S. has tried to have more women leaders as senators, governs, supreme court justice leaders and have a woman as president. But there are still many boundaries that exist in the United States relating to female leadership such as stereotypes between men and women leadership experiences and women not feeling confident in themselves to run for a leadership position. This leads us to never having a women president and having less women leaders in the United States. I find this topic to be important because in the United States women are not seen to be leaders and are seen to not be a good role model for the government. In 2018 only 125 women were elected to the United States Congress and in 2023 only 60 women served as senator. Only 28 percent of American CEO’s are women. We want more women leaders because it will inspire more women to make an impact in our world and help us have more diversity in leadership. To find out more information on different leadership experiences I sent a survey out to students and staff at the College of Saint Benedict and Saint John’s University. From the survey I received over 40 responses that

were 5 males and 44 women. Many of the women responses included that they did not feel comfortable in the leadership position they have held or still hold to this day. Compared to the male responses that felt to be more privileged to have been treated fairly in their leadership role.

Abstract Name: Inclusion and Accessibility in Theatre

The present study is exploring the lack of inclusivity and accessibility within the theater industry. It investigates the relationship between audience members with disabilities, and their attending of shows in which accessibility measures were taken when compared to previous shows with no accessibility measures. We are comparing multiple pre-built AI accessibility programs. These programs include GalaPro- an application used on Broadway that provides subtitles and audio description, Azure AI Vision which provides Optical Vision Recognition, as well as programs like HARPA which has the capability of providing video descriptions. Through our research, we found that, while there are a few programs on the market that address these specific issues, many of them are inaccessible as a result of high prices, slow running systems, as well as not addressing all of the issues listed above. In order to combat this, we have started to develop our own programs using open-source codes as a way to integrate these systems into our machines and combat many of the issues that come with using pre-made programs. The study further tests whether or not solutions presently enlisted in theaters can achieve the proposed goals, as well as other possible plans of study that can solve these issues of inclusivity. To answer these questions, during our 2023 theater season, we integrated different accessibility measures into our live shows, and are currently exploring further paths of inclusivity. In our previous theater season, we enlisted the help of ASL interpreters, to live-interpret our showing of Sweat, a contemporary play written by Lynn Nottage. By doing this, we found a way to combine the worlds of hearing theatre with deaf culture. We plan to continue this study to find more ways of combining inclusivity and theatre.

Abstract Name: Surgical procedure to monitor neuroactivity and expression in freely moving animals for the advancement of Rett syndrome therapy.

The overarching goal of this research project is to better understand how altered neural activity at the circuit level underlies behavioral phenotypes in a mouse model of Rett Syndrome (RTT). We will focus on the social interaction behavior in the RTT mice, as it is a robust phenotype with clinical relevance. Previous work from our lab and others has also found altered network activity in the hippocampus of the RTT mice, a brain

structure known to play a role in social memory. To establish causality between abnormal hippocampal network activity and deficient social interaction in the RTT mice, we plan to simultaneously record population neuronal activity in the hippocampus and monitor animal behavior in freely behaving mice. By employing this innovative method that acquires time-locked neuronal activity patterns and animal behavior, the study aims to contribute crucial insights into the RTT disease mechanism. The ultimate purpose is to leverage this understanding to inform the development of targeted therapeutic strategies, thereby advancing the prospects of effective treatments and, potentially, a cure for Rett Syndrome

Abstract Name: Developing an HPLC Method to Evaluate the Impact of Deafening Noise on GABA and Glutamate in the Central Auditory System

The analysis of the levels of gama-aminobutyric acid (GABA) and glutamate in the brain are important, as they influence behavior and indicate the physiological state of the subject. GABA and glutamate are respectively the primary inhibitory and excitatory neurotransmitters within the brain. In addition, they are implicated in hearing loss and tinnitus. However, the analysis and quantification of GABA and glutamate in brain tissue is challenging, as a result of their lack of fluorescent and ultraviolet/visible light absorbent characteristics. The process of derivatization provides a way to work around these challenges. Naphthalene-2,3-dicarboxaldehyde (NDA) has been observed to be superior in derivatizing amino acid based neurotransmitters to ortho-phthalaldehyde (OPA). Additionally, NDA provides a more intense signal of fluorescence after reacting with a primary amine, when compared to OPA. On the other hand, fluorescamine (4'-phenylspiro[2-benzofuran-3,2'-furan]-1,3'-dione) has been shown to readily react with primary amines under alkaline conditions. Fluorescamine is primarily used to detect amino acids with primary amines. Fluorescamine is also known to create an intense fluorescent signal after reacting with primary amines. Since GABA and glutamate contain primary amines, the present work explores the ability of fluorescamine to derivatize GABA and glutamate and subsequently, analyzing the derivatives with high performance liquid chromatography (HPLC). The current data demonstrates unique advantages of the fluorescamine derivatives of GABA and glutamate over that of NDA and present a new HPLC-fluorescence detection method for analysis of GABA and glutamate. This method has been used to compare the levels of the two neurotransmitters in noise exposed subjects versus their control counterparts. Overall, the work does not only provide an efficient chromatographic based method of analysis of GABA and glutamate but also reveals changes in these neurotransmitters that could underline noise-induced hearing disorders.

Abstract Name: Landslide Detection System Using RPi and Strain Gauge

This project is a part of more extensive research on landslides to make a multimodal device for landslide prediction. Landslides are a force of nature that causes loss of life and property damage. Detecting a landslide before it happens would allow these consequences to be mitigated. The sensors used for landslide detection in the lab sandbox experiments include a type of load cell (commonly used in digital scales) that detects strain applied, temperature sensors, and moisture sensors. Our strain gauge sensor's previous data collection was based on sampling multiple data points a second. Recording until a landslide occurred in the experimental sandbox often created a file that is difficult to work with in Excel. Our project is to create a program for our Raspberry Pi (RPi) to collect strain gauge data at variable rates. Varying the data collection rate removes superfluous data points when no significant change is recorded with the sensors in the sandbox and improves the long-term usability of the data collection system. We have revised the data collection program to decrease the data collection rate when little activity in the simulated geological slope is detected and drastically increase data collection when something starts happening. The program monitors the data collection and looks for abrupt changes in the recorded values that may signify a shift in the slope before a landslide.The path leading up to this project included timestamp synchronization between two RPis and imaging the RPis' micro SD cards. After installing real-time clocks, the RPis saved their system time through power cycles. With SD card images, we have created backups, allowing us to easily experiment with the current program on other test RPis.This presentation will showcase the algorithm that changes the RPi's sampling rate when it detects changes in the slope before a landslide.

Abstract Name: Spatio-Temporal Analysis of Algal Blooms in Lake Pontchartrain Using Landsat

Located in New Orleans, Louisiana, Lake Pontchartrain is the second-largest brackish estuary in the United States and is connected to the Gulf of Mexico. The elevation of New Orleans varies from -13 feet elevation to 328 feet, averaging 3 feet of elevation. This makes New Orleans susceptible to flooding events from the Mississippi River. This susceptibility to flood events led to the Bonnet Caraway Spillway (BCS) building in 1937. The purpose of the BCS is to divert flood waters from the Mississippi River into Lake Pontchartrain. The BCS aids in preventing significant flooding events but leads to major changes in water quality in Lake Pontchartrain. Among some of these changes are excess nutrients and organic matter, which leads to eutrophication and algal blooms. Algal blooms can significantly affect the delicate marine ecosystem. Since the building of the BCS in 1937, it has been opened 15 times; since 1997, the BCS has been opened 8 times. With an increased frequency of BCS openings within the past 25 years and climate change leading to changes in atmospheric conditions, we can expect to see even more BCS openings occurring. Using remote sensing and NDVI, we can assess historical algal blooms in relation to the BCS openings. This study uses Landsat 5 and 8 data and NDVI to derive a thematic map of algal blooms near the BCS opening dates to assess changes in algal content in Lake Pontchartrain. Results show that algal blooms are detectable using NDVI in non-turbid waters.

Abstract Name: Effect of Nerve Injury on Shoulder Muscle Fibers in Brachial Plexus Birth Injury Rat Model

Brachial plexus birth injury (BPBI) occurs when the nerves innervating the shoulder are damaged by excessive stretching of an infant's neck during childbirth. It is one of the most common pediatric neuromuscular injuries, occurring about 1 in every 1000 live births. Up to 40% of those affected by BPBI have long-term limb impairments including musculoskeletal deformities, paralysis and reduced range of motion. The underlying changes to muscle architecture throughout development are unknown. Previous murine studies at 4 and 8 weeks post-injury have reported decreased optimal fiber lengths in shoulder muscles following BPBI. Our goal is to establish when these muscular changes occur and how they persist throughout development following BPBI. Sprague Dawley rats underwent surgery on one forelimb at postnatal days 3-6 (postganglionic or preganglionic neurectomy, forelimb disarticulation, or sham) and were sacrificed 2, 3, 4, 8, or 16 weeks post-injury. Eleven muscles surrounding the glenohumeral joint were dissected from injured and uninjured limbs (pectoralis major, acromiodeltoid, spinodeltoid, supraspinatus, infraspinatus, teres major, teres minor, subscapularis, triceps, biceps long head, and biceps short head). Mass and length were measured, and then muscle fibers were dissected and sarcomere length was measured using laser diffraction. Optimal fiber length and physiological cross sectional area (PCSA) were calculated for each muscle. Metrics were compared for each muscle between groups via 2-Way ANOVA with tukey post hoc test (GraphPad Prism 10, α<0.05).Preliminary results indicate that at 4 weeks post-injury, sarcomere length tends to be shorter for postganglionic and disarticulation groups relative to sham and tends to be shorter for disarticulation relative to postganglionic for the injured and uninjured biceps short head. PSCA tended to be smaller for postganglionic injured acromiodeltoid relative to sham. Understanding the changes occurring to muscle architecture throughout development following BPBI may inform treatment planning.

Abstract Name: The Effect of Algal Biomass Replacement on Fresh and Hardened Properties of Metakaolin Mixes

Ordinary Portland cement (OPC) is the predominant concrete binder due to its cost-effectiveness and wide availability. However, the process of OPC manufacturing contributes significantly to greenhouse gas emissions, necessitating the exploration of more sustainable alternatives. One promising approach is the use of alkali-activated metakaolin geopolymers. Obtained through kaolinitic clays, metakaolin offers greater abundance and accessibility compared to other geopolymer binders. Despite its benefits, metakaolin's calcination process still emits carbon dioxide, and its formulation demands a substantial amount of alkaline activators to achieve desired compressive strength, as highlighted in prior research. In order to overcome these challenges, this research explores the incorporation of algal biomass, specifically Chlorella algae and algal biochar, into metakaolin geopolymer mixes with the aim of enhancing sustainability and properties of

metakaolin mixes. To address these challenges, this study evaluates the fresh and hardened properties of metakaolin mixes with varying percentages (1%, 5%, and 10%) of algae and biochar. The testing of fresh properties includes setting time and hydration kinetics, while the evaluation of hardened properties contains compressive strength, phase development, and morphological changes. The outcomes of this study are anticipated to provide a comprehensive understanding of these novel metakaolin geopolymer mixes and contribute to the development of more sustainable building materials, addressing the environmental concerns associated with traditional cement production.

Abstract Name: Optical Coherence Tomography-Based Indentation to Measure the Elasticity of Engineered Tissues

Fibroblasts are a type of cell that synthesizes and organizes the extracellular collagen matrix. These cells apply traction and tensile forces that are essential for maintaining the form and material characteristics of the collagen matrix, which in turn impact cell differentiation and functions. The goal of this study is to characterize the changes in mechanical elasticity of the fibroblast-populated collagen matrices (FPCM) during development and treatment and to correlate these changes with corresponding cellular processes. Using a microsphere-based indentation system with optical coherence tomography (OCT) imaging, we measured the regional material properties of the FPCM during development. We found that the stiffness of these engineered tissues increases during development, which is correlated to their increased compaction and contraction mediated by fibroblasts. Our findings suggest a substantial influence of cell type and initial arrangement on morphological and mechanical alterations during tissue development. The results from this project will improve our understanding of the biomechanics and mechanobiology of tissue during developmental, fibrotic, and wound healing processes.

Abstract Name: Rapidly assessing the cellular composition of neural stem and progenitor cell populations using qRT-PCR

Neural stem and progenitor cells (NSPCs) differentiate into neurons, astrocytes, and oligodendrocytes during

embryonic development to form the central nervous system (CNS). NSPC transplantation has therapeutic potential for CNS ailments since CNS tissue poorly regenerates. However, previous NSPC transplantation studies found variable effects in alleviating symptoms, partly due to difficulties in predicting transplanted NSPCs' cell fate. To improve NSPC therapeutic potential, our lab sorted NSPCs to enrich neuron- and astrocyte-biased sub-populations. However, assessing cell fate of the sorted cells was time consuming. In this study, we aimed to develop a reliable qRT-PCR assay to rapidly identify fate-biased NSPCs by their gene expression signatures. We hypothesized that differences in mRNA expression for neuron-, astrocyte-, and oligodendrocyte-biased NSPCs can be detected using qRT-PCR and that specific gene expression combinations will reliably predict the cellular composition of NSPC populations.Primers were designed to assess cell fate based on highly expressed genes found in scRNAseq data. Fate-biased mNSPC samples for analysis were generated by either sorting or isolating NSPCs from different embryonic stages of cortical development or different brain regions. The qRT-PCR data for each cell population was compared to analysis of differentiated cells (neurons, astrocytes, and oligodendrocytes) by immunocytochemistry to identify genes reliably expressed by each progenitor type.I found NeuroD1, Dclk2, and Mgat3 reliably detected neuron-biased progenitors and of these, Mgat3 is a newly identified neuron progenitor marker. For glial progenitors, I found Egfr and Sparcl1 detected astrocyte-biased progenitors and Pdgfra and Pcdh15 identified oligodendrocyte-biased progenitors.A rapid qRT-PCR assay for cell fate will improve the efficiency and efficacy of cell therapeutics by providing a quick assessment of the fate bias of cells for transplantation, making it possible to better tailor the cell type utilized for each neurological condition.

Abstract Name: Obstacles for Senior Citizens Obtaining Basic Needs

Poverty has increased among Americans 65 and older from 8.9% in 2020 to 10.3% in 2021. An average of 13.7% of Texas households experienced food insecurity between 2019 and 2021. Texas is one of many states that experience food insecurity above U.S. average prevalence rates. Most Texas residents live in completely rural counties where resources are not easily accessible. Older adults have reported they have had to face the decision between paying for food, medicine, medical care, utilities, rent or mortgage, transportation, or gas for a car. This research focuses on barriers seniors experience to obtain basic needs in rural communities. The study also focuses on the extent transportation impacts the ability to obtain basic needs. The student researchers thoroughly analyzed 15 peer reviewed journal articles to inform their study to advocate for seniors to more easily obtain basic needs. Within the last year student researchers have also participated in volunteering with their community partner, a local church who provides basic needs to seniors. The student researchers developed an English and a Spanish survey with demographics, close ended and open-ended questions. The student researchers target a sample size of 100 participants. This research generates new knowledge of barriers and helps inform solutions to resolve the issue at hand. The student researchers will distribute a hard copy of the consent form to willing participants during the Thursday weekly food pantry gathering. The results will help student researchers to better advocate and support the needs of seniors in rural communities.

Abstract Name: Student Perspectives on Inclusive Education: A Framework for Teaching and Learning

Inclusive education involves cultivating learning environments where all students feel they belong because they are treated equitably, have equal access to learning, and feel valued and supported in their pursuit of knowledge. Listening to student voices can help educators understand what an inclusive classroom looks like and consider how inclusivity attributes can be addressed within the dynamic of research engagement. In this qualitative research study, students from a graduate course at a Canadian institution were invited to complete a survey and participate in follow-up interviews. Survey data from four open-ended questions (13 students), interview responses (6 students), and information collected from a teaching workshop (12 instructors) comprised the data set. The following three themes were identified as key factors contributing to inclusive education: persona, practice, and partnership. In persona, students named the characteristics and actions of educators that made them feel included. For practice, they emphasized the learning environment, including setting the tone, teaching strategies, learning materials, and assessments as essential in shaping and fostering inclusion. Partnerships were manifested as building relationships amongst students, and between students and the instructor and Teaching Assistant. These findings reveal how persona, practice, and partnership translate into a holistic learning environment centred on becoming, belonging, and well-being as depicted in our inclusive framework. The researching classroom is one approach to supporting student professional and interpersonal development (becoming), working together for a shared goal (belonging), and engaging in a nurturing and caring space that values the individual (well-being).

Abstract Name: Modesty and Modernity: A study on French modest fashion brands

Current scholarship on post-Orientalism and other ways of framing and centering the narratives of Muslim women allows the deeper exploration of how Muslim women navigate the sometimes-conflicting intersections of faith, fashion, and identity, particularly in secularized Western spaces. Moreover, current research on modest fashion and Muslim women within the sector, particularly those living in Western countries, places less of an emphasis on modest fashion designers in comparison to modest fashion bloggers, consumers, and/or models. The primary data of this project will include the official Instagram accounts of three specific modest fashion brands. To analyze the data, this project will utilize a two-pronged approach revolving around a semiotic analysis of the data, followed by the coding of any recurring themes apparent in the data. In doing so, the recurrence of specific concepts (i.e., modernity, ethical consumption, and environmental consciousness) begins to materialize. Overall, this research project will demonstrate how modest fashion brands utilize certain motifs—like modernity, ethical consumption, and environmental consciousness—to market their brands and products to a secularized French society.

Abstract Name: Teaching Away Anxiety: The Efficacy of a Short-Term Interactive Anxiety Program on 2nd and 3rd Grader's Mental Health with College-Aged Mentors as a Mediating Factor

Anxiety impacts children of all ages and has increased greatly over the past five years. While interventions are frequently used on a case-by-case basis to assist students in navigating this disorder in school, few studies have addressed anxiety within the collective classroom. Research has indicated the promising impact of school-based intervention methods that help individuals for anxiety, in addition to those with no formal diagnosis.School-based interventions for anxiety in children involve the creation of a comprehensive and inclusive support system that includes counseling services and a nurturing environment to address the specific needs of individual students, as well as the school population at large. The purpose of this cross-sectional study is to address the deficit in anxiety interventions and treatment for clinical and subclinical anxiety for school-aged children at this larger scale.This study uses the COMPASS for Courage curriculum from PBS, which has been validated for children struggling with anxiety. The curriculum dictates a short-term interactive group anxiety education program, which is being implemented in a non-profit afterschool program for 2nd and 3rd grade children for the purposes of this study. Children's anxiety levels, understanding of mental health concepts taught by the program, their perception of their assigned mentor, and their acceptance of the program will all be measured. Additionally, volunteers that are apart of the study will be measured for their evaluation of their assigned students' reception to the material, as well as their active participation in the program.Results generated from this study will provide important information for afterschool programs, anxiety education instructors, mentor-based programs, and general children's anxiety intervention research in the future. Programs such as these have the potential to greatly improve children's mental health across all diagnoses and clinical significance, in school settings of all kinds for children of all ages.

Abstract Name: Study on CubeSat Technology for Early Detection and Prevention of Chaparral Ecosystems

This research project focuses on the innovative application of CubeSat technology for the early detection and prevention of wildfires in delicate and fire-prone Chaparral ecosystems. The study recognizes the increasing threat posed by wildfires to these unique ecosystems, which are vital for biodiversity and environmental stability. The primary aim is to explore the feasibility of utilizing CubeSats as a cost-effective, real-time monitoring solution to safeguard Chaparral regions. The research encompasses CubeSat design, remote sensing instrumentation, and data analysis techniques. By harnessing satellite technology, this project seeks to revolutionize our capacity to detect and respond to wildfires in these ecosystems, offering a proactive approach to wildfire management. The study underscores the potential for CubeSats to protect these valuable environments and contribute to global wildfire prevention efforts while also providing a practical educational experience for aspiring aerospace engineers and environmental scientists.

Abstract Name: Escaping the Stigma: How Black Men in America Can Overcome Negative Connotations Towards Mental Health and Emotional Exhaustion

As a young black man, I have personally experienced the impact of mental health challenges in the black male community. Through my documentary film project, I aim to delve into this crucial issue and promote greater awareness and healing. Through personal storytelling and a series of interviews with experts and black men who have gone through emotional stress and are dealing with mental health issues, I hope to shed light on the stigma surrounding black men and mental health. This project is driven by a dual purpose: to create a thought-provoking cinematic experience and to shed light on mental health in the Black Male community. The film blends fiction and non-fiction elements, emphasizing emotional vulnerability and open communication. The authentic narratives will benefit a broader audience, highlighting the urgency of addressing mental health in Black communities where such conversations are lacking. My goal is to shed lights on the stigmas and to create a safe space and encourage other black men to become more introspective and embark on a journey of self-improvement. As the director of this film, I am committed to using my storytelling abilities to challenge the prevailing stereotypes and create a brighter, more hopeful future for the black community.

Abstract Name: Expression of an Antibody-Antifungal Hybrid Protein with Potential Therapeutic Effects Against Candida Infections.

Candida albicans is a human commensal fungus that can cause superficial infections, but it has also emerged as the fourth leading cause of hospital-acquired bloodstream infections. Hematogenously disseminated candidiasis is life-threatening and associated with an extremely high mortality rate despite treatment with currently available antifungal therapies. Therefore, there is an urgent need to develop novel therapeutics to combat this pathogen. Previously, we have developed human recombinant antibodies against C. albicans that have been shown to be protective in a mouse model of hematogenously disseminated candidiasis. These antibodies promote phagocytosis, but they do not have a direct fungicidal effect. Our current goal is to identify anti-fungal proteins that can be fused with these anti-Candida antibodies as a hybrid protein where the antibody directs the fungicidal protein to C. albicans cells for direct killing. This project aimed to express recombinant chitotriosidase in bacteria. Chitotriosidase is a human chitinase that breaks down chitin in the fungal cell wall and is therefore expected to be fungicidal. The pET expression system was utilized for recombinant protein expression in Escherichia coli. A 6X-HisTagged human chitotriosidase gene (CHIT1) was cloned into the pET28b expression vector. DNA sequencing and restriction digests confirmed correct DNA sequence and proper orientation of the chitotriosidase gene in the pET28b expression vector. SDS-PAGE and western blots probed for human chitotriosidase and 6X-HisTag showed bands consistent with predicted protein size. Cell lysates tested by ELISA were positive for both human chitotriosidase and 6X-HisTag. Taken together, these data suggest the successful expression of recombinant human chitotriosidase in bacteria. Biological assays performed with recombinant chitotriosidase showed an inhibitory effect on C. albicans germ tube formation. The CHIT1 gene was subsequently subcloned into the anti-Candida antibody construct to create an antibody-antifungal hybrid protein that may be used as a potential therapeutic for Candida infections.

Abstract Name: Design and Implementation of Modular Thermoelectric Generators for Energy Harvesting

The utilization of thermoelectric generators (TEGs) for low-yield power generation has broad and promising applications in environmental monitoring. Harvesting energy from a temperature gradient between a tree's internal temperature and ambient air provides a stable, low-maintenance solution for powering sensors and other low-power electronic devices, without the need to replace batteries in the field. A rod-shaped thermoelectric harvester design using a single TEG has been developed. The rod-shaped harvesters are inserted in pre-drilled holes in the trunk of a tree. The harvester prototype design in this study emphasizes modularity and stacking of multiple stages to allow the harvester to maximize the thermal energy of a wide range of tree trunk diameters, in contrast to past prototypes that use a solid metal rod connected to one external TEG, which limits power output and thermal transfer efficiency. This study documents the design process, manufacturing considerations, final specifications, and experimental power output of a 2 inch diameter prototype unit. The design's idealized output wattage of 36.7 milliwatts is estimated using a numerical model of n and p-type Bi2Te3 using material properties at room temperature (constant property

model) for a given temperature difference. This will be validated with experimental testing of the developed TEG harvester.

Abstract Name: More May Not Mean Better: A Senegalese Consortium on Pearl Millet

Senegal is a country whose agricultural system currently relies on traditional, unstable practices and is very sensitive to climate change. The combination of these factors has resulted in very vulnerable crops, which ultimately impacts their availability negatively, leading the country to be food insecure. To address this, research is underway to innovate the agricultural system. Previous studies have analyzed the effects of plant growth-promoting rhizobacteria (PGPR), which have resulted in improved plant growth and yield. Recent investigations extend upon this work, exploring bacterial consortia, and reveal their potential to surpass individual strains in enhancing plant growth. This study focuses on creating a consortium using indigenous bacterial strains from Senegal: Bacillus depressus (NLLB3), Bacillus subtilis (TYB11), Priestia megaterium (MKR2A5) (formerly Bacillus megaterium), and Cellulosimicrobium cellulans (MKLB1). Additionally, a nitrogen-fixing bacteria, Azospirillum lipoferum (B-4469), from the United States Department of Agriculture was incorporated. Although compatibility between the strains was observed, the data revealed no significant enhancement with the consortium in comparison to the negative control and individual strains control. This suggests that the key to an effective consortium may involve factors beyond solely selecting strains with plant growth-promoting properties. This research sheds light on the complexity of bacterial interactions in enhancing crop productivity, emphasizing the need for a nuanced approach in developing effective bacterial consortia for sustainable agriculture in Senegal.

Abstract Name: Flicker to Fade: High Schoolers' Perceptions of Self and Fast Fashion

From little black dresses to ballgowns, fashion dancewear is iconic for high school students. Popular fast fashion brands such as ZARA and Shein target teenagers exposed to social media (Tokatli 25) identify these brands “send manufactured clothes to their stores almost immediately” (qtd in Reinach 23), aggressively hyping their products on Instagram and TikTok as the anticipation for these events grow. As students know the risk of duplicate fashion styles at dances, pressure to find cheap and unique styles that stand out rises (Hemphill & Suk 1153). However, due to the yearly pressure to innovate, this encourages students to relegate their garments to their closet, creating space for their next significant dance purchase.I hypothesized that because of the increasing social media pressure, high school students prefer to purchase different dance attires for each dance. To investigate this, I conducted a survey with a random sample of high school students. The survey questioned participants about their grade, gender identity, presence of dance dates, frequency of

dance attendance and dance attire reuse, and motivations for shopping for dance attire to analyze the correlation between social media and the pressures put on high school students to stand out amongst their peers. As a result, we intend to discuss the variations in preferences for high school students' motivation to their dance attire. By researching how fast fashion's characteristics alters high schoolers' mindsets, we can improve students' confidence while encouraging them to reconsider how they approach fast fashion and its highly publicized business model.

Abstract Name: Addressing ASR Challenges in Concrete through Cutting-Edge High-Performance Concrete (HPC)

The Alkali-Silica Reaction (ASR) presents a significant challenge to the longevity and safety of transportation structures, necessitating considerable financial investment for effective mitigation. This research investigates the pervasive issue of ASR by thoroughly examining material factors influencing concrete structures. ASR, resulting from the interaction of alkalis in cement with silica in aggregates, leads to gel formation, volumetric expansion, and eventual structural failures. Recognizing the limitations of the current assessment model, which often overlooks testing condition variabilities, this study advocates for more extensive research to enhance our understanding of ASR.The research focuses on evaluating various supplementary cementitious materials (SCMs) (such as fly ash, slag, and silica fume) in conjunction with Ordinary Portland Cement (OPC) to identify their efficacy in mitigating ASR. Emphasizing statistical analysis, the study compares the performance of different concrete mixtures (binary and ternary) to OPC under varying testing conditions, addressing the existing limitations in testing methodologies. Additionally, the study explores the overlooked impact of different aggregate types on ASR and aims to develop guidelines for optimal concrete mixtures, considering aggregate types and gradings.The research involves statistical analysis of datasets provided by one of the Federal Highway Administration comprehensive reports, examining parameters like shrinkage strain and compressive strength. It establishes correlations between ASR expansion testing (ASTM C1567) and other tests to identify the factors affecting concrete mixture performance. Varying aggregate reactivity is considered, and controlled environmental conditions are employed to minimize errors.The objectives encompass comparing High-Performance Concrete (HPC) mixtures with OPC, determining optimum blends, offering insights into aggregate effectiveness, and providing practical guidelines for transportation-related projects. The research aims to optimize concrete mixtures for improved performance, durability against ASR problem, and cost savings, thereby contributing to the sustainability of transportation infrastructure.

Abstract Name: SEX DIFFERENCE IN RECOVERY IN A NOVEL RODENT MODEL FOR PRETERM HYPOXIC-ISCHEMIC ENCEPHALOPATHY

Preterm infants are susceptible to maternal stressors whose subsequent inflammatory response can heavily influence neuronal and motor development over short- and long-term post-natal timescales. Preterm hypoxic-ischemic encephalopathy (pHIE) can occur in utero, yet commonly-used rodent models do not accurately mimic the events occurring in pHIE in the developing brain. Our laboratory has developed a novel rodent model that more accurately represents human HIE. In this model, we induced HIE in preterm neonatal mice by producing an inflammatory response in the maternal rodent using lipopolysaccharides (LPS) injection followed by preterm and post-natal exposure to hypoxia (10% O2). This method incorporates a direct interaction between the maternal inflammatory response and the mouse fetus as opposed to the Rice-Vannucci (RV) model that involves direct insult to the infant mouse brain. Using this model, we assessed differences in pHIE recovery between males and females as is seen clinically. We conducted behavioral tests testing general motor function in preterm mice, by running front- and hind-limb suspension, negative geotaxis, surface righting, and ambulation. We hypothesize that sex differences in recovery from preterm hypoxic-ischemic injury in neonatal mice will be observed, with females showing a more robust recovery in motor function than male littermates. Our results, gathered through behavioral analysis of the preterm mice, show no significant sex bias in female and male neonatal mice using our model. This is in contrast to the commonly used RV model of HIE. Our results suggest an absence of post-injury recovery in response to the pHIE seen in the RV model. Overall, our behavioral data provides evidence that a pHIE model that incorporates both maternal and neonatal factors more accurately mimics the melange of effects seen in human HIE, further highlighting the importance of involving the maternal inflammatory response in pHIE studies.

Abstract Name: Life Cycle Assessment of Biodegradable Plastics Packaging Subject to Comprehensive Organic Sorting

Organic waste rotting into methane in landfills causes approximately 14% of methane emissions in the United States, and a significant portion of the world's energy is used to generate plastic packaging. A holistic solution for reducing energy in packaging and organic waste could have significant environmental benefits. This paper presents a potential solution called "The Big Green Loop" (BGL), in which high-performance organic packaging is generated from organic waste diverted from landfills. This value chain is enabled by recent advances in organic waste valorization and a high-value packaging technology developed by a startup,

Corumat, Inc. This new packaging technology enables high-performance packaging to be made from as little as one-third of the material of competitive technologies, and prototypes have been made from organic waste diverted from landfills. The paper systematically analyses each step in the BGL process value chain and calculates the impacts based on various scenarios and scopes. Calculations estimate that sourcing organic waste diverted from landfills, displacing traditional packaging with reduced amounts of environmentally friendly material, and enabling the diversion of additional organic material through superior value chain economics could reduce greenhouse gas emissions and may also have other positive environmental effects.

Abstract Name: Monitoring Subsidence Trends of Underground Water Exploitation Areas in Vietnam Using DInSAR Technique

Land subsidence is an escalating concern in Vietnam, particularly in urban centers like Ho Chi Minh City, Hanoi, and the Mekong Delta region. A 2019 report by the Copernicus EMS program highlights trends in ground subsidence, using InSAR technology. Subsidence rates vary spatially and in intensity, with hotspots in certain areas. Techniques like deep boreholes and traditional methods are employed to monitor subsidence in the Mekong Delta region. The project aims to delineate, assess, and monitor subsidence using InSAR technology in key regions. Results indicate diverse subsidence patterns from 2007 to 2010, with varying levels across different provinces. Notably, certain regions experience higher subsidence funnel centers. However, while the SBAS-INSAR technique ensures accurate monitoring, natural and human-induced factors must be considered during data acquisition, affecting actual subsidence rates. Despite challenges, this technique offers reliable insights into the complex phenomenon.

Abstract Name: Exploring the Effects of Antidepressants on the Human Microbiome

IntroductionThe gut-brain axis (GBA) involves bidirectional communication between the gastrointestinal tract and brain, which contains many species of bacteria that play an important role in this communication. Major depressive disorder is often treated with antidepressant medications (ADMs) that pass through the gastrointestinal tract; however, the possible adverse effects of ADMs on the gut microbiome are not well characterized.MethodsThis project investigates the impact of three selective serotonin reuptake inhibitors, sertraline, fluoxetine, citalopram; one norepinephrine and dopamine reuptake inhibitor, bupropion; and one

tetracyclic antidepressant, mirtazapine, on the growth of seven species of gut bacteria, Bacteroides fragilis, Bifidobacterium longum, Bacteroides uniformis, Collinsella aerofaciens, Prevotella copri, Escherichia coli, Akkermansia muciniphila, and Lactobacillus plantarum. Bacteria were treated with various concentrations of each ADM to determine potential impact on growth. We calculated the concentration of drug needed to inhibit growth by 50% (IC50) using spectrophotometry.ResultsSeveral ADMs inhibited gut bacterial growth. At 50% bacterial growth inhibition, the most prominent was sertraline (28.742 μM), followed by bupropion (43.976 μM), then fluoxetine (76.449 μM). Citalopram (244.738 μM) and mirtazapine (294.316 μM) exhibited far less inhibition. DiscussionThese findings suggest ADMs have antibiotic effects that disturb the microbiome resulting in potential consequences for microbiota-GBA interactions. Building on these results, future experimentation will measure uptake and metabolism of ADMs by exposing bacteria to each drug longitudinally. Metabolites will be characterized using liquid chromatography-mass spectrometry.ConclusionGiven the profound impact of the gut microbiome on the gut-brain axis, these data provide novel insights into potential mechanisms by which ADMs could have unintended consequences on the gut that may perpetuate, instead of treat, mood disorders thus the microbiome should be further investigated in relation to ADMs.

Abstract Name: Impact of NIL Deal Announcements on Issuing Company Stock Prices: An Event Study

This research examines the impact of the announcement of Name, Image, and Likeness (NIL) deals with college athletes on the stock prices of partnership companies. As the sports industry undergoes significant changes with the allowance of NIL compensation for college athletes, this study seeks to shed light on the financial implications for businesses involved in such agreements. The research employs an event study methodology, leveraging data aggregated from various news and sports announcements related to NIL deals. By analyzing stock price movements surrounding these announcements, we aim to identify trends and patterns in the market response. Preliminary findings indicate that NIL deals, particularly those involving high-profile athletes, have a discernible influence on the stock prices of issuing companies. This suggests that investors and market participants are reacting to the potential marketability and revenue impact associated with these agreements. As the sports landscape continues to evolve in the era of NIL compensation, this research provides valuable insights for investors, analysts, and stakeholders interested in understanding the financial dynamics at play in this emerging market.

Abstract Name: Adhesion of Metal-Complex Particle Free Inks Using Low Temperature Cures on Polymetric Substrates

Metal-complex particle free conductive inks are a new class of conductive inks with applications in printed circuits, displays, and wearables. These particle free inks hold an advantage over the current generation nanoparticle inks since they can achieve conductivities as high as 90% of bulk silver with annealing temperatures as low as 40 C. In this study, the adhesion and resistivity of a screen printable metal complex ink was investigated based on the surface chemistry of the substrate used during printing. A 1.5-micron layer of silver was deposited and cured at temperatures as low as 60 C. Using ASTM Tape test, profilometer, and multimeter, the resistivity and adhesion of the particle free ink on each type of substrate was analyzed. The type of substrate printed on was found to largely affect adhesion and resistivity of the ink with certain polymetric substrates showing a resistivity of 20 uohm-cm with adhesion at 60 C. This study offers an insight regarding which substrates offer the best adhesion and lowest resistivity values when printing conductive inks. Further studies are needed to evaluate the long-term adhesion and resistance values of the ink prints.

Abstract Name: Fluorescent Probes for Detection and Quantification of Heavy Metals in Disposable Vaping Products

The United States has witnessed a troubling surge in the consumption of disposable vaping products, which currently lack adequate regulation by the FDA compared to traditional tobacco products. This rise in popularity has raised concerns due to potential health risks associated with heavy metal contamination. The accumulation of heavy metals in vital organs has been linked to various carcinogenic and toxicological effects. A study was conducted to observe how different fluorescent probes including riboflavin, fluorescein, and sulforhodamine 101 react in the presence of heavy metals such as lead, cadmium, tin, and nickel. Employing a Cary-Eclipse fluorometer, changes in fluorescence for each metal-dye interaction were observed. The Stern-Volmer equation was then applied to calculate the quantum yield of each dye and assessed how it changed in the presence of the metal quenchers. This provided insights into each fluorescent molecules' responsiveness to each heavy metal. These fluorescent probes have the potential to play a crucial role in evaluating the presence of heavy metals in vaping devices and a wide range of other consumer products. This could enable informed decisions and regulatory actions to safeguard public health in the future.

Abstract Name: Implementing a Lesson Plan to Analyze Sand Dunes

Sand dunes provide essential ecosystem services to coastal areas such as protection during storm surges and increased biodiversity. As such, for students living in coastal areas, education on sand dunes should not start only in college but as early as middle or high school. In 2021, an Environmental Science Teaching major and a Math Teaching major developed a lesson plan on analyzing sand dunes using Pythagorean theorem and estimating vegetation percentages under the guidance of Dr. Phillip Schmutz and in partnership with a high school science teacher Ms Hailee Hawkins. This lesson plan however had not been implemented with students to test its practicality or its efficacy.In the summer of 2023, Environmental Science Teaching major Mikala DuBose and Math Teaching major Rachel Ledford, revised and implemented the lesson plan with a partnered high school math department. They were able to take students into the field at Pensacola Beach and collect data on sand dunes. Students conducted a land survey of the sand dune allowing them the opportunity to use equipment in the field and observe the sand dunes height and vegetation percentages. Through this process, the STEM teaching majors were able to identify the strengths and weaknesses of the lesson and learn how to translate scientific research into classroom instruction. Using the overview from the previous Noyce Scholars and the field experience, they were able to construct three detailed lesson plans with malleable standards and instructions for teachers to use for their own classroom lessons, particularly for science or math.

Abstract Name: Jack of All Trades Becomes a Master of One in Higher Education - Personal Reflection

As of 2021, 15.44 million individuals are enrolled in some types of postsecondary education setting in the U.S. Among them, 56% of them are first generation college students and they tend to have various issues which prevent them from having smooth academic success compared to their counterparts. Specifically, first generation college students commonly present including, but not limited to, larger amounts of educational debt, lower graduation rates, limited campus engagement, and little use of formal campus resources. As an educator in higher education, engaging in diversity, equity, and inclusion should be the first concern to practice true stewardship. To better serve students, especially for first generation college students, stimulating their academic curiosity and bringing the outcomes of their efforts can strengthen their commitment in education. These can be handily achieved by engaging them in faculty's research projects. As a junior faculty, I have closely worked with first generation college students for one of my research projects, emotion regulation for ethnic minority young adults. Students took an initiative role in this particular research project considering their personal experience and expertise. Individual interviews were conducted via Zoom to reconnect and understand the impact of research collaboration with them. To that end, the majority of students who engaged in the research project pursued additional education such as double majoring and graduate studies. Detailed research project progress and specific student outcomes will be further discussed.

Abstract Name: Stories for the Road: Trauma & Internal Dialogue

My creative research project explores how telling trauma stories through poetry can heal an individual and a group/community. I have worked extensively to create a submission based publication titled Stories for the Road centered on trauma and narrative. Previous research has shown that "Poetry writing is a process of using the whole self in the writing process as a way to understand our lived social worlds and articulate them (Bolton, 1999)." Writing can also "produce short-term increases in physiological arousal and long-term decreases in health problems." Trauma stories are distressing experiences from an individual's past or present that have an emotional or psychological effect on their lives. Individuals who have experienced trauma often have recurring memories that appear daily, unconsciously, or consciously. My project aims to identify ways a person's trauma impacts their intrapersonal communication, and its influence on their attachment and communication styles. My proposed presentation will discuss the ways that writing can be beneficial to healing and how it can help individuals integrate the trauma they've experienced into their stories. For my research, I have explored the psychology of narrative and storytelling with the intersections of trauma. This topic is important because it stems from the notion that generational trauma and childhood trauma curate changes in the way the response system works. The goal is to offer insight into the private and personal expression of trauma through this presentation and give insight to how creative writing can help in the healing journey. I would also like to showcase the first edition of Stories for the Road and briefly explain the impact it has made on individuals within my community.

Abstract Name: In Silico Multi-Objective Optimization of Palladium-Catalyzed Reactions

Palladium-catalyzed reactions are widely used for both industrial and academic purposes. Their wide range of tolerated functional groups and often exceptional chemo- and regioselectivity allow for the safe, quick, and efficient synthesis of many organic molecules. Notably, the Suzuki and Buchwald-Hartwig reactions are among the most important and useful of these reactions, especially from a pharmaceutical synthesis perspective. These reactions are at the forefront of medicinal chemistry and drug development: Suzuki reactions are involved in the synthesis of drugs like clonazepam, lapatinib, and losartan, making it a valuable reaction in the pharmaceutical industry. Likewise, the Buchwald-Hartwig reaction is a helpful tool for the coupling of heteroaryl chlorides and bromides to NH2 groups in C-amino-1,2,4-triazoles, used in the anticancer drug Bemcentinib and antidepressant JNJ-39393406.Despite their utility, Palladium-catalyzed reactions are costly to run, making reaction optimization through simulation valuable for conserving resources. One way that simulation can be achieved is with kinetic models. Kinetic models use chemical relationships to build a physical model that can extrapolate data, allowing scientists to predict the outputs of chemical reactions.In my research, I propose a method of reaction simulation and optimization using kinetic modeling and the coding language MATLAB. First, I simulate two Suzuki-Miyaura coupling reactions for proof of concept of my simulation method. Then, I use my method of simulation to multi-objective optimize the Palladium-catalyzed Buchwald-Hartwig amination of 4-methylaniline and 4-iodoanisole by predicting the

outputs of reactions run in varying bases, solution, catalyst loadings, reaction times, and initial 4-methylaniline concentrations. To overcome the difficulties of having multiple “optimal points,” I quantify the trade-offs between price and productivity using a Pareto front. Thus, I propose a simulation and optimization technique that allows for the efficient optimization of pharmaceutically important reactions, which would be otherwise difficult in a real laboratory environment.

Abstract Name: The Impact of Pro-Diversity Social Media Messages on Women of Color

Many organizations employ recruitment strategies (e.g., promotional materials showcasing racial and gender demographics, diversity statements on brochures, recruitment events targeting underrepresented groups) to attract prospective applicants from diverse backgrounds. Particularly, social media has emerged as a significant tool in the hiring process to exhibit such recruitment materials. In this present work, we examine an often-overlooked downside of this recruitment strategy, diversity dishonesty – belief that an organization inaccurately portrays its actual diversity – during social media recruitment. We seek to examine how conflicting signals in social media messages about an organization’s diversity impact the perception of women of color.Our survey experiment involves a participant pool ranging from 77 to 127 undergraduate students who identify as women and racial minorities. The experiment aims to examine the effects of DEI-focused or neutral social media messages coupled with exposure to layoff statistics targeting racial minority women. Our investigation centers on participants’ sense of belonging, comprehension of diversity dishonesty, and attraction to the organization. We hypothesize that participants exposed to pro-diversity social media content with layoff exposure will report a lower sense of belonging, identify the dishonest information, and perceive the organization as less attractive, compared to those who only saw the social media post. This study attempts to address the discrepant findings in the literature regarding diversity dishonesty within the context of social media recruitment strategies. Moreover, the findings may help to guide diversity recruitment efforts to accurately represent workplace cultures for women of color working in male-dominated industries and further promote genuinely inclusive environments for marginalized groups. As such, the study will have broader implications for the use of social media messaging which focuses on diversity that may inaccurately portray racial and gender inequalities in the workplace.

Abstract Name: Grip Strength Decline and Its Determinants Across the Lifespan: Insights from the National Health and Nutrition Examination Survey (NHANES) 2011-2014 Data

Grip strength has become a potential indicator of overall health and biomarker for aging. By evaluating the variations in grip strength with focus on the entire lifespan, this could lead to valuable insights into population health. The purpose of this research is to investigate the dynamic variations in grip strength throughout the lifespan, expressed in rates of change measured in kilograms per year and percentage per year, while also identifying the determinants influencing these trends. Additionally, data from the grip strength portion of the National Health and Nutrition Examination Survey (NHANES) from 2011-2014 was used. The cleaned data sample included approximately 13,700 people aged 6-80 years old. The grip strength of the dominant hand was assessed using a Takei Digital handgrip dynamometer, with the best values determined from three trials. The 'Y2-Y1 rate of change' (in kg/year) represented the difference in grip strength between consecutive observations. Preliminary results show that male grip strength increased from 2.00 to 3.58 kg/year in ages 6-19, showed a slight increase in early adulthood (0.25 to 0.71 kg/year at ages 20 to 34), and gradually declined post 35 (-0.08 to –1.11 kg/year in ages 35 to 75+). Similarly, in females, grip strength increased from 2.00 to 2.32 kg/year in ages 6 to 15, slightly rose in early adulthood (0.09 to 0.68 kg/year at ages 16 to 34), and gradually declined after age 35 (-0.06 to -1.15 kg/year in ages 35 to 80+). This study illuminates the evolving patterns of grip strength across the lifespan, contributing valuable insights into grip strength as a potential biomarker of aging.

Abstract Name: Creating and Directing Successful Interdisciplinary Research Experiences for Undergraduate Students: Lessons from the NSF-funded LAKES REU

Many of the most significant problems we face in our society and around the world are "wicked" problems that require complex, interdisciplinary thinking. Preparing students to research and tackle these problems is often challenging, especially for faculty who might not be accustomed to working across disciplines. In this presentation, we discuss our experiences from the NSF-funded Linking Applied Knowledge in Environmental Sustainability Research Experience for Undergraduates (LAKES REU), a summer research experience that has been in existence since 2014 at the University of Wisconsin-Stout (a regional polytechnic) which trains students to research watershed pollution and its mitigation in rural Western Wisconsin. This program has trained 8 cohorts so far (almost 100 students) and has included an interdisciplinary team of mentors including faculty from anthropology, biology, economics, engineering, geography, geology, mathematics, political science, psychology, and sociology. The program provides students with a big picture view of the issue as well as concrete methods training. After providing an overview of the program, we share lessons learned including the need to build relationships, to listen deeply, and to create experiences that allow students to work across projects. Tips for organizing and funding such a program and working with community partners, as well as pitfalls to avoid, will also be shared.

Abstract Name: Organophosphate Flame Retardant Compounds Arrest Oligodendrocyte Maturation

In contemporary societies, humans are routinely exposed to an immense variety of chemicals through their daily interactions with the environment. Toxicity assessments conducted by the Environmental Protection Agency utilize a standard approach to evaluate the safety of chemicals in terms of their toxicological impacts on the human body. However, most of these studies are typically conducted at a macro-level, failing to adequately account for the intricate effects that chemicals can have on individual cell types. Oligodendrocytes are a class of glial cells that play a critical role in neural transmission, are responsible for myelination and provide metabolic support for neurons in the central nervous system. The development of oligodendrocyte progenitor cells is impressionable during critical periods of development that occur in childhood. Dysfunction of oligodendrocytes is associated with the development of severe neurodegenerative and neurodevelopmental diseases such as Multiple Sclerosis and pelizaeus-Merzbacher disease.We have undertaken an extensive toxicity screen of oligodendrocytes, consisting of 1823 chemical compounds, aimed at identifying those that are cytotoxic versus non-toxic to oligodendrocytes. Along with data from an EPA database, we found that 49 of the 292 chemicals identified as cytotoxic were specifically cytotoxic to oligodendrocytes. Dose-response experiments on these 49 chemicals led to the identification of a class of organophosphate flame retardants, which were shown to arrest oligodendrocyte maturation, as the number of O1 positive cells were reduced compared to the primary screen. Human exposure is likely, given that these compounds are commonly used in textiles, electronics, and furniture. Daily oral gavage of mice models starting from postnatal day five to postnatal day fourteen revealed the flame retardants are able to cross the blood brain barrier at concentrations as low as 10 mg/kg per day, depleting oligodendrocytes in the hippocampus and cerebellum. Inhibition of maturation was also seen in human cortical organoids.

Abstract Name: Characterizing how chronic unpredictable stress promotes habit formation

The brain uses two strategies to control our behavior: goal-directed actions and habits. Goal-directed behavior relies on prospective consideration of potential actions and their consequences. Thus, they are more flexible but require more cognitive energy. Habits are more efficient, but, since they are executed without consideration of their consequences, are also more inflexible. A balance between goal-directed and habitual behavior ensures adaptive and efficient decision making. Our lab and others have found that chronic stress promotes premature habit formation in rodents. However, the strength and persistence of these stress-induced habits is unknown. Given that overreliance on habits can contribute to the types of compulsive behavior that can characterize substance use disorders, obsessive-compulsive disorders, and anxiety, characterizing stress-induced habits and their neurobiological mechanisms is critical to understanding these conditions and improving future treatment approaches.We have developed a mouse model for premature habit formation whereby subjects are exposed to two weeks of chronic unpredictable stress (CUS), followed by instrumental reward-seeking training and sensory-specific outcome devaluation to test sensitivity to changes in outcome value. Habits are marked by their insensitivity to devaluation. CUS mice display habits early in training when control subjects maintain goal-directed behavior. We will now evaluate how long the effects of CUS persist to

begin determining boundaries for CUS's effect on habits. To test this, we will first incorporate a month-long delay period between CUS exposure and training/testing. We expect that stress-induced habits will be robust to this delay, and as such, expect that stressed subjects will also prematurely develop habits even when trained and tested one month post- CUS. The information from this research will lay the foundation for future studies to understand the neural circuit mechanisms that allow stress to promote premature habit formation.

Abstract Name: A simplified and scalable synthesis of 7β-hydroxyartemisinin

The goal of this study is to prepare stronger antimalarial drugs derived from the natural product artemisinin. Malaria is still a serious threat to a significant percentage of the world's population, especially those living in the most impoverished countries. Despite being considered eradicated in the US for more than 6 decades, recent cases of locally transmitted malaria in Florida and Texas, creating concern that this disease may once again become endemic in our country.In our efforts to enhance the activity of artemisinin, our laboratory investigates the remote C-H activation of its carbon number 7 (C-7), inherently difficult to activate without affecting the endoperoxide bridge, indispensable for biological activity. We currently obtain 7β-hydroxyartemisinin through the metabolic biotransformation of artemisinin by the fungus Cunninghamella elegans. Using this starting material, we developed a series of novel C7 artemisinin analogues, with some of them displaying antimalarial activity ten times stronger than classical artemisinin-based antimalarial drugs, such as artemether and artesunate.Though these results are promising, access to the starting material is limited by scale-up difficulties and slow production of the microbial metabolite by biotransformation. To overcome these challenges, we have developed an efficient and economically viable approach for the large-scale conversion of artemisinin into 7β-hydroxyartemisinin and 7β-hydroxyartemether. This advanced synthesis includes a TBADT-catalyzed photochemical oxidation, followed by the Corey-Bakshi-Shibata reduction. In sharing our results, we report a facile and scalable synthetic route for the preparation of 7β-hydroxyartemisinin and 7β-hydroxyartemether from artemisinin in high yields.

Abstract Name: Fostering Belonging: Social Support Networks' Impact on the Sense of Belonging of Racial Minority Students in STEM

Racial minority groups continue to be underrepresented in STEM fields in higher education and report a

lower sense of belonging on campuses. Initiatives like NSF's Michigan Louis Stokes Alliances for Minority Participation (MI-LSAMP) address this underrepresentation, participation, and retention of minority students in STEM fields at various Michigan colleges. Using the Bowman Strengths-Based Model, the MI-LSAMP research program's purpose is to understand multilevel strengths that can help underrepresented students succeed in college. As part of the research program, this study focuses on the impact of students' social support networks (SSNs) on their sense of belonging. A semi-structured interview protocol containing questions related to student challenges, sense of belonging, and connections students have on campus was developed. Seven MI-LSAMP students who began participating prior to fall 2023 were interviewed. The research team took preliminary steps, such as memoing ad verbatim transcripts, before using Dedoose software to test intercoder agreement. Two team members then coded the transcripts for sense of belonging and SSNs. Themes emerged after discussions of how a student's sense of belonging is influenced by their social support networks and the implications for educational practice and policy. We found that students' support networks include faculty, staff, family, friends, peers who share social identities, programs like MI-LSAMP, and social clubs, and that these networks increased students' sense of belonging while attending college. Nonetheless, students also mentioned a lack of sense of belonging due to imposter syndrome, coursework difficulty, discordant relationships with professors, and a desire for more representation of their social identities on campus. These relationships between student sense of belonging and their SSNs can inform programs like MI-LSAMP and aid the development of strategies to increase campus connectedness. Further research will include a larger sample size and additional codes to better understand the experiences of minority students in STEM.

Abstract Name: Optimization of Human Carboxylesterase Activity Assays to Enable Personalized Medicine

Human carboxylesterases (CESs) are serine hydrolases that play a key role in the metabolism of different medications that contain ester, amides, thioester, carbonate, or carbamate functional groups. These moieties can be found in a variety of small molecule pharmaceuticals that are commonly prescribed, such as oseltamivir (Tamiflu), meperidine (Demerol), and temocapril (Acecol). CES activity levels among individuals has been known to be impacted by a variety of biological and environmental factors. In addition to drug-to-drug interactions (DDIs), CES activity is known to be influenced by alternative RNA splicing and single nucleotide polymorphisms (SNPs) which can result in alteration of the protein sequence of CESs. Despite the established influence of these factors on human drug metabolism, the activity of CES sequence variations are poorly studied. We hypothesize that this is due to the high cost and time-consuming nature of the current state of the art methods used to study their activity. To address this, we have previously developed a fluorescence microscopy-based approach using a CES1-specific fluorogenic chemical tool, FCP-1, that can be used to monitor the activity of overexpressed CES1 isoforms in live cells. Here, we present our work to optimize these assays to enable rapid annotation of the activity of known CES1 sequence variants. Improvements in the ability to study CES sequence variant activity will result in better treatments with CES substrate drugs by enabling the implementation of personalized medicine approaches to address interindividual drug metabolism variations.

Abstract Name: The Exploration of G-Quadruplex Binding Mechanisms of SRSF1 Expands its RNA Binding Capability Beyond the Norm

Serine-Arginine rich Splicing Factor 1 (SRSF1) is a prototypical SR protein that has been well characterized as a single-standard RNA (ssRNA) binding protein. The RNA Binding Domain (RBD) of SRSF1 consists of a disordered N terminal region followed by two tandem RNA Recognition Motifs (RRMs) known as RRM1 and RRM2 tethered by a flexible linker. The RBD governs the RNA binding specificity of SRSF1. Like other SR proteins, SRSF1 carries an intrinsically disordered C-terminal region called RS tail containing several Serine-Arginine dipeptides repeats which have been predicted to interact with RNA non-specifically. SRSF1's interactions with a tumor-related RNA G-quadruplex (RNA GQ) called ARPC2 have been poorly characterized. We investigate how the structure of SRSF1 facilitates such a non-canonical mode of RNA binding and its effect on the GQ structure. For the first time, by employing fluorescence Polarization (FP) assays, we find that SRSF1 requires both the RBD and RS tail to achieve tight binding to the RNA-GQ which has the consensus sequences of both RRMs. Further, our binding studies on the RBD mutants suggest that the RBD shares similar binding sites between ssRNA and the ARPC2 GQ. Moreover, our Circular Dichroism (CD) data implicates the RBD's potential to partially disrupt the RNA GQ. However, our Fluorescence Resonance Energy Transfer (FRET) data reveal that the RS tail is the main contributor to the ARPC2 RNA-GQ destabilization driven by SRSF1. Our FP and FRET data suggest that the Arginine residues of the RS tail govern the GQ unfolding activity of the RS tail. In the future, we will investigate whether SRSF1 regulates the ARPC2 GQ's inhibitory activity of translation using dual Luciferase assays. This study sheds light on how SRSF1 mediates multiple biological processes by simultaneously distinguishing between different nucleic acid structures and maintaining a broad RNA specificity.

Abstract Name: Charlotte Hawkins Brown Museum: A Case Study in Public History

This paper examines the development of the Charlotte Hawkins Brown Museum in Sedalia, North Carolina, with regard to historic preservation, community engagement, and museum operations from 1985 to 1999. This historic site was the first established in the state to honor an African American woman. From 1902 to 1971, the Palmer Memorial Institute operated as a private boarding school for African American students and established itself as an exceptional provider of liberal-arts education. The school was led for fifty-one years by its founder, Dr. Charlotte Hawkins Brown. She was an accomplished speaker, teacher, writer, and activist, who believed that education was essential to individual success during a time when racial division rampaged the South. To commemorate Dr. Brown's legacy, the state of North Carolina opened the Charlotte Hawkins Brown Museum in November 1987, having purchased the property two years prior. From 1985 to 1994, the North Carolina Department of Historic Sites and Properties took measures toward the preservation of the

forty-acre complex. The state hired a team of historic specialists to complete a nomination form for placement of the site on the National Register of Historic Places. This research, compiled in 1987 and 1988, is the main record of the site's geographical data, property classification, structural inventory, and historic significances. Despite the publication of an ambitious ten-year master site plan in 1988, most decidedly imperative action for the site was delayed. This study examines government documents, letters, educational programming, financial information, and operations reports to evaluate the progress of the museum from 1985 to 1999. From the assembled knowledge, this paper aims to support the continued mission of the Charlotte Hawkins Brown Museum and to enlighten the public on the necessity of this historic place that upholds foundational twentieth-century African American history, women's history, and social history.

Abstract Name: Quenching Potential of Aqueous Solutions on Lumazine's Interaction with DNA Base Pairs using Fluorescence Anisotropy Spectroscopy

Lumazine is a molecule that exhibits properties of a photodynamic therapy drug (PTD), which works by activating through UV light, killing cancerous cells. Two pathways are possible for lumazine; Type I cell death involves the process of excited state electron transfer from lumazine to DNA and Type II cell death is due to the excited state energy transfer of lumazine to oxygen generating a reactive singlet oxygen. However, this exact pathway is unknown. The Type I process is dependent upon the electronic structure of lumazine and the nucleotide. If the excited state electron transfer occurs from the singlet state, this reaction must occur within the lifetime of lumazine's excited state, typically less than 1 nanosecond (ns). Excited state spectroscopy of lumazine indicates that its excited state has a lifetime longer than 2 ns. This suggests that the lumazine in its excited state can occupy the triplet state. If lumazine occupies the triplet state when excited, then the Type I process of the excited-state electron transfer could occur from the triplet state of lumazine to the triplet state of the nucleotide. To test this Type I pathway, the singlet-singlet excited state electron transfer will be shut down, allowing both singlet-singlet and triplet-triplet electron transfer or only triplet-triplet electron transfer to occur, creating a more efficient process of cell death. This will be achieved by monitoring the intensity of the fluorescence of lumazine as the concentration of heavy ions (KI) are increase within a lumazine and nucleotides solution.

Abstract Name: Data Privacy and Security In Autonomous Vehicles

The advent of autonomous vehicles represents an exciting innovation but also raises critical concerns around data privacy and security that must be addressed. As self-driving cars rely on vast amounts of data collection

and transmission to function, from maps to sensor data to V2V and V2I communications, it opens the door to risks like tracking of location and passenger profiling, hacking of vehicles and networks, and unauthorized data access. This study examines technical and policy approaches to safeguard privacy and security in the autonomous vehicle ecosystem. On the technical side, solutions like anonymization and encryption of data, intrusion detection systems, and blockchain/distributed ledger technologies show promise. Equally important are policy and regulatory actions by both public and private sector stakeholders. Companies developing autonomous vehicles must make data ethics a priority, while governments need to provide strong legal protections around data use. Ultimately, a balanced framework is needed - one that allows the benefits of data sharing for autonomous vehicle integration but has safeguards to prevent misuse and abuse. If designed and implemented judiciously, data can drive innovation in the autonomous vehicle space while preserving core values of privacy and security. The paper aims to promote an informed and nuanced dialogue on this critical challenge.

Abstract Name: The Effects of Higher CO2 Environments on the Growth of Brassica rapa

Atmospheric CO2 concentrations are currently increasing exponentially and are expected to double by the end of the century. Research has found elevated CO2 levels to change plant growth patterns and physiology, but the effects of elevated atmospheric CO2 concentrations on the model organism Brassica rapa have not been thoroughly studied. To investigate these effects, seventy-two Brassica rapa plants were grown in two nearly identical greenhouses, with the control group in a greenhouse containing ambient atmospheric CO2, 400 to 600 PPM, and the experimental group in another greenhouse containing levels projected for the end of the century, 900 to 1100 PPM. The plants were measured after a 19-day growth period. The results suggested that Brassica rapa plants grown under elevated CO2 concentrations do not experience increased plant heights, root lengths, or number of leaves. Moreover, the experimental Brassica rapa did not gain a higher overall dry mass and instead had a decreased leaf mass and increased root mass compared to the shoots. Essentially, Brassica rapa seemed to allocate less mass to its leaves and more mass toward its roots. This could be attributed to increased photosynthetic rates and stomatal conductance. Finally, the experimental Brassica rapa plants experienced a higher average growth rate than that of the control plants. This could indicate that although higher CO2 doesn't significantly increase final plant height, it could speed up the growth rate of Brassica rapa due to photosynthetic acclimation. In summary, this work developed a system to test Brassica rapa's physical responses to CO2 enrichment and identified areas for improvement for future experiments. Because of Brassica rapa's role as a model organism, an understanding of its responses to elevated CO2 could help researchers better understand the effects of climate change on plants.

Abstract Name: Monitoring Bumblebee Populations on UW-Parkside's Campus

Purpose Bumblebees (Bombus) are effective pollinators and contribute to healthy ecosystems. In Wisconsin, UW-Parkside falls within the known range of the federally endangered Rusty-Patched Bumblebee (Bombus affinis), along with nineteen other native bumblebee species. Following a pilot season in 2022, surveys continued in 2023 to monitor resident bumblebee populations on UW-Parkside's campus and establish a long-term dataset to understand the dynamics of pollinator activity among managed areas on campus. In response to expanded habitat restoration efforts following the initial field season, another restoration phase (phase 5) was included in the monitoring process, along with an unmanaged control phase (phase 0) to provide comparisons among phases. Thus, individual bumblebees (Bombus) were located and identified in six distinct phases (phase 0: control, phases 1 and 2: completed restoration, phase 3: current restoration, phases 4 and 5: pre-restoration). Methods and Materials Within each restoration phase, weekly, one-hour surveys were conducted under appropriate conditions between 23 May and 1 October 2023. Sites comprised a 15m radius and were sampled for Bombus activity. During surveys, information regarding location, weather, and topography was recorded and specimens were tallied and photographed for later identification. Results Across 70 surveys in 2023, 834 bumblebees were recorded on UW-Parkside's campus including several B. affinis. In comparison to the previous field season, 20 more surveys were completed, and 635 more bumblebees were observed. This greater sampling effort will help to track trends in phase occupancy throughout each season. Annual surveys of Bombus populations on the campus can be used to guide future habitat restoration efforts both on and off campus.

Abstract Name: Unraveling Love Addiction: A Multivariate Study Investigating the Intersection of Love Addiction and Other Mental Disorders

In contemporary society, dysfunctional relationships are a prominent concern, with a notable subset of individuals exhibiting characteristics suggestive of "Love Addiction." Despite its prevalence, love addiction remains a concept that lacks substantial empirical support and is deficient in a well-defined theoretical framework. This deficiency extends to understanding potential comorbidities that may accompany or exacerbate love addiction. To address this gap, this study proposes to engage 200 participants in a self-administered survey, aiming to explore potential correlations between love addiction and three key psychological dimensions: mania, risky behavior, and magical thinking. By delving into these dimensions, the research aims to unravel the intricate interplay between love addiction and psychological factors, shedding light on whether individuals with love addiction tendencies are more prone to engaging in manic states, risk-taking behaviors, or harboring magical thinking patterns. This study investigates how specific partners may act as catalysts, potentially eliciting and exacerbating these traits, thereby contributing to toxicity within the confines of the relationships. This research endeavors to bridge the existing gaps in the

understanding of love addiction by providing empirical insights into its associations with psychological dimensions and exploring the role of specific relational dynamics in perpetuating dysfunctional patterns. The findings may contribute to a more nuanced comprehension of love addiction and inform therapeutic interventions tailored to address the multifaceted nature of dysfunctional relationships.

Abstract Name: Isostatic Pressure Testing of Fused Deposition Modeling Materials

The relevance and convenience of Additive Manufacturing (AM), sometimes known as 3D printing, for the usage in rapid prototyping has been long known. However, polymeric materials fabricated using fused deposition modeling are structurally weaker than those manufactured using more traditional means like injection molding, because of the poor interlaminar bonding between printed layers. Prior research on novel filaments for polymer additive manufacturing has shown promise in overcoming weak interlaminar bonding through post process annealing mechanisms. Novel filaments previously described utilize two spatially segregated polymers in the filament cross-section which persist during manufacturing to offer structural healing and geometric stability during the post-printing annealing process. Here, we investigated the performance of AM materials made using novel filaments to those made using traditional filaments in high-pressure isobaric applications. To evaluate, thin AM plates were fabricated, sealed, and pressurized to failure where their burst pressure was then recorded. Thin plate material, printing orientation, and annealing conditions of AM plates were varied, and pressure testing results were compared against control samples made of injection molded acrylonitrile butadiene styrene (ABS). Testing shows that samples fabricated with dual-material filaments, then annealed for 72 hours at 135C, have similar burst pressures of control injection molded sheets of ABS, while sample made of ABS alone and not annealed, failed at burst pressures of 10% the nominal injection molded value. Given the high burst pressure of annealed AM plates, we believe these filaments may be used to fabricate pressurized tanks and vessels not normally fabricated using AM methods, such as: canteens, windshield wiper fluid reservoirs, oil reservoir plugs, liquid/gas manifolds, or more.

Abstract Name: Intersectional Marginalized Identity

It is crucial for students, especially minority students, to have a sense of belonging at their university. Students who do not find belonging at universities have greater rates of both transferring to other universities and ultimately are less likely to complete a degree. This study evaluates the influence that affinity and/or race groups have on belonging and hope for minority college students at a Predominantly White Institution (PWI).

Intersectional theory (Crenshaw, 1991) suggests that we may see an increase in both of these factors among students who are engaged in affinity groups organized around race, ethnicity, and/or gender. We surveyed over 100 students at a small private liberal arts institution as a part of a larger study investigating belonging. Using an adaptation of the Departmental Sense of Belonging and Involvement (DeSBI; Knekta et al., 2020) and the Comprehensive Hope Scale (Scioli et al., 2011) we tested the hypothesis that involvement in race, ethnicity, and/or gender affinity groups resulted in greater levels of belonging. While the results did not attain statistical significance, there is a trend toward difference. The results also indicated that contrary to what was expected, students in affinity groups reported lower levels of belonging. The implications of these findings are discussed as are areas for further study.

Abstract Name: Increased Endocannabinoid Tone at Various Concentrations Modulates Zebrafish Adiposity and Development

In Dr. Seth Kullman's molecular toxicology lab at North Carolina State University, I investigated the connection between endocannabinoid tone and adipose accumulation to deepen the current understanding of zebrafish development under environmental stress. I led a research project where I investigated Dr. Megan Knuth's finding that zebrafish (a widely-celebrated model organism) under vitamin D deficient (VDD) conditions experienced increased endocannabinoid tone, adiposity, and stunted growth. My work focused on inducing increased endocannabinoid tone by mixing anandamide (a ligand of Endocannabinoid Receptor 1) in the diet of larval and adult zebrafish, hypothesizing that the promoted endocannabinoid tone would lead to upregulated adiposity and stunted growth. Anandamide was included in the diet of the zebrafish at two different concentrations (one micromolar and five micromolar) to assess the severity of developmental impacts when compared to experimental controls. I quantified growth at two endpoints (adult at six months post-fertilization and larval at six weeks post-fertilization) via standard length measurements and analyzed adiposity through H&E histology and ImageJ analysis, where all data was separated by sex to account for developmental differences in length and adiposity. While findings are still forthcoming, it seems that all five micromolar anandamide cohorts are similar enough in length, mass, and adipose accumulation to make the inclusion of the diet insignificant. The one micromolar anandamide adult cohort, however, was found to have increased ventral adiposity when compared to the controls, while larval cohorts had severely upregulated adiposity as compared to the controls. Overall, these findings suggest there are unknown interactions occurring at certain thresholds in upregulated endocannabinoid systems, whether to promote or combat adipose accumulation and stunted growth. Future directions for the project include gene expression analysis via RT-qPCR and further histological analysis.

Abstract Name: Gilded Emojis: Exploring 18th Century Letter Writing

Modern communication among friends and colleagues typically involves utilitarian electronic formats such as texts or email, with little consideration for the message's beauty or form. But at the court of King Louis XIV of France, letter writing was its own art form, as exemplified by the Michel Janet Gilding Kit, circa 1770s, at the University of Kentucky Libraries Special Collections Research Center. A rare example of a letter-embellishing gilding kit that was likely used by members of the court at Versailles, the kit includes a squirrel hair brush for application, the pillow and windshield for shaping and support, and small flecks of leftover gold leaf. Research into this method of decorating letters will uncover the richness and meaning of letter writing techniques such as calligraphy, symbolism, codes, and letter-locking during 18th century France. At a time when reading and writing was reserved for those in the upper class, research will investigate how letters signify status, prosperity, and connections to power. Since this gilding kit was likely owned by a woman, research will focus on these issues within the patriarchal structure at that time. Research will involve learning how to gild letters, comparing examples of letters originating from women within the court of Versailles, and researching letter writing techniques of the time. Comparing 18th century letter writing with modern correspondence will demonstrate how we went from gilded letters to cute emojis to decorate our communication.

Abstract Name: Pictures at an Exhibition: An Illustrated Symphony Collaboration

This presentation describes a multidisciplinary performance with the collaboration of a team of Illustration Minor students and the Wind Symphony at the University of Central Oklahoma (UCO). The concert centered around Pictures at an Exhibition; a symphony written in 1874 by Russian composer Modest Mussorgsky. Mussorgsky composed the piece after the passing of his friend and painter, Viktor Hartman. Mussorgsky used Hartman's paintings as inspiration for each movement of the suite, capturing the emotion of each painting he felt for his beloved friend. In turn, a team of five UCO illustration students reverse-engineered Mussorgsky's symphony by creating illustrations for each of the ten movements and the promenade based on how the music made them feel. They used Mussorgsky's score in this project as inspiration to create, illustrate, and animate imagery for a live performance conducted by Maestro Alexander Mickelthwate of the Oklahoma City Philharmonic and the UCO Wind Symphony. The imagery was projected above the concert in tandem with the music. A similar performance was held once before in 2016. Crowman Burana was a reimagining of Carmina Burana, a composition by Carl Orff, which included black and white illustrations created by many students across multiple illustration classes. In contrast to Crowman Burana, Pictures at an Exhibition includes far more elaborate full-color illustrations and animation. Influenced by Modest Mussorgsky, UCO's rendition of Pictures at an Exhibition was the product of a unique and innovative partnership that intended to evoke emotion and imagination in observers.

Abstract Name: Carter G Woodson, A Visionary Creating a Legacy for Black Children: A Duo Ethnographic Conversation

In this paper, this research highlights and foregrounds the accomplishments and contributions of Carter G. Woodson to the field of education. Beyond pedagogy and content dissemination, the unique lived experience of Carter G. Woodson comprises an expansive site of exploration, promise, and possibility – particularly for the students they serve. Dr. Cleveland and I perform a soulful dialogue as a mechanism for better articulating the nuances, overlap, subjectivity and overall messiness inherent in rigorous research. In order to present our performative duo ethnography (Juarez & Hayes, 2010), we use the device of a narrated collegial conversation between Darius and Cleveland meeting for Soul Food. Woodson dedicated his life to rectifying the historical neglect of African American contributions and achievements. In 1926, he initiated "Negro History Week," which later evolved into Black History Month, celebrated annually in February. His efforts aimed to highlight the importance of acknowledging African American history throughout the year, rather than relegating it to a designated month. Woodson's scholarship challenged prevailing racial prejudices and underscored the significance of African American history in shaping the broader American narrative. His seminal work, "The Mis-Education of the Negro," critiqued the educational system's failure to provide a comprehensive understanding of African American history and culture. Carter G. Woodson's enduring legacy lies in his commitment to promoting historical awareness, equality, and cultural pride. His contributions have had a profound impact on the study and recognition of African American history, influencing subsequent generations of scholars, educators, and activists.

Abstract Name: Novel Therapeutics Targeting the Abberant Nuclear Export Machinery in Colorectal Cancer

Introduction: XPO1 is a nuclear export receptor responsible for exporting >200 proteins out of the nucleus, including many cancer-related proteins. To determine the prevalence of XPO1 mutations across cancer types, we performed a large-scale genomic analysis of 217,570 cancer patients to identify and characterize XPO1 variants from real-world patient tumors. Methods: Solid tumor samples representing 14 cancer types were submitted for Next-generation sequencing of DNA (592 genes). TMB-High was defined as >10 mt/MB. We engineered CRISPR knock-in HCT116 and LS-174T colon cancer isogenic cell lines bearing heterozygous XPO1 R749Q mutations and STORM analysis was performed. Results: 96 patients with XPO1 R749Q mutations were identified. TMB-H was observed in 92% of XPO1 R749Q mt tumors, while 86% of XPO1 R749Q mt tumors were POLE-mutated. STORM imaging revealed that XPO1 R749Q mutant cells had significant localization of XPO1 in the cytoplasm compared to XPO1 WT cells. Mass spectrometry analysis confirmed that XPO1 R749Q mutant cells had increased protein export compared to XPO1 WT cells. A library screen of >200 FDA-approved drugs revealed a strong therapeutic resistance of XPO1 R749Q cells. XPO1 inhibition with selinexor synergized with chemotherapy in XPO1 R749Q mutant cells in vitro and overcame resistance to irinotecan in vivo in xenograft mice models. Conclusion: This study sheds novel insights into the role of nuclear export in cancers. Specifically, XPO1 R749Q mutations are

enriched in colon cancers and increase nuclear export of key proteins that confer resistance to therapies using DNA damaging agents in vitro. XPO1 R749Q mutations occur in endometrial and colon cancer with high TMB and co-occur with POLE mutation. Cell models of XPO1 R749Q reveal decreased proliferation but resistance to DNA damage and topoisomerase I inhibition. The novel combination of Selinexor and irinotecan showed synergy in vitro and in cell line xenografts.

Abstract Name: Behind the Model Minority: Impact on First Generation Asian American Students

In the world of college and education, an idea called “model minority myth” is greatly affecting Asian Americans, especially those who are the first in their family to go to college with the lack of a support system. Beyond the achievements often associated with the model minority myth, this research delves into challenges faced by first-generation Asian American college students, diving into the relationships between childhood experiences, family pressures and societal expectations. Utilizing the cases of lived experiences of being part of first-generation category, the first gen American and first gen College student, the presentation will share that the model minority myth, although seems positive on the surface, has done more harm than good. This myth has always praised Asian Americans for their success and achievements, but it doesn’t capture the real challenges that many has had to face along with the mental health struggles coming from it. This leads us to the exploration of childhood experiences with society and family, how cultural differences and microaggression can come to play. This study aims to discover the effects of how just the model minority can lead to various factors that all collectively play into the mental health problems in the Asian American community. It is crucial to have open conversations about mental health to break the silence and get rid of the idea that seeking help is something to be ashamed of due to the community trying to play into the model minority stereotypes.

Abstract Name: Using FIRE-2 Simulations to Visualize How Open Star Clusters Form and Evolve Within Giant Molecular Clouds

Giant molecular clouds (GMCs) are massive, hydrogen rich clouds that serve as ideal sites for the emergence of open star clusters and are the birthplaces of the majority of new stars. We used the Friends-Of-Friends (FOF) code, as well as our own developed code, to visualize the GMCs and the star clusters. In this work, we present an analysis on a galaxy simulation drawn from the FIRE-2 (Feedback in Realistic Environment)

simulations website, specifically from the Latte suite, which contains Milky Way-like mass galaxies. An important part of our analysis includes visualizing the same GMC at different moments in time to track how it evolves. In the future, we plan to perform this process on all of the near present day Latte galaxies. We will publicly release our code so it will be accessible to other simulators in the astrophysicist community. Studying the evolution and stages of GMCs will help contribute to the knowledge of the relationship between GMCs and open star clusters, helping us expand our understanding of galactic structures and star formation.

Abstract Name: Manipulation of PACAP+ Cell Activity in the Paraventricular Thalamus of Binge-eating Mice

Binge eating disorder is characterized by the overconsumption of palatable food in a short time period. Our laboratory is investigating the contribution to binge eating by pituitary adenylate-cyclase activating polypeptide (PACAP)-containing neurons in the paraventricular thalamus (PVT). We trained PACAP-Cre transgenic mice to engage in binge eating through limited access (2 hours/day, 4 days/week) to Milk Chocolate Ensure Plus®. Using Cre-dependent excitatory (n = 4 males; 3 females) or control (n = 3 males; 2 females) designer receptors exclusively activated by designer drugs (DREADDs) to activate PACAP+ PVT cells with systemic delivery of the designer drug, clozapine N-oxide (CNO, i.p.) compared to saline, we found that PVT PACAP activity inhibited binge eating in male mice. We then gave mice a final injection with CNO or saline, perfused them, and extracted and sectioned their brains. To ensure that the excitatory DREADDs did activate PVT PACAP+ cells, we performed immunohistochemistry for c-Fos (a marker of neuronal activation), PACAP, and Cre. Ongoing analysis will quantify labeling in images taken of the PVT on an epifluorescent microscope. We anticipate that mice injected with the excitatory Cre-dependent DREADDs and CNO prior to sacrifice will show greater c-Fos labeling in Cre+ PACAP cells than those injected with saline or the control virus. Our results will provide insight into the role of PVT PACAP activity in binge-eating behavior.

Abstract Name: A Generalizable Platform for One-Step Purification and Near-Scarless N-Terminal Bioconjugation of Proteins

Bioconjugation, or the covalent linkage between a biomolecule and another chemical group or material, allows for the creation of hybrid molecules that exhibit the properties of both biomolecules and exogenous moieties. Such conjugates are crucial for a wide range of applications in biotechnology, chemical biology, and biomaterials science. The N-termini of proteins often fall outside of their final folds, making the N-terminus an optimal site for conjugation while preserving a protein's native folding and bioactivity. Consequently, N-terminal modification of proteins and peptides has been a long-standing goal in fields like drug delivery, biotherapeutics, and cellular imaging. However, the current techniques for N-terminal protein conjugation are limited by either the introduction of bulky protein assemblies at the conjugation site, the need for multiple costly and complicated steps, or low site-selectivity. In this project, we aimed to develop a generalizable platform for single-step purification and near-scarless N-terminal bioconjugation of proteins by leveraging the chemistry of split inteins. These are pairs of protein elements that can selectively recognize each other in solution, self-catalytically splice out, and ligate the polypeptides originally fused to each element. Specifically, we used the atypically split intein VidaL. To evaluate the effectiveness of our platform, we first examined the kinetics and reaction conditions of VidaL bioconjugation and confirmed its ability to modify the N-termini of proteins successfully and selectively. Then, we used our platform to conjugate an alkyne, biotin, or FAM biotin moiety to the N-terminus of fluorescent proteins (EGFP and mCherry), a model enzyme (beta-lactamase), and a model growth factor (EGF). We found that, regardless of the moiety added, this conjugation did not impact the native function or activity of any of these proteins. As a result, we concluded that our platform provides an improved route for N-terminal protein and peptide bioconjugation.

Abstract Name: The impact of political instability on exchange rates in developing countries

This study explores the complex relationship between political instability and the volatility of exchange rates in developing countries. We have utilized an extensive dataset from the World Bank and the International Country Risk Guide (ICRG) for our analysis. The focus of this research is on a select group of developing nations, specifically Brazil, Palestine, and Egypt, to illustrate the typical patterns of exchange rate fluctuations that occur in response to political turmoil. Such fluctuations are typically characterized by a significant devaluation of national currencies, which has profound effects on both the domestic business environment and the broader economy.We applied the Generalized Autoregressive Conditional Heteroskedasticity (GARCH) model to analyze over 3,000 daily data points of exchange rates, examining their relationship with indicators of political instability. Our study reveals that political instability often leads to market uncertainty, driving investors to seek safer investment options. This behavior typically results in the depreciation of the currency in countries experiencing political unrest. Furthermore, our analysis shows that political disturbances can also indirectly affect exchange rates. This happens through changes in crucial economic factors, including foreign direct investment, the dynamics of international trade, and the stability of financial markets.Our research provides a detailed understanding of both the direct and indirect impacts of political instability on exchange rates. It highlights the underlying mechanisms of this relationship, offering valuable insights for policymakers and economic strategists in developing countries. These insights are crucial for devising effective strategies to address and mitigate the challenges posed by political instability on economic stability and growth.

Abstract Name: The Virgin Queen and The Grandmother of Europe: A Comparative Analysis of Women’s Status in Elizabethan and Victorian England

The portraits of Queen Elizabeth I and Queen Victoria show images of women in power in the sixteenth and nineteenth centuries of England. Previous scholars have contrasted and discussed their iconography, in particular their masculine or feminine appearance. While Elizabeth is portrayed as androgynous, chaste, and divine to show her power, Victoria is featured as a good mother and wife with a feminine and secular image. Yet scholars haven't looked at how their portraits might reflect women's status, because as female monarchs, Elizabeth and Victoria's images epitomize women's positions in their respective times. This research uses royal portraits as a window to interpret the positions of women before and after the Protestant Reformation and industrialization. By comparing and examining the iconography including clothing, atmosphere, and setting in paintings, I analyze how these elements reflect Elizabethan and Victorian women's status in marriage, economy, and public sphere, as informed by contemporary historical documents such as pamphlets and poems. Elizabeth's portraits reveal women's silence and invisibility, while Victoria's portraits embody women's dependence and submission to men. Although women's status can not be generalized by queens, royal portraits may have adapted to the prevailing cultural values and even consciously reinforced them to win the hearts of subjects and maintain rule as political propaganda. This comparison of royal portraits not only offers a deeper understanding of women's roles in the societies represented by the two queens but also provides insights into how female rulers intruded into the patriarchal society and utilized portraits to their advantage.

Abstract Name: Extracting the Internal Quantum Efficiency of InGaN LEDs

Light emitting diodes (LEDs) have become ubiquitous as an efficient, highly luminous lighting source in the modern world. However, there are still strides to make in improving LED efficiency to its maximal potential, specifically in the green wavelength regime.A roadblock to creating more efficient LEDs is that measuring the internal quantum efficiency (IQE) of the LED - the ratio of the electrons injected to photons emitted from the LED - is physically and experimentally difficult to do accurately. This is due to the inability to analyze the IQE directly, and thus many assumptions need to be made to fit the relevant data. The IQE of an LED is an indicator of the quality of epitaxial growth, so accurately extracting IQE is vital to assessing the progress of LED technology.The goal of this research project is to compare two different experimental methodologies for extracting the IQE on a single device. I will specifically be using electroluminescence and photoluminescence methods to extract the IQE from commercial InGaN CREE green & blue LEDs. The

electroluminescence methods are based on the ABC model described in the literature and involve fitting the optical power of the device at different current biases. The photoluminescence methods involve measuring the non-resonant photoluminescent response to different excitation powers at different temperatures. I will also conduct device preparation techniques such as lens removal and wet etching to prepare the sample for the experiment. By the end of this project, we expect to assess the current efficiency and epitaxial quality of commercial LEDs. We also want to compare the accuracy and values of the two different IQE extraction models, as well as the theoretical implications behind the comparison.

Abstract Name: CIRTS Constructs are Effective in Targeting Microsatellite Repeat Expansion Disorders

Microsatellite repeat expansion (MRE) disorders are caused by sequence repetitions within the human genome. These repetitions cause aberrant repeat-expanded RNA, leading to disorders such as Huntington's disease (CAG repeat), frontotemporal dementia (GGGGCC repeat), and myotonic dystrophy (CUG repeat). One viable way to treat these diseases is to knock down the repeat expanded RNAs. A tool previously utilized for this purpose is CRISPR-Cas13d, which can target and degrade RNA transcripts. However, Cas13d is a bacterial protein and thus can cause an immune response, limiting its therapeutic utility. In contrast, CRISPR-Cas-inspired RNA targeting system (CIRTS) overcomes this limitation by engineering programmable RNA effectors from human proteins. By eliminating bacterial proteins, this strategy avoids triggering an immune response. CIRTS has previously been validated only for non-repetitive target transcripts. Thus the objective of this project is to determine the effectiveness of CIRTS in eliminating RNAs that cause MREs. To test this, we transfected HEK293T cells with three plasmids: 1) a repeat plasmid encoding 105 CAG or CUG RNA repeats, 2), corresponding guide RNAs (gRNAs) targeting these repeats, and 3) the CIRTS construct. Then we extracted RNA and performed RNA dot blots to quantify the repeat-containing transcripts. We observed a strong knockdown of CAG and CUG repeats using their appropriate gRNAs when compared to non-targeting gRNAs. In contrast, there was no significant knockdown of CAG repeats by the CUG-targeting gRNA, or vice versa, suggesting strong sequence specificity. These results demonstrate that CIRTS could be an effective RNA targeting technology in MRE disorders.

Abstract Name: Investigating Accessible and Green Methods for Lead Detection in Drinking Water

Lead detection in drinking water is a pressing issue even in the present day. In Minnesota and across the

United States, many water service lines are still made from lead components. This can cause major problems, particularly to households with young children who suffer the worst from lead exposure, which can lead to lowered IQ scores, damage to the brain, kidneys, and issues with the production of red blood cells. This makes the accessibility of sensitive lead detection in drinking water a high priority in preventing exposure. Because of this, we aim to develop two economic methods to detect lead ions in drinking water. One is to synthesize bismuth nanoparticles to replace gold and silver nanoparticles used in surface-enhanced Raman spectroscopy. The other is the applicability of using 4-aminothiophenol (4-ATP) to directly react with lead ions. For bismuth nanoparticle synthesis, we successfully used lemon juice as both a reduction and capping agent, which helps to serve as a green alternative to traditional nanoparticle synthesis. The diameter of the bismuth nanoparticles were found to be around 50 nm through scanning electron microscopy characterization. As for the 4-ATP method, we found that lead ions and 4-ATP react to form a visible shard-like precipitate as well as a much smaller branch-like precipitate that sticks to microscope substrates. Light microscope images showed differences in the amount and morphology of the precipitates as the concentration of lead was changed from 25 μM to 2.5 μM. These findings will help us to further utilize bismuth nanoparticles for Raman spectroscopy and to understand the reactions between 4-ATP and lead ions for assessing lead ions in water.

Abstract Name: Exploring the Moieties of VER-155008: Targeting Hsp70 Inhibition for Breast Cancer Therapy

Breast cancer remains a significant global health challenge, necessitating novel therapeutic strategies for improved patient outcomes. One target for these new strategies is heat shock protein 70 (Hsp70), which is overexpressed in breast cancer and is associated with disease progression. VER-155008 is a known inhibitor of Hsp70. This research analyzed the structural features of VER-155008 in order to determine the essential structural components for inhibition of Hsp70. Inhibition was tested using a commercially available chemiluminescent assay kit that analyzed the ATPase activity of Hsp70. Initial results indicate the adenosine moiety of VER-155008 interacts with the active site of the ATPase region of Hsp70 in order to inhibit the protein, whereas both the benzonitrile and 1,2-dichlorobenzene moieties do not cause the inhibition.

Abstract Name: BEING & NOT BEING: DOUBLE CONSCIOUSNESS AND THE MULTIRACIAL SELF

Being & Not Being: Double Consciousness and the Multiracial Self Despite the significant growth of the multiracial population, there is a lack of sociological literature about the process of multiracial identity

development. This research uses theories of intersectionality and racial authenticity to understand how W.E.B. Du Bois's theory of "double consciousness" affects multiracial identity formation. Double consciousness refers to the internal conflict experienced by marginalized or minoritized groups in an oppressive society. Although this theory has been applied to the lived experience of many monoracial racial and ethnic minority groups, it has yet to be applied to multiracial people. I created an interview guide and conducted a series of semi-structured interviews with various individuals who self-identify as multiracial. Analysis is currently ongoing, but findings are expected by Spring 2024. I expect to find that double consciousness would be extremely relevant to multiracial identity formation, but its influence would vary based on individual characteristics in a particular multiracial person's racial identity and lived experiences. As the multiracial population grows, this work is increasingly important. Multiraciality will continue to challenge social understandings of race and identity. As this population grows so too must the work representing their experiences and voices in order to understand them and create a world where multiracial people can have an identity on their own terms, as well as push for policy targeting multiracial specific stigma.

Abstract Name: Western Cultural Influences on Eastern Music Listening Experiences

This presentation discusses a new experiment in a multidisciplinary study conducted at the Digital Humanities and Literary Cognition Lab and the Timing, Attention, and Perception Lab at MSU called "The Role of Narrative Listening in Music Perception." Our research explores whether participants imagine or "hear" stories while listening to musical stimuli. In a previous iteration of the study, Western participants responding to Chinese music excerpts frequently tied their narrative interpretations of the pieces to individual instruments and centered them on familiar tropes and themes, such as rural America, Native Americans, and cowboys. We utilized these patterns to design a new single-instrument experiment, in which Western participants were prompted to provide narrative responses to a variety of music excerpts, including one that featured the pipa, a Chinese string instrument. This presentation explores the cultural training and biases that the music-inspired stories reveal. When exposed to unfamiliar music, Western audiences leaned on adjacent Westernized media to explain foreign cultural narratives. These narratives are constructed from a simplified idea of what, in this study, constitutes broadly East Asian cultural motifs. Specifically, the proximity to East Asian cultural influence branches over to what Western audiences have traditionally been exposed to. Most prominent was the association of the pipa, a Chinese string instrument, with the traditional Western notion of the cowboy. Through a comparison of the pipa responses to narratives based on Western instruments, we intend to explore the Orientalist flattening of East Asian cultures and the cultural exchanges taking place in post-war Japan that may have led to these associations.

Abstract Name: The Effect of Dietary Amino Acids Glycine and Serine on Body Composition

Globally, the population >65 years is growing, and most of this population experiences a loss of mobility due to skeletal muscle (SkM) deterioration. Although SkM deterioration is multifactorial, it has been linked to tissue remodeling, the loss of SkM mass and gain of adipose tissue. While adipose is a source of lipid during exercise, an excessive amount can lead to the disruption of organ function. Glycine/Serine (Gly/Ser) are nutritionally non-essential amino acids involved in nutrient metabolism. My research mentor demonstrated that SkM regeneration is suppressed and adipocyte number is enhanced with reduced Gly/Ser availability in advanced age. The therapeutic potential of Gly/Ser for age-related SkM deterioration and SkM regeneration post-injury will be explored by measuring the effect of dietary Gly/Ser on body composition, as well as protein markers of lipid droplets in adipocytes. In this experiment, both old (20-22 months) and young mice (4-6 months) were randomized to a control, supplemented, or depleted diet (isonitrogenous, isoenergetic). After 28 days of the diet, the body weight and lean mass of the mice were measured, and tibialis anterior (TA) muscle and liver samples were taken; RNA was isolated, quantified, and quality-checked. Perilipin, thought to be involved in lipid metabolism, is being measured. After 28 days of the diet, mice on the supplemented diet had a greater body mass, while mice on the depleted diet had the least body weight. However, differences in body mass was not due to changes in lean and/or fat masses. Immunohistochemistry will be performed on TA and liver samples to see if changes in body weight were due to increased adipocyte number, which MRI may not detect. Gly and Ser are likely therapies for improving age-related SkM deterioration. Experiments are ongoing to elucidate the effects of Gly/Ser for SkM health.

Abstract Name: Internalized Racism and Racial Color Blindness Ideology Among Asian American College Student

Historically, Asian Americans have experienced legal and societal discrimination such as the anti-Asian sentiments that denied their rights of obtaining citizenship. The rise of racial hate crimes towards Asian individuals that include physical violence and harassment has escalated significantly ever since COVID-19 (Gover et al., 2020). Unfortunately, this results in negative consequences such as Asian Americans being pinpointed to be the model minority. Park et al. (2022) suggested that Asian American college students who hold color-blind racial attitudes that deny blatant racism and racial issues have a stronger relationship between internalization of the model minority myth and race-related stress. Internalizing the model minority myth is only one component of internalized racism. Therefore, this research aimed to investigate the relationship between racial color blindness and multiple components of internalized racism among Asian American College Students such as endorsement of negative stereotypes, denial or minimization of racism, sense of inferiority, emasculation of Asian American men and within-group discrimination (Liao, 2016). This research hypothesizes that high racial color blind attitudes will predict high internalized racism among Asian American college students. The study will also test if years spent in the U.S will moderate this relationship. Using a Qualtrics online survey, participants who identify as Asian (Asian American or Asian international

student) will respond to a series of measures designed to assess their belief that race should not matter (Racial Color Blindness Scale, Neville et al., 2000), their internalized racism beliefs (Liao, 2016), and demographic questions such as age, gender, race/ethnicity, and international student status. Data collection in process and will end in December 2024. Correlational and multiple regression analyses will be conducted to test the hypotheses. Finding of this study could be beneficial in generating ideas for interventions to improve Asian American college students' relationships with their racial identity.

Abstract Name: The Forgotten Women: An Examination of Migration Policy and Technology in the Covid-19 Era and its Detrimental Impacts of Resource Scarcity on Displaced Women in Tijuana

The reinstatement of Title 42, alongside technological advancements, has revived past migration policies, enabling the immediate expulsion of asylum seekers under the guise of COVID-19 preventive measures. This disproportionately affects women at the U.S. border seeking asylum, with their unique needs accentuated in migrant facilities within border cities. Forced into diverse roles due to the consequences of illegal migration, these women face amplified challenges, exacerbated by Title 42. While some argue that COVID-19-driven migration policies were essential for disease control, I contend that the enforcement of Title 42 has intensified the concept of Marianismo. This societal norm expects women to embody self-sacrificial characteristics, adversely impacting their visibility and acknowledgment of physical and mental health needs. Understanding women's gender roles and the grand role that religion, culture, and society play in shaping these roles is crucial when discussing Marianismo through a historical context. Our study delves into the Examination of Historical Migration Policy, Technology, and Sociocultural Roles and their Evolution in the Covid-19 Era, specifically focusing on women in Latin America. Employing a comprehensive blend of quantitative and qualitative research analyses, we explore the positive correlation between gender sociocultural roles and migration crises. This heightened state during the COVID-19 era results in diminished attention to the well-being of these women, emphasizing the urgent need for a nuanced understanding of their evolving needs.

Abstract Name: Extent of oyster shell burial in Newport Bay, CA

Oysters deliver important ecological functions to intertidal estuarine communities, including provision of microhabitat for various marine species and filtration of the water column. In southern California, two oyster species, the native Ostrea lurida and non-native Magallana gigas, co-occur. Increased sedimentation by human activity threatens to bury oysters and lead to a loss of the ecological services they provide. Ostrea lurida is especially vulnerable as they are found at lower intertidal elevations and are smaller than Magallana gigas. To assess the extent of burial on oysters, we conducted a series of surveys at three sites in Newport Bay, CA, including the Pacific Coast Highway, 15th Street and Coney Island. Our main objectives were to characterize the percentage of oysters that were buried and the extent to which individual oyster were buried. Following the surveys and several statistical tests, about 85% of oysters found at 15th street were buried and only about 20% of oysters were buried at the other two sites. There were no significant differences between the two oyster species in percentage buried. Understanding the impact of sedimentation on oysters is integral to successful conservation and restoration efforts. Further knowledge will allow for more comprehensive approaches in aiding the native Ostrea lurida from various threats it is facing in human impacted bays.

Abstract Name: Developing Predictive Models of Foot Fracture and Edema using Machine Learning on MRI

Bone fracture and edema are commonly found in individuals experiencing foot pain, yet they can be easily overlooked during diagnosis, potentially resulting in substantial long-term consequences if left untreated. This project aims to investigate methods to assist physicians in making precise diagnoses and recognizing patterns in MRI images, represented as automatic diagnoses and bounding rectangles, streamlining the diagnostic process. One of the advantages of working with MRI is that the fluid associated with the fracture can assist in identifying the fracture and its severity. In this study, it involves the development of a machine learning model, utilizing MRI images to precisely identify fractures and edema based on physician labeling. Through this project, an experimental methodology to identify parts of the fracture will be proposed; and from the identified fracture, clinical diagnoses can be provided more quickly by the physicians. These findings from the project will carry significant implications for clinical practices, as the developed model could serve as a reliable tool for early and accurate diagnosis and treatment, potentially leading to more timely and effective treatments. The model is trained and tested on an image dataset comprising 115 patients, all of whom are boot camp trainees in Great Lakes, Illinois. The labeling process in this study involves both the physician's pathology assessment of healthy or unhealthy feet and a bounding rectangle outlining the pathology. Initial predictions of fractures directly from MRI slices are acceptable at 70% accuracy but warrant further testing and refinement. We will continue to explore new architectures and clipping strategies to enhance performance.

Abstract Name: C3 knockout mice are protected against memory deficits, astrogliosis, and inflammation induced by prolonged seizures

Status epilepticus (SE) can increase the risk of temporal lobe epilepsy and cognitive comorbidities. A potential candidate mechanism underlying memory defects in epilepsy may be the immune complement system. The complement cascade, part of the innate immune system, modulates inflammatory signaling, and has been shown to contribute to learning and memory dysfunctions in neurodegenerative disorders. We previously reported that complement C3 is elevated in brain biopsies from human drug-resistant epilepsy and in experimental models. We also found that SE-induced increases in hippocampal C3 levels paralleled the development of hippocampal-dependent spatial learning and memory deficits in rats. Thus, we hypothesized that SE-induced C3 activation contributes to this pathophysiology in a mouse model of SE and acquired epilepsy. In this study C3 knockout (KO) and wild type (WT) mice were subjected to one hour of pilocarpine-induced SE or sham conditions (control; C). Following a latent period of two weeks, recognition memory was assessed utilizing the novel object recognition (NOR) test. In the NOR test, control WT+C or C3 KO+C mice spent significantly more time exploring the novel object compared to the familiar object. In contrast, WT+SE mice did not show preference for either object, indicating a memory defect. This deficit was prevented in C3 KO+SE mice, which performed similarly to controls. In addition, we found that SE triggered significant increases in the protein levels of GFAP along with the inflammatory cytokine interleukin 6 (IL6) in hippocampi of WT mice but not in C3 KO mice. These findings suggest that ablation of C3 prevents SE-induced recognition memory deficits and that an interplay between C3, astrocytes and IL6 may play a role. Therefore, it is possible that enhanced C3 signaling contributes to SE-associated memory decline suggesting that C3 may serve as a potential therapeutic target for cognitive deficits in epilepsy.

Abstract Name: Molecular Nanomachines Can Drill through Buccal and Aorta Tissues and Open Up MCF-7 Cancer Cells

Light-activated molecular nanomachines (MNMs) are synthetic organic molecules that, when exposed to certain wavelengths of light, act as drills to penetrate and damage cells. In previous studies, MNMs were shown to kill cancer cells, bacteria, and viruses by opening up cell membranes via mechanical damage. Here, we wanted to test whether MNMs can penetrate tissues and potentially destroy disease tissues if applied topically. Therefore, we tested two different MNMs, a slow and a fast rotor activated by 405 nm light, to investigate their effects on tissues. We hypothesized the light-activated fast rotor (spins unidirectionally at 2-3 million revolutions per second) can drill into tissues. We used the slow-rotor MNM (undergoes cis-trans isomerization) as a negative control. 500 nM MNM was applied to porcine buccal tissue, murine arterial tissue, and human breast cancer cell lines and activated by 405 nm light for 15 minutes. 10% Sodium Dodecyl Sulfate was used as a positive control. Samples were then stained with Acridine Orange/Ethidium Bromide solution to visualize the action of the MNMs in these tissues through an EVOS M5000 fluorescent microscope. The resulting images show clearly the activated fast-rotor MNMs cause significant damage to the tissues based on the staining visualized by the microscope. However, the unactivated MNMs do not show tissue and cell damage whatsoever, showing the activated MNMs were able to destroy tissue by their drilling action, not by toxicity or generating reactive oxygen species. The slow motor seemed to cause some damage but not of any significance comparatively.

Abstract Name: Online Oncological Obfuscation: How Social Media Circulates Medical Misinformation and Betrays its Core Demographic

This article analyzes the origins of naturopathic medicine and how it has influenced the online discourse surrounding oncology dietetics, which has negatively impacted the health and wellbeing of innocent cancer patients. The problems of this discourse are two-fold; on the one hand, online misinformation about oncology dietetics grievously harms cancer patients, a particularly vulnerable group. This creates a barrier for patients who might otherwise welcome nutritional intervention as part of a treatment plan. On the other hand, social platforms fail to punish creators who peddle medical misinformation. Rather, the algorithms reward content deemed inspiring, controversial or shocking, with money and attention. This incentivizes people to spread medical misinformation and share false testimony while ignoring the effects of their actions. This article utilizes both academic literature and empirical research to dissect the problems outlined above. By analyzing the research of nutritional oncologists and medical psychologists, this article concludes that the disregard for these fields is a major factor which permits the perpetuation of deceptive health information on social platforms. In addition, a lack of clarity and patient-centered care from providers pushes cancer patients away from proven practices into the realm of pseudoscience. Social media echo chambers then capture their attention and direct them toward circles which perpetuate a skepticism of legitimate medical intervention and allow oncological misinformation to thrive. To illustrate, this article analyzes the Belle Gibson case to both highlight the actual harm that peddlers of phony oncology dietetics cause and argue that social platforms need to more rigorously enforce anti-misinformation policies. Additionally, oncologists need to better address patient questions and concerns, increase public knowledge of chemopreventive and chemotherapeutic measures, and strengthen the field of oncology dietetics if the prior harms are to be combatted.

Abstract Name: Titan Green - Hydrogen-Powered Boats: Pioneering Eco-Adventures of Tomorrow

This research project introduces "Titan Green," a groundbreaking initiative focused on the development and implementation of hydrogen-powered boats, heralding a new era of eco-friendly maritime adventures. The project leverages cutting-edge hydrogen fuel cell technology to propel watercraft, thereby mitigating the ecological footprint associated with traditional marine propulsion methods. The research encompasses a comprehensive investigation into the design, fabrication, and optimization of hydrogen-powered propulsion systems tailored specifically for marine applications. This involves the integration of fuel cells, energy storage solutions, and innovative engineering practices to ensure optimal efficiency, safety, and reliability in the maritime environment. Through rigorous testing and simulation, the project aims to establish the viability of hydrogen-powered boats as a sustainable alternative to conventional fossil fuel-powered vessels. Furthermore, the study addresses the broader implications of adopting hydrogen-powered boats within the realm of eco-adventures. It explores the potential for fostering a new wave of sustainable tourism and recreational activities that prioritize environmental conservation. The project considers economic feasibility, regulatory frameworks, and public perception to provide a holistic understanding of the socio-economic and environmental impact of Titan Green.

Abstract Name: The Triad: How They Proved to be More than Just Sports

The crossover between graphic design and sports is a prominent topic and holds endless information. Through the years, sports design has evolved and lent itself massive success to the teams it represents. This paper aims to discuss Major League Baseball, the National Football League, and the National Basketball Association, and how design has played a large role in marketing strategies, individual team influence, and the organizations' successes. With sports gaining viewership during the rise of technology, organizations had to find strategies to utilize this new era to their advantage. Other topics such as how MLB, NFL, and NBA logos were created, as well as the evolution of team logos, will be discussed. For many teams, a change led to a downfall, but it also may have changed how many see them today. Team logo variations, multiple jersey types, and the influence on their audiences will be investigated to find what level of success emerged due to these factors. Rebranding has also played a large role in the history of sports design, and many times has proven to be unsuccessful, or a big hit. A simple adjustment may mean the loss of income to the team for years to come as a result. Throughout this paper, the design world and sports world will be connected to find how each sphere of influence impacted each other, as well as what it will leave behind in the years to come.

Abstract Name: Using Anti-oxidative and Anti-inflammatory Properties of Ginger to Temporarily Relieve Respiratory Symptoms from Flavored Vaping Pods

Despite the extensive research conducted on the respiratory implications of e-cigarette usage, a significant research gap persists regarding treatments for respiratory dysfunction specifically induced by flavoring pods within e-cigarettes, aiming to minimize adverse effects. Among the range of vapes available, vanillin emerges as a prevalent flavor choice and has been associated with a reduction in antioxidant efficacy, potentially escalating lung inflammation and oxidative stress. Vapes, regarded as a solution for heavy smokers, are promoted as a safer substitute for tobacco, yet evidence suggests the contrary. Commonly prescribed for e-cigarette-induced respiratory issues, corticosteroids exhibit detrimental effects upon prolonged usage, including osteoporosis, myopathy, and temporary side effects. The introduction of an alternative treatment devoid of symptomatic implications could substantially benefit individuals grappling with respiratory dysfunction stemming from e-cigarette flavoring chemicals. Ginger, renowned for its potent anti-inflammatory and antioxidative properties, offers a multifaceted spectrum of health benefits. It aids in digestion, alleviates inflammation-linked conditions like arthritis and nausea, fortifies the immune system, and contributes to cardiovascular wellness. Widely used in Eastern and alternative medicinal practices, ginger serves as a remedy for various health concerns, encompassing digestive problems, respiratory issues, and headaches. This research initiative endeavors to explore the potential of ginger extract as an alternative remedy for vanillin-triggered respiratory dysfunction. Ginger's antioxidative and anti-inflammatory attributes position it as a promising candidate to mitigate vanillin-induced oxidative stress while potentially minimizing associated side effects. By investigating ginger's therapeutic potential, this study aims to shed light on alternative treatments for managing respiratory complications arising from e-cigarette usage, striving to bridge the current treatment gap and enhance patient care.

Abstract Name: The Story of Pests: Non-humans on the Boundaries of Human Spaces and How They Define the Culture of the Anthropocene

In the era of the Anthropocene, humans have significantly altered the environment of the planet. Through shaping and changing the natural world we live in, we have developed several cultural habits. One of those habits is our need to condition our spaces for our own comfort, furthering a divide between what is considered “human” and “natural”. Between that divide live pests, the creatures that invade and infest our spaces despite our efforts to keep them out. By studying pests, their relationship with us, and our methods of pest control, we can learn more about the culture of the Anthropocene and how we can change our habits and perspectives in the face of climate change. This project employed a variety of methods to investigate pests. Firstly, textual research was conducted on different types of pests and their histories paired with historical research on 20th century chemistry and pest control methods, while also exploring the parallels between

animal pests and those groups of humans considered pest-like. The second part involved collecting oral histories by interviewing people in the surrounding neighborhoods on their encounters with pests. Through this, the project revealed several cultural habits of the Anthropocene. Pest control is another of the many ways we condition our space for comfort, regardless of the consequences on the so-called “natural” world. Our identification and actions towards pests show how we expect total ownership and dominance over our spaces. When they break through into our homes, we see them as leaving their proper place in the “natural” world. This is the divide we create between the human and natural world through conditioning our spaces. Pests transgress that divide, so they are detested.The culture of the Anthropocene, as shown by pests, is one of human-centrism, where human needs and wants are placed above all others.

Abstract Name: Investigating the interaction between clozapine and norclozapine with HLA proteins in the pathogenesis of clozapine-induced agranulocytosis

Clozapine-induced agranulocytosis (CLIA) is a rare but serious reaction associated with the usage of clozapine, a highly effective yet often reserved medication for patients with treatment-resistant schizophrenia. Previous literature has suggested that specific human leukocyte antigen (HLA) alleles may be linked to a higher risk of CLIA. The HLA gene expresses a protein complex that helps the immune system detect foreign pathogens. Polymorphisms in HLA classes B, DQ, and DR contribute to the risk of CLIA. Despite these associations, the underlying mechanism remains unclear. We postulated that clozapine, or its metabolite norclozapine, may interact with HLA proteins to produce the intracellular aberrations that ultimately lead to CLIA. Using crystal structures from the RCSB Protein Data Bank and homology modeling, molecular docking simulations using UCSF Chimera and Autodock Vina were employed to explore the interactions between clozapine and its primary metabolite norclozapine with HLA-B. Docking preparations included solvent ion removal and the addition of protons and charges. Findings reveal that the HLA-B protein complexes encoded by alleles associated with CLIA exhibit stronger binding affinities for both clozapine and norclozapine. This conjecture was reinforced by testing controls, which were protein complexes from HLA-B alleles that were not associated with CLIA. The average free energy of binding was more negative for CLIA-associated HLA-B protein complexes compared to the controls for both clozapine (-8.9kJ/mol against -7.8kJ/mol) and norclozapine (-8.3kJ/mol against -6.9kJ/mol). Patterns in free energies of binding between these compounds suggest a common factor facilitating their interactions with HLA-B alleles. Moreover, with CLIA-associated HLA-B protein complexes, three hydrogen bonds tended to form with aspartate and threonine residues, while common contact residues for Van der Waals forces also tended to form with phenylalanine, threonine and aspartate. This research advances our comprehension of the molecular dynamics governing the CLIA pathway.

Abstract Name: Investigation into Connections between Openness and Perceptions of Artificial Intelligence

The field of generative deep-learning models, colloquially referred to as “artificial intelligence” or “A.I.”, has rapidly grown in recent years, both in terms of available services and societal impact (Li, 2023). However, comparatively little psychology-based research has been performed with regard to generative A.I., especially in regards to the most current services available. It is therefore the purpose of this study to expand the available research on how one’s psychology interacts with their perception of A.I., specifically version 3.5 of ChatGPT. Previous research suggests that there is a link between individual differences in personality and the perception of A.I. risk (Wissing & Reinhard, 2018). On the other hand, individual traits such as openness and attitudes toward A.I. do not seem to affect one’s immersion in creations known to be made by A.I. (Messingschlager & Appel, 2022). Thus, the current research seeks to examine the personality trait of openness in greater detail in conjunction with participants’ perceptions of A.I. and its level of threat. To measure the personality traits of participants, the current study uses the extra-short form of the Big Five Inventory-2 with 15 items (Soto & John, 2017). Broad opinions on A.I. are collected using the General Attitudes Towards Robots Scale with 20 items (Koverola et al., 2022). For perceptions of A.I. threat, the 12-item Threats of Artificial Intelligence Scale (Kieslich et al., 2021) is used with some modifications. Correlational analyses will be utilized to determine whether there are any significant connections between participants’ openness scores and their general attitudes of A.I. or perceptions of A.I. threat. Findings can be useful in terms of future development of A.I. models as well as individual users’ decision to interact with these services. Such practical implications will be explored in greater detail in the presentation.

Abstract Name: Meteorology Misconceptions Held by Students in General Education and Preservice Earth Science College Courses.

One of the goals of K-12 science education is to help future citizens become scientifically literate, that is, they should be able to understand science concepts and how science creates evidence, assess its significance, and make informed decisions based on this information. Since weather is one of the natural events people are constantly exposed to, meteorology literacy is of critical importance. To enhance weather literacy, one crucial step is to assess the meteorology knowledge of college students. One group of interest was students enrolled in ESS 102, Dangerous Planet, a general education earth science class. In addition, pre-service students

enrolled in ESS 112, Earth and Space Science for Teachers, participated in the study. These students were selected because the ESS courses may be their last opportunity to challenge their weather misconceptions through direct instruction. The purpose of this study was to use the Survey of Meteorology Concepts (SMC) to identify weather misconceptions among 50 and 19 students enrolled in ESS 102 and ESS 112, respectively. The research questions were (a) What questions in the SMC are, statistically, the best suited to measure weather-related misconceptions among college students in Kentucky? (b) What were the topics in which students showed limited content knowledge? and (c) What were the topics where students showed significant misconceptions? Participants completed the SMC as a pre-survey in August 2023 and a post-survey in December 2023. A second group will complete the SMC in the Spring 2024 semester. Preliminary data suggests that, on average, 30% of the questions were answered correctly, but guesses exceeded high-confidence responses. 70% of the questions were answered incorrectly; about 3/4 were guesses as well, with relatively few misconceptions. The students, particularly the pre-service teachers, showed a very limited knowledge of meteorology, which is of concern.

Abstract Name: Investigation of Voltage-Gated Proton Channel Interaction with Cytoskeletal Motor Protein in Model of Male Infertility

The voltage-gated proton channel Hv1 plays an essential role in capacitated sperm motility with radially asymmetrical localization on flagellar membranes. However, the anchoring mechanism of this arrangement is not well understood.. Understanding the mechanism of Hv1 localization in sperm would allow for targeted therapies for male infertility and development of male pharmacological contraceptives. Preliminary two-hybrid screening indicates potential interactions between Hv1 and other proteins expressed in human testes, including the cytoplasmic protein motor complex cargo adaptor, dynein light chain Tctex-type 1 (DYNLT1). Human Embryonic Kidney 293 cells were stably transfected with third-generation lentiviral vectors to produce epitope-tagged Hv1 and DYNLT1 proteins separately in singly-transfected cell lines, and together in a doubly-transfected cell line. Cell lysates were co-immunoprecipitated in two iterations by separate pull-downs with both antibodies, and western blot analysis was performed. Initial results tentatively demonstrated native state protein-protein interactions of DYNLT1 and Hv1 in vitro, in confirmatory agreement with previous two-hybrid study results. Further studies entail protocol optimization to clarify results, and evaluation of mutant Hv1 and DYNLT1 isoforms derived from diseased sperm to elucidate mechanisms of male infertility.

Abstract Name: How is "Readiness" Met?: The Case of Oakland Unified School District in Oakland, CA

Readiness, often defined as the level at which students meet the qualifications to succeed in college and career, has long been a metric of the success of K-12 education in preparing students for post-secondary lives. In Oakland, California, the Oakland Unified School District (OUSD) has highlighted their top priority as "All students graduate college, career, and community ready.", implementing different goals and actions throughout the years to achieve this priority. However, what does it mean to be ready for college, career, and community? How does the district measure readiness and support initiatives targeted at increasing student readiness? The aim of this study is to understand how school districts, focusing on OUSD, back up their goals of preparing students for the real world. Through a critical approach, this in-depth case study seeks to shed light on how metrics of readiness are understood and used by districts in supporting students. The implications of this study aims to problematize contemporary definitions of readiness, highlighting the ways school districts can improve standards and practices as it relates to college and career readiness to better serve its students. The findings indicate that there must be more transparency on the data behind how and why goals lead to readiness, and how specific actions align with the success of such goals. Better data practices can ensure that proposed actions to meet stated goals are met, as school districts place emphasis on readiness through meeting state standards, rather than preparing students for their post-secondary lives and beyond.

Abstract Name: Investigating the Molecular Mechanism of 14-3-3γ-mediated Inhibition of the Kappa Opioid Receptor

Between 2001 and 2007, 48% of New York elderly chronic pain patients voluntarily discontinued opioid treatment, mainly due to adverse side effects. Opioid medications reduce pain by binding to G protein-coupled receptors (GPCRs), specifically, mu, delta, and kappa opioid receptors. In practice, typical clinical opioids target mu opioid receptors (MORs) in the central nervous system, which mediate both analgesia and adverse effects such as abuse liability and respiratory depression. Recently, peripheral kappa opioid receptors (KORs) have become a promising alternative target to MORs as they avoid such effects. However, unknown signaling pathways in these peripheral neurons limit opioid-mediated analgesia. Our previous work demonstrated that expression of the scaffolding protein 14-3-3γ was sufficient to eliminate KOR-mediated signaling. While ubiquitously expressed and highly conserved, little is known about how the 14-3-3 family of proteins may interact with GPCRs. We hypothesized that 14-3-3γ binds to KOR's C-terminal tail and interrupts the formation of signaling complexes required for KOR-mediated antinociception. To determine if KOR and 14-3-3γ form a complex within cells, we performed co-immunoprecipitation in transfected HEK 293T cells using western blot detection. Pulldown via 14-3-3γ antibodies within cells expressing both KOR and 14-3-3γ resulted in co-immunoprecipitation of KOR, indicating that these proteins can form a stable complex. To assess the functional effects of 14-3-3γ expression, we measured KOR-mediated reduction in cAMP in living cells with a genetically encoded biosensor (GloSensor) after 14-3-3γ transfection. Presence of 14-3-3γ in such cells dampened cellular changes in cAMP when KOR agonist U50488 was added, suggesting that 14-3-3γ inhibits KOR activity. These results support that a 14-3-3γ-KOR complex can occur in cells and result in inhibition of KOR-mediated analgesic signaling. Ongoing studies are investigating the molecular underpinnings of this interaction, which may be widely applicable to the GPCR family as ~90% of GPCRs have predicted 14-3-3 binding motifs.

Abstract Name: Machine Learning in Material Science through Cloud Platform

New materials are discovered now not only by physical lab experiments, but computational design can also contribute to discoveries. Machine learning has been one significant tool helping scientists and researchers to conduct experiments with new materials. By using various computing methods, material data can be recorded and computed. With new technologies, many models can be provided for scientists to efficiently screen materials with specific properties, reducing experimental time and cost. One challenge in increasing the impact of publishing machine learning models is in maintaining and using others codes. In this article, we will demonstrate how the cloud platform can be used to increase the useability of Machine Learning models and the ability of researchers to efficiently use other's trained models. To do this we will focus on one material's property and dataset. We will retrain and assess this previous model/dataset using errobar analysis to better understand performance. By utilizing the cloud framework we will demonstrate successful applications in material science through machine learning. Finally, we will evaluate the opportunities and challenges in material science brought by machine learning and big data.

Abstract Name: Online Modules for Teaching Blockchain

Blockchain technology offers the capability to create a distributed and tamper-proof ledger, even in the presence of untrusted agents. Despite substantial financial resources and attention devoted to blockchain tools, the underlying technology remains less comprehensible to the general population. This paper introduces a newly developed online tool designed to bridge this knowledge gap, enabling users to learn and create their own blockchain. Featuring a user-friendly graphical interface and code, the module is freely accessible on nanoHUB.org. It comprehensively covers all components of the blockchain, including SHA256, Proof of Work, and other features crucial for its tamper-proof ledger functionality. The tool has proven effective in instructing students unfamiliar with blockchain technology. Survey responses from students demonstrate the tool's efficacy as a means of educating the general population about blockchain technology.

Abstract Name: Widefield Time of Flight Diffuse Optical Tomography with an Unrolled Neural Network Reconstruction

Time of Flight Diffuse Optical Tomography (Tof-DOT) is a bioimaging technique that utilizes light from a pulsed laser in the near-infrared region. Previous efforts to implement Tof-DOT have focused on confocal approaches in which a pulsed laser is raster scanned over an array of detectors. While potentially improving image quality, this approach increases the image acquisition time. Widefield Tof-DOT uses a single light source to illuminate all detectors simultaneously. We plan to implement a Widefield Tof-DOT system with a 500×1000 Single Photon Avalanche Diode (SPAD) camera detector system. We hope to demonstrate that Widefield Tof-DOT, combined with a noise-robust machine learning-based reconstruction algorithm, will demonstrate both fast image acquisition times and accurate reconstructed images. Our specific approach will implement an unrolled neural network architecture in which each layer of the neural network corresponds to one iteration of a linear inverse solver. Because the number of layers in the neural network is smaller than the number of iterations needed to reach sufficient convergence in a linear inverse solver, a speed-up in reconstruction time is possible. A unique training method will be implemented in which Poisson noise at variable SNR ratios will be used to increase noise robustness. In addition, a refinement U-Net and VGG perceptual loss will be incorporated into the network architecture to further enhance the accuracy of the reconstructed images. In addition, whilst previous efforts have demonstrated real-world systems with 24×24 and 32×32 SPAD detectors, we hope to demonstrate that the 500×1000 SPAD camera detector system will show superior spatial resolution, perhaps opening the way for novel applications at the sub-millimeter level. We also hope to show that the noise-robust machine learning-based reconstruction algorithm will generate accurate results with minimal depreciation in photon-starved conditions, allowing for greater accuracy beyond 3-5 cm of tissue.

Abstract Name: A Quantitative Comparison of Post Intensive Care Syndrome Knowledge Between Critical Care Nurses and Physicians

Background: As technology advances, intensive care unit (ICU) survival rates also increase, contributing to an increase in post-intensive care syndrome (PICS) cases. No official diagnostic criteria for PICS currently exists, but clinicians agree that PICS describes new or clusters of worsening physical, cognitive, or psychological impairments that originate from critical illness and persist beyond hospitalization. Previous studies explore PICS from the outpatient perspective. There is a gap in in the literature regarding how well PICS is recognized by ICU clinicians. Purpose: Compare the baseline PICS knowledge among ICU nurses and physicians as a foundation for educational interventions.Methods: This cross-sectional, observational,

non-randomized study used a REDCap® survey with 17 fill-in-the-blank and multiple-choice questions about PICS. Possible scores ranged from -24 to 31; higher scores indicated more accurate knowledge of PICS. The survey was developed using the Post-Intensive Care Syndrome: Concept Analysis framework. Consented clinicians were given a description of the study aims before completing the survey. There was time limit for the survey and protected health information was not collected. Results: Participants (37 nurses, 10 physicians, 2 NP's, 1PA) completed the survey between 07/11/2023 and 08/05/2023. The mean score was 16.1 (3.7) with a range of 9 to 23. There was no difference in mean scores by clinician role using an omnibus test (P = .163). The mean score for nurses [15.6 (3.5)] was similar to MDs and APPs [17.4 (3.9); P = .111]. Conclusions: This study addressed an important gap in the literature in this emerging topic. The general lack of knowledge about PICS, regardless of role, was widespread. Educational interventions are needed to increase early detection and prevention of PICS prior to discharge. These interventions will ultimately improve patient outcomes. Findings from the study will guide the development of interprofessional educational programs.

Abstract Name: Electrospinning for Corneal Tissue Engineering

A lack of transplanted tissues used to treat patients with corneal damage-related vision impairment negatively impacts millions of people worldwide[1]. Enhancements in the tissue engineering of human corneas may alleviate the donor shortage. One approach to solving this issue is using the method of electrospinning to create transplants that closely resemble the extracellular matrix of a native cornea. Previous studies in our lab have shown that growing corneal cells on aligned collagen fibers significantly downregulates -smooth muscle actin protein, promoting a more transparent phenotype. In this study, we are producing collagen and laminin-PLLA fibers, both aligned and unaligned, to understand the relative importance of fiber alignment and fiber material on corneal cell phenotype. Fibers are electrospun, sputter coated with gold, imaged using scanning electron microscopy, and analyzed for fiber diameter to ensure consistency in diameter. Fibrous mats are then crosslinked using glutaraldehyde and cultured for 7 days on 6-well plates with corneal fibroblast cells isolated from New Zealand white rabbit eyes. Protein expression is evaluated using western blot assay. Results from this study will inform the material used for our tissue engineered cornea replacement. As well as help accomplish the overall goal of electrospinning a cornea, which is common to the niche field of tissue engineering.

Abstract Name: Accommodations for Instrumental Music Students Who are Deaf/Hard of Hearing

Within the Deaf/Hard of Hearing (D/HH) community, many individuals often have far fewer opportunties to

participate in music in the classroom (Darrow & Gfeller, 1991; Churchill & Bernard, 2020). While there has been a fair amount of research within the D/HH community and their experiences within general music (Darrow, 1993), there have been fewer studies specifically with d/hh studnets learning instrumental music (Churchill & Laes, 2021; Hash, 2003). The purpose of this project is to provide suggestions for instrumental educators based on past literature and findings in interviews from instrumental musicians who are d/hh and music educators who have taught this population. Categories in past literature being presented include; (a) scientific research on what works for different types of hearing loss (Drennan & Rubenstein, 2008), (b) audiological technology that can be helpful within the classroom (Looi et al., 2008), (c) studies d/hh musicians' sucesses within music (Churchill, 2016), (d) research from music educators working with d/hh students (Sheldon, 1997). Suggestions based on the literature include; (a) open-ended communication between the parents, student, and educator about the individual medical diagnosis, (b) willingness to discuss and create proper accomodations, (c) sharing with student and parents instrumental specific information to make informed decisions of what will work best. Research questions framing the interview part of the study will include; (a) how do d/hh musicians describe their experiences within instrumental music, (b) what suggestions do d/hh musicians have for music educators, (c) what experiences do music educators that have worked with d/hh musicians and their suggestions on what educators should know. Interview data will be coded using traditional qualitative research methods and emergent themes will be connected back to the past research. Intending to interview 3-5 participants, information from the interviews will be constructed into the results of this study.

Abstract Name: Data-Driven Solutions for Community Development: Bridging the Eviction Data Gap in Lafayette, IN through Data Automation and Analysis

The city of Lafayette, IN faces significant challenges related to transience, homelessness, and evictions, particularly in the Lincoln, Hanna, Vinton, Monon, St. Lawrence McAllister, and Historic Jefferson neighborhoods. Despite having sufficient funds for community development projects, there exists a crucial gap in modern eviction data that hinders the Lafayette city officials' neighborhood revitalization efforts. This project aims to address this data deficiency through an automated data collection and analysis process. We implemented Selenium to web scrape Indiana public court records, focusing on the Tippecanoe Country 6th Superior Courts to properly collect modern Lafayette eviction cases on a quarterly basis, beginning in January of 2021. The collected eviction data is further processed and refined using Python's "pandas" library to isolate critical statistics, such as the number of eviction cases in each of the identified at-risk neighborhoods, and allow a comprehensive review of eviction trends. The trends found from the refined eviction data are then transformed into actionable insights such as dashboards and visualizations using Tableau. The user-friendly dashboards, including a choropleth map, serve as visual tools for Lafayette city officials, providing a comprehensive overview of eviction trends across the targeted neighborhoods. This automated collection and analysis process not only bridges the gap in updated, usable evictions data, but also provides Lafayette city officials with the necessary tools to make informed decisions in community rebuilding initiatives. Initial results suggest that the Lafayette city officials' access to useable visualizations, contemporary statistical data, such as the targeted neighborhoods with the highest evictions rates and

fluctuations in evictions post-2021, and an automated process to update this data has helped combat Lafayette's data deficiency problem on multiple fronts allowing for more promising development projects.

Abstract Name: Frontier Legalism in Early Kentucky: The Settler and the State

The idealism of Manifest Destiny shrouds perceptions of early American frontier settlement. This process is often seen through a romantic, almost mythological lens, placing frontiersmen in the role of heroes creating civilization from the ground up in an untamed and dangerous land. However, the reality of settlement west of the Appalachians was much more pragmatic and tightly intertwined with both existing and emerging legal and financial systems. State governments strongly encouraged settlement, while individuals and companies sought financial gain through land speculation. Using the archival collection of Squire Boone Family Legal Documents, 1779-1894, at the University of Kentucky Special Collections Research Center, this research will explore the processes and risks associated with early Anglo-American frontier land ownership and settlement and the legacies this process left behind. Squire Boone and his more famous brother, Daniel Boone, were pioneers who helped open Kentucky to Anglo-American migration through the Cumberland Gap. Settlers poured through the Wilderness Road into Kentucky, displacing its traditional inhabitants and radically altering the landscape and history of the region. Records in the collection portray the often unseen legal and financial risks resulting from their endeavors. This research will utilize records of Virginia land grants, archaeological surveys, and accounts of settler life with Squire's documents and other related sources to explore the legal structure and organization of early frontier settlement and the complex relationship between the settler and the state. In addition, this project aims to create a more accurate picture of the systems utilized to organize westward migration and how the legacies of land claiming, ownership, and settlement from over 200 years ago influence Kentucky's landscape, culture and people today.

Abstract Name: How Do We Process Music? The Role of Instrument Identification in Determining Thematic Responses to Music Pieces

This presentation discusses a new experiment in a multidisciplinary study conducted at the Digital Humanities and Literary Cognition Lab and Timing, Attention, and Perception Lab at MSU called "The Role of Narrative Listening in Music Perception." The original experiment explores whether participants imagine

or “hear” stories while listening to musical stimuli. Participants from the U.S. and Dimen, China listened to instrumental music and were asked to describe any narratives they may have perceived. A surprising number of people “heard” stories and many patterns in how these participants responded emerged. Based on the largely single-instrument Chinese music chosen for listeners, we were inspired to design a “single instrument” study. Each music excerpt in this new study featured only one instrument—ten Western instruments and one traditional Chinese instrument. Our presentation will discuss this study with a focus on participant identification of instruments both in their narratives and at the end of the survey. We will explore the relationship between prominent themes within instrument groups and how these relate to correct—and incorrect—instrument identification. Each narrative and memory response has been analyzed for a range of metadata categories, such as setting, themes, characters, and pop culture references. This helps us distinguish whether certain themes are inherent to the music itself or if they are more directly linked to the participant’s perception of the physical instrument. We conclude by exploring the significance of listener perception when listening to music, arguing that the audience’s pre-existing instrument associations are a key factor in determining the type of narrative they imagine in response to an excerpt.

Abstract Name: Understanding the Role of Lipid-Protein Interactions in Modulating the Function of Glutamate Carboxypeptidase II (GCPII)

Glutamate carboxypeptidase II (GCPII) is transmembrane zinc metallopeptidase that is found in a variety of organisms, including humans. Human GCPII (hGCPII) plays key roles in human physiology and disease development. hGCPII is produced as five paralogs in various tissues including the central nervous system, intestine, kidneys, angiogenesis of most solid tumors, as well as in cancerous prostate. Activated hGCPII in the brain leads to excess glutamate production, which has been proven to contribute to many neurological disorders including brain tissue damage and stroke. While GCPII’s role in glutamate production in the brain is known, many functions and behaviors in other tissues are not known. GCPII transmembrane domain (TMD) contains a unique amino acid sequence known as GXXXG, where G stands for the amino acid glycine and X is a set of hydrophobic amino acids. The GXXXG protein motif is known to induce protein dimerization with the help of the surrounding lipids. It is not known whether GXXXG induced dimerization in GCPII is influenced by surrounding lipids, thus impacting the functions of GCPII in a tissue-dependent manner. If the lipid compositions that surround the GCPII-TMD in the plasma membrane can be controlled, then the influence of membrane lipids on GCPII function in conjunction with GXXXG motif can be investigated. In this study, a synthetic membrane system known as lipid nanodiscs with unique cellular lipid compositions, such as neuronal and intestinal cell membrane lipids, were synthesized and used to incorporate GCPII-TMD to study lipid-protein interactions. We produced GCPII-TMD with fluorescent protein labels to characterize the lipid mediated protein dimerization via fluorescence energy transfer (FRET) spectroscopy technique. This artificial membrane system study will lead to greater understandings of how lipids influence protein functions in general as well as the function and behaviors of GCPII in different tissues.

Abstract Name: How Adolescents Use Smartphone and Social Media Overnight: Objective Observations from Passive Sensing and Gender Difference

Adolescents' smartphone and social media use overnight has been associated with negative health outcomes(Mireku et al., 2019; Elhai et al., 2017). Research has also revealed gender differences, including girls using social media more frequently than boys (Twenge & Martin, 2020). However, previous studies often relied on self-reports with subjective biases and inaccuracies. This study leveraged continuous smartphone passive sensing data to objectively describe adolescents' smartphone and social media use overnight and investigate gender differences in their use.Over 38 million screenshots and associated metadata were collected from 139 adolescents (47.48%female, 44.60%male, 7.19%other; Mage=15.40, SD=1.34; 53%Caucasian, 16%multiracial, 14%African American, 7.3%Latinx/Hispanic, 7.8%Asian) by a passive sensing app installed on their smartphones. The screenshots were automatically captured and collected every 5 seconds whenever the screen was on for up to 6 months. Apps being used were also collected. With this data, we could tell at any time during participation, how long adolescents use their smartphones and what apps they were using.On average, between 10pm and 7am, adolescents used smartphones for 79.65minutes (SD=86.60), with apps being switched for every 2.61minutes (SD=2.96) and social media use for 15.88minutes (SD=20.90). Independent two-sample t-tests comparing boys and girls revealed no significant differences in overall smartphone use ($t(126)=-0.87$, $p=0.39$) or app switches ($t(126)=-0.16$, $p=0.87$). However, girls spent significantly more nightly time on social media apps (19.64±24.75 minutes) than boys (11.19±15.55 minutes), $t(126)=-2.30$, $p=0.02$. Findings with our objective observation data validate previous findings about gender differences and highlight adolescent girls being the vulnerable group for social media impacts. Next step is to study how gender moderates the association between nighttime smartphone and social media use and sleep and mental health outcomes.

Abstract Name: Hybrid 3D-1D Strategy for Computational Study of Airflow Dynamics within Human Airways

Aerosolized drug delivery is an effective strategy for the treatment of various respiratory ailments such as asthma, cystic fibrosis, and chronic obstructive pulmonary disease. By targeting drug deposition towards the diseased pulmonary regions, effective treatment can be provided with minimal side effects. Recent advancements in radiological techniques have resulted in more detailed anatomical information, but this information still tends to be limited, which leads to ineffective treatment. Therefore, computational tools can provide insight that can further guide and increase the efficiency of treatment procedures. The aerosol dynamics within airways are dictated by the airflow dynamics, which exhibit features such as laminar-to-turbulent transition, flow separation, and reattachment, shear layers, etc., which makes investigation of airflow dynamics a challenging task. For the reasons of computational affordability and accuracy large-eddy

simulation (LES) tends to be a promising tool to investigate the airflow dynamics within realistic human airways. However even with LES, the simulation of transient and three-dimensional flow in all lung generations tends to be expensive, thus requiring alternate strategies for parametric studies. Therefore, in this study, we assess the performance of a hybrid 3D-1D strategy to simulate airflow within the well-established SimInhale benchmark case by comparing it with full 3D LES. In the hybrid strategy, the upper part of the airways is simulated in 3D, and a trumpet-shaped simplified 1D model is used for the lower part of the lungs comprising up to seven generations. The airflow features within the airways will be discussed in terms of the instantaneous and time-averaged behavior of the flow field.

Abstract Name: The Design Destiny of Astrid Stavro

.The visual language of graphic design fills in communication gaps in a world where images are used more and more. It is a dynamic discipline that uses visual components like typography, color, and imagery to communicate ideas while combining creativity and functionality. Its importance derives from its ability to captivate, educate, and advertise. Effective graphic design improves user experiences and influences opinions. Captivating design is essential for keeping viewers' attention in the face of the constant flow of information in today's digital world. By balancing aesthetics with intentional communication, it fosters connections and increases engagement. The visual language of graphic design is the embodiment of creativity, problem-solving, and strategic thinking. That is what Italian graphic designer Astrid Stavro did with her work throughout her career and still does to this day. From an early age Astrid was raised surrounded by her family's printing business. Her early years were filled with traveling for her family's business, which started giving her inspiration. Astrid's journey from a driven journalist to a design professional had changed when she came across graphic design as a young adult. Her education at the London-based Royal College of Art solidified her career path. Astrid Stavro, and her multicultural upbringing shaped her design approach, her path, from playing as a kid in front of printing presses to setting standards for editorial design, is an inspiration to aspiring designers, demonstrating the transformational power of diverse cultural influences. Prominent graphic designer Astrid Stavro has designed magazine covers and logos for businesses, among many other projects. Because of the wide range of cultural influences in her upbringing, Astrid has developed a distinctive viewpoint on design. Astrid's enduring passion for visual communication, as well as her remarkable work, have left an inevitable mark on the design industry.

Abstract Name: Multi-Channel Communication Campaign to Promote HPV Vaccination in Chambers County, Alabama: Preliminary Results

Cervical cancer is a public health problem in the state of Alabama. Based on the 2016-2020 data, Alabama was ranked sixth in cervical cancer incidence and fourth in mortality in the U.S. Across the state of Alabama leaders gather to address this issue and launched Operation Wipe Out, which is a collaborative strategic plan to eliminate cervical cancer as a public health problem in Alabama. Chambers County was identified as the county with highest cervical cancer incidence in the state and more focused efforts have taken place in this particular county. With support from the Chambers County School District and funding from the National Cancer Institute, high school students have been engaged in the development, implementation, and evaluation of a multi-channel campaign to promote HPV vaccination. Twenty-nine high school students are currently being trained and provided with the knowledge, skills, and support toward the development of the campaign. Pre-test assessments showed that in this group of 16 and 17 years olds most were female (90%) and none have attended a training like this previously. When asked where students heard of HPV, many said through a teacher (65%), parents (30%), or social media (35%), where TikTok was the most chosen platform. To date, students have identified their target audience (parents of children/adolescents between the ages of 9 -18 and 13–18-year-old adolescents) and developed the campaign branding/slogan and health messages. They are currently working on the multi-channel dissemination strategies with the goal of launching the campaign in January 2024 which will culminate with school-based vaccinations in the Spring. Impact will be evaluated by comparing the number of children/adolescents receiving the HPV vaccine at the schools and county (state registry) to 2022 uptake. If successful, this program can be disseminated to other counties and states.

Abstract Name: Staphylococcus epidermidis Biofilm Formation and Quorum Sensing AgrA Transcription Levels in Various In Vitro Environments

Staphylococcus epidermidis is a common human commensal and opportunistic pathogen that is one of the leading causes of nosocomial infections related to indwelling medical devices. This pathogenesis most often occurs through the formation of biofilms on membranes or device surfaces. Although some bacterial quorum sensing has been shown to control virulence factors, current studies on the quorum sensing system of S. epidermidis, accessory gene regulator (Agr), and its relationship with biofilm formation are contradictory. Here, we aim to better elucidate the role of Agr on biofilm formation of S. epidermidis through analysis of AgrA transcript level changes in various in vitro environments. Through semi-quantitative reverse transcription polymerase chain reaction (SQ RT PCR) of bacterial colonies and simultaneous staining of their biofilms, we estimated how this Staphylococcus quorum sensing system influenced changes in biofilm formation in response to varying temperatures, cell densities, and growth media. Identical methodology was conducted for the sdrG biofilm gene for comparison and analysis. Data is currently being collected and we anticipate reporting the results at the time of the 2024 National Conference on Undergraduate Research. We believe the results of this study will elaborate on the function of quorum sensing in biofilm formation in S. epidermidis.

Abstract Name: Black Sociologists Underrepresented in PhD Programs, an Examination of Racism and Roadblocks

Black scholars in higher education make up for the most sociology degrees among non-white students but not many of these black students make the transition to a P.h.D. because of what could be a leaky pipeline. I will be approaching this project with both qualitative and quantitative methods; the qualitative being in the form of a literature review and the quantitative in the form of a survey. The online survey was taken by Black Sociologists with a Ph.D. in the United States and asked participants questions about their experience in upper education and how it may have been affected because of their race. I will be researching how racism/roadblocks interfere with the advancement of Black sociologists in higher education. The purpose of my research is to research the relationship of higher education with race for black sociologists. the problem is that there seems to be a blockage in the pipeline for black scholars.

Abstract Name: Breaking the Mold: Disrupting the Dominant Narrative as First-Generation College Students

This research aims to bring forth the experiences of three undergraduate first-generation students navigating higher education. Our narratives aim to help contest the dominant narrative within higher education. We expose the predetermined expectation behind the romanticized American college dream, which we define as the freedom and ability to pursue higher education as a form of upward mobility toward a successful career. We reclaim our narrative by engaging in writing workshops that allow us to write, revise, and critically critique others through open discussion with the help of the Health Careers Opportunity Program (HCOP), a federally funded eight-week summer research seminar. The research employs autoethnography as a qualitative methodological tool, allowing us to reflect on lived experiences and draw connections between personal stories and scholarly insights. By engaging in self-reflexivity and introspection, we question and critique systems of power that aim to oppress us. We utilized the narrative research approach to explore college culture, systemic barriers in higher education, first-generation challenges, and the unique perspectives stemming from our underrepresented ethnic backgrounds. Through this process, we navigate and articulate the complexities of our identities, examining how our cultural backgrounds impact our academic pursuits, social interactions, and overall sense of belonging in an institution not designed for us. This collection of autoethnographies serves as a means for personal expression and liberation and invites others to explore their positionality. We expect our preliminary findings to be contextualized within cultural studies and educational frameworks, offering significant insights into the challenges and accomplishments of navigating higher education as first-generation college students. Ultimately, these autoethnographies offer a counter-story narrative framework for empowerment, liberation, and social justice. Our collaboration exemplifies the

potential for shared narratives to foster understanding, challenge stereotypes, and inspire others within and beyond the academic community. Keywords: First-generation, Narrative, Autoethnography, Liberation, Higher Education

Abstract Name: Use of Total Oxidizable Precursor Assay to Determine the Fate and Transport of PFAS Throughout Wastewater Treatment Facilities

Per- and poly-fluoroalkyl substances (PFAS) are highly persistent contaminants of emerging concern given their broad distribution and link to harmful health environmental effects. They are used in everyday items such as cookware coatings, food packaging, and firefighting foams. Due to their aggregation and abundance in wastewater, the fate and transport of PFAS in wastewater treatment processes needs to be better understood. While highly oxidized perfluorocarboxylic acids (PFCAs) are routinely measured through conventional methods, thousands of PFCA precursors with fluorinated tails and larger headgroups are less frequently quantified. The total oxidizable precursor (TOP) assay provides a means to quantify PFCA precursors through the •OH-mediated oxidation of unquantified precursor PFAS. We used the TOP assay to quantify the transformation of precursor PFAS throughout the treatment process in six wastewater treatment facilities. The results indicate that precursor PFAS transform into PFCAs in each unit in the wastewater treatment process. These results also inform our understanding of the total PFAS concentration of wastewater effluent and potential burdens on downstream aquatic ecosystems. These results will help to guide future research related to how PFAS in wastewater effluent impacts aquatic and human life.

Abstract Name: Blast Off An Investigation on the Development of Fusion Energy for Deep Space

This research assesses the development and implementation of nuclear fusion for space propulsion systems in deep space to determine which fusion reaction operates best under deep space conditions. While scientists have long searched for an energy source that could transport humans through deep space to explore the universe, setbacks in finding an energy capable of reaching a high specific impulse and exhaust velocity to propel rockets through deep space have made this development difficult. Fusion energy presents itself as a potential solution to these obstacles. To explore such a possibility, a literature review of fusion reactors and fusion propulsion was conducted to understand the fuel cycles of fusion energy, compare the types of fusion reactors, and assess the potential fusion energy could have on propulsion. Foundational research conducted by experts in nuclear energy, such as the Lawrence Livermore National Laboratory, indicate energy fuel

needed for deep space must have a high payload fraction for cargo transportation and short mission duration for human transportation. Based on the criteria needed for deep space missions, fusion energy demonstrates the capability of meeting these expectations. Additionally, a detailed comparison of the energy produced and the percentage of charged particles was conducted between the main contenders for fusion energy fuel, which are deuterium-deuterium, deuterium-helium-3, and deuterium-tritium. The research displayed a clear advantage to using deuterium-helium-3, an energy source that is abundantly available on the Moon, because of its high number of charge particles compared with other energy candidates, such as tritium. From this critical literature review, this project concludes that fusion energy, specifically deuterium-helium-3, provides a possible solution to a decades-long limitation on developing fusion propulsion.

Abstract Name: Light-responsive Active Motion and Assembly Using Gold Nanoparticles

Active particles absorb energy from the environment and transform it into motion, allowing for the realization of autonomous movement at the micro- and nanoscale. We demonstrate a simple experimental system where gold nanoparticles and high intensity LED light are used to design active motion and assembly in colloidal particle suspensions. Because of the surface plasmon resonance, gold nanoparticles absorb light and generate a temperature gradient around the center of the illumination that causes a convective flow. We captured the active motion of larger particles (with a size of about 1 micrometers) in this flow for different conditions of light intensity, gold nanoparticle concentration, and sample height. We calculated the MSD (mean square displacement) over time plot to characterize active motion, and found that particle activity increases with light intensity, gold nanoparticle concentration, and the height of the sample. We observe accumulation of large particle clusters towards the center of the light after 5-10 minutes. Additionally, we developed a patterned light illumination system using a DMD (Digital Micromirror Device) that allows us to define bright and dark regions, hence the local temperature. In our preliminary experiments, we used a bright rectangular-shaped region surrounded by a dark background. We find that the size of the accumulated particle crowd near the center increases with the area of the bright region. Our work provides an opportunity to connect the fundamental understanding of photothermal convection to applications where particle motion and assembly can be engineered precisely at the microscale.

Abstract Name: Applying Computer-aided Textual Analysis to Understand Employee Recruitment in Start-up Companies

New ventures may be at a disadvantaged position regarding talent attraction due to reasons such as a less established reputation and job seekers' perceived uncertainty regarding their career trajectory. Employment webpages and job postings are common places where start-up organizations can convey an attractive organizational image in a textual format to job seekers. However, little is known about whether such textual information reflects the actual experience of employees or the effectiveness of such textual information in attracting talent. In this study, we collected texts related to organizational culture, employee benefits, and diversity statements from the websites of approximately 250 new ventures featured in the Forbes 2022 and 2023 lists of AI50, Fintech 50, and Next Billion-Dollar Startups. We will first use computer-aided text analysis (CATA) in R to score the startups regarding several organizational attributes, such as emphasis on teamwork and work-life balance. We will download employee ratings of each company from Glassdoor.com, where employees rate their employer regarding overall favorableness and specific aspects such as work-life balance and management. The start-ups' financial performance will be obtained from the Crunchbase database. We will use multiple regression to examine whether organizational attributes communicated in the job postings and career webpages are significantly related to the Glassdoor ratings by employees and firm financial performance. To test the effectiveness of using texts to increase organizational attraction, we will conduct an online experiment with real job seekers recruited from Prolific. Specifically, we will manipulate textual elements in a job posting (e.g., presence vs. absence of employee benefits, short vs. elaborated diversity statement, etc.) and test whether the inclusion of certain texts can enhance job seekers' attraction to the organization and intention to apply for the job. Our findings will have important practical implications for job seekers and talent recruitment strategies in the start-up scene.

Abstract Name: The State of Student Media at HBCUs and HSIs

This research explores the state of student media at Historically Black Colleges and Universities (HBCUs) and Hispanic Serving Institutions (HSIs) given the decline of student media outlets in the past decade due both to the challenges of newspapers in general and the pandemic. It is an attempt to document the presence of student media at these non-White institutions, an effort that does not appear to have been completed before now.Despite ample research on student media, there is a void of data specific to HBCUs and HSIs. Research also has been conducted on journalism programs at HBCUs (Crawford, 2012; Jeter, 2002; Sturgis & Johnson-Ross, 2019), but not addressing student media at these unique institutions. At least journalism at HBCUs has been researched. Hispanic Serving Institutions, a much newer federal designation, have been the subject of some work in the academy, but little if any research has been done on journalism, let alone student media, in these bilingual institutions.The most current lists available show a total of 666 HBCUs and HSIs in the United States, including Puerto Rico (The Hundred Seven, 2018; Hispanic Association of Colleges and Universities, 2021). This study started by gathering information from the institutions' websites and social media, and by making phone calls to the newsrooms when no information was available on websites or social media. Through this initial step, we identified 220 HBCUs and HSIs with student media, including newspapers, radio stations, broadcasts, and podcasts. This team deployed a questionnaire to learn more about these outlets to help us shed light on their production operations, publishing styles, diversity inside of the newsrooms, and work methodology. We also have created a unique dataset for future research on student media. We expect to have results from that survey in time for the conferences.

Abstract Name: Determination of H+ of NIS Synthetase Mechanism Via pH Kinetics

Our bodies contain metal chelators which absorb iron and process it, the same goes for bacteria within our body.Iron is crucial for aerobic organisms, and pathogenic bacteria secrete siderophores to compete for host metals. Primarily these siderophores are synthesized via two pathways: one much more well-known nonribosomal peptide synthetase (NPRS)-dependent pathway, and NPRS-independent siderophore (NIS) pathway, the less studied pathway. In spite of the two pathways having the similarity of synthesizing siderophores, the host is able to intercept NRPS siderophores and keep them from retrieving iron. NIS siderophores evade the human immune system and therefore are virulence factors for pathogenic bacteria. Streptomyces coelicolor, a bacterium, can synthesize two NIS siderophores, Desferrioxamine B and Desferrioxamine E (dfob and dfoE), which are both produced in their final steps by the enzyme Desferroxiamine D (DesD). DesD, is a model enzyme for the NIS synthetases and their pathways. The Hoffmann Lab is pursuing structure based drug design targeting these understudied NIS synthetases, including establishing the basic biochemical mechanism and function. The focus of my current research is to finish a kinetic profile at different pHs to explore the proton-dependence of DesD and its substrate Desferroxiamine G (dfoG). Utilizing a single injection kinetics assay created previously in lab, I will use an Isothermal Titration Calorimeter (ITC) and GraphPad Prism Software, to analyze the changes in kinetics at systematically varied pH.The kinetic curves and constants discovered will be used to hypothesize the mechanism of catalysis, and in the future, to design catalytic inhibitors.

Abstract Name: Usage Frequency and Prestige Levels of Spanglish amongst Memphis' Second-Generation Hispanic Latino Community

Extensive research on the usage, characteristics and impact of 'Spanglish' on bilingual communities in majority Latino/Hispanic areas such as the streets of Miami, San Antonio, and other high-density bilingual populations across the United States have seldom been replicated in primarily monolingual communities such as Memphis, TN. To explore the linguistic practices of our local Spanish-speaking communities, this study investigated the connection between different aspects of 'Spanglish', a phenomenon of language contact between English and Spanish, such as code switching, lexical borrowings, and calques, and the frequency of their usage by second-generation bilingual Latinos/Hispanics, that is, children of Latino/Hispanic immigrants, living in Memphis, TN and the surrounding areas. Methodology included both written questionnaires on the participants' attitudes regarding 'Spanglish' and oral interviews conducted in Spanish to simulate conditions in which bilinguals incorporate 'Spanglish'. Following transcription of oral interviews, the data were

analyzed and coded for the aforementioned characteristics of ‘Spanglish'. Initial results indicate that users of ‘Spanglish’ employ codeswitching with a higher degree of frequency than their usage of calques and borrowings. In addition, users tend to associate ‘Spanglish’ with a higher level of prestige than originally hypothesized, deepening our awareness of the level of prestige ‘Spanglish’ holds within this particular community of users. These conclusions contribute to the field of language variation and contact by opening the door towards the creation of a warm and welcoming space for 'Spanglish' in academia and society as a whole. Being on the cusp of an exploding influx of Latino/Hispanic presence in this country, this work, studying and analyzing the communicative practices of this community, contributes to a stronger understanding of how language practices form in this bilingual and bicultural space.

Abstract Name: Understanding the American Dream Through the Eyes of First Generation Latinx Students

First-generation Latinx college students with immigrant parents experience divided beliefs about the American dream. Despite existing literature highlighting Latinx immigrant parents' support for the American dream, there is less research on the transference of this belief to second-generation Latinx citizens. In this study, a clashing narrative approach is used to examine two opposing narratives. The first narrative stresses that the American Dream is attainable through educational success and in turn leads to upward mobility. Contrary, the systemic racism narrative exemplifies ways in which minoritized communities are held back by institutional and systemic issues. Research indicates that Latinx students are more likely to start but not complete their degree. This study uses an experimental approach that presents Latinx college students with two prompts that represent the personal barriers Latinx students encounter, such as the adaptation to an individualistic culture that is college life from a collectivist culture the Latinx community tends to embody. The second prompt will focus on statistical findings that demonstrate degree gaps Latinx students have in comparison to White students. Prior, a manipulation check will be used to evaluate whether participants view education as the path to achieving the American dream. Participants will then complete a survey that includes scales measuring whether they support the American Dream or the systemic racism narrative. With anticipated findings including heightened support for the systemic narrative, this study aims to examine the credibility of the American Dream among first-generation Latinx college students at a Hispanic-serving institution. To better understand the generational shifts in support of the American dream it is crucial that the largest growing minority within the U.S. is allowed to express their educational concerns as a way of constructing an educational system that supports and nurtures Latinx excellence in academia.

Abstract Name: Computational Investigation of Sulfonamide-Aldehyde Derivatives

The increasing microbial resistance to antibiotics underscores the pursuit of novel antibacterial compounds. Sulfonamides, known for affordability and low toxicity, have been vital in combating infections. However, persistent bacterial resistance necessitates a deeper understanding of their molecular intricacies. In this investigation, a repertoire of theoretical techniques, encompassing semi-empirical and ab-initio methodologies, is harnessed to scrutinize the stability, reactivity, and antioxidant attributes of the following sulfonamide-aldehyde derivatives: 4-(2-(1,3-dioxo-1-(p-tolyl)propan-2-ylidene)hydrazinyl)benzenesulfonamide (M1), 4-(2-(1,3-dioxo-1-(p-tolyl)propan-2-ylidene)hydrazinyl)-N-(pyrimidin-2-yl)benzenesulfonamide(M2), 4-(2-(1,3-dioxo-1-(p-tolyl)propan-2-ylidene)hydrazinyl)-N-(4-methylpyrimidin-2-yl)benzenesulfonamide (M3). The semi-empirical method PM3 is employed to attain geometrical optimization of the compounds, while the theoretical methods Hartree-Fock (HF) and Density Functional Theory (DFT) are harnessed to unravel chemical properties. Computational simulations are meticulously executed using Gaussian 16 and GaussView software packages, lauded for their precision in electronic structure calculations grounded in quantum mechanics. Our findings elucidate the preferential electrophilic attack at ketone sites, highlighted by their prominent Highest Occupied Molecular Orbital (HOMO) lobes. In vacuum, M3 exhibits the highest electrophilicity index, whereas, in a polar solvent, HF results favor M2, while DFT consistently suggests M3. Intriguingly, in cyclohexane, HF predicts that M1 has the highest electrophilicity index, while DFT predicts that M3 has the highest value. Also, Molecular Electrostatic Potential (MEP) analysis unequivocally maps the highest electron density regions to the aldehyde groups, juxtaposed with the lowest electron density regions attributed to amine and amino groups. In addition, based on the energy gap between HOMO and LUMO using both theoretical methods HF and DFT results, M2 was the most reactive on a polar solvent, while M1 was the most reactive on a non-polar solvent. These revelatory insights pave the way for the strategic design, reactivity and development of novel antimicrobial agents, addressing the critical need for efficacious alternatives amidst the relentless tide of bacterial resistance.

Abstract Name: Investigating Hippocampal Subfield Volumes in Older Adults with Down Syndrome

Individuals with Down syndrome (DS) are at a higher risk of developing Alzheimer's Disease (AD), which is thought be due to the overexpression of the amyloid precursor protein, an initiator in the cascade of AD pathology development. AD development is associated with an increase in hippocampal atrophy, and subsequently a decline in memory. Previous late onset AD studies have observed a relationship between decreases in hippocampal subfield volumes, particularly the CA1 and subiculum, and predictions of future cognitive decline. Here, the relationship between hippocampal subfield volume measures in the cornu ammonis 1 (CA1), subiculum, and antero-lateral entorhinal cortex (aLEC) and future changes in cognitive state were assessed longitudinally. Decreases in volume measures in the CA1 and subiculum were hypothesized to be associated with conversion of cognitive state. Volume measures of these subfields were also measured against current memory performance in the modified cued recall test (mCRT). Lower volumes in the CA1 and subiculum were expected to be associated with worsened memory performance measured by the mCRT. Results showed no association between volume measures for the CA1 and subiculum regions and conversion of cognitive state, with no significant difference between these two subfields. Additionally, the mCRT scores were positively associated with volume measures in the subiculum. Future directions will focus on further investigating structural changes in the subfields in younger DS cohorts as well as integrating other pathological hallmarks of AD and their impact on the hippocampal subfields and memory performance.

Abstract Name: The Regression of Hungarian Democracy Through a Case Study of LGBTQ+ Populations

In the late 1980s, Hungary arose as one of the most rapidly democratizing states after the fall of communism. It established a democratic Constitution, complete with checks and balances, protections for minority groups, and the promise of free elections. But unlike many of its former Communist neighbors, it has defected from the progress of the latter part of the twentieth century. Hungarian Prime Minister Viktor Orbán and the Fidesz party have consolidated illiberal democracy in Hungary, characterized by the backsliding of democratic institutions, promotion of nationalist ideologies, and marginalization of minority groups. A democracy in which a majority elects to separate, expel, or otherwise injure its minorities is not a functioning democracy. The rights of Hungary's minorities, such as the LGBTQ+ community, have been undermined by an electoral autocracy; leadership of the past decade has consolidated the legislative, executive, and judicial branches, eroding a fundamental building block of democracy. The government has also mounted a campaign that dismisses the social and legal autonomy of LGBTQ+ people through propaganda and regressive legislation. This is done to strengthen support for Orbán, positioning him at the metaphorical helm of defense of Hungarian children, "traditional family values", and the longevity of the nation. The clash of traditional beliefs and progressivism has allowed Orbán to further his agenda of nationalism and fuel anti-Western and anti-European Union rhetoric. Methods of research to substantiate these claims include the analysis of relevant academic literature, review of Orbán's public statements, synthesis of qualitative reports by Hungarian LGBTQ+ organizations (e.g., Háttér Society and the Hungarian LGBT Alliance), and interviews with various LGBTQ+ organizations in Budapest in January 2024. Findings add to a limited body of existing research on the impacts of illiberal regression specifically on the Hungarian LGBTQ+ community, as this group has been understudied.

Abstract Name: Monitoring Wildlife Activity Using Game Cameras

Game cameras are a common tool for monitoring communities of larger wildlife and the impact human recreation has on them. Motion activated cameras were used to survey the wildlife communities and human visitation rates of Herngt 'Aki' Preserve (HAP) and San Timoteo Nature Sanctuary (STNS), open space reserves in Redlands, California. The goal of this research was to provide the Redlands Conservancy with data to help better manage their reserves not only as wildlife habitat but for recreational use as well. Weekly human visitation was compared to weekly wildlife occurrence per camera site, which demonstrated only a weakly positive correlation. More people visited STNS per week than HAP. The most common wildlife

species observed in both reserves was Canis latrans (coyote), followed by Corvus corax (common raven). Preliminary analysis found no significant correlation between weekly human recreation and weekly wildlife presence. Further statistical testing is planned to look at potential long term (over multiple seasons/years) and short term (daily temporal patterns) effects.

Abstract Name: Determining PFAS Soil-Biota Accumulation Factors in Earthworms

During the latter half of the 20th century, the Duluth Air National Guard Base (DANGB) tested Aqueous Film Forming Foam (AFFF) as a firefighting agent against petroleum fires. AFFF, while effective as a fire suppressant, contains the PFAS chemicals PFOA, PFOS, and PFBS in high concentrations. These environmental contaminants are still found at ecologically relevant concentrations in and around historic release sites. Research into the ecological toxicity of PFAS is ongoing in and around DANGB through the Great Lakes Toxicology and Ecology division of the US EPA. To quantify PFAS contamination in earthworms, PFAS soil-biota accumulation factors (SBAF) were established across DANGB and nearby sites. The SBAF is a simple and effective method for ecological risk assessment; however, it does not give you any information about how a contaminant bioaccumulates. Earthworms consume organic matter and microorganisms in soil and are therefore considered to be both primary and secondary consumers. Bulk stable isotope analysis was performed to determine the trophic level of earthworms at these sites through quantification of δ15N and δ13C. Determining the trophic level of earthworms allows us to understand how biomagnification of PFAS may affect them. Over 100 grams of earthworm samples were collected across 22 sampling locations among four sites of varying levels of PFAS exposure. Approximately 1-2 g (wet weight) of tissue from each sample were analyzed for total PFAS concentration (across 40 analytes) by Battelle Analytical Chemistry Services Laboratory under US EPA method 1633. Initial results show PFOS earthworm concentrations averaging 145 ng/g-wet weight (n=5) near DANGB, while soil samples at the same site had PFOS concentrations averaging 11.2 ng/g (n=3). We expect to see biomagnification of PFAS in earthworms as PFAS moves from the soil to earthworms and through subsequent trophic levels.

Abstract Name: DEVELOPING THERAPIES FOR OPA1 DISEASE USING A HUMANIZED C. ELEGANS MODEL

Background: OPA1 (Optic Atrophy 1) encodes a mitochondrial dynamin-like GTPase that regulates mitochondrial fusion. Therefore, mutations in OPA1 can lead to fragmented mitochondria, resulting in the accumulation of dysfunctional mitochondria and triggering mitophagy, a highly regulated mechanism of

mitochondrial degradation. Triggering mitophagy can upregulate mitochondrial biogenesis, activating an energetically costly feedback loop, which we hypothesize to cause disease symptoms. OPA1 disease primarily results in childhood onset vision loss and 20% of patients experience additional sensory and neuromuscular defects. To address the dearth of medical interventions, preliminary studies have been done in two C. elegans strains carrying mutations in eat-3, the worm homolog of OPA1. One carries a R289Q missense mutation homologous to the human pathogenic R290Q mutation and the other carries a V328I missense mutation. Both show increased mitochondrial stress and neuromuscular dysfunction. Screens in the eat-3(R289Q) strain identified Thiamine as a reliable control and potential therapy, in addition to Hemin and Tripterin. Here, we are testing (a) whether mitophagy modulation can rescue disease symptoms and (b) the efficacy of the therapeutic compounds to rescue neuromuscular defects.Results: We found that reducing mitophagy via RNAi in the eat-3(V328I) animals results in reduced mitochondrial stress and this result repeated twice. We found that therapy treatment from day 2 to 4 of adulthood consistently rescued the neuromuscular defects in both eat-3(R289Q) and eat-3(V328I) strains over three biological replicates. Conclusions: Our data supports that upregulation of mitophagy may cause OPA1 disease pathology, suggesting that mitophagy modulation could be exploited to develop therapies for OPA1 disease. Additionally, the candidate hits identified in mitochondrial stress screens can rescue neuromuscular function as indicated by thrashing studies. Overall, we have identified a pathway that can be exploited to develop therapies and identified compounds that can be utilized in preclinical studies for OPA1 disease therapy development.

Abstract Name: Development of a Natural Silk Fibroin Approach for Biocompatible Ink

Silk fibroin (SF) from silkworms has been identified as a promising material for creating sustainable biomaterials for many polymer fabrication applications. Currently, the method for creating SF uses a regenerative approach and post-spun silk from Bombyx mori silkworm cocoons. However, it has been seen that this method for producing regenerative silk fibroin (RSF) reduces the admirable mechanical properties of native silk such as strength, toughness, and elasticity. Current methods to increase these properties in RSF have included injecting growing silkworms with metal ions to induce particular conformational changes. This project proposes an alternate, under-researched solution for optimizing the process of extracting native silk fibroin (NSF) to use as a biocompatible ink for 3D printing. By extracting the silk pre-spinning, the NSF properties may remain more similar to that of native silk. This method eliminates the RSF process of degumming the cocoons which leads to the denaturation of the protein structure. To achieve this, 5th instar, fully mature silkworms were harvested and their two silk glands were extracted. Next, the epithelium layer was gently removed and the gland was washed to remove the outer layer of sericin from the silk. With the middle section removed from the rest of the gland, many methods were tested to achieve the desired NSF results and properties. These include using the sections of the silk gland like lincoln logs to create a simple 3D structure, diluting the concentrated gland with milli-q water to use as a bio-ink in an INKREDIBLE+ bioprinter, and transferring the original gland into the bioprinter to use the pressure and alignment to spin silks as a silkworm would. The results from this experiment were compared regarding ease of SF preparation, mechanical properties, and potential for further development.

Abstract Name: Changing Control: China and the Development of Dual-Use Technology Export Controls

Chinese controls and regulations on dual-use technology exports used in the production of weapons of mass destruction, their delivery systems, and advanced conventional weapons have changed significantly since the beginning of the Reform and Opening period. The current paper will explore how the Chinese government's approaches toward dual-use technology export controls have changed since the 1980s. Despite China's growing economic, military, and technological importance, contemporary literature has not focused on examining the trends and factors that influenced the development of contemporary Chinese approaches to dual-use technology export controls. Particular gaps in the literature exist related to the development of Chinese dual-use technology export controls in the 2010s. The paper will use methods, such as analyzing China's defense white papers, changes in Chinese dual-use export control laws, and participation with the Multilateral Export Control Regime (MECR) to measure stated interest in participating in international dual-use technology export controls. Through textual and content analysis, I will compare Chinese dual-use export-control laws and statements over time with individual case studies that demonstrate (non-) enforcement of those laws. The results will likely show China's interest in selectively engaging with the MECR in an attempt to maximize sovereignty over exports while simultaneously attempting to position China as a responsible international actor. This research will reveal deeper trends toward China's view of the MECR and showcase China's intentions to reshape, support, or undermine that aspect of the international system.

Abstract Name: Examining the Interplay between the Chicano Movement and Hispanic Americans': Educational Attainment, College Enrollment, and Occupational Segregation

The Chicano Civil Rights Movement emerged from the discriminatory treatment and marginalized experiences Mexican Americans faced in the United States. The movement inspired students in East Los Angeles to initiate a series of protests to change the educational system within schools. Instead of preparing Mexican Americans academically for college, educational institutions would steer students towards domestic training and vocational occupations. The research analyses the possible correlation between the movement and the increase in college enrollment in Los Angeles and tests to see if this alteration further led to changes in the Hispanic-American labor market. Using data collected by the United States Census, we examined the evolution of education levels and occupations over time. Our results indicate an improvement in education levels and college enrollment. Specifically, the number of years of education pursued by Hispanic Americans has increased from 9 years in 1960 to 11 years in 1980. Furthermore, the college enrollment rate in Hispanic-American communities increased from approximately 11% in 1960 to 20% in 1980. As for occupational segregation, our data shows a constant decrease in segregation within the workforce. In light of these observations, the data provides insight into how social movements like the Chicano movement, to a degree, can result in positive outcomes for communities and individuals' rights.

Abstract Name: Towards the Synthesis of Bismuth Compounds at Multiple Oxidation States Using Redox-Active Ligands

Bismuth is an abundant element that is uniquely a non-toxic heavy metal. Despite its potential for applications in synthetic chemistry and photochemical processes, our general knowledge of the structure and reactivity of Bi-containing compounds is very limited. Due to these limits, it's important to design new Bi-containing compounds that would both expand the fundamental knowledge of this class of compound but also do this in a way that explores the impact of the Bi-oxidation state. We're interested in preparing and studying Bi-containing compounds that feature multi-dentate ligands that can participate in redox processes. This presentation will describe efforts towards the synthesis of neutral tridentate pyridine diimine, neutral bidentate alpha-diimine, and monoanionic bidentate acetylacetonate ligands and their subsequent metallation reactivity with various Bi(III)-salt precursors.

Abstract Name: Opening The Black Box: Explainability and Introspection in Deep Reinforcement Learning for Robustness in Control Systems

As the research field of Artificial Intelligence expands, the level of abstraction held by Machine Learning models becomes increasingly complex and harder to navigate. Like human consciousness, an ensemble of thinking neurons usually don't convey their reasoning in interpretable formats without the tools and the instructions to do so. As humanity developed, language arose as the number one bridge between thought and interpretation, allowing humans to suddenly develop the ability to socially communicate reasoning and logic. With machines and agents, this doesn't have to be any different. Present-day models of artificial intelligence rely solely on the concern of outputting optimal values from a multitude of inherently different scenarios given a set of experiences or expected outcomes (and loss functions thereof) that it was trained on. This makes the task of interpreting and fine-tuning models rather troublesome given the abstractions derived from hidden layers of information in Deep Learning. In the context of optimizing for model transparency, this research utilizes algorithms of Integrated Gradients on top of scenarios inherited from Deep Reinforcement Learning from OpenAI Gymnasiums to expand on how learning attributes could be grasped from training pipelines in Reinforcement Learning, communicating to trainers what parts of the state-space input the agent pays attention to the most when performing its Markov-guided decision-making. Diving into the reasons behind action inference should provide information that was initially hidden at first look, but that may be

pivotal in improving the robustness and transparency of control systems in fields of robotics, avionics, aeronautics, and more.

Abstract Name: PARENT PERCEIVED SELF EFFICACY FOLLOWING COMMUNICATION PARENT COACHING PROGRAMS

Before children enter school, their parents/caretakers act as their first teachers. In order for parents to gain advice and techniques regarding how to teach communication skills to their children, they may enroll in a parent coaching program. Parent coaching programs are designed to improve parent confidence/parental self-efficacy. Parental self-efficacy refers to a parent's perceived capability to successfully parent. When parents feel confident in their ability to support the development of their children, research shows that children benefit. The University of Northern Colorado has implemented the parent coaching program, Treasure Chest, since 2018. In this program, graduate clinicians from the Speech-Language Pathology Master's program are assigned to a family and are responsible for coaching the parents on how to involve age-appropriate communication opportunities for their children. In this qualitative phenomenological research study, four to six parents who have already participated in a semester of the Treasure Chest Program will be interviewed and asked a series of nine questions. This research will explore parents' perceived self-efficacy as a communication facilitator during play, early literacy experiences, and daily routines. A thematic coding approach will be used to look for significant statements (this process is also known as Horizontalization). After recognizing common themes, clusters of meaning will be developed and reported as results. Completing this study and involving the Greeley community acts as a starting point to discovering how parents and families can feel more confident following these parent coaching programs. Learning parent perspectives may also benefit clinicians and professionals in the speech-language pathology (SLP) world by educating SLPs and other professionals on how parents view their ability to support their child's communication.

Abstract Name: Correlating Music Preference and Anxiety Levels in College Music Students

In a previous study conducted by Rentfrow and Gosling in 2003, a correlation between music preference and depression was found. However, there is a lack of research on the relationship between music preference and anxiety levels, particularly among college students. The purpose of this study was to explore any potential links between music preference and anxiety levels in college students. By incorporating contemporary music genres, this quantitative study has the potential to enhance our understanding of music preference and depression levels. The study involved 32 participants who completed two surveys. The two established measures were the Short Test of Music Preference (STOMP) and the State-Trait Anxiety Inventory (STAI). These instruments were selected to assess participants' musical preferences and anxiety levels, respectively. The STOMP is a reliable tool that has been widely employed in previous research to measure individuals' music genre preferences. On the other hand, the STAI is a well-established self-report questionnaire that provides a comprehensive assessment of anxiety as a stable trait and a temporary state. This project aimed to examine the relationship between music preference and anxiety levels. Data was analyzed using the Pearson-product moment correlation procedure. Descriptive statistics and figures were generated using Microsoft Excel (2018) and IBM Statistical Package for the Social Sciences (SPSS, Version 27). The results indicate that there are similar trends of music preference across different age groups. Furthermore, the current state and trait anxiety levels are in the highest percentile rank across normal groups of the same age. The findings also revealed that two similar genres, Rock and Alternative, were negatively and significantly correlated with state anxiety. Pop and Soundtrack had positive and significant correlations with trait anxiety. Rock and Alternative may soothe anxiety levels with higher preference, and Pop and Soundtrack may stimulate anxiety levels with increased preference of genres.

Abstract Name: Simulating Conditions of Slope Failure in the Lab with Sand and Water Using a Multimodal Monitoring Device for Data Collection

Slope failure is becoming increasingly common along the Great Lakes due to high wave action, and increased rainfall caused by climate change. Our main goal is to understand the precursors to slope failure so we can

better monitor and predict them. Raising public awareness of the dangers of slope failure and protecting communities near shorelines are a few of the benefits of our research. We conducted our lab experiments on slopes with different layers, each defined by varying grain sizes, utilizing a multimodal monitoring device consisting of a strain gauge sensor, and 4 moisture and temperature sensors. Our setup consists of a plastic container to hold sand with a 45-55-degree sloped surface. A buried sandbag attached to the strain gauge sensor communicates strain information to the Raspberry Pi. The moisture and temperature sensors are placed on top of the slope. To simulate failure, we pour 60 cc of deionized water at the top of the slope for 10 seconds over 30-second intervals and repeat until failure occurs. The strain data pattern appears to correlate with the depth of the buried sandbag and the size of the sand grains that make up the slope. The correlation between soil moisture data and strain gauge data is not yet conclusive. Our future work will involve further analyzing the changes in strain data and its relation to the soil moisture data. Moreover, we want to incorporate liquid nitrogen to simulate freeze-thaw conditions. Our project ultimately will lead to designing a system for collecting reliable field measurements for monitoring different triggers of slope failure and remotely transmitting the data in near-real time. This will allow continuous slope monitoring to help protect the public from the aftermaths of slope failure.

Abstract Name: Advanced Aerial Mapping with Computer Vision: Enhancing Aircraft Recognition and Localization through Object Detection and Feature Point Tracking with Kalman Filtering

In the realm of aviation, accurate aircraft recognition and localization are paramount. This study delves into the application of computer vision in conjunction with aerial maps to enhance aircraft recognition, location estimation, and real-time tracking. In particular, the use of Oriented FAST and Rotated BRIEF (ORB) for keypoint (distinctive points in an image identified as having unique properties) detection and You Only Look Once (YOLO) for object detection, coupled with Kalman filtering to enhance aircraft tracking capabilities. The methodology centers on developing an autonomous system for identifying and localizing aircraft while assessing the performance of integrated computer vision systems against standalone methods. A significant part of the investigation concentrates on the synergy between ORB's efficient keypoint tracking and YOLO's Convolutional Neural Networks which augments the understanding of a scene's 3D structure. The fusion of these technologies with Kalman filtering promotes an understanding of the aircraft's movement and position with improved accuracy and reliability. This research offers practical tools for air traffic control to track and identify aircraft, enhancing airspace safety and regulatory compliance. Additionally, it offers a potential alternative to aviation cybersecurity, providing an independent substitute to verify aircraft identity if a cyberattack were to happen.

Abstract Name: Machine Learning for Human Activity Recognition using Wearable Devices

Human Activity Recognition (HAR) is a growing field in machine learning. With the growing popularity of wearable devices that enable data collection and quick analysis of that data, HAR will become increasingly useful. Recognition of different activities has several beneficial applications in healthcare, security, and beyond. As the range of human activities is large and the activities complex, accurately categorizing the activity being performed is a difficult task. Machine learning is often applied to this problem to classify the data obtained. This research project aims to collect data from many participants using common wearable devices, such as an Apple Watch, and classify it properly into the activity being performed. This dataset will be obtained with participants performing a set range of abilities under observation, with time periods being measured. Different types of smart watches will be used, to provide further comparison between the effectiveness of popular devices. As this is a relatively new field, there is no standard dataset, and the addition of another publicly available dataset will help aid future research. Once this data is obtained, we will perform machine learning methods on them to properly classify the activity performed during this time period. Several different machine learning algorithms will be used to provide comparisons between the effectiveness of the individual algorithms. We expect at least one of the algorithms to have an acceptable level of activity recognition, however, depending on the activities performed, different algorithms will have different effectiveness. These differences will provide valuable insight on the machine learning algorithms, as well as the devices used to collect and analyze this data. Conclusions will be drawn about an effective algorithm and device combination regarding the different activities performed.

Abstract Name: Green Tea Mouthwash and the Prevention of Porphyromonas Gingivalis: Decreasing the Risk of Developing Alzheimer's Disease

Alzheimer’s disease affects 10% of all deaths in the United States and severe periodontitis also affects 10% of the population worldwide. The connection between the two has been explored, therefore oral hygiene is suggested to decrease periodontitis that could possibly lead to Alzheimer’s disease. A notable oral pathogen, Porphyromonas gingivalis (P. gingivalis), has been identified in the connection between Alzheimer’s and periodontitis. In this study, green tea mouthwash is being analyzed to find out if the mouthwash can reduce the mechanisms of P. gingivalis to decrease the risk of developing Alzheimer’s. Green tea mouthwash contains catechins, EGCg and ECg, that have been found to decrease Gram-negative and Gram-positive oral bacteria, plaque, and proinflammatory cytokines such as IL-1β, IL-6, and TNF-α that P. gingivalis can induce orally and in the brain. In comparison to the traditional chlorhexidine mouthwash, green tea mouthwash can be used as drinking tea on top of its ability to plaque reduction that is comparable to chlorhexidine. However, since Alzheimer’s primarily affects the elderly, a proposal of green tea mouthwash being implemented in young adults aged 20 to 30 to proactively prevent Alzheimer’s may be proposed since the risk of severe periodontitis and plaque, as well as amyloid beta (Aβ) concentration, increases with age and elevates at age 60. In addition, early-onset Alzheimer’s has been found to occur at an average age of 56, however, the disease could affect those between the age of 30 and 40. Therefore, implementing green tea mouthwash into the dental care of young adults may prevent the risk of these individuals developing Alzheimer’s prior to the age where the treatment may no longer be effective.

Abstract Name: Diurnal Fluctuations in IL-1B expressing choroid plexus cells

Sleep represents a complex biological state, an active state of unconsciousness where the brain responds primarily to internal cues. Its regulation, governed by the circadian rhythm, intertwines deeply with the immune system. Cytokines, immune signaling molecules, appear to wield influence over sleep, orchestrated by the circadian rhythm. Studies administering IL-1β, a cytokine, into rodent brains, underscore its somnogenic potential, hinting at circadian control over brain IL-1β levels. Yet, the precise brain regions and cellular sources influencing these IL-1 activities remain unknown.Our research centers on the proinflammatory cytokine IL-1β within the central nervous system, using an innovative IL-1BTRAP mouse model. We seek to unveil if IL-1β expression across multiple brain regions differs during key transitions from wakefulness to sleep. Previous work in our lab unveiled high IL-1R1 and IL-1β expression in the choroid plexus (CP) and others suggest a correlation between IL-1 expression and light cycles, prompting our hypothesis of diurnal IL-1 fluctuations within the CP, potentially linked to sleep patterns.Our aim is to explore IL-1β expression in various brain regions during wakefulness-to-sleep transitions, elucidating possible connections between IL-1β levels and daily sleep patterns. This investigation, delving into the CP's role in sleep—a relatively unexplored domain—aims to contribute fresh insights. Our anticipated findings could pave the way for comprehending how immune signaling from ventricular sources influences broader brain function.

Abstract Name: Higher neighborhood deprivation is associated with higher symptom severity and distress among survivors of multiple primary cancers

Introduction: Three-fourths of cancer survivors develop a subsequent, or multiple, primary cancer diagnoses (MPC). While long-term effects of cancer and cancer treatment are increasingly recognized, gaps remain about social determinants of health (SDoH) and symptom experience among MPC survivors. We aimed to explore relationships between neighborhood deprivation and symptoms in a sample of MPC survivors. Methods: Secondary analysis of a cross-sectional study of adults who were diagnosed in the prior 10 years with 2+ primary cancer diagnoses, the first being a commonly survived cancer diagnosis and stages I-III at first and second cancer diagnoses. Area Deprivation Index (ADI), a composite measure of income, education,

employment, and housing quality domains, determined neighborhood deprivation (0-100, higher=worse). The MD Anderson Symptom Inventory (MDASI; 0-10, higher=worse) assessed symptom severity (13 symptoms), burden (top five rated symptoms), and distress/interference. Self-report, medical record, and cancer registry data characterized sociodemographic and clinical variables. Spearman's rank-order correlations summarized associations between neighborhood deprivation and symptoms. Results: The median (IQR) participant age was 72 (65-77) years. Most were female (62.4%), white (90.4%), and retired (64.2%), with high school or less education (45.5%). 78% were overweight (n=48) or obese (n=48). 37.4% endorsed some or extreme difficulty paying for basic needs. Median neighborhood deprivation was 67.2 (20.2, 22-100). Median symptom scores were: severity=1.1 (0.4-2.5); burden=1.6 (0.4-3.4); and distress/interference=0.5 (0-2.4). The top-rated symptom was fatigue (median=2 (0-5), range: 0-10). Weak positive associations existed between neighborhood deprivation and symptom severity and burden (r=.210 and .219, p=.02). Discussion: Neighborhood deprivation was above national norms. Symptom scores were low but variable. Higher neighborhood deprivation correlated with higher symptom severity and burden. Clinicians should assess symptoms and SDoH among MPC survivors. Larger, longitudinal symptom studies should determine symptom patterns and related neighborhood factors among MPC survivors.

Abstract Name: The Preservation of Entanglement due to Correlated Environments using Quantum Trajectories

Many proposed applications in the field of Quantum Information Science, such as quantum computing, quantum communication, and quantum cryptography, depend largely on our ability to harness and control entangled quantum particles, known as quantum bits or "qubits". One major drawback, however, is the decay, and in some cases sudden death, of entanglement due to the qubits' interaction with their local noisy environments and our inability to counteract this persistent trend. In prior work, it has been shown analytically via solution to the master equation that for Markov environments (modeled as white Gaussian noise), introducing a statistical correlation between the noise environments can diminish the decay of entanglement through time and for certain initial states, it can be fully preserved. We now aim to expand the model into the Non-Markovian noise regime to understand how different types of correlated noise can preserve the evolution of entanglement.By deriving the exact non-Markovian quantum state diffusion equation for two qubits in the presence of correlated noise, we will employ the quantum trajectory technique to allow us to numerically solve for a large set of quantum state unravelings. This will allow us to gain a deeper insight into the inner workings that lead to the preservation of entanglement in the Markov case and allow us to seamlessly evolve the ideology into the non-Markovian case. By comparing various initial states and various levels of correlation between the noise environments we will present our findings on what conditions are most beneficial for preserving two-qubit entanglement.

Abstract Name: Nutrivigilance and Regulatory Challenges in Monitoring Nutraceutical Safety: A Comparative Evaluation of the United States and Europe

Nutrivigilance, a burgeoning field dedicated to the detection, assessment, understanding, and prevention of adverse effects associated with the consumption of food, dietary supplements, and medical foods, is gaining prominence amid the proliferation of nutraceutical products. This presentation conducts a comparative analysis of the nutrivigilance landscape in the United States (US) and Europe, navigating through the regulatory challenges and opportunities.The interchangeable use of "nutrivigilance" and "nutravigilance" highlights regional spelling variations, with both terms converging on the same concept. The escalating market of nutraceuticals, claiming diverse health benefits, underscores the imperative for a robust nutrivigilance system. In the US, the Food and Drug Administration (FDA) assumes a post-market oversight role for dietary supplements, lacking pre-market approval authority. Europe also grapples with regulatory complexities, as individual countries operate distinct surveillance systems. The absence of a unified nutrivigilance framework within the European Union facilitates the free movement of dietary supplements, potentially compromising consumer safety. This paper delves into the exigency, impediments, and prospects for fortifying nutrivigilance in both regions. The presentation posits that despite recent regulatory initiatives to enhance nutrivigilance, dependence on voluntary reporting by manufacturers introduces inherent conflicts of interest. Establishing an effective nutrivigilance system mandates dedicated national surveillance, heightened consumer awareness, and proactive reporting from healthcare providers and patients.In conclusion, the presentation underscores the pivotal role of integrating pharmacovigilance principles into health programs, advocating collaboration among academic institutions, policymakers, and companies to elevate public awareness and ensure the judicious and secure use of nutraceuticals. Addressing regulatory gaps in both the US and Europe is imperative for advancing nutrivigilance and upholding public health amid the evolving landscape of dietary supplements and functional foods.

Abstract Name: Transforming Learning Environments: The Synergy of Reggio Emilia Philosophy and Interior Design for Multilingual Youth

The fusion of education and interior design holds great promise in shaping transformative learning experiences for multilingual youth. This study delves into the seamless integration of the Reggio Emilia philosophy within the architectural and interior design aspects of educational spaces tailored for K-5 students, with a specific focus on those learning English as a second language. Reggio Emilia's child-centric approach synergizes harmoniously with design principles, fostering increased engagement, language proficiency, and cross-cultural exchange. This research endeavor aims to uncover the myriad benefits that Reggio Emilia-inspired spaces offer, including enhanced communication skills, heightened motivation, and a more profound cross-cultural awareness. This will be achieved through a comparative analysis of these innovative spaces against traditional learning environments. The insights gleaned from this investigation will contribute to the establishment of best practices for the development of culturally inclusive learning environments, effectively bridging the realms of the Reggio Emilia philosophy and interior design innovation. Ultimately, the conclusions drawn from this research will serve as a vital foundation for informed design solutions tailored to educational spaces, particularly those catering to young learners of English. The findings of this study will

advocate for adaptable, engaging, and holistic Reggio Emilia-inspired spaces that foster language acquisition and creativity among the diverse and dynamic population of multilingual youth.

Abstract Name: Developmental changes in neonatal Fc receptor (FcRn) expression in thymic antigen presenting cells.

Immature T lymphocytes develop in the thymus, where they are screened for functionality and self-reactivity. The resulting T cells emigrate to peripheral tissues in the gastrointestinal tract, where they aid in discerning between harmful or commensal antigens. Dysregulation of this mechanism can lead to sustained inflammation against commensals, as in Crohn's Disease. The Diehl Lab recently showed that colonization of mice at weaning with epithelial-adherent E.coli leads to its trafficking to the thymus, specifically by dendritic cells (DCs) expressing CX3CR1. This mechanism does not appear to function in adult mice, suggesting that it may have a role in the development of the mucosal immune system. The environmental factors in the early life gut that promote this thymus trafficking remain to be defined. The neonatal Fc receptor (FcRn) is an IgG receptor that can bind to IgG-bound commensal bacteria and promotes antigen sampling by DCs in the early-life intestine. This project focuses on how changes in FcRn expression in antigen presenting cells over developmental periods can affect the trafficking of microbes in early life. First, immunofluorescent staining of the thymus from young and adult mice was optimized to visualize and quantify FcRn expression. We show a slight, non-significant decrease in the average number of FcRn+ cells in the adult mice. Additionally, flow cytometry is used to analyze intracellular FcRn expression in CX3CR1+ DCs in the thymus and intestine of young and adult mice. In the thymus, FcRn was shown to have a higher expression in young mice, with a statistically significant drastic change from two weeks to three weeks. However, this intensity was similar in all age groups in the large intestine. Altogether, our data suggests that thymic migratory DCs have a higher expression of FcRn in early life. How this impacts thymocyte development to commensal microbes remains to be seen.

Abstract Name: Parental Anxiety and Perceptions of Pain Medication Administration

All children will at some point experience acute pain, making deciding whether to administer pain medication to children a common responsibility of parents. The opioid crisis brought attention to the dangers of the misuse of narcotic pain medication and created misconceptions endorsed by parents regarding the analgesic treatment of children's pain. Previous research that analyzed a dataset collected between 2007 to 2009 investigated how parents perceived analgesic administration to treat their children's pain found that parents were uncertain of the safety of analgesics. There is a lack of guidelines from the CDC instructing parents on when to administer opioids to treat children's chronic pain. Past studies have reported that parents lack knowledge of analgesics and their side effects. Certain personal characteristics of the parent may play a role in their analgesic administration decision-making. Parental anxiety and the potential impact it could have on their perception of the administration of analgesics to treat their children's pain has not been extensively studied. Our current research will determine the relationship between parental anxiety and their comfortability administering analgesics as well as any misconceptions and beliefs they may endorse regarding analgesics. Participants were recruited by students enrolled in an advanced psychology laboratory class. Those parents included in the study completed a survey that was distributed in the summer and fall of 2021. It is hypothesized that parents with higher anxiety scores on a PROMIS anxiety questionnaire will be less comfortable administering analgesics for the treatment of their child's pain and will endorse more misconceptions about analgesics. The results of this study will provide insight to the medical community on how to educate parents on analgesic administration to their children and bring awareness to the impact parental anxiety may have on children's healthcare, allowing for improvements to be made in the management of pediatric pain.

Abstract Name: "Chip Kidd" The Enthusiastic Book Designer!

Chip Kidd is very passionate about his career and wants to teach and share his knowledge with other people, especially those who are interested in graphic design. Chip Kidd, who is the world's most renowned for designing book covers, grew up in Reading, Pennsylvania, and went to school at Pennsylvania State University. He graduated with a Graphic Design degree and moved to New York to pursue his dreams. He has been designing book covers for over 26 years and he has loved every second of it, designing for the biggest names and companies, he has shown no sign of slowing down, he always keeps going, always thinking and planning his next big thing. Talking about his life's work, personal life, and his books is a pleasure but only scratches the surface of how wonderful this person is. Throughout his career, he initially focused on graphic design and book cover design, but soon expanded to author and editor and he has written graphic novels, as well. Arguably his most recognizable work is the Jurassic Park (1990) logo, originally the cover for the book by Michael Crichton. But he has done more amazing work designing for DC Comics. His portfolio is diverse with lots of different cover designs. Talking and referring to his work from his portfolio and mentioning his childhood, and his novels are a great way to get to know him. He has a passion for the field of Graphic Design and he's also a nerd. I would call him an enthusiastic person!

Abstract Name: Operation brainstorm: developing molecular biomarkers to detect the pathology of cerebral malaria in wild birds

Cerebral malaria, the most severe and fatal form of malaria, is grossly understudied in avian models. Due to a lack of effective non-lethal methods, diagnosing cerebral malaria currently requires finding malaria parasites in brain tissue post-mortem. The ever-present threat of malaria to avian biodiversity and the risk of spillover from wild to captive birds makes it essential to diagnose cerebral malaria in living birds as a first step before treatment. We conducted the first investigation of avian cerebral malaria pathology using qPCR to identify a potentially non-lethal biomarker of the disease in wild birds. Using cerebral tissue from wild-caught house sparrows (Passer domesticus) experimentally inoculated with Plasmodium relictum, we correlated cerebral inflammatory cytokine expression (a hallmark of cerebral malaria) with cerebral parasite load. We predicted that the ratio of pro-inflammatory cytokine expression to anti-inflammatory cytokine expression would be higher in birds with cerebral malaria than in birds with simple malaria, and that this would positively correlate with cerebral parasite load in brain tissue. Future work will correlate cerebral cytokine expression with cytokine expression in whole blood to assess whether qPCR could potentially be used as a non-lethal diagnostic tool to detect cerebral malaria infections in wild birds.

Abstract Name: Avast Ye! Exploring Women’s Roles During the Golden Age of Piracy and Their Legacy Today.

The Golden Age of Piracy (~1650s-1730s) is often recollected and depicted as a time of seafaring buccaneering escapades. Men navigating the sea with their fleets in search of treasure and adventure. Despite this, a severe lack of female representation exists within the recounting and general history of piracy. Their impact on the swashbuckling lifestyle as a whole, specifically during the Golden Age, is incessantly disregarded. This research seeks to uncover the reasons why the stories of female pirates go untold and how sexism influences the lens through which we view women’s roles in Piracy then and now. By highlighting the lives of Women pirates and analyzing historical data such as Captain Charles Johnson’s firsthand account A General History of Pyrates written in 1724, this research hopes to answer the following question: How did women contribute during the Golden Age of Piracy and how does their legacy continue today? The analysis will discover the complex lives that women had during the era by studying secondary roles, such as smugglers and prostitutes, to primary roles, such as Captains and crewmembers, as well as reviewing the depictions of female pirates starting from the 1800s with the rise of Pirate literature to the modern era with film and TV. By uncovering the reasons in which female piracy is erased from history and the sexist depictions of them, the researcher endeavors in emphasizing the importance of women's roles in history across all fields of study. In doing so, this research will educate those unaware of the lives of women pirates and affirm the relevance of discussing female representation within the context of academia.

Abstract Name: The Acute Effects of Blood Flow Restrictive Bicep Curl Exercise on Arterial Stiffness- Pilot Study

The purpose of this study was to investigate the effects of autoregulated (AR) and non-autoregulated (NAR) BFR biceps curl exercise on arterial stiffness. AR BFR cuffs adjust pressure as the muscle undergoes concentric and eccentric contractions, maintaining a constant pressure in the limb throughout the entire range of motion, however, NAR BFR training cuffs do not. How this exercise acutely impacts arterial stiffness is not well understood. METHODS: 22 adults (21±2 years; 9 female) participated in 3 randomized sessions with AR-BFR, NAR-BFR, and no-BFR (no cuffs) separated by 1-week washout periods. Using 20% of the 1 repetition maximum (1-RM) with 2-second concentric/eccentric cadence, participants performed 4 sets of biceps curls to failure. Training limb occlusion pressure (LOP) was set at 60% of supine LOP for both BFR sessions using the Delfi Personalized Tourniquet Device. Measurements before and immediately following the training session included blood pressure acquisition, arterial tonometry, and ultrasonography of the carotid artery. Between and within effects of treatment on central systolic blood pressure (cSBP), central diastolic BP (cDBP), central pulse pressure (cPP), central mean arterial pressure (cMAP), pulse wave velocity (PWV), beta-stiffness index (β-stiff), and arterial compliance (AC) were analyzed with two-way ANOVAs. RESULTS: There were no baseline differences in cSBP, cDBP, cPP, cMAP, cf- (carotid-femoral) PWV, cr- (carotid-radial) PWV, β-stiff, and AC (all p > 0.05). cfPWV did not change in the AR-BFR group (p > 0.05), while it increased in the NAR-BFR (mean difference = 0.6±1.3 m/s, p = 0.04). And there was an interaction effect in β-stiff between AR-BFR and no-BFR (mean difference = 0.9±1.5 U, p < 0.05). CONCLUSION: The present findings show acute AR-BFR training did not impact arterial stiffness while acute NAR-BFR and no-BFR training appears to increase central stiffness.

Abstract Name: Mothering in the Patriarchy: Defining and Constructing Motherhood for African Decedent Women

African descendant women have continuously been subjected to patriarchal definitions and standards placed upon motherhood and womanhood, which serve to perpetuate their subjection and suppression in the societies that they exist in. Centering the lived experiences of African descendant women through literature, such as Doreen Baingana’s Tropical Fish and Toni Morrison’s Sula, allows for the dismantling of these strict and harmful definitions. These novels, as well as others, are written by and for African descendant mothers

and daughters and expose their realities and exemplify how they have continuously fought in innovative ways to overcome the oppression they face for existing in spaces where they are not valued as individuals. These works of literature are examples of women's self-expression and showcase how patriarchal standards affect how they are perceived in society and, conversely, how they view themselves as individual women and mothers. They also approach motherhood and womanhood as an experience, rather than an institution, and bring about themes of coming into one's sexuality and the common inability to communicate with one's mother. Through literary analysis, this paper uses Clenora Hudson-Weems' theory of Africana Womanism to examine how African descendant women's search for agency and self-representation is reflected in select novels by African descendant women, which allows them to develop new definitions of their own experiences as women living in male-dominated and colonized societies.

Abstract Name: Lasting Legacies: Franklin College 'Spirit of Community'

This project encompasses several aspects of the history of a small liberal arts college in Indiana. Founded in 1834 in Franklin, Indiana, Franklin College houses significant archival collections and continues to preserve its rich history. Our research produced nine online collections on impactful alumni and community partners and was the foundation for an online digital story about FC's significant history of collegiate sports, hosted by the Indiana Historical Society. With the support of a Council of Independent Colleges Humanities Research for the Public Good grant, this research examined the impact Franklin alumni have made in their communities and how Franklin incubated their success. Under the mentorship of a history professor and our library director/archivist, we amassed sources and followed leads to determine whose stories to collect, preserve, and make broadly accessible. In addition to constructing this online digital repository, a Community-Engaged Alliance grant supported the collection of oral histories that expanded and diversified the holdings of the Franklin College library and the Johnson County Museum of History. These oral histories include: Robert "Chip" Harrod '70, Cincinnati lawyer, social rights activist, and founder of the National Underground Railroad Freedom Center; Judi Warren, Indiana's First Miss Basketball and Title IX advocate; and Pastor Douglas Gray, Black engineer and community leader. This "Lasting Legacies" collection includes primary sources such as college photos, newspaper articles, official college documents, and the transcriptions and audio files of the oral histories. The culmination of these efforts to collect, catalog, and disseminate campus and community histories provided unique undergraduate research opportunities that themselves provide a lasting legacy and create avenues for future projects. Preserving more complete campus histories—including stories of individuals who made significant contributions to campus, the community and beyond—serves the institutional mission and provides greater resources to campus partners and the broader public.

Abstract Name: The American Woman Suffrage Movement on College Campuses in Indiana

The American woman suffrage movement began in New York in 1848 and quickly became one of the most prominent nationwide debates until women were finally given the right to vote with the ratification of the 19th amendment in 1920. Historians such as Anita Morgan, author of "We are Fearless: The American Woman Suffrage Movement in Indiana" and Kelly Marino with her research on the College Equal Suffrage League have studied the suffrage movement in regard to Indiana and universities, but Morgan omits college women, while Marino omits the Midwest in general. This history capstone project focuses on filling the gap in the historiography and finding the impact of the American woman suffrage movement on college campuses in Indiana. Centered on Indiana State University (previously the Indiana State Normal School) and Purdue University, this analysis of 50+ years of primary sources establishes how the movement affected collegiate women and men through campus suffrage organizations, articles, art, and debates. At Indiana State University, a branch of the Equal Suffrage League was established in 1912, detailed in the campus journal, The Normal Advance. It was dedicated to education, expanding the movement beyond the university, and boasted over 200 members. At Purdue University, women's suffrage was discussed as early as 1883 and the Purdue Girls' Franchise League's was established in 1917, outlined in the student newspaper, The Purdue Exponent. This organization also focused on education and preparing women for when they received the ballot. The suffrage movement expanded college women's views and allowed them to explore ideas related to their identity that they never would have been exposed to at home. The real importance of the suffrage movement on college campuses in Indiana was to create an environment that educated women as well as incubated the next generation of women's rights activists.

Abstract Name: An Analysis of Interwar German Politics

Recent discussions about the rise of the Nazis and how subversive political movements lead to the fall of democracies have largely focused on the Nazis themselves and not their political opposition. Although opposition parties were major actors in the events that led to the rise of the Nazis, we most often view events like these from the perspective of those who are subverting democracy, or the average person who goes along with the subversion. Instead of this perspective, I sought to understand why the other parties seemed helpless to stop the rise of the Nazis and what role they had to play in the fall of the Weimar Republic. I thus analyzed what strategies each political party employed in their pursuits to secure power and what effects these varying strategies had. To do this, I gathered primary documents from the era and coded them for different political strategies and their outcomes, primarily based on election results. My analysis of these documents seems to indicate there was a widespread perception that the mainstream parties were incapable of dealing with the many economic crises of the day. This, combined with their general unwillingness to cooperate with other political parties, led to the erosion of trust in the government and the mainstream political parties. Additionally, it caused a rise in radicalism, particularly during said economic crises. Just as we are not immune to radical politics in the modern day, we are perhaps even less secure against economic crisis, and recognizing the linkages between these two factors and a government's ability to affect them is vital in ensuring the continued survival of any given democracy, even in the modern day.

Abstract Name: Impact of Average Daily Rate on Hotel Cleanliness in Game Theory

Cleanliness is directly linked to the average daily rate (ADR) of a hotel, since it has a significant influence on guests' choice of accommodation and how much they are willing to pay for it. The core competency of the hospitality industry is often attributed to room cleanliness due to its substantial impact on maintaning a competitive advantage. A hotel manager can use key performance indices to indicate whether to adjust room rates to maximize revenue. However, the manager does not know what to do next after the competitor's response. The present study has used game theory with the purpose to eximine the effect of average daily rate on cleanliness. Game theory strategies were conducted to forecast the outcomes of the relashionship between Average Daily Rate and cleanliness in the hotel business. There are two matrices for two players. Each player's matrix comprises two rows and two columns, representing either an increase or a decrease in average daily rate percent change. In these matrix tables, one player is referred to as "Suburban," while the opposing player is known as "Resort." The results pertaining to the growth of cleanliness are reported in the four quadrants of the matrix. The matrices of two players showed that the levels of cleanliness of the two players significantly changed when there were an increase/decrease of ADR. A win-win game is designed in the Nash equilibrium where both players can profit in a variety of ways. There was a Nash equilibrium in the peak season where both players receive highest payoff. There was a Nash equilibrium in the low season where both players receive the highest payoff. The use of these matrix tables assists hotel managers in gaining a clearer understanding of the strategies.

Abstract Name: Enhancing Play with EMG: Investigating Usability and Engagement in a Serious Video Game

Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disease that induces a loss of functionality and independent mobility, requiring reliance on assistive devices such as powered wheelchairs. Most powered

wheelchairs use a joystick, an inoperable interface for many patients. Past studies by this research team have examined the efficacy of surface electromyography (EMG) systems on the temporalis muscle as an alternative control modality, producing movement outputs based on varied flexion strengths. Although independent wheelchair control was demonstrated in the scope of the testing, learning to use the system proved complex. A serious game was developed to prioritize low-stress training, incorporating identical electromyographically-controlled character steering for task-specific training. Eye-tracking UI selections are also integrated to maintain autonomous interaction with the game. To evaluate the game's efficacy, a "talk-aloud" usability study was designed for 15 participants between the ages of 18 and 64 with complete motor control. This study requires vocalized feedback while playing through four unique game levels using EMG leads placed on the preferred temporalis laterality. Participants were split into three cohorts: eye tracking, mouse control by the participant, and mouse control by the researcher. The data has been collected and analysis is being conducted. In addition to the talk-aloud narration, quantitative surveys, including the Game User Experience Satisfaction Scale (GUESS) and the System Usability Scale (SUS), were conducted. Analysis of the fifteen participants' GUESS scores demonstrated overall positive perceptions of every category aside from Social Connectivity. Additionally, the mean SUS score was 62.5, indicating the usability as "OK." Quantitative investigation revealed some usability issues, which will be combined with qualitative evaluations to inform additional changes and improvements that will be refined prior to the completion of a follow-on usability study.

Abstract Name: Break Free from the Past: Mindfulness as a Path to Regret Resolution

Markman and Miller (2006) found that regret leads to anxiety, depression, and cognitive distortions. Regretful decisions and actions from the past can create persistent thoughts of how things could have gone differently in the form of "Counterfactual Thinking." (Olatunji et. Al., 2013). However, if we can find ways to lessen persistent regrets, there is an opportunity to transform them into valuable lessons that can guide better choices moving forward. (Seta & Seta, 2013; Seta et. Al., 2008).Research indicates that mindfulness meditation helps diminish relentless negative thinking patterns (Blanke et. al., 2020). Additionally, if we can cultivate an internal landscape of self-compassion and non-judgment, regret can shift from punitive rumination to become a growth opportunity that reinforces our commitment to increased wisdom (Valshtein & Seta, 2019).Participants completed pre and post self-report ratings using a 7-point Likert type scale indicating the amount of regret, sadness, and responsibility they felt regarding their recollection. Additionally, participants filled out the short version of the 12 item 5-Facet Scale and 12 item Self-Compassion Scale before and after the mindfulness meditation sessions. Upon arrival to the lab, participants were asked to recall a regretful experience. After reflecting on the experience, participants completed self-reported ratings. Participants then practiced a guided meditation and completed the post-emotional measures. Participants were provided with an audio recording of a guided meditation to practice at home a minimum of twice per week. At the end of the week the participants were interviewed via phone, where they were debriefed and thanked for their participation.In this study we investigated techniques of mindful awareness to evaluate their efficacy in helping people achieve closure from lingering regrets. We explored how regretful experiences, when called upon for reflection during meditation, might lead to a shift and reorientation of the regret on cognitive and emotional levels.

Abstract Name: Ann Richards Rise to Governor to Texas

Ann Richards, the first female governor elected whose husband had not also been governor, fought the political establishment in Texas eventually becoming governor. She advanced politically by first volunteering in important campaigns and then running for office herself. Enroute to becoming governor, she was heavily involved in campaigns such as Henry B. Gonzales. Next, she won election for county commissioner in Travis County (Austin area), and then State Treasurer. Throughout these efforts, she showed her witty character and determination to change Texas. Albeit during this time she persevered while facing alcoholism and the breaking of her marriage with David Richards. Her most famous speech lifted the Democratic spirit while delivering good jokes about the opposing party at the 1988 Democratic National Convention. Richards used that event as a springboard to win the 1990 gubernatorial race against two better known and well-funded primary candidates, former governor Mark White and Attorney General Jim Mattox. She then surprised the nation by beating Republican businessman Clayton Williams. This paper is based on primary sources such as newspapers, television recordings, and Richards' autobiography, Straight from the Heart. In addition, the work is grounded in secondary sources of both Womens' history and Texas politics such as Shropshire and Schaefer' The Thorny Rose of Texas and the Handbook of Texas.

Abstract Name: Voting Rights and Federalism: Understanding the California Voting Rights Act

While Latino and minority populations in California continue to grow, their representation in elected government positions fails to reflect this growth. The disconnect between the two signifies the urgency and importance of having conversations regarding apportionment and equal representation among these communities. Since the passing of the California Voting Rights Act in 2002, over 88 cities have been mandated to change their at-large elections to district elections; in hopes of extending minority groups' protection from voter dilution. The CVRA was created to expand voting rights protections provided under the Federal Voting Rights Act by altering existing forms of electoral systems to enhance the voting power of minority voters in local elections. Per CVRA advocates, at-large elections have historically reflected racially polarized voting that has prioritized the preferences of the white majority and left non-white minority voters at a systematic disadvantage. While cities continue to be under intense scrutiny and litigation threats for failure to change their electoral systems, debates as to whether such a change makes a significant difference in increasing minority voter turnout and representation at the local level concur equally. This research project aims to uncover and fill in the gap in knowledge regarding the relationship between the switch from at-large

elections to district elections and their effect on Latinx voters and representation. Using a quasi-experimental design to observe levels of Latinx representation before and after changes from at-large elections to district elections, I determined that district elections have demonstrated that the CVRA has increased Latinx political representation.

Abstract Name: Voting Rights and Federalism: Understanding the California Voting Rights Act

While Latino and minority populations in California continue to grow, their representation in elected government positions fails to reflect this growth. The disconnect between the two signifies the urgency and importance of having conversations regarding apportionment and equal representation among these communities. Since the passing of the California Voting Rights Act in 2002, over 88 cities across the state have been mandated under law to change their at-large elections to single-member district elections; in hopes of extending minority groups' protection from voter dilution while simultaneously increasing their voter turnout. The CVRA was created with the intent to expand voting rights protections provided under the Federal Voting Rights Act by altering existing forms of electoral systems to enhance the voting power of minority voters in local government elections. Per CVRA advocates, at large elections have historically reflected racially polarized voting that has prioritized the preferences of the white majority and left non-white minority voters at a systematic disadvantage. While cities continue to be placed under intense scrutiny and litigation threats for failure to change their electoral systems, debates as to whether such a change makes a significant difference in increasing minority voter turnout and representation at the local level concur equally. This research project aims to uncover and fill in the gap in knowledge regarding the relationship between the switch from at-large elections to district elections and their effect on minority voters and representation.

Abstract Name: Flexximeter: A Flexible Inclusive Pulse Oximeter using Discrete Devices

The surge in wearable electronics stems from users seeking easy access to features once exclusive to phones and computers. Health monitoring and biometric data, in demand from companies like Apple, Garmin, and Fitbit, drive the market's projected growth to $99.06 billion by 2030. This growth fuels technological innovation, with the Photoplethysmography (PPG) sensor emerging as a pivotal hardware component in wearables. Despite its utility, many challenges exist in extracting accurate information from PPG sensors.

Our research introduces “Flexximeter,” a novel flexible electronic wearable that addresses the common challenges in photoplethysmography (PPG) sensors, such as skin pigmentation variation and environmental factors. The proposed system is implemented using a high-precision (60 μV) low-noise op-amp-based Programmable Gain Transimpedance Amplifier equipped with a dynamic feedback system. This innovative, affordable, and flexible device ensures accurate blood oxygen measurements, overcoming limitations due to skin pigmentation, ambient light, and temperature variations. This research will first discuss measurements and errors from the off-the-shelf measurement system (AFE4490 Integrated Analog Front End for Pulse Oximeters Evaluation Module). The design and Implementation of the Flexximeter will be described using a Voltera V-One PCB Printer on flexible Polyonics XF102 Polyimide Sheets. The device's accuracy and reliability are compared with the off-the-shelf measurement system.

Abstract Name: Tolerances of Retinas in Different Turtle Species to Changes in Temperatures

As global temperatures increase, species must learn to adapt or otherwise become extinct.Turtles are no exception. Their vision, and how it adapts to changing temperatures, is especiallyimportant for their survival because vision allows organisms to identify prey, predators, andpotential mates. The purpose of this study is to examine two different species: red-eared sliderturtles (Trachemys scripta), which are invasive and has a higher optimal temperature range, andeastern painted turtles (Chrysemys picta picta), which are non-invasive and have a lower optimal temperature range. This was done by first harvesting retinas from each of the eyes and loading cells with Fluo-4 dye, which fluoresces green in response to levels of calcium. The retinas were imaged by a Zeiss LSM 800 confocal microscope and glutamate was added. This was done under three temperatures: 15°C, 25.5°C, and 32°C. Changes in fluorescence were recorded, graphed, and compared for significant differences with regard to species and temperatures. Applications of glutamate to retinal ganglion cells generated significant changes in both species of turtles for all of the temperatures tested. This was observed for whole data sets and spikes. However, it was observed that maximum changes for eastern painted turtles at 15 °C was significantly higher than their changes at 32 °C. In contrast, red-eared slider turtles had the same activities for all temperatures. The difference between responses for the species suggests that red-eared slider turtles have a wider functional range for warmer temperatures. This tolerance could support the success of red-eared slider turtles as an invasive species.

Abstract Name: Young women's perspectives on social services in the slums of Kampala, Uganda: qualitative focus group findings from the TOPOWA study

Slum dwelling youth in Sub-Saharan Africa (SSA) experience significant social vulnerabilities and health disparities, and young women in these contexts are disproportionately impacted. At the same time, communities in SSA do have existing resources which provide some amelioration of the difficult circumstances faced by these young women. This research project, based on an ongoing NIH R01, explores young women's perspectives on the social services they are receiving from a local organization. Using a combination of inductive and deductive thematic methods, we analyzed baseline focus group data from a community-based cohort study (6 groups, 60 participants).We found a variety of themes related to the benefits of these services, as well as some themes related to service-related challenges. Benefits included: increased economic autonomy; increased confidence, motivation, and self-reliance; increased optimism, pride, and satisfaction; increased social connection; improved social standing; and improved stress management. Challenges included: negative community perceptions of the social service organization; other program participants as sources of stress; and challenges being on time to training, traveling to training, or balancing training with other responsibilities.Young women in SSA are an underserved, understudied population, and their perspectives on social services are not frequently reported in the scientific literature. Our work begins, therefore, to fill a research gap by providing insight into the emic perspectives of these key stakeholders. Despite some challenges, overall, the young women reported significant benefits of training, with improvements in confidence, social standing, and economic success in response to their training experiences. These findings should prompt future research on how to build on the successes of existing programs and address the challenges that these young women report.

Abstract Name: Chip-firing Stability within the Unknown Stability Interval

The chip-firing game is a well-studied dynamic system with simple rules leading to complex behavior. It is particularly important in studying networks of self-governed objects with no influence from outside agents: neurons, avalanches, circulation of currency, and other entities able to be represented by a graph having vertices weighted by values. In a network given n chips with e number of edges and v number of vertices, stability is guaranteed if n < e, and unstable behavior is guaranteed when n > 2e − v, leaving an interval with graphs' stability ungoverned by these theorems. In our research, we examined stability for particular graph configurations within the unknown stability interval to find a relationship between stability and number of chips. A relationship is found for cycles and complete graphs, and our exploration of three-regular graphs has led to generalized theorems for graphs in the unknown stability interval. This work was funded by the CC-REU NSF REU grant (DMS-2050692).

Abstract Name: On the Essence of Thought Experiments: A Neo-Aristotelian and Phenomenological Approach

Thought experiments feature prominently in both scientific and philosophical method. In this paper, I investigate two questions surrounding knowledge in the thought experiment process. The first I call the metaphysical question: Given that thought experiments are often thought to rely on implicit background knowledge within the subject, what is this knowledge of or about? The second I call the justification question: Because thought experiments are ideally intended to yield knowledge, and since knowledge is usually understood as requiring justification, what provides epistemic justification for beliefs acquired through the process? I draw upon neo-Aristotelian metaphysics and Husserlian phenomenology to respond. First, I answer the metaphysical question by proposing that the most important response is the subject's implicit knowledge of essence. Knowledge of essences not only allows the subject to mentally instantiate objects in imagination, but also serves to link the imagined possibilities involved in thought experiments to the actual world since essential truths are true necessarily. Second, I answer the justification question by arguing that if new beliefs acquired through the thought experiment process are in fact justified, they are given their prima facie justificatory force by the phenomenological character of the thought experiment quasi-experience. This phenomenological character includes the givenness of the presented thought experiment scenario with all its related objects, whose essences ground the possibility of frustration, which I argue is necessary for justification.

Abstract Name: Exoskeleton Response During Infant Physiological Knee Kinematics

Spina bifida is a type of neural tube defect that affects the nervous system and can lead to problems such as total leg paralysis. Treatment requires physical therapy and rehabilitation. Robotic exoskeletons have been used for rehabilitation to train muscle movement and assist in injury recovery; however, most studies focus on the adult populations. The proposed framework aims to couple a novel musculoskeletal infant model with a robotic exoskeleton using vacuum-powered artificial muscles to provide rehabilitation to infants affected by spina bifida. The study that drove the input values for the robotic exoskeleton used motion capture technology to collect data from the spontaneous kicking movement of a 2.4-month-old infant lying supine. OpenSim was used to develop the musculoskeletal model and Inverse kinematics was used to estimate hip joint angles. A total of 4 kicks (A, B, C, D) were selected and the selection was based on range, transient response, and stable response. Kicks had at least 5° of range of motion with a smooth transient response and a stable period. The robotic exoskeleton used a Vacuum-Powered Artificial Muscle (VPAM) the structure comprised of cells that were clipped in a collapsed state and unclipped when desired to simulate infant's age [1]. The artificial muscle works with vacuum pressure. When air is removed the muscle contracts and when air is added, the muscle relaxes. Bench testing was performed using a 6-month-old infant mannequin. The previously developed exoskeleton worked really well with controlled ranges of motion and frequencies which are typical of rehabilitation protocols for infants suffering with spina bifida. However, the random kicking motion contained high frequency kicks and was not able to accurately replicate all the investigated kicks. Kick 'A' had a greater error when compared to the other kicks. This study has the potential to advance the infant rehabilitation field.

Abstract Name: Effects of Roommate Compatibility on UCI Undergraduate Students' Average Hours of Sleep: A Pilot Cross-Sectional Survey

A lasting effect of the global pandemic in 2020 was a heightened awareness surrounding the chronic nature of mental disease as a result of mass reductions in physical activity and increased stress overall. While there are many novel treatments for stress, proper sleep hygiene plays an essential role in maintaining both good mental and physical health overall. The Centers for Disease Control and Prevention (CDC) recommends adults, eighteen to sixty years old, sleep seven or more hours within a twenty-four hour time period. Studies have shown that getting even two hours less sleep the CDC recommendation can lead to worsened bodily inflammation and academic performance equivalent to two days of sleep deprivation. In conducting a cross-sectional survey of UCI undergraduate students, a possible link between roommate compatibility and a student's average hours of sleep each night can be established, connecting sleep to a constant in many students' undergraduate experiences. This study, however, faces several limitations, including many confounding variables (housing arrangements, academic responsibilities, prior relationships with roommates, etc.), the limited sample size relative to the population, and the innate bias of surveys. While a larger scale followup study is required to address these shortcomings, the present goal is to draw attention to the multifaceted and highly affected nature of sleep, and to help students make conscious, informed decisions with good sleep hygiene in mind.

Abstract Name: Implementing a Deep Learning Model using U-Net for Mountain Glacier Segmentation

Modeling spatiotemporal glacier variations can help to understand climate change and its impacts on glacier retreat that affect water resources of people who depend on glacial runoff. Remote sensing is a feasible option to monitor glacier changes over time. With recent advances in machine learning, deep learning methods have shown promise for the segmentation of satellite images. The goal of this research is to use remote sensing for

the quantification of glacier changes due to climate change. To this end, the Landsat family of satellites and GLIMS (Global Land Ice Measurements from Space) database were used in this study to train a deep learning algorithm that was implemented using U-Net for the segmentation of glacier boundary. Landsat satellite imagery were processed using a geographic information system to create satellite composites of region of interest around Mt. Aoraki in New Zealand. GLIMS glacial outlines were used as ground truth for annotation. To augment the number of outlined boundaries, synthetic ground truths were generated. The Landsat scenes with available ground truths were then divided into patches of 256 x 256 pixels in the training phase, to reduce the computational cost. To accelerate the training phase, the model's weights were initialized using a pretrained VGG16 convolutional layers.The trained model was then used to segment Landsat scenes taken between 2000 and 2023. To evaluate the performance, segmented scenes were compared with the ground truth glacier boundaries while using the Jaccard index to quantify the accuracy of segmentation results. Achieving a promising performance with a Jaccard index of 0.8, the model could correctly separate ice from snow at a rate of 98%. However, the segmentation accuracy along the boundary of image patches is subpar and hence our future work is focused to improve the proposed technique to increase the accuracy at boundaries of image patches.

Abstract Name: Weather Whiplash in Global Mediterranean Climates

How do sudden shifts in extreme weather events due to climate change affect streamflow in global Mediterranean regions, and how do the regions compare to each other? Recent years have witnessed prolonged droughts succeeded by abrupt and intense floods in Mediterranean regions. California endured its most extensive recorded drought in 2022, followed by a wet year in 2023, alleviating the drought conditions. The Emilia-Romagna region in Italy faced substantial rainfall and devastating floods following a drought. Previous work has identified various Mediterranean regions in the world where weather whiplash in precipitation is persistent in future data. The primary objective of this research is to discern patterns in historical streamflow conditions, aiming to enhance our comprehension of these phenomena. This study compares all global Mediterranean regions based on the historical annual streamflow records from several stations in California, Italy, Australia, Chile, and South Africa. Comparative analyses of the durations, conditions, and frequencies of wet and dry periods offer insights into the similarities and disparities among these regions. The results underscore a historical trend wherein wet years were more prevalent until the 1980-2000s, after which dry periods increased in frequency and intensity. Despite similarities in the range of durations for both wet and dry periods across the five regions, each of the 20 evaluated stations exhibits variability in the magnitude of streamflow and the ratio of streamflow, as quantified by the indicator of whether the annual value was wet or dry divided by the mean annual streamflow. This research contributes to the evolving field of hydroclimatology in Mediterranean regions, emphasizing the critical role of understanding streamflow patterns in shaping future water supply dynamics. The implications of this study extend to water resources management, emphasizing the need for proactive measures to address the complex challenges posed by climate-induced hydrological variability in Mediterranean regions.

Abstract Name: Fear As A Barrier To Cervical Cancer Screening Amongst Black Women

IntroductionScreenings have reduced the incidence rates of cervical cancer. A Healthy People 2030 goal is to increase cervical cancer screening to 79.2% but current rates lag at 73.9%. Racial disparities in cervical cancer screening, morbidity, and mortality persist for non-Hispanic Black women. Reasons for these disparities are multi-factorial for this population including but not limited to racial discrimination, medical mistrust, limited knowledge and understanding of the healthcare system, lack of health insurance, and fear. This study aims to identify major barriers to cervical cancer screening and understand if fear affects Black women's decision to screen for cervix cancer.MethodsThirty-seven Black women over 21 were recruited from the community. All women completed a demographic survey and participated in one of six focus groups about their experiences with cervical cancer screening. The sessions were audio-recorded, transcribed verbatim and checked for accuracy by research staff prior to data analysis. Two qualitatively trained research staff analyzed data using content analysis for themes. ResultsThe participants' mean age was 33.67 ± 9.03. Participants expressed different types of fears associated with cervical screening including fear of the results, fear of the medical procedure used for screening, fear of embarrassment from screening, fear of hospitals, and the fear of death.ConclusionOur findings indicate that culturally tailored cervical cancer education is needed to promote screening among Black women. The process of screening should be explained in a manner that does not scare women but rather empowers them to take their health into their own hands and screen for cervical cancer. Screening should be explained as an early treatment intervention, not posed as a death sentence. There also needs to be more research conducted with larger sample sizes to verify if fear has a significant influence on Black women's decision to screen for cervical cancer.

Abstract Name: Women's Influence on Convenience Foods: Product Creation to Preparation

In 1950 Mason Haire published a study in the Journal of Marketing which asked focus groups to give descriptive words for a hypothetical woman based on two different shopping lists. The shopping lists were identical except for the inclusion of instant coffee on one list and traditional ground coffee on the other. The study revealed that people had harsh judgements for the hypothetical woman who used instant coffee. Just 20 years later in 1970 a replication of the study was published which revealed that people had far lower levels of judgment for the woman using instant coffee. Laura Shapiro is one of the biggest contributors to writing about convenience foods and women's role in their preparation. Specifically Something from the Oven: Reinventing Dinner in 1950s America addresses the process of presenting convenience foods in more elegant and altered fashions. The role that Betty Crocker played as a fictitious woman herself and the team of women, a large contribution to the literature on Betty Crocker comes from Susan Marks in her book Finding Betty Crocker. The advertising aspect is covered by Katherine J. Parkin in her book Food is Love: Advertising and Gender Roles in Modern America which addresses the emotional heartstrings that food advertisers pulled to influence women to buy their products. My work will contribute to the existing literature

on convenience foods and women's roles and agency in their increased social acceptance by addressing women's role in food production, food purchasing, and food preparation in a thematic chronological timeline during the twenty years from 1950-1970. I believe that it is important to view this process through the tracing of how women influenced the acceptance of these foods and were not merely passive adopters of change forced by corporations.

Abstract Name: Gods and Bases: U.S. Military Presence and Its Impacts on Japanese Spiritual Customs

Japan continues to be impacted by World War II, perhaps most clearly in the continued presence of U.S. military bases. Our historical research analyzes how the occupation of Japanese spaces by the U.S. military has impacted Japanese spiritual customs in these areas over time. We interviewed various Japanese groups to learn how bases affect spiritual practices, including the ability to visit ancestral tombs, and how traditions have changed since 1945. We also visited base towns to understand broader memories and feelings around the continued base presence.

Abstract Name: Evaluating the Fatigue Resistance of sustainable Modified Binder Blends

Fatigue resistance is the ability of an asphalt mixture to resist the repeated traffic load under the surrounding environmental conditions without being fractured. The performance grades (PG) obtained from the Dynamic Shear Rheometer (DSR), along with the G*sin( ) fatigue parameter, for the tested asphalt is only based on small strain rheology and do not consider the damage resistance. Accordingly, the Linear Amplitude Sweep (LAS) test is implemented to study the fatigue behavior of the tested asphalt binders considering the damage. This paper studies fatigue cracking resistance of various modified asphalt binders by comparing their different rheological properties. Based on this comparison, the most promising modified asphalt to resist fatigue cracking was specified. The samples tested in this research were sourced out from two main Egyptian asphalt binder sources. Each of which has six different eco-friendly additives, either waste and/or industrial

byproducts: crumb rubber (CR), Low-Density Polyethylene (LDPE), CR and LDPE, Fiber-elastomer commercial modifier (Viatop), Fly Ash (FA), and silica fumes (SF). Along with these six blends, an unmodified control blend of each binder source is considered, making it a total of fourteen blends. Geopolymerization of FA and SF was conducted to produce two different geopolymer modified asphalt blends. Based on the Viscoelastic Continuum Damage (VECD) analysis, the fatigue life criterion Nf, the number of load cycles to reach failure, from LAS analysis, was determined. Master curves are obtained from the DSR machine to determine the dependency of the time and temperature to further analyze the rheological behavior of tested asphalt binders. Results show that CR+LDPE, then CR modified asphalt blends are the most promising blends to resist fatigue cracking.

Abstract Name: Engaging Minds: Leveraging Asynchronous Learning with Books and Movies to Cultivate Enthusiasm for Neurology among College Students

BackgroundBy 2025, the number of neurologists in the United States is expected to decrease by 19% despite increasing demand for neurologic care. Early exposure to neurology encourages students interested in pursuing medical careers to consider neurology residency.ObjectiveWe explore asynchronous methods of introducing neurology education through books and movies to foster interest in neurology among college students.MethodsEight college students interested in clinical neurology and related fields developed a schema for selecting and evaluating books and movies for a neurology-related curriculum. Using a publication of popular neurology-related books for potential neurology book clubs and a systematic Google search for movies on stroke, migraine, Alzheimer’s disease, dementia, meningitis, and epilepsy, conditions with the highest global burden of disease among all neurological conditions, students generated a list of 5 books and 5 movies for possible inclusion into the curriculum. Students rated each book/movie on relevance to career and academic goals, informativeness, versatility, authenticity, positive impression, relevance to neurology/neuroscience (books only), and strong emphasis on disease/disorder/core topic (movies only) using a Likert scale from 1-5, with 1 being the lowest, and completed written reflections (N=96). A priori to analyses, students selected > 4.5 as a cutoff for inclusion into a curriculum.ResultsThe books Do No Harm: Stories of Life, Death, and Brain Surgery, The Man Who Mistook His Wife for a Hat, Being Mortal, and the Elective Books had grand means > 4.5. The movies My Beautiful Broken Brain, Out of my Head, Brain on Fire, Patch Adams, Still Alice, and I Never Thought to Ask: A Mom’s Quest for Answers had grand means > 4.5.ConclusionsFuture work will focus on implementing the books and movies into college neuroscience courses and clubs and creating a national book and movie club for students facilitated by neurologists.

Abstract Name: Islam and Me: A study on Muslim woman and Opression.

Since the beginning of Islam, women have had to suffer violations of their human rights. In Western countries, Muslims are denied the freedom to practice their religion whereas in Muslim countries, patriarchal interpretations of Islam have denied women equal civil rights. This paper researches the oppression of women in Islam in both Western and Muslim countries by studying different interpretations of the Quran, secondary scholarship on feminism and Islam, and conducting surveys and interviews with Muslim and non-Muslim peers. I do not deny that Muslim women are oppressed. But, as I argue, many observers have failed to understand the true sources of this oppression. Popular media tends to fixate on violations that occur in Muslim-majority countries, but as I argue, Muslim women also face oppression in “liberal” Western democracies, ironically, sometimes because of policies that are designed to “save” them. Muslim women are oppressed, but contrary to popular belief, this is not the fault of Islam; rather, I argue that the true and more fundamental source of the oppression stems from patriarchal interpretations of Islam both by Muslims and by Western liberal ideologies.

Abstract Name: Cracking the Code: Assessing the Communication Potential of Mammals with FACS and Python

Mammals can create various facial expressions by combining different facial muscle movements. Facial muscle movement combinations have been documented across species (using Facial Action Coding Systems, or FACS), along with the socio-ecological factors that result in interspecific differences. However, it is unclear whether the documented repertoires of each species represent their full communicative capabilities or only a fraction of them. The goal of our current project is to compile an inventory of all potential facial muscle movement combinations in mammals (such as dogs, cats, and non-human primates), utilizing FACS coding and Python programming. Facial Action Coding Systems (or FACS) were initially developed by Paul Ekman to dissect and catalog human facial expressions by decoding individual muscle movements, known as Action Units (AUs). In recent years, researchers have expanded upon the FACS to include the facial muscle movements of other species. Our current project uses FACS-coded data for chimpanzees, gibbons, and domesticated cats. Using Python programming, we are developing specialized algorithms to adhere to FACS guidelines and physiological constraints. This program generates all feasible combinations of AUs while respecting species-specific limitations, ensuring that biologically implausible combinations are excluded. The outcomes promise to unravel a deeper comprehension of the evolution of mammal facial communication, showing the details in signaling abilities and potentially revealing unexplored nuances in the expressive behavior of dogs, cats, and primates.

Abstract Name: Investigating the effect of UV light on skin microbe cell survival

There are well-recognized risks and side effects of excessive solar exposure with solar radiation itself being the top environmental risk factor for skin cancer. People are exposed to UV radiation nearly every day, whether from the sun or artificial sources like tanning beds and some types of lasers. Excess UV light is associated with skin aging and burning and furthermore, it can kill cells by inducing DNA damage that prevents the cells from replicating. In order to investigate the effects of UV light exposure on cell growth, this study will utilize common skin microbiota. The microbes on Staphylococcus aureus, Escherichia coli, and Staphylococcus epidermidis will be exposed to UV radiation. These cell lines will be plated and exposed to UV radiation at increasing lengths of time. To determine if UV radiation affects the cells' ability to grow, cell survival rates of cells without radiation exposure will then be compared with cell survival after exposure to UV light. Presented along with information about skin damage and sun protection strategies, this research hopes to promote community awareness of the dangers of excess UV exposure.

Abstract Name: Democratic Erosion in Uzbekistan: An In-depth Analysis of Historical Dynamics, Precursors, and Future Prospects

This case study, conducted by Leetavious Maines, delves into the complex landscape of democratic erosion in Uzbekistan. The study spans the period from the country's establishment as a republic with legislative, executive, and judicial branches to its contemporary political trajectory under President Mirziyoyev. The research combines historical analysis, international perspectives, and firsthand experiences hosting Uzbek students, providing a comprehensive exploration of Uzbekistan's political, economic, and cultural dimensions.The study identifies the challenges to democracy during the 2000-2001 period, highlighting President Islam Karimov's threat to democratic values under the guise of safeguarding national interests. The shift in Uzbekistan's liberal democracy score in 2018 and subsequent developments are examined, with a focus on human rights, democracy, and the authoritative approach of the country's leadership. The impact of the Russia-Ukraine War on Uzbekistan's democracy is considered, emphasizing the country's historical ties with Russia and the current conflict's implications.The historical context is explored, emphasizing Uzbekistan's journey from a Soviet Republic to a nation experiencing intense democracy erosion. The role of the Liberal Democratic Party, limited political pluralism, and the challenges faced during President Karimov's rule lay the foundation for understanding Uzbekistan's political dynamics. The study analyzes the symptoms of erosion, precursors rooted in weak institutional checks and mainstream power structures, and methods of resistance employed by civil society groups and human rights advocates.The analysis provides an in-depth examination of the direction of democratic erosion or autocratic consolidation in Uzbekistan, considering the

delicate balance between reform and control. President Mirziyoyev's initiatives, international relations, and economic liberalization are scrutinized, offering insights into the thawing autocracy in the country. The study concludes with a prediction for democratic progress, acknowledging positive steps while highlighting the need for continuous monitoring and international scrutiny.

Abstract Name: Factors that impact participation in Payment for Ecosystem Services programs in the Tar-Pamlico watershed of eastern North Carolina

Payment for ecosystem services (PES) programs are a recent policy approach designed to encourage the adoption of agricultural best management practices. These programs provide financial incentives to landowners who voluntarily adopt conservation practices. The decision of a farmer to participate in a PES program is primarily influenced by two factors: the specific attributes of the contract offered and the individual characteristics of the decision-maker. We examine the influence of both factors. We surveyed 197 farmers in the Tar-Pamlico watershed, presenting them with demographic questions and a choice experiment that involved two choices per respondent. Farmers were asked to choose between two hypothetical conservation programs for each choice. Respondents were also allowed to choose a status-quo option of neither conservation contract. For our experiment, contract attributes include limits on nitrogen (N) application, cover crop requirements, funding source, and payment per acre enrolled in the program. Decision-maker variables include the age, education, and experience of the land-operator, as well as farm income, land ownership, and previous participation in a conservation program. They also include the farmer’s threat appraisal (i.e., their perceived level of concern regarding nutrient loss on their farm). Performing a conditional logit regression model, we analyzed the effect of each contract attribute and decision-maker variable on the willingness of a farmer to participate in a PES program. Consistent with previous literature, we observe a highly significant positive relationship between payment and participation. As expected, we find a negative effect for strict N limits. Land ownership, farmer experience, and farmer age all demonstrate negative correlations with a farmer’s willingness to participate. We also observe a significant positive relationship between threat appraisal and participation. By understanding and optimizing these factors, we can inform policy decisions for how PES programs are implemented and targeted.

Abstract Name: Impacts of primary and secondhand exposure to e-cigarette aerosols on lung function and respiratory symptoms

The current knowledge on the adverse effects of e-cigarette use (vaping) on the lungs remains extremely limited, with existing studies showing mixed and inconclusive results. Therefore, this study's objective was to investigate the impact of vaping on lung function and symptoms, with a focus on comparative effects between primary and secondhand exposed individuals. A total of 30 individuals (≥19 years old) were recruited: 10 vapers, 10 non-vapers/non-smokers living with the vapers, and 10 non-vapers/non-smokers not exposed to vaping (control). Vaping/smoking status was confirmed using a urinary cotinine test and an exhaled carbon monoxide test. Repeated lung function measurements (forced expiratory volume in the first second (FEV1) and forced vital capacity (FVC)) were obtained using a portable spirometer for three time periods over 6-months (n=28). Respiratory symptoms were recorded using a questionnaire. Forced oscillation technique (FOT) measurements were obtained in the third month (n=16). These measurements include resistance (Rrs) and reactance (Xrs) measurements. Preliminary results show that primary vapers experienced lower FEV1/FVC ratios while experiencing higher average symptom scores and higher ΔXrs (change in reactance) scores. FEV1/FVC<0.7 is used to diagnose obstructive respiratory diseases. While ratios below 0.7 were not observed for any study participants, a statistically lower mean ratio in vapers compared to controls may suggest possible early onset of airway obstruction amongst vapers. The higher symptom scores demonstrate that primary vapers, on average, experienced more adverse respiratory symptoms as well as increased severity. ΔXrs>2.8 has been used to suggest expiratory flow limitation. ΔXrs>2.8 were not observed for any participants in this study; however, increased ΔXrs observed in primary vapers may suggest a greater risk for future expiratory flow limitation. Given these preliminary results, further studies are warranted and are being conducted, including exploring the effects of vaping on distal airways.

Abstract Name: Bean Consumption During Pregnancy and Birth Outcomes

Objectives: We assessed associations of maternal bean consumption during pregnancy with birth outcomes. Methods: We conducted a secondary data analysis of 1,121 U.S. pregnant individuals from the Infant Feeding Practices Study II. Frequency and amount of maternal bean consumption were approximated using a food frequency questionnaire completed during the third trimester of pregnancy. A birth screener questionnaire and neonatal questionnaire asked mothers to report birth outcomes including birth weight, birth length, gestational age, and Neonatal Intensive Care Unit (NICU) admission status. Associations between maternal bean consumption and risk for birth outcomes were examined using multivariable logistic regression models and linear regression models. Results: Overall bean consumption during pregnancy was low: an average of 0.30 cups/week of dried beans, 0.14 cups/week of chili, and 0.09 cups/week of bean soup. Maternal bean consumption varied by socio-demographic factors. Consumption of dried beans was highest among Hispanic mothers, mothers living in the West South Central region (0.44 cups/week), and mothers who did not smoke during pregnancy. Chili consumption was highest among mothers who were non-Hispanic Black, attended 1-

8 grade school years, had a household income of <$25,000, lived in households with 5+ people, and were WIC-recipients. Compared with non-consumers, mothers who consumed dried beans 2-3 times per month had a higher risk of NICU admission. Risk of NICU admission did not differ by chili or bean soup consumption. No significant association was found between dried bean, chili, or bean soup consumption and the risk for other birth outcomes including birth weight, birth length, gestational age, preterm birth, small-for-gestational-age (SGA), and large-for-gestational-age (LGA). Conclusions: Maternal bean consumption was low among U.S. pregnant women. Fetal growth and gestational age did not seem to vary by maternal bean consumption during pregnancy. Moderate consumption of dried beans may lead to a higher risk for NICU admission.

Abstract Name: The effect of technology on life satisfaction: Case study of elderly population in Oshkosh.

Social scientists who study well-being know that money alone cannot buy happiness, and that happiness also varies with age. While achieving material well-being, such as home ownership and stable employment, can positively contribute to happiness among the working-age population, they are not significant factors explaining happiness among older adults. With declining health and social isolation, the elderly population are more vulnerable to depression, heart disease and stroke without contact with family, peers or others. Communication technology, such as social media and the internet, has been found by numerous studies to be helpful in coping with loneliness among older people. This project utilizes statistical analysis of survey data collected from correspondents in the Oshkosh retirement community regarding their level of happiness. The analysis is used to understand how modern communication technology, such as social media and the internet can meet the needs of the community and create suggestions for policymakers and assisted living communities to improve the well-being of aging populations.

Abstract Name: Crowdsourcing Antibiotic Discovery in an Eight-Week Microbiology Course.

Providing authentic research experiences is a transformative learning strategy and a powerful and effective tool that leads to increased student engagement and persistence in STEM. Herein, I share my experiences, insights, best practices, and lessons learned from implementing the Tiny Earth Antibiotic Discovery Project in an eight-week microbiology course. Starting in Week 1, students collected soil samples from various locations in Southern California. They then determined the potential antibiotic-producing isolates by culturing and testing the bacterial isolates against gram-positive and gram-negative bacteria. Using Qiagen BiOstic Bacteremia kits, students extracted bacterial genomic DNA from isolated colonies to amplify the

16srRNA gene for 16S Sanger sequencing. Sequencing results were further analyzed using the NCBI Basic Local Alignment Search Tool (BLAST) website. In the last two weeks of the course, students completed an e-poster and uploaded it to the online shell of the course via a discussion board posting in BrightSpace/D2L. Students were encouraged to present their findings in a clear and organized fashion using pictures with well-labeled legends and to discuss their results in depth. Students had to give constructive feedback to two other students who were not their lab partners and comment on the e-poster content. The peer-to-peer engagement was substantial. The constructive criticism was empathetic. Students found the process “very educational and fun” and “enhanced their overall understanding” of the project. Students felt they were active research participants in antibiotic discovery while honing their perseverance, critical thinking, communication, and collaboration skills, potentially transforming their negative beliefs and attitudes toward science.

Abstract Name: Associations between Interpersonal Violence Exposure Over Time and Adolescent Girls’ Romantic Competence through VR Simulations of Unwanted Romantic Advances

During adolescence, youth begin to forge romantic relationships (Viejo et al., 2020), a facet of social development signaling the transition from childhood to adolescence. Interpersonal violence exposure (IVE) may affect romantic development, however. Research suggests that exposure to trauma disrupts social development, resulting in low social competence manifesting in unhealthy future partnerships (Daly & Marshall, 2021). There has been limited research into the effect of IVE on romantic development during adolescence. Therefore, the current study examined the associations between IVE and romantic competence during VR simulations of age-typical romantic scenarios for adolescents. The scenarios assessed whether greater exposure to IVE led to lower competence.In a longitudinal study, participants were 64 adolescent females starting in middle school (time one) through high school (time four). At time four, participants completed a VR simulation with an avatar who had a romantic interest in the participant--participants were told they were not interested. Romantic competence for each participant was coded (ICC - .804, 95% CI = .699-.897), and the average number of instances of interpersonal violence was assessed across all four time points. IVE was not associated with social competence (r = -.003, p < .98). Exploratory analyses discovered an association between perceived aggression from the avatar and social competence (r = .25, p < .05). This suggests that increased perceived aggression may contribute to increased competence. The need to develop more social skills may be an adaptive strategy to obtain the safest outcome. Further research should explore the association between social competence and the relationship between exposure to violence and vigilance of aggressive outcomes. The results of such outcomes could have implications for youths' future relationships.

Abstract Name: Poaching: Experiences in Motherhood of Justice Involved Black Women

Black incarcerated women experience neglect and maltreatment when seeking maternal health services, which results in higher odds of maternal hardship and poor perinatal health. The incarceration of parenting Black women erodes family structures and can permanently damage family units due to the disruption of attachment bonds between mothers and their children. The purpose of this research is to investigate these experiences as historical reiterations of the destroyed motherly bondage of enslaved mothers due to poaching. My research defines Poaching as stealing maternal bodily autonomy, agency, and the choice of motherhood. We use convenient sampling to identify participants and leverage resources at rehabilitation or re-entry programs to recruit participants with a $25 incentive. Qualitative semi-structured interviews were conducted with participants lasting up to 30 minutes to ascertain their personal experiences when interacting with correctional facilities regarding their maternal health. After data collection, each interview will be professionally transcribed and analyzed using the Dedoose software to identify consistencies among the respondents' experiences. These consistencies will create codes, which will then be grouped into thematic categories. Thematic analysis was conducted to interpret the meanings associated with participants' experiences. Current literature proposes that the experiences of maternal bondage of enslaved mothers are parallel to the experiences of incarcerated Black women today and that there are historical motifs of Black women that affect their experience as mothers and as US citizens. Preliminary data suggests that these historical perceptions of Black women in the United States as undeserving mothers may impact their maternal experience while Justice-Involved.

Abstract Name: Examining the virulence of the fungal pathogen Candida albicans in Galleria mellonella

The Center for Disease Control estimates that approximately 25,000 cases of candidemia (fungal bloodstream infection) occur nationwide each year.Candida albicans is an organism known for its ability to cause infection from surface-associated microbial communities known as biofilms, particularly on implanted medical devices. A biofilm is a microbial community that forms on surfaces consisting of an extracellular matrix with interspersed yeast and hyphal cell layers. Biofilms form in a sequence that begins with yeast cells adhering to a substrate; yeast cells then spread across the adhered substrate and elongate. During maturation, fungal cells proliferate, initiating the change from yeast to a filamentous cell; once enough hyphae are grown, an extracellular matrix forms and the biofilm has reached maturation. After it has matured, any cells that have

not adhered to the matrix are released into its environment. This is the cause of infection by biofilms. The research done was focused on examining the components of adherence to determine a defect that could be a possible drug target. We look for defects by running a virulence assay in-vivo using strains from a mutant library, along with a wild type, and a negative control.

Abstract Name: Refining Masses and Radii in Eclipsing Binary Systems for the Purpose of Calibrating the Asteroseismic Scaling Relations

Binary systems play a significant role in astronomical research by offering insights into stellar properties and behaviors. Eclipsing binary systems are particularly intriguing because they provide the opportunity to determine precise masses and radii. Eclipsing binary systems featuring a red giant are of particular importance as they allow us to investigate the asteroseismic scaling relations. In this research, we focus on the red giant binary system: KIC 7037405. Inspired by previous studies, we reanalyze the system and increase the precision of kinematically determined masses and radii. We begin by analyzing the binary system's light and radial velocity curves, where we apply detrending techniques that remove excess noise and systematic effects. Using the PHOEBE (PHysics Of Eclipsing BinariEs) software, we use estimators to derive critical parameters that provide insights into the physical characteristics and interactions between the stars within the binary system. We then optimize the light curve and radial velocities using the Nelder-Mead method to minimize residuals. Our future endeavors involve the application of the MCMC (Markov Chain Monte Carlo) technique to increase our confidence in the masses and radii and their uncertainties. Through this research, we aim to achieve red giant mass and radius measurements to better than 1% relative precision, which then enables independent calibrations of the scaling relations.

Abstract Name: Lichen Density Effects on the Abundance and Diversity of Native Plants in the Understory of Oak Woodlands

Lace Lichen (Ramalina menziesii) is widespread within oak woodlands in Central California, growing in moist areas where it traps water in the canopy from fog, rain, or dew. This water can drip from the canopy, depositing moisture and nutrients that affect plant growth in the understory. Along with the natural temperate climate of oak woodlands, the lichens may therefore affect the growth of native plants. Our research focuses on how lichen abundance affects the native understory flora in oak woodlands. We collected data in areas of oak woodlands with high and low lichen cover near Monterey, CA. We selected oaks within each woodland

area and conducted three point-intercept surveys of canopy cover and ground cover from each. Our analysis showed a slight positive correlation between lichen frequency and the presence of native plants. For non-native species, there is a greater difference in the abundance of individual species between high lichen and low lichen sites than for native species which were more evenly distributed across sites. This indicates that non-native species were more specialized to specific environmental conditions, and native plants were able to better respond to variations in moisture and nutrients. The results of our analysis indicate there may be a relationship between lichen and the relative growth of native versus non-native plants.

Abstract Name: Environmental Impacts of Drone/Sensor Combinations in UC Remote Sensing through Life Cycle Assessment

Drones are a common tool for remote sensing and imaging applications in many sectors. This technology is often used to help answer questions about the environment and sustainability, yet the sustainability of drone-based remote sensing platforms has yet to be assessed. Previous research at UC Merced has begun to identify the environmental impacts of drone-based remote sensing platforms by performing a life cycle assessment to analyze carbon dioxide-equivalent emissions and their contributions to global warming throughout their entire life cycle. This study expands upon that research to produce more accurate and generalizable results by adding an additional scenario to the life cycle assessment on an Open-Source Hyperspectral Imager mounted to a DJI Phantom 4. We also gathered user data from others who utilize the DJI Phantom 4 across the UC system to inform and further constrain our models. This behavioral data regarding the use, reuse, maintenance, and disposal of drones and imaging sensors allowed for an understanding of the scale of human influence on life cycle emissions. Calculating emissions from materials and processes reveals that the Phantom 4/Open-Source Hyperspectral Imager combination produces more emissions that contribute to global warming than other sensor options, due to its complexity in resources and functionality, especially concerning data storage. The user data helped allow us to understand variability in parameters concerning drone user behaviors, such as the distance traveled to field sites or the average duration of a drone flight, which, in turn, allowed us to track how user behaviors influence emissions. Conducting life cycle assessments provides the opportunity for users to make informed changes to reduce harmful environmental impacts at any stage of a product's life.

Abstract Name: Small-molecule Tip60 HAT Activator as a Potential Alzheimer's Therapeutic

Alzheimer's Disease (AD) is a neurodegenerative disorder that impairs patients' cognitive functions and, in late stages, can diminish locomotor functions. The pathophysiology of AD is an interplay of many biological, genetic, and environmental factors. Recent studies, including research from the Elefant lab, identified epigenetic dysregulation as a hallmark of AD. Epigenetics is the study of proteins and biological mechanisms that regulate chromatin packaging, which in turn controls gene expression. Epigenetic dysregulation refers to the disruption of the homeostasis between epigenetic proteins. The two main epigenetic proteins being investigated are histone acetyltransferases (HATs) and histone deacetylase (HDACs). Specifically, TIP60 HAT levels in a Drosophila AD model are significantly lower compared to wild-type flies. Additionally, the Elefant lab published articles demonstrating Tip60 and HDAC2 target the same neuroplasticity genes, and when Tip60 levels are decreased, there is decreased expression of these neuroplasticity genes resulting in cognitive and locomotor impairment in a Drosophila AD model. Conversely, genetic overexpression Tip60 in a Drosophila AD model has been shown to restore expression levels of neuroplasticity genes, rescuing cognitive and locomotor functions. Current work in the Elefant Lab focuses on developing small-molecule compounds that are Tip60 HAT-specific activators that restore expression levels of neuroplasticity genes in order to rescue cognitive and locomotor functions. Three compounds have demonstrated the ability to increase Tip60 activity in an in vitro HAT assay. Thus this poster presents the investigation of one compound in vivo using a larval locomotor assay to identify a candidate drug and an optimal concentration.The findings from this study help us identify small-molecule compounds that rescue cognitive impairment associated with AD.

Abstract Name: Climate Conscious: Assessing and Addressing Eco-Anxiety in the USC Student Body

Over the past decade, eco-anxiety is a phrase that has emerged at the forefront of both public and academic consciousness. Eco-anxiety is described by current research as a negative psychological response to the Anthropocene climate crisis. Despite a growing interest in the phenomenon, it is largely understudied– particularly concerning its frightening proliferation worldwide. Eco-anxiety is felt in some way by a majority of people across the globe, including by ⅔ of American adults. While much of the research on eco-anxiety has been theoretical, there has been a recent push to quantify and more accurately measure eco-anxiety, its causes, and its symptoms via survey and scale-based research. The goal of our research is to understand the causes and levels of eco-anxiety in students at the University of Southern California (USC). There has been a growing consensus that environmental awareness or knowledge is linked to increased environmental anxiety. If this is the case, then those directly involved in sustainability and climate change (like college students) are likely to be most adversely affected by eco-anxiety. It is vital for those in the fight against climate change to cope meaningfully with the reality of climate change and cultivate healthy mindsets when engaging with ecological crises. This survey, distributed over the Fall 2023 semester, has used a modified version of the Hogg Eco-Anxiety Scale (HEAS-13) to gauge levels and manifestations of eco-anxiety in students. The HEAS-13 is a 13-item scale that aims to understand eco-anxiety as a culmination of behaviors and emotions in response to climate change. After synthesizing our data, we will emerge with a list of best practices and educational interventions that will engage and empower students in the environmental field as they fight against climate change. These practices will be synthesized into a toolkit course to be taught at USC (pending approval).

Abstract Name: Determinism & Freewill: An Exploration of Gender Identity & Moral Responsibility

Determinism is a philosophical concept asserting that every event and action in the universe has been determined by previous causes, which has caused considerable debate within philosophy. Two critical issues within this discussion are the implications of determinism for human agency and moral responsibility. This research addresses these issues, asserting that our world is compatible with human free will, rejecting a deterministic viewpoint. It is vital to understand compatibilism, the assertion that determinism and free will can coexist. From this perspective, free will is not inherently opposed to determinism. Instead, our choices and actions can still be considered free under a deterministic framework. This paper extends the scope of compatibilism by applying it to the field of identity and gender, pulling from queer theory the argument that gender identity is innately performative. Through this lens, gender is considered a social construct subject to change, personal interpretation, and performance. These views align with compatibilism, challenging traditional notions of gender and allowing inclusivity and coherence in understanding our identity within the self. This paper utilizes comparative analysis, logical reasoning, and thought experiments to examine the connection between determinism and gender identity. This article explores how these seemingly disconnected concepts can inform one another. Furthermore, it highlights the implications of a compatibilist stance on moral responsibility and states that individuals can be held responsible and accountable for their actions within a deterministic world. The development of this perspective of gender identity and moral responsibility will shed light on philosophical inquiries of the self and human experience.

Abstract Name: Brand Awareness of the Oxnard Performing Arts Center Corporation (OPAC): Significance of age

The current study focuses on the Oxnard Performing Arts Center (OPAC), a historical, cultural, and artistic site whose objective is to serve the community through performance. Not everyone in the Oxnard community is aware of OPAC as a non-profit organization or knowledgeable about OPAC's activities, so our research team collaborated with OPAC on a volunteer project to evaluate brand awareness. These findings will be utilized to inform OPAC of practical solutions to increase positive brand image. Items were adapted from previously validated scales, focusing on general awareness of OPAC, brand image (Michaelidou et al., 2015), brand personality (Aaker, 1997), brand associations (Schivinski, 2021), brand commitment (Das et al., 2019), etc. My main research question was how age was related to brand awareness. Participants were recruited via social media, in-person OPAC events, and email. A total of 111 valid responses on Qualtrics were collected, with an average age of 48.86 years (SD = 16.6). Participants were primarily female (66.1%), with various ethnicities identified: Latinx (50.8%), White (29.7%), Asian (7%), African American (4.7%), and Native American (3.9%). Regression analyses were utilized, which showed that age significantly predicts efficiency ($F[1, 105] = 4.21$, $p = .04$; $R2 = .039$), dynamism ($F[1, 102] = 4.48$, $p = .04$; $R2 = .042$), excitement ($F[1, 99] = 4.60$, $p = .04$; $R2 = .044$), and brand awareness ($F[1, 101] = 4.47$, $p = .03$. $R2 = .046$). A multiple regression analysis was employed, which determined that excitement and brand Associations can significantly predict brand awareness. ($F[2, 99] = 123.86$, p <.001; $R2 = .71$) Overall, OPAC could include more events aimed at older community members through outreach, senior discounts, free bringing of friends, and increasing accessibility. These findings can help OPAC and center the importance of brand awareness in marketing for similar non-profit organizations.

Abstract Name: Integrating Scat Collection and Hair Snares to Explore Marine-Terrestrial Connectivity along the Gaviota Coast in California

Noninvasive survey methods are becoming increasingly crucial in field studies, as they allow for larger sample sizes, cover wider areas of research, and are beneficial in the long-term studying of elusive and rare species. This research project investigates the marine influence on the diets of large terrestrial mammals at the Jack and Laura Dangermond Preserve in California, aiming to understand their potential role as ecological connectors between the coastal and terrestrial environments. This study includes a comprehensive analysis of marine-trophic interactions by surveying scat samples collected from the six target species– coyotes (Canis latrans), bobcats (Lynx rufus), mountain lions (Puma concolor), American black bears (Ursus americanus), wild pigs (Sus scrofa), and mule deer (Odocoileus hemionus). Additionally, this study also includes an independent project to design and test different hair snare designs, with the goal of evaluating the effectiveness and capabilities of these hair snares for noninvasively capturing hair samples from the same

target species. Three distinct hair snare designs were researched and constructed, and a 4-week deployment and collection plan was implemented to evaluate their performance. Isotope analysis of the hair samples will provide valuable insights into the feeding habits and trophic ecology of these mammal species. The integration of scat collection and hair snares provides a noninvasive approach to studying diet distribution, offering significant insights for wildlife management and conservation along the California Gaviota coast.

Abstract Name: The Lived Experience of Those Accessing Social Services

This study aimed to understand the lived experiences of those who access social services. What experiences did those accessing social service have in Nanaimo? And did their experience showcase any social barriers or gaps impeding the efficacy in accessibility? Findings offered insight into areas in need of improvement when assessing accessibility to social services in Nanaimo. Previous studies have explored the lived experience of populations in vulnerable circumstances' (PVCs) accessibility to social services in high income countries (HICs) such as Canada, the United States, Australia, and the UK. These studies focused on national populations, and/or larger cities. Less research has been focused on access to social services in smaller cities. Nanaimo, like many cities in Canada has experienced an influx of homelessness due to multiple social and societal determinants. This makes nonprofit organizations necessities in urbanized spaces to support those in need. Nanaimo is increasing in cost of living annually along with the greater Vancouver Island region. Furthermore, access to amenities is not always readily available based on where an individual lives. The time it takes to commute to access social welfare services in Nanaimo became a factor that concerned those volunteering at Risebridge. This organization wanted to find out how much it took their guests to gain access to the resources they needed. Using an ethical framework of an individual-based approach data was collected using qualitative methods. Individual interviews with Risebridge guests were conducted. Findings in this research can identify possible gaps in the current level of social services provided in developing cities in other regions. As well, it can help with future implementation of social services like Risebridge, to better offer low barrier services to those in need based on a more individualized understanding of their needs instead of one that treats PVCs like a homogenous group.

Abstract Name: Oscillator’s comparison and analysis using different types of Integrated Circuits

Oscillator’s comparison and analysis using different types of Integrated Circuits Quatarius Flowers, Kobie Manning, Savion PeakFort Valley State UniversityEngineering Technology Department Abstract This research project explores the use of different types of operational amplifiers as oscillators, with the goal of increasing their adaptability and performance across a wide range of applications. A function generator (FG) is a circuit that generates a repetitive different shape of waveforms with the capability of controlling its amplitude and frequency without any external input signal. FGs are used to generate signals for testing, measurement, and calibration in fields such as electronics, telecommunications, and scientific research. The research investigates unique waveform-generating techniques and frequency synthesis procedures using different types of Ics such as the 741 op-amp and 555 timer. Additionally, user interfaces, compactness, and energy efficiency are being prioritized. The research aims to contribute insights that will not only broaden understanding of function generator principles but also pave the way for the development of next-generation devices with improved functionality and adaptability through a combination of theoretical and design analysis, computer simulations, and practical experimentation. The project's achievements have the potential to aid businesses that depend on accurate signal creation by supporting technological and innovative breakthroughs.

Abstract Name: Drosophila nutrition as a factor of altered sex ratios

Sex ratios have long been researched, but many questions are still left unanswered. It has been found that sex ratios are close to 1:1 for organisms including Drosophila melanogaster. Some studies have suggested that these ratios could be altered, however. The Trivers-Willard hypothesis states that sex ratios could be altered due to the relative stress that a mating pair may face while reproducing. One form of stress that could impact sex ratios is nutritional input. This hypothesis has few experimental results from scientific studies, and it could benefit from more research to either prove or disprove the hypothesis. Drosophila melanogaster will be tested in various nutritional mediums to see whether nutrition has an effect on the produced sex ratio or not. In the previous year, we had 7 different nutritional fly food mediums. Along with a control food medium, a 30% increase and decrease in protein, carbohydrates, and fats was tested in the other six test vials respectively. Out of all the studies conducted, the 30% increase of fat fruit fly food medium produced significant results with a p-value of less than .05 ($p = .031$). We will further test this food mixture, along with 9 new food mixtures: 15% fat, 30% fat, 50% fat, 3% omega 3, 5% omega 3, 3% omega 6, 5% omega 6, Na K, and Ca Mg. Here we ask, does a change of nutrition cause a skewed sex ratio; if so, what change in nutrients causes it? The results of this test will further offer evidence supporting or limiting the Trivers-Willard hypothesis and expand the understanding of sex heritage.

Abstract Name: Comparing religious experience during Hindu and Muslim prayer

The questions that will be addressed are: 1) to what extent are the religious experiences of prayer in Hinduism and Islam similar or different? 2) What modes of prayer are used in these two major religions? and 3) how egalitarian are the two religions when it comes to involving different genders in prayer? Although using science to study religious experiences may seem counterintuitive or even controversial, the experience of prayer or the feeling of closeness to God can be studied scientifically as indicated by the emerging field of neurotheology. Neurotheology is defined as the study of the connections between the brain, religious experience, forms of prayer, and the well-being of different groups who pray. Experimental studies in neurotheology have found that subjective religious/spiritual experiences measured by psychological methodologies (self-reports, ratings, questionnaires, etc) can be linked to brain activity measured by functional brain imaging techniques. My study will use a scientific lens to explore the differences and commonalities in prayer as practiced by Hindus and Muslims. Peer-reviewed journal articles and scholarly analyses of sacred texts will be used to explore the nature and modes of prayer in the two religions. Existing findings in the neurotheology literature will be used to assess the extent to which there are commonalities and differences in the subjective experiences of prayer of Hindus and Muslims. Though Hinduism and Islam are anchored in very different sacred texts and followers engage in quite different modes of worship using various modes of prayer in order to induce feelings of closeness to God, it is quite likely that Hindus and Muslims likely experience prayer in a similar way, given the extant literature in neurotheology. A particular focus of the research will be the roles played by different genders in prayer.

Abstract Name: Chinese Rock and Roll: Resisting Censorship

Chinese rock and roll has been deeply entwined with politics since its conception, as reflected in both artistic expressions and creative limitations. Lyrics, instrumentals, and musical compositions are all characterized by Chinese culture and social politics. Chinese rock rose to prominence during the 80’s struggle for democracy, through music, youths openly expressed their discontent towards the corrupt authoritarian regime and an increasingly bleak future. The rock scene hit a critical turning point post 1989’s Tiananmen Square pro-democracy protests; the government escalated censorship tactics, impacting the rock community and its genre evolution.Chinese rock has always been a way to silently rebel against the oppression of daily life under authoritarian China. And this project serves as an investigation into the censorship tactics faced by the rock discourse in the 21st century. The methods of censorship discussed includes both internalized censorship and state enforced censorship. Data for this project is collected by combing through Chinese social media posts, internet forums, and other first-hand accounts. As well as examination of interviews, songs, and other publications by rock musicians to better understand their social and musical landscape. For a more in depth understanding, these investigations will be primarily done in Chinese and subsequently translated to and analyzed in English.As the fundamental principles and themes of classic Chinese rock and roll became increasingly applicable again in modern China, findings of this project will indicate why Chinese rock will continue to flourish in the oppressive environment, as well as how it will stay prevalent amongst progressively severe censorship tactics. By the conclusion of this project, I expect to build a sample data base

documenting instances of non-violent activism and censorship in the Chinese rock discourse, along with commentary and analysis of Chinese rock and roll's influence on recent sociopolitical events in China.

Abstract Name: Organic Pollutant Absorption in Synthesized Metal-Organic Framework (MOF): Computational Investigation

Benzene and toluene are hazardous organic pollutants due to their potential health effects. Benzene is a known carcinogen and exposure to high levels of toluene can cause central nervous system depression. Applying porous materials for the removal of benzene and toluene can be an effective approach for mitigating the environmental and health impacts of these organic pollutants. Metal-organic frameworks (MOFs) are a type of porous material consisting of metal nodes connected by organic linkers. MOFs have unique properties such as high surface area, tunable pore size, and the ability to adsorb small molecules, making MOFs promising candidates for various applications including removing pollutants. In our study, we focus on MOF-TW1, which was formed from the crystals of the reaction of Cu(I) and Ag(I) precursors witn pyrazine (Pyz) and piperazine (Ppz) and boasting a signficant surface area (1278 m2/g) and porosity of 23.7% void volume. We applied computational chemistry methods to investigate the interaction of organic pollutants and MOF-TW1 which can guide the design and modification of MOFs for organic pollutant absorption and removal.

Abstract Name: Feminine Brushstrokes: Unveiling the Role of Women Artist after the Mexican Revolution.

In this paper I will be analyzing the role of women artists in the formation of the Mexican art world after the Mexican Revolution. First, the historical context of the Mexican Revolution is provided. Second, the changes in the social role of women in the post-revolutionary period are discussed. Third, post-evolutionary artworks produced by Mexican women artists, Aurora Reyes Flores, Lola Cueto, Carmen Mondragón, and María Izquierdo, are discussed. In addition, the movement to a more traditional Mexican style of artwork rather than the European influence that art had is addressed. The examination of the Mexican revolution establishing a more democratic republic after the Mexican Revolution is analyzed. In this discussion of artwork, the emphasis is on women as soldaderas and adelitas during the war and how their feminism advanced in Mexico. In addition to formal and iconographical examination of artworks, I utilized multiple academic articles and books in both English and Spanish to demonstrate these artwork's historical specificity. This research is important since the general audience considers women as a very passive receiver of revolutionary

change, rather than an active agent. By delving into their experiences and artistic achievements, this research aims to inspire deeper appreciation for Mexican Women's lasting impact on Mexican art and culture.

Abstract Name: Analysis of Racial Differences in Emerging Adults Substance Use and Psychological Well-Being

The prevalence of substance use among college students is a major public health concern, particularly with the recognition that the brain is still developing for those under 25 years of age (NIH 2013) and the links between substance use and negative psychological outcomes (Cranford et al., 2009; Kandel, 1984; Morgan et al., 2011; Sumstine et al., 2018). Additionally, there are ethnic-racial differences in the association between substance use and race/ethnicity (Sumstine et al. 2018), which may be attributed to differential experiences with racial microaggressions within college campuses. The current study examined ethnic-racial differences in substance use patterns and psychological distress among college students from the National College Health Assessment (NCHA) from Virginia Commonwealth University. Participants were American Indian or Native Alaskan (n=6), Asian/Asian American (n=78), Black/African American (n=68), Hispanic/Latinx (n=42), Middle Eastern/North African or Arab origin (17), Native Hawaiian or other Pacific Islander (n=3), White (n=268), and Biracial or Multiracial (n=29) Multiracial students reported higher levels of alcohol use (low: n=13, 59%; medium: n=39, 12.2%; high: n=9, 2.8%) than their monoracial peers; a Tukey post hoc test revealed that alcohol risk was significantly higher among Black students (1.13 ±.404 min, p=.048) and Multiracial students (1.50 ±.673 min, p=.049). There was a greater statistically significant difference between Multiracial students and students with other racial/ethnic identities, as determined by a one-way ANOVA ($F(6, 330) = 2.137$, p=.049). Our current findings support previous data suggesting heightened rates of substance use among Multiracial populations (SAMHSA, 2014). Providing more research on substance use and the themes mentioned above can help leaders create programs, legislation, and discussions to understand the matter at hand better.

Abstract Name: Implementation of a Single-Phase Water Liquid Cooling System for NVIDIA High Power Density Servers in a Data Center Rack

The high-speed computations that are ubiquitous in today's world, from credit card transactions, to on-line shopping, to web browsing, using mobile-phone apps, or running sophisticated AI software, are all performed in data centers. Data centers are buildings that house interconnected servers (i.e. the "computers") mounted in equipment racks about the size of a large refrigerator. Servers require power and generate heat. Servers running powerful high-speed applications increasingly dissipate so much heat that they must be cooled using indirect water cooling using cold plates. Cold plates are metal blocks strapped onto the heat dissipating CPUs or GPUs in the server. The coolant (water) passes through cold plates through internal channels and absorbs the heat dissipated into the cold plate. In the current project, a test reference rack was assembled in order to experimentally characterize the performance of a liquid-cooled system mock-up. The first task was to build a 3-D CAD model of the overall system in order to develop a list of components that needed to be designed, manufactured, or purchased. Simulated servers that utilize thermal test vehicles to mimic the heat generated from high performance chips were then provided by NVIDIA and installed in the rack. Cooling loops consisting of interconnected cold plates were provided by vendors and were mounted on multiple thermal test vehicles simulating the GPUs. They were instrumented with over a hundred temperature, pressure, and flow sensors to thermal-hydraulically characterize each component of the cooling systems. Experimental data was collected under conditions of maximum power in order to assess the system performance under the most stressful conditions. The experimental data showed that the flow distribution network providing cooling water to the cold plates had design flaws that caused the flow to vary over the different cold plates. Nevertheless, the vendor-supplied flow loop satisfied the thermal design targets.

Abstract Name: Vessels of Violence: Understanding Adherence to Violent Group Action and Ideology

As widely understood in past and present polarized sociopolitical climates, adopting radical ideologies can lead to organized violent group action. Though, what individual, organizational, and state-level factors can determine when members of groups adopting radical ideologies escalate to taking these violent actions? Throughout my thesis, I aim to explore the social, political, and psychological conditions that scholars argue give rise to a commitment to and indoctrination of radicalized group ideologies, drawing on theories of deviance such as differential association, strain, and anomie to inform my analysis. I then examine how individuals ultimately find themselves transformed into 'vessels of violence' within a small group organization. I aim to understand the 'construction of commitment' to extreme violence as a socializing process, negating beliefs that brainwashing is the sole influence of the adoption of deviant stigmatized ideological identities. I apply insights from scholarly work to examine what factors may help explain that commitment. These factors possess a chronological order and are 1) familial upbringing 2) presence of a repressive agent 3) sociopolitical dysfunction 4) creation of an idioculture 5) organizational practices and management 6) shared living environment 7) conformity to peer influence 8) role-taking actions. I use case studies of the radical and violent groups of the Red Army Faction, Al-Qaeda, and Heaven's Gate to explore these ideas. The data used in the profiling of these three groups are oral histories and scholarly accounts of group history and action. I highlight how existing theories help explain some commitment to violence, where these theories fall short, and what further research is needed. By conducting this sociological analysis, I intend to contribute to current discussions of violence and groupthink that have become increasingly important in the face of enduring sociopolitical violent conflicts, gauging how we may best understand the conditions giving rise to their continuation.

Abstract Name: Rethinking Fear

Traditionally, fear has been perceived as a wholly negative emotion, while bravery has been praised as the only admirable response to fear. Those who overcome their fear are considered praiseworthy, and those who succumb to it are viewed as weak or otherwise morally deficient. I analyze the themes of fear and its role in the transformation of one's self through presenting regret not only as a feeling or affect, but as an emotion that is of great moral significance that underwrites how we understand ourselves and each other. In this project, utilizing insights from both psychology and philosophy, I argue that the traditional approach to fear and bravery is misguided. We ought not dismiss our responses to powerful, fear-inducing experiences; rather we ought to acknowledge, and even embrace, our fears, since our fears provide us with a deeper understanding of ourselves as moral agents. In other words, an acceptance and greater understanding of fear as an important moral emotion can eventually lead to greater self-understanding, empathy, and a broadening of one's perspectives and imagination.

Abstract Name: "There Have Always Been Women Like Us:" Three Women Writers of the Beat Generation

The Beat Generation was a postwar literary movement, which took place largely from 1940-1960. Writers such as Jack Kerouac, Diane Di Prima, and Allen Ginsberg wrote about taboo subjects such as drugs, sex, and queerness. They lived beyond the conservative 50s norms: not prescribing to traditional marriages, jobs, or lifestyles. This counterculture movement was progressive in many ways. However, the more well-known Beat writers are overwhelmingly white and male. Their writing often contains misogynistic undertones which expose the attitudes of the time. For men, ambition and out of the box writing was scandalous but ultimately well-received. The stories of Beat women show how hard it was to be a woman writing in the 50s, as histories of mental institutions and young suicides were unfortunately all too common. Beat women are much lesser known and their work is understudied; those that are known are often just represented in their relationships to Beat men. My project aims to address this. After reading anthologies of Beat women writers, I focused on Hettie Jones, Joyce Johnson, and Anne Waldman. I read memoirs by these writers. It was important to me to learn about their life in their own words, as they have often been underestimated by media representations. I also read two collections of letters, one between Hettie Jones and Helene Dorn, and the other between Joyce Johnson and Jack Kerouac. Lastly, I read poetry and fiction by the writers, to finally understand what they were creating and how it relates to styles and subject matters popular to the Beat generation as a whole. After my reading, I compiled an annotated bibliography featuring work by these three Beat women, to be shared with Warren Liu's Postwar American Poetry class. My hope is that interested readers will be introduced to new authors or work.

Abstract Name: Witchcraft and Enlightenment: Reconstructing Witch Belief in Scotland During Enlightenment

Scottish witchcraft studies is a highly developed field, yet gaps in the literature exist, and misconceptions are substantially embedded in modern understanding. One such misconception, sustainable by modern historians and Scottish Enlightenment-era historians alike, is the idea that Enlightenment-era beliefs, such as rationality and new ideas on civility, caused both peasant and elite circles to dismiss witchcraft as superstition instead of a threat early on in the 1800's. However, analysis of legal stature, narratives of religious leaders, and Enlightenment-era Scottish histories within the context of the broader English-Scottish conflict reveal that the erosion of witchcraft belief was much more complicated. Instead, members of religious, elite, and peasant classes in Scotland still held deep-seated witch-related fears but were repressed by the changing legal landscape of Scotland, introduced by England in the 1707 Union of Nations. This union, and other Scottish-English relations during this era introduced strict concepts of scientific rationality to Scotland and its legislature, which forced Scottish elites to comply with English standards. These standards were much more progressive in terms of anti-witch belief and did not allow for the existence of superstition to inspire legislature and action. While these changes were reflected in Scottish legal codes and the end of the large-scale witch hunt Scotland was so accustomed to, they were still deeply entrenched in the Scottish population. While this belief shows up in many different facets, it arises most clearly in the last major witchcraft trials in Scotland, occurring in 1705 and 1805. Finally, this belief was further propagated by the great Scottish thinkers of the Enlightenment, such as William Blackstone, David Hume, and Walter Scott, whose works were colored with an anti-witch belief sentiment.

Abstract Name: The Colonial American Historical Significance of St. David's Church

Located approximately twenty miles west of Philadelphia St. David's Episcopal Church in Wayne/Radnor, Pennsylvania is one of the oldest churches in southeastern Pennsylvania. This paper started out as an extra-credit assignment for a Colonial American History course offered last fall. However, through Dr. Sam Smith's passion for colonial church history, I became passionate about sharing the history of St. David's as it is located only two miles from my home. This paper discusses the foundations of this important church highlighting the history and growth of Episcopal churches throughout the colonial period in Pennsylvania. This paper also discusses how St. David's transformed from a small Welsh missionary community to a battleground of ideas during the Great Awakening. Overall, St. David's is an important area of colonial significance and dramatically impacted the foundations of its local community.

Abstract Name: Impact of Roasting on the Antioxidant Capacity and Polyphenol Content in Coffee

This study explored the dynamic relationship between the roasting process of coffee and its implications on the antioxidant capacity and polyphenol content. Coffee, a widely consumed beverage, has been renowned for its high antioxidant levels, contributing significantly to its health benefits. Notably, raw or green coffee beans are abundant in chlorogenic acid, a potent polyphenol with notable antioxidant properties, offering health benefits like reducing inflammation and protecting cells against oxidative stress. This stress is implicated in various chronic diseases, including heart disease, cancer, and neurodegenerative disorders. The roasting process, while diminishing chlorogenic acid levels, leads to the formation of melanoidins, another type of polyphenol, thereby maintaining the coffee's antioxidant properties. This study quantitatively examined the total antioxidant capacity and total polyphenol content in relation to varying roasting times. The Trolox Equivalent Antioxidant Capacity (TEAC) and Folin-Ciocalteu methods were employed to evaluate the levels of antioxidants and polyphenols respectively. Preliminary findings indicated a significant influence of the roasting process on both the antioxidant capacity and polyphenol content of coffee. These results underscored the complexity of coffee's chemical composition and its transformation through roasting. Detailed findings and further insights will be presented at the upcoming conference, contributing to a deeper understanding of coffee’s nutritional properties.

Abstract Name: Impact of Living Learning Communities on Sense of Belonging in First-Year College Students

University of California, Merced (UCM) has a large population of first-generation students, many of which have difficulties adapting to their new environment. Being the first in their family to attend a four-year university, these students may struggle to find resources, adapt to rigorous course schedules, and be actively involved on campus. Living Learning Communities (LLC) have been shown to aid undergraduate students with the social and academic transition in that first year. However, there is limited research on students’ Sense of Belonging (SB) and how it is impacted by LLCs. The current study aims to close this gap in the literature and find the best practices to cultivate SB in first year students at UCM. Our hypothesis is that the LLC will improve SB among the students enrolled, which will lead to a smoother transition to college in their first semester. A cohort of 30 students will be recruited into the LLC and observed as they take part in weekly seminars, focus groups, and various social and academic events designed to aid their development. They will be compared to a control group of 30 non-LLC students. Data will be collected using the General Belongingness Scale (GBS; Malone et al. 2012), and results will be compared throughout their time at UCM.

Abstract Name: Lazarus Cultures: Society-Specific Colonial Perception in Relation to Cultural Reclamation for Michigan Anishinaabe

Current research concerning colonial influence on indigenous cultural reclamation in the United States lacks group-specificity which leads to the decentralization of the US as a colonial power and an overly simplified view of colonial perceptions within reclamation for many individual native groups. Narrowing in on the Anishinaabe, an aboriginal group that has fallen victim to this disparity, this paper will answer the question of how unique indigenous populations conceptualize and reinforce perceptions of colonialism as they pertain to their reclamation efforts. Following a focused ethnographic method, this research uses five (5) separate field observations, seven (7) expert interviews, and ten (10) dialogues with practitioners to demonstrate how the Anishinaabe have incorporated their culture, ontologies, and history in the distinct colonial understanding that informs their restorative cultural practices. This ethnography diverges from the previous emphasis placed on the French and British periods in academic discourses, instead highlighting a societal interpretation of colonialism as fundamentally linked to US-Anishinaabe interactions. Conversations with Anishinaabe leading recovery movements reveals the importance of their culture-based and differentiated understandings of colonialism as a society-specific motivator for reclamation that has been reinforced through experiential ontological methods. The diverse range of restorative efforts analyzed, crossing cultural universals, also illustrates a discrepancy in colonial understandings between indigenous and outsider-focused reclamation projects. These conclusions demand a reconsideration of the panoramic views on colonial perception within Indigenous America that are perpetuated by contemporary scholarship. They also advance the existing debate to include a critical distinction between broad audience and insider-intended forms of reclamation. From here the floor is opened for new literature relating to group-specific indigenous understandings, as told by indigenous voices, of colonialism and restorative practices.

Abstract Name: Strengthening Coastal Communities' Prosperity: The Role of Local Marine Conservation Projects in Pemuteran, Bali, Indonesia

Around the world, many established marine conservation projects have crumbled, and ongoing ones are stagnating because of lack of stakeholder engagement, making community buy-in vital to their long-term success. In turn, such communities can experience sustained economic benefits, as one formerly poor fishing village of about ten thousand permanent residents in Pemuteran, Bali, demonstrates. Conducted from September to November 2023, this qualitative case study research project explored Pemuteran community members' perceptions of the success or otherwise of locally established marine conservation projects in

increasing local prosperity, income and environmental knowledge. Drawing on participant observation, an online survey and semi-structured interviews with community members knowledgeable about marine conservation projects in the area, the case study applied a decolonial sustainable livelihood framework to analyze the data. Findings indicate that the establishment of the Biorock marine conservation project in Pemuteran in 2000, initiated and championed by community leaders through the education of local residents, is perceived by the community as a pivotal marine conservation project that has significantly contributed to the rise of local prosperity, with particular impacts on increased environmental knowledge. While the opinions of community members differ regarding the ecological impact of marine conservation projects, there are strong sentiments that the economic success of these initiatives has transformed people's connection with the natural environment, shifting it from an extractive relationship to a regenerative-based one. The research also indicates that community members perceive ongoing marine conservation projects as important due to their ability to attract tourism, thereby generating income and jobs for locals.

Abstract Name: The Effect of Antibiotic Adjuvants on Linezolid-Resistent Staphylococcus aureus

Antibiotic resistance is a growing concern in modern healthcare as the overuse of antibiotics becomes more frequent. More than 70% of bacteria that can cause serious infections are resistant to one or more antibiotics. Our lab is particularly interested in combatting this problem by utilizing compounds called antibiotic adjuvants to make existing antibiotics effective again in resistant strains of bacteria. Currently, we are interested in studying antibiotic adjuvants that are effective in Staphylococcus aureus, a Gram-positive pathogen responsible for over 100,000 infections and 20,000 deaths annually. Linezolid-resistant Staphylococcus aureus (LRSA) is a multidrug-resistant strain of S. aureus that is becoming increasingly prevalent. We have tested two lead compounds, loratadine, and 4-bromocarbazole, for the ability to potentiate linezolid and oxacillin in a panel of LRSA clinical isolates. Biological results and preliminary conclusions will be presented.

Abstract Name: Propaganda and Visual Persuasion in Contemporary Consumer Advertising

This research looks at the relationship between graphic design and consumer behavior, focusing on the impact of propaganda-inspired design in advertising. The primary goal is to understand how design elements derived from historical propaganda posters influence consumer desires and decisions. The review of literature emphasizes the importance of advertising design in selling products, establishing brand identity, and fostering consumer recognition. To understand the origins and significance of propaganda graphic design, historical

contexts, specifically World Wars I and II, are investigated. The research delves into visual psychology, focusing on the use of color, imagery, and emotional engagement in advertising. Modern marketing campaigns are examined to demonstrate the long-lasting influence of propaganda aesthetics on modern advertising strategies. Case studies, such as the "Share a Coke" campaign, show how design elements influence consumer perceptions and decisions. The historical and contemporary approaches to propaganda design are contrasted, with simplicity, clarity, and emotional response emphasized as long-term goals. Ethical considerations are raised, with advertisers urged to prioritize transparency, honesty, and consumer autonomy. Finally, the study confirms the long-term impact of propaganda-inspired advertising design and emphasizes the importance of ethical, socially conscious campaigns in shaping consumer preferences and societal ideals.

Abstract Name: Vaping Cessation for Young Adults in Rural Areas

The "Vaping Cessation for Young Adults (YAs) in Rural Areas" study aims to investigate the feasibility and preliminary efficacy of a text message-based e-cigarette cessation intervention for YAs in rural areas. E-cigarettes contain nicotine, which binds to specific receptors in the brain structure, triggering the release of various neurotransmitters. This release leads to the reinforcing effects that contribute to addiction. E-cigarette use rates among YAs, particularly in rural communities, have reached alarming levels. Our current study is of paramount importance as it seeks to address the need for effective cessation interventions tailored to the unique challenges faced by rural populations. Grounded in preliminary study insights and guided by Transtheoretical Model behavior change constructs, our team developed a text messaging e-cigarette cessation intervention program. This is a randomized controlled trial designed to assess the efficacy of the targeted intervention through text message support, multiple evaluations, salivary cotinine testing for cessation verification, and monetary compensation. These methods are used to collect participants' cessation outcomes and encourage participation. Participation criteria encompasses YAs (18-24 years) living in rural counties of Wisconsin, Minnesota, North Dakota, and South Dakota, where e-cigarette prevalence is higher than national average. Interested individuals are invited to a comprehensive Zoom session for informed consent before being randomized into either the treatment (intervention) or control (standard care) group. Intervention group participants receive automated text messages for 8 weeks, while the standard care group receives a short message with a link to national e-cigarette cessation resources during the same period. The outcomes of this study focus on the feasibility and preliminary efficacy of the intervention and can have a significant impact on public health, tobacco cessation science, and tobacco control policy by providing evidence for e-cigarette cessation among YAs in rural areas.

Abstract Name: Narrative Memory Differs by the Race of the Protagonist

Two experiments analyze how a narrative and its protagonist are remembered depending on the participants' race. The cross-race effect (CRE), a phenomenon where individuals have poorer memory for faces outside of ones' race compared to faces within their race, was examined. It was hypothesized that White participants would experience more race-based errors when the protagonist was a Black male in comparison to a White male. Also, White (Black) participants would be more likely to confuse the Black (White) protagonist with other Black (White) characters. Black participants (experiment 1 only) and White participants were given a short narrative about a male protagonist, Jackie. Four faces would appear: Jackie and the loiter, who alternated being Black and White, and the cashier and server, who were both White females in experiment 1, but Black or White females in experiment 2. After reading the narrative, the participants responded to a series of questions to test their memory of events and character faces. In both experiments, findings suggest that White participants had a higher rate of race-based memory error when presented with Black Jackie than White Jackie. The results suggest that patterns are used to aid in filling in memory gaps and those patterns can be related to racial expectations. Additionally, White participants, in experiment 1 and 2, misidentified Jackie the most when he and the loiter were both Black. In contrast, Black participants misidentified Jackie the most when both he and the loiter were White. In short, the CRE was supported in both experiments and in Black and White participants. Implications are that race and culture may influence the way we remember and misremember details of an event.

Abstract Name: Oral Delivery of Intracellular Proteins via Carbamoylated Guanidine Modified Polymers

The protein therapeutic industry is a rapidly growing market, expected to reach a global value of approximately $250 billion by 2028. Proteins are effective medications; however, they face limitations in cellular penetration and serum stability. As such, research and development of polymeric protein delivery systems are increasing due to their cellular permeation abilities without causing cytotoxicity. This project focuses on effective oral administration and cellular entry of carbamoylated guanidine (CG) modified polymers. Previously, our group demonstrated the success of intracellular protein delivery via polynorbornene (PN) modified with the coplanar, hydrophobic, charge-neutral, hydrogen-bonding enhanced phenyl-CG (Ph-CG). Further modifications to Ph-CG should improve biodegradability, complex stability, and intracellular delivery. Oral delivery routes for protein-polymer complexations are favored over injection techniques, as these methods may lead to pain, increased risk of infection, bleeding, phlebitis, subcutaneous port placements, high financial costs, and decreased patient compliance. When therapeutics are orally ingested, they must be resistant to the digestive tract's acidic environment and traverse the intestinal cellular layer to reach the bloodstream. The human intestine comprises a single-celled epithelial layer and mucous membrane that pose a barrier to the absorption of compounds from consumed products. Adjustments to CG-polymers will be analyzed for optimization of intestinal diffusion and resistance to gastrointestinal degradation. To replicate the intestinal environment, human colon carcinoma cell line (Caco-2) monolayers will be experimentally produced. CG-modified polymer-protein complexes will be administered to CaCo-2 monolayers, with aims of improving permeability, delivery, and absorption of orally administered therapeutics.

Abstract Name: Titan Genesis: AI Empowered 3D Manufacturing

3D printing has emerged as a manufacturing method over the past 10 to 15 years. This advancement enables the average individual to learn how to model objects in Computer-Aided Design software, making it possible to create anything from affordable prosthetic limbs to replacement parts for unsupported machinery. However, most of the advancements in 3D printing technology have been confined to massive private companies with the financial resources for extensive research and development. Consequently, these advancements are often kept sheltered and private to avoid indirectly aiding their competitors. To address these issues, we propose a publicly available enhancement of consumer-grade printers, enabling the public to access most of the features through software and hardware implementations, creating a Computer-Aided Manufacturing System. To achieve our goals, we integrated a Raspberry Pi into an Anycubic 3D printer and loaded it with custom open-source software. This software allows users to create and assign tasks to multiple printers, effectively establishing a mass manufacturing program. Within this program, various features such as live monitoring, estimated print times, optimized support structures, and slicing will empower individuals to harness tools that were once reserved for industrial applications. Once this vertically integrated software is stable, AI can be introduced to speed up or increase the efficiency of it through removing tedious and recursive mathematical calculations related to point clouds, vectors, and 3D spaces. This software is of paramount significance, as it liberates individuals who were once constrained by limited resources, igniting a wave of innovation and invention that will have a profound and far-reaching impact on society as a whole.

Abstract Name: Analysis of Sediment Composition and Microplastics in Waters around the Nueces/Corpus Christi Bay Area

The proliferation of microplastics and erosion both pose concerns to the Nueces/Corpus Christi bay area. Microplastics (< 5 mm) are known to irritate organic tissue and leach chemical additives, affecting both humans and the environment. Although the risks caused by microplastics, are a notable point of interest to research, little information is available on active changes and degrees of microplastic contamination in this area. Moreover, erosion constitutes a source of coastal breakdown and a threat to waterside ecosystems and communities, making its investigation crucial as it is already eating away at the valuable coast in this area. This paired study sought to gather helpful data points on microplastic concentration in major tributaries to Corpus Christi Bay, as well as provide sediment composition data to aid in erosion modeling and prevention. In order to achieve this, sediment and water samples were collected from Oso Bay under the Yorktown Bridge, Nueces River near the Port of Corpus Christi and at Labonte Park, and Oso Creek at the Cedar Ridge Park Drainage Canal (only water). Water samples and controls were analyzed by using H2O2 to digest organic matter, a NaCl solution to separate microplastics through buoyancy and a filtration device to collect them in order to observe them through a compound microscope. Furthermore, sediment samples were examined by conducting a mechanical sieve analysis and hydrometer testing. The microplastic research was redirected by contamination issues in the negative controls, highlighting issues with the procedure, and providing insight into modifications of the process to ensure more reliable data in the future. The sediment analysis revealed that the particle size distribution in these sites consists of around 13-40 % gravel, 55-83% sand, and 4-5% silt (by mass). These data will hopefully be used in future research to aid in remediation and protection against environmental damages.

Abstract Name: Determining the Role of the Volume Regulated Anion Channel in Astrocyte Volume Reduction by Hyperosmolar Solution

The volume-regulated anion channel (VRAC) is a ubiquitous anion channel expressed by all cells which plays a role in cell volume regulation. Upon cell swelling, VRAC are triggered to open, releasing anions such as chloride as well as a number of negatively charged ions and amino acids, resulting in a regulatory volume decrease of the cell. Astrocytes, a type of glial or support cell, undergo constant changes in volume in response to neuronal activity. They are important regulators of the brain's extracellular space (ECS), which plays a critical role in brain tissue excitability. However, the role of the astrocyte volume-regulated anion channel in transient or prolonged changes in astrocyte and ECS volume is unknown. Therefore, in this study, we have used transgenic approaches to selectively ablate, or conditionally knock out (cKO), astrocytic VRAC using astrocyte-specific promoter-driven Cre lines to determine the role of VRAC in acute astrocyte volume changes. I will use confocal microscopy to record real-time volume changes in fluorescently-labeled astrocytes in acute mouse hippocampal slices from VRAC cKO vs. littermate control mice by adjusting osmolarity of artificial cerebrospinal fluid (ACSF). The role of VRAC in rapid astrocyte volume reduction will be determined by application of hyperosmolar ACSF to induce cellular shrinking. The data thus far have shown that when VRAC is ablated, the astrocytes' ability to recover their volume is significantly impaired. This work has important implications for understanding mechanisms of acute cellular edema and reduction of the brain ECS.

Abstract Name: What's in Our Water? Identifying uncharacterized bacteria from recreational sites in Tampa Bay

While bacteria are part of all ecosystems on earth, the presence of pathogenic bacteria such as Escherichia coli, Staphylococcus, and Vibrio species pose a risk to human health. Recreational waterways are monitored for fecal indicator organisms in order to minimize adverse health conditions within the community, but the presence of other pathogens may go undetected. Between 2019 and 2021 a University of Tampa research team sampled different recreational waters across Tampa Bay to test for the presence of Staphylococcus aureus and Methicillin-resistant S. aureus (MRSA) using microbial and genetic tests. Of the samples that displayed common microbial markers for S. aureus, many lacked the S. aureus genetic marker NucA, indicating the presence of other unidentified potentially pathogenic organisms. To identify these uncharacterized organisms, the 16srRNA gene was amplified by PCR and sequenced using the ABI seq studio analyzer system. MEGAx software and the NCBI GenBank database were used to analyze the sequence results, and a variety of genera were identified. Our data suggest the presence of mostly non-pathogenic environmental bacteria such as Cobetia, Exiguobacterium, Priestia, and Bacillus, with only a few pathogenic bacteria identified. Here we will present our current findings and discuss our approach to analyzing the diversity of the organisms we have identified. This projects' findings provide insight into the diversity of organisms in Tampa Bay and will help guide new approaches to determining the health and safety of our waterways.

Abstract Name: Older sister trauma in the Latinx immigrant household

Hello, my name is Emily Martinez. I am a women's gender and sexuality studies major at the University of Central Oklahoma. I am from a Latinx household, and I am an older sister. My research came with the passion of not only advocating for older sisters who've been parentified and who have always been the third parent, but also having the background character to have a voice. My research is a niche topic and is not always talked about due to the stigma of mental health within the Latinx immigrant community. Just like me, my mother is an older sister as well. She has also given up her hopes and dreams of raising her siblings,

seeing them grow into adults, and enjoying childhood while she had to sit back, raise them, and take care of them as if she were a third parent. My research discusses the trauma that is experienced by elder sisters within the Latinx immigrant household, the potential effects on the mental health of Latinx women, and the creation of this information into poetry. The methods that I used to do this research were reading psychology journals and personal accounts of older sisters, creating an artistic formula to transform it into poetry, adding a twist to my experience, and understanding the likelihood of what being an older sister is like for somebody who isn't an older sister. For the conclusion of my research, there is not much; it is ongoing research, and the creation of more poems is on the way. I will be doing an oral presentation of my research and having a live poetry reading of some of the poems I have compiled from my research while taking feedback from the audience.

Abstract Name: Working Within and Around Anti-Trans Legislation: A Mixed-Methods Investigation of Gender-Affirming Healthcare Providers' Strategies of Resistance in Tennessee and Texas

Informed by Fontanari et al.'s (2020) insights linking gender affirmation to mental health, our study delves into the need for tailored, accessible care. Referencing Puckett et al. (2018) and Gridley et al. (2016), we tackle barriers like financial constraints and a shortage of knowledgeable providers, seeking support mechanisms crucial for sustaining care for transgender and gender-expansive (TGE) youth. Building on Hughto et al.'s (2020) exploration of gender affirmation, our goal is to understand the intricate relationship between affirmation and mental health outcomes. In 2023, the United States witnessed a concerning surge in anti-transgender legislative proposals, totaling 591 bills, including 85 focused on restricting healthcare, across 49 states (Trans Legislation Tracker, 2023). Amidst this hostile legislative environment, our research focuses on the effects of such laws on gender-affirming healthcare workers, especially in explicitly anti-trans states like Tennessee and Texas. Employing a mixed-method approach—surveys and interviews—we aim to elucidate the multifaceted impact of anti-trans legislation on gender-affirming care provision. We are planning to recruit 300 participants for a comprehensive survey and conduct 48 in-depth interviews with various healthcare providers, including therapists, counselors, social workers, physicians, endocrinologists, and psychiatrists. Anti-trans legislation contradicts medical consensus on gender-affirming care, challenging healthcare providers (Transgender Legal Defense and Education Fund, 2023).We anticipate identifying barriers resulting from legislation criminalizing gender-affirming healthcare. Moreover, our work sheds light on how providers navigate restrictive legislation to ensure continuity of care for TGE young people. We will develop recommendation booklets for practitioners, sharing strategies emerging from our research. Our overarching goal is to bridge the gap between academic insights and practical applications, contributing to both the theoretical understanding of challenges faced by gender-affirming healthcare providers and the practical enhancement of TGE youth's well-being. These implications underscore the urgent need for nuanced, evidence-based approaches in clinical practice and policy development.

Abstract Name: Multiple Myeloma: Increase Longevity and Quality of Life through Early Detection

Multiple Myeloma is a rare form of bone marrow cancer where plasma cells accumulate in the blood stream attacking the skeletal system, nervous system, and kidneys of predominantly African Americans, and results in high mortality rates within 5 years of initial diagnosis. Multiple Myeloma has subtle symptoms of bone pain; doctors often send people to physical therapy missing the diagnosis. Blood tests that predict Multiple Myeloma, are listed on the International Myeloma Foundation website, but what is the best predictor of the most aggressive stage of Multiple Myeloma, Stage 3?Using 21 blood test results and demographic information on 203 Multiple Myeloma patients from 2008-2019 in Algeria, this study identifies the best predictor of Stage 3 Multiple Myeloma versus Stage 1 and 2. Logistic Regression was conducted using blood and urine tests results and demographics. Wald Confidence Intervals were used to estimate the odds ratios. Cost savings were calculated by determining the cost differential of less invasive blood tests versus the more invasive bone marrow biopsy.The Logistic Model was able to distinguish 65.43% of the time between whether patients have Stage 3 versus Stages 1 and 2. The odds of having Stage 3 Multiple Myeloma increase 1.04 to 1.56 times for each one g/dL decrease in MCHC. Lower patient MCHC levels are more indicative of the patient having Stage 3. Using an MCHC blood test has an estimated cost savings of $1734 per patient as compared to a bone marrow biopsy. Testing a patient with bone pain for MCHC can facilitate earlier Multiple Myeloma diagnosis, allowing physicians to administer earlier treatments, thereby improving patients' longevity and quality of life while coping with the disease.

Abstract Name: Making Sense of the Movies: How to Better Understand and Predict the Theatrical Window

This project investigates the connection between a film's theatrical window and its theatrical run. Its purpose is to help better understand how the timing of a film's digital release impacts a film's overall box office performance and assess whether a film's theatrical window can be predicted ahead of time. As such, this project is centered around three primary research questions: Are the theatrical window and theatrical run decreasing or increasing over time? Are the theatrical window and theatrical run correlated? Can existing box office data be used to build a framework that can predict a film's theatrical window? Existing research has shown that timing a film's transition from theatrical to digital is crucial as putting a film onto digital too soon or leaving a film in theaters for too long leaves millions of dollars on the table. Yet, it has shown neither the historical patterns of nor the statistical relationship between the timing of a film's transition from theatrical to digital. Moreover, it has not yet explored the predictive power of box office data as a potential solution to studios' timing dilemma. This project uses archival domestic box office and digital release data of 500 films released theatrically over the past decade in order to identify patterns, run correlation and regression analysis, and leverage results pertaining to the theatrical window and theatrical run in order to build a predictive equation. Data from 2013-2022 is used to build the equation while data from 2023 is used to verify the equation's predictive power. As such, results are expected to show that the theatrical window and theatrical run have decreased over time, a positive correlation, and the ability to form the basis of a predictive equation. This would emphasize the importance of studios' timing problem and provide a possible multi-million dollar saving solution.

Abstract Name: Repression and Cooptation: How the Lack of Civil Society Accessibility Affects Climate Change Treaty Outcomes

This project blends participatory action research (PAR) and collaborative ethnography event (CEE) approaches — based on observations and participation at over 100 remote UNFCCC events by a team of faculty, graduate and undergraduate students, as accredited observers for the Demand Climate Justice Network — to examine the nuanced ways in which COVID-19 provided both opportunities and limitations for justice-based civil society to influence the processes and outcomes of COP26, COP27, and COP28. For this project, we focused specifically on the ways in which civil society faced cooptation and repression in these unique summitry events and how this limited access played out in relation to treaty decisions on carbon trading and loss and damage.

Abstract Name: Design, Synthesis, and Testing of Novel Small Molecule Interleukin-6 Inhibitors for the Amelioration of Inflammatory Bowel Disease

Inflammatory Bowel Disease (IBD) is a prevalent autoimmune condition that affects 3.1 million Americans and is characterized by an excess of inflammatory cytokines. Interleukins, a class of cytokines, regulate immune cell differentiation and response. Specifically, Interleukin-6 (IL-6) is key in IBD, binding to membrane bound receptors, phosphorylating downstream targets and activating inflammatory pathways such as JAK-STAT and MAPK. IL-6 induced inflammation can be suppressed by reducing IL-6 production or blocking IL-6-mediated signal transduction. Monoclonal antibodies like tocilizumab, which target the IL-6 receptor, are currently used as IL-6 inhibitors. However, there are no small molecule inhibitors on the market that directly target IL-6. Small molecules are attractive due to their lower immunogenicity, reduced costs, and oral administrability. This project aims to computationally design, synthesize, and test novel small molecule drugs that have the ability to inhibit the IL-6 cytokine signaling cascade. The drug discovery platform Schrödinger Maestro was used to design these drugs, employing the natural compound curcumin as a template structure. More than 350 compounds were generated and a scoring profile was developed to identify the most optimal small molecules. Two compounds, Curcumin Derivative 1 (C1) and Curcumin Derivative 2 (C2) emerged as the most promising candidates due to their ideal binding affinity and high absorption

through the gut-blood barrier; these compounds were synthesized and characterized. Based on in-vivo testing in model organism Drosophila Melanogaster, both C1 and C2 are highly effective in ameliorating IBD. Subsequent investigations will focus on conducting in-vitro cellular IL-6 inhibition assays.

Abstract Name: Between Conflict and Coexistence: Intra-Islamic Relations in Iraq

This research explores the developing relationship between Sunni and Shi'a Muslims in Iraq during and after the presidency of Saddam Hussein and the continuously shifting relationship between religion and politics in the country. In Iraq, Saddam ruled his country with an authoritarian “iron fist," oppressing many of his people and keeping them in check. The US invasion of Iraq in 2003 left a power vacuum that manifested in sectarian violence, causing many to flee the country. Scholarly research on this topic tends to take a geopolitical approach, privileging perspectives of political parties and leaders, at the expense of understanding the everyday experiences of Iraqis from both sects. This research takes a comparative memory approach examining how Sunni and Shia Iraqis remember sectarian relations pre- and post-Saddam. To examine this relationship, this research employs ethnographic fieldwork, participant-observation, and interviews with both Shia and Sunni Iraqis in the diaspora, including the US, UK, and Jordan. Additionally, interviews with 2nd generation Iraqis further aid in understanding how these perspectives change generationally. This research applies the concept of sectarianization, which holds that sectarian identities are not static and essential but politically and socially produced, to examine shifting sectarian identities across generations in the diaspora. This research finds commonalities among Shia and Sunni Iraqis who contend that identities such as tribe, class, geography, and family were even more important than religious identities, but that the removal of Saddam Hussein from power dissolved the coexistence between the two sects into sectarian conflict. Moreover, structural sectarianism continues to permeate diaspora communities through the physical separation of spaces. However, though many Iraqis inhabit sectarianized spaces in the diaspora, they attest to easing sectarian tensions in Iraq itself.

Abstract Name: Police Reform and How Citizen Review Boards May Alleviate The Problem of Police Misconduct

The lack of accountability in law enforcement for police misconduct is an issue that has polarized the law enforcement landscape as well as the nation, awakening a renewed call from community leaders, policymakers, and advocates for citizen review boards and other methods of improving police transparency and accountability. How can Citizen Review Boards improve the rates of police misconduct and ensure greater police accountability? What methods do Citizen Review Boards employ to supervise police

misconduct? What are the limitations and problems associated with Citizen Review Boards? The primary method of inquiry employed is a literature review of social science research in the areas of law and society, criminal justice, and policing, containing keywords such as police reform, accountability, police oversight, and citizen police complaints. Online searches using JSTOR, Google Scholar, and SAGE Publications were utilized to gather information on this topic. Based on the literature, one can hypothesize that Citizen Review Boards may affect police behavior and they have the potential to play a significant role in shaping police accountability and improving public safety. Previous work on this topic exposes the issue of legitimacy with Review Boards. To combat this, Citizen Review Boards must be given power to be able to reprimand police officers for misconduct. With adjustments and requirements, Citizen Review Boards can help reduce the problem of police misconduct and lead to a safer and more just society for its citizens.

Abstract Name: Chronometric Investigation of Object Representation Strength Yields Evidence of Compensatory Processing

Object-based attention (OBA) allows for deeper processing of an attended object among overlapping, unattended objects. Attended object representation strength is influenced by very long (1000 ms) vs very short (200 ms) preview times (Shomstein & Behrmann 2008). However, it remains unclear whether gradations in exposure duration would lead to a graded object strength. To test this, we used a rapid serial visual presentation (RSVP) paradigm to display partially-scrambled overlapping faces and houses in which preview time is related to the duration of each frame. Subjects were asked to respond when they detected a target (a specific face or house) and we evaluated performance at 6 different frame durations, across two experiments (Experiment 1: 500 ms, 750 ms, 1000 ms; Experiment 2: 600 ms, 900 ms, 1200 ms). A repeated measures ANOVA was used to compare accuracies with frame duration and block number as within-subject factors. No main effects nor interactions were significant (Experiment 1: f’s<.9, p’s>.62; Experiment 2: f’s<0.74, p’s>0.57). T-tests were used to compare reaction times (RTs) for correct versus false alarm responses. Correct RTs were significantly slower than false alarm RTs at all frame durations (all p’s<0.002), except the 1200 ms (p = 0.064) frame duration. Average RTs steadily increased from 1150 ms (500 ms frame duration) to 1860 ms (1200 ms frame duration), suggesting that object representation strength did not solely influence target detection. Furthermore, observed slower RTs for correct responses at shorter frame durations suggests that subjects compared attended objects to those appearing in subsequent RSVP frames in order to make accurate determinations. Utilizing more processing time to ensure a correct decision allowed for compensatory processing during situations of high sensory uncertainty, suggesting that OBA representation strength can be modulated by length of preview time.

Abstract Name: Characterizing Novel PROTACs Against TG2 in Ovarian Cancer Cells

Background: Epithelial ovarian cancer (EOC) has been known for its rapid growth and is particularly challenging to treat in later stages, developing chemotherapy resistance and metastasis. Tissue transglutaminase (TG2) is an upregulated protein in ovarian cancer and is linked to EOC metastasis. The goal of our study was to characterize novel PROTACs (Proteolysis Targeting Chimeras) that most effectively decrease TG2 protein levels, causing EOC cells to lose their migrating, invading, and proliferation capabilities. Methods: We used an ovarian cancer (OC) cell line that expresses TG2 (SKOV-3) to assess TG2 protein levels by Western Blot after treatment with different PROTACs, at different concentrations. Migration and adhesion assays were used to characterize phenotypical changes caused by TG2 reduction induced by PROTACs.Results: We found that Protacs P404 and P405 induced decreased TG2 protein levels by Western blot. Of the concentrations used (0.1, 1, 10 μM), only 10μM induced a significant reduction of TG2 levels at 6 and 24 hours. In the migration assay, the % scratch area closed compared to the cells treated with PROTACs and to the control cells revealed a difference in cell migration induced by PROTACs, likely because of decreased levels of TG2 (p < 0.001). The solid phase adhesion assay demonstrated that fewer SKOV-3 cells treated with PROTACs attached to the fibronectin compared to control treated cells (p-value < 0.01). Conclusions: Our data suggest that novel PROTAC molecules are effective at inducing TG2 degradation in-vitro in OC cells. As a consequence of down regulating TG2, the PROTACs blocked cell migration and adhesion to fibronectin. We are continuing to optimize TG2 directed PROTACs structure in order to improve potency and pharmacokinetic properties with the goal of developing a novel drug that blocks metastasis and drug resistance.

Abstract Name: The Unfulfilled Duty of the Federal Aviation Administration to Eliminate Airlines' Carbon Footprints

Exploring the intersection of ethical business practices and the environmental benefit of carbon credits, this research has identified elements of how the airline industry is one of the leading polluters of carbon dioxide. This research asserts that there is a moral responsibility for airlines in the United States to purchase carbon credits in order to decrease thier carbon footprints, facilitated through the Federal Aviation Administration (FAA).Some statistical figures which will be highlighted in particular are ones that indicate that the aviation industry is a top carbon polluter. For example, a total carbon emission of 179 million metric tons is produced by commercial airlines from the U.S. (around 12% of total global emissions). Yet, airlines included in the EU Emissions Trading System (EUETS) have reduced their carbon emissions by more than 17 million tons in contrast to U.S. airlines. Alongside the numerical statistics, legal policies implemented for the FAA will be analyzed and dissected, as they don’t fulfill ethical obligations to protect the environment (in contrast to the EUETS.)My methodology consisted of collecting information and analyses from research papers published by peer-reviewed sources, and interviewing individuals at my flight school and airport in order to gain a more personal insight into how certain pilots feel on an individual scale. Through an informative presentation, I will examine my findings pertaining to the possibility that carbon credits have to salvage our country’s environment, as well as why the FAA should be held to ethical standards.The morality of decisions being made by airlines are questioned in this research. The main purpose is to educate the audience on the concept and importance of carbon credits, particularly as they pertain to the FAA. The FAA has the moral obligation to take into consideration their environmental impact, and they should be upheld to such ethical standards.

Abstract Name: Deployable Human Detection Device

The U.S. military requires advanced threat detection technology to determine the number of enemies in a restricted or indoor environment. Current threat detection technology includes drones and handheld thermal sensors which are not optimal for indoor deployment. To develop a tactical indoor human detector, a range of sensor types were evaluated for potential use. Pyroelectric infrared sensors (PIR) and microwave radar sensors were chosen. To further evaluate potential performance, two Panasonic long-range PIR sensors were fixed to a pivotable breadboard to determine an ideal sensor arrangement. The range, detection window, and lenses were tested, and it was determined that overlapping fields of detection would allow a microcontroller to distinguish the direction of a threat based on which combination of passive sensors were triggered. Implementation involved building a ring of staggered PIR sensors that rotates relative to the bottom section of the device. As the PIR sensors rotate, they observe changes in heat to calculate the direction of human threats and trigger the microwave radar sensor to ping the distance between the sensor and the threat. Initial testing of the microwave radar sensors concluded that an object's presence could be detected through low-density obstacles. By further researching and implementing an IR camera into the device, the threat could be analyzed with AI for human characteristics.

Abstract Name: CFD Validation of Formula One Aerodynamics

Computer-aided design (CAD) has shaped the world around us, with significant contributions ranging from everyday life to the height of competitive sport. Formula One (F1) racing is the pinnacle of motorsport where vehicle aerodynamics is consistently improved to optimize performance. This research study seeks to validate simulated data from a CAD model with wind tunnel and test track data. F1 wings are inverted to create a force above the car that suctions it to the track, this is called ground effect. Well-designed airfoils take advantage of changes in airflow to create significant downforce during sharp turns and still provide low drag for high speeds on the straights. CAD significantly reduces the cost of the design process allowing greater innovation between physical builds. Computational Fluid Dynamics (CFD) is a special type of CAD and can be used to simulate the airflow around wings. This study uses CFD to evaluate the effects of downforce and drag on car bodies. Using CFD to optimize the design helps minimize design costs for airfoils that can maximize the car's performance in the wind tunnel and on the racetrack. The ANSYS CFD software provides airflow models over different F1 front wings, varying wing shapes, and mounting angles. A wind tunnel and R/C car validate CFD predictions for downforce and drag. The data from this study suggests a correlation between CFD predictions and physical world measurements. Previous publications indicate this work can be extended to applications for aircraft design.

Abstract Name: Exploring Biomimetic Patterned Surfaces to Combat Bacterial Biofilm Growth

Biomimetics involves observing nature and copying or mimicking designs to develop new materials for the objective of solving complex real-world problems, like bacterial growth on surfaces. In nature, the cicada wing has bactericidal capabilities, with its sub-micron features that penetrate bacterial cell membranes, effectively killing bacteria. Patterned surfaces, like those of a cicada wing, show promise as a model for developing new technologies to fight bacterial adhesion. When bacteria adhere to surfaces, they can build up and form biofilms. When those surfaces reside in the human body, such as catheters or IVs, biofilms can lead to serious infection and death. Within the human body, biofilms cause up to 80% of chronic bacterial infections, and biofilm growth on these devices is difficult to treat because of device location. Antibiotics is one method of treatment, but the use of antibiotics may lead to a rise in deaths due to antibiotic resistance that is expected to surpass cancer and diabetes combined by 2050. Thus, researchers are exploring how surface characteristics such as stiffness, physical features, and chemical treatments can affect biofilm growth. We have investigated how varying physical patterns on surfaces can affect biofilm growth. The patterns range in

shape and size, are on the order of micrometers, and were fabricated on a silicon wafer using photolithography. We created copies of the patterns using polydimethylsiloxane, and embedded the copies into 48-well plates. Plates were incubated with Staphylococcus aureus for 24 hours and absorbance was measured to indicate bacterial growth. Surface patterning may provide a pathway toward reducing bacterial adhesion on indwelling medical devices, thereby improving the health of patients without antibiotics.

Abstract Name: Systemic or Cell Autonomous? The Nature of ARR7 Downregulation by Geminivirus Infection in Arabidopsis

Almost all aspects of plant growth, such as cell division and shoot initiation, rely on cytokinin signaling. Cytokinins initiate growth pathways through a phosphate relay system between a His kinase and a response regulator. Arabidopsis response regulator 7 (ARR7) is among the group of type A response regulators observed to exhibit the greatest fold increase in expression upon cytokinin signaling. Type A response regulators are known for their ability to negatively regulate further cytokinin signaling and thereby lead to a reduction of plant growth. Microarray analysis of samples from A. thaliana infected with the geminivirus cabbage leaf curl virus (CaLCuV) indicates that ARR7 is downregulated during infection. It can therefore be proposed that geminivirus propagation may be reliant on some downstream growth effect of cytokinin signaling, and that ARR7-mediated negative feedback may interfere with this. It is hypothesized that geminiviruses directly induce downregulation of ARR7 expression in a cell autonomous manner, as opposed to being a systemic effect resulting from some indirect action of geminiviral components. Screening of ten A. thaliana ARR7::GFP lines identified one with the most reliable fluorescence, and preliminary immunohistochemistry assays were used to detect Rep in the cells of CaLCuV-infected tissue. Further immunohistochemical methods, in combination with the use of GFP-fused ARR7, are being developed to co-localize ARR7 with Rep in the cells of leaf and meristem sections from infected A. thaliana. It will be investigated whether fluorescence from GFP-fused ARR7 can be detected following immunohistochemical staining. In the case that it cannot, a double-staining or double-fluorescent localization method using an anti-GFP antibody may be utilized.

Abstract Name: The Interactions of Botrytis cinerea with Radula complanata Endophytes and Metabolic Profiling

Radula complanata is a leafy liverwort that, although phylogenetically far from Cannabis sativa, produces structurally similar secondary metabolites to those of C. sativa plants. Previous research identified endophytes that are common in Radula marginata and C. sativa plants. Known for causing bud rot in C. sativa, Botrytis cinerea is a pathogenic fungus of concern in the cannabis industry. This study investigates compounds produced by endophytes isolated from R. complanata when in competition with B. cinerea, shedding light on potential interactions between these compounds and the mold. We collected R. complanata from various locations around Marquette County, MI. The samples were surface sterilized, and bacterial and fungal endophytes were isolated. The bacteria and fungi were identified based on morphology and sequencing of the ITS (internal transcribed spacer) of the 16S and 18S ribosomal subunit. To investigate their usefulness as a biocontrol of B. cinerea and other pathogens, we co-cultured the endophytes with B. cinerea. Extracts of the endophytes and the growing media were assayed to identify candidate metabolites that may play a role in the interaction. Compounds identified from the assays could be good candidates for use as antimicrobial agents that can be applied as a biocontrol agent in place of chemical fungicides. Chemicals isolated from R. complanata have shown bioactivity; for example, previous work has demonstrated that radulanin A possesses herbicidal activity.

Abstract Name: Sensory Design Approach for Indoor Soccer Complex and Wellness Center

Indoor soccer complexes struggle to encourage a healthier lifestyle due to a lack of community engagement, upkeep, and sanitation, as well as a lack of programs. The project's purpose is to construct an indoor soccer complex as well as a wellness center to encourage a healthy lifestyle for people of all ages in the community. Further examination of current facilities reveals that the major issues with indoor soccer facilities are a lack of accessible applications, technology incorporation, and community engagement. A survey was done at a local indoor soccer arena, and participants were asked whether they would like to upgrade the current facility or create a new one, as well as what spa therapy services they would like. According to the study, 76.7% would like to see a cold plunge feature, 66.7% would like to see a sauna/steam room, and 60% would like to see a massage area. Several case studies show that engaging sensory design provides meaningful environments for people by assisting them in developing a healthy lifestyle through the use of their senses. The implementation of sensory design principles enhances the therapeutic effects, giving users a multisensory journey toward improved physical and mental health. Visual aspects, such as natural lighting and natural features, for example, combine to produce an aesthetically pleasant ambiance that encourages relaxation and focus. Auditory elements, such as carefully designed soundscapes and acoustics, can help to create a peaceful and motivating workplace. In addition to the indoor soccer fields, the wellness center offers a variety of services to complement the physical activities. The center caters to a wide range of wellness needs, from individualized workout programs to mindfulness workshops. Using textured flooring and wall materials, as well as technology that mimics the sound and shape of water, will help people open their senses.

Abstract Name: Fabrication of Radiopaque Polycaprolactone Filament for Biomedical Applications

Visibility of endovascular devices such as stents and flow diverters during and post-insertion are critical for safe and successful implantation. However, the visibility of fully bioresorbable implants has been a challenge. This research presents the fabrication and analysis of a radiopaque, medical grade polycaprolactone (PCL) filament by blending two biocompatible radiopaque and stable metal compounds with PCL. PCL is placed in a glass beaker and filled with acetone. A sonicator is used to stir the mixture and dissolve the PCL in the acetone. Then, a radiopaque material, such as Bismuth trioxide or Tantalum (V) oxide, is added to the PCL solution. In each trial, 0.25 grams of PCL and 3 mL of acetone are used and kept constant while the amount of the radiopaque material starts at 0.25 grams and increases by 25% for each trial up to 0.5 grams. After each trial and changing the amount of the radio-opaque material added, the mixture is pipetted out immediately after sonication and made into small chips. The chips are then placed under the X-ray camera at a fixed distance, photos are then taken, and the intensity of the X-ray reflection is measured. The chips are then put into the extruder to fabricate a 1.75mm filament. The fabricated filaments are also examined under X-ray, and images are taken. The X-ray images are analyzed, and intensity values are recorded using ImageJ software. The results show a direct correlation between radiopacity and the mass of the radio-opaque material added for individual chips and filaments. The filament visibility was much better than the individual chips due to a higher concentration of radiopaque material. The Bismuth trioxide appeared to have more radiopacity than the Tantalum (V) oxide. This study will help in developing fully bioresorbable, biomedical, endovascular implants and devices.

Abstract Name: Decentralized Machine Learning Approach on ICU Admission Prediction for Enhanced Patient Care Using COVID-19 Data

The Intensive Care Unit (ICU) represents a constrained healthcare resource, involving invasive procedures and high costs, with significant psychological effects on both patients and their families. The traditional approach to ICU admissions relies on observable behavioral indicators like breathing patterns and consciousness levels, which may lead to delayed critical care due to deteriorating conditions. Therefore, in the ever-evolving landscape of healthcare, predicting whether patients will require admission to the ICU plays a pivotal role in optimizing resource allocation, improving patient outcomes, and reducing healthcare costs. Essentially, in the context of the post Covid-19 pandemic, aside from many other diseases, this prediction not only forecasts the likelihood of ICU admission but also identifies patients at an earlier stage, allowing for timely interventions that can potentially mitigate the need for ICU care, thereby improving overall patient outcomes and healthcare resource utilization. However, this task usually requires a lot of diverse data from different healthcare institutions for a good predictive model, leading to concerns regarding sensitive data privacy. This paper aims to build a predictive model using deep learning techniques while maintaining data privacy among different institutions to address these challenges.

Abstract Name: Understanding Service: Georgian Military Perspectives of Cooperation with NATO Members

The Republic of Georgia has long wanted to join the European Union (EU) and North Atlantic Treaty Organization (NATO), to the extent that the government sent troops to serve in Afghanistan and Iraq with NATO soldiers. The team involved in this paper conducted over 70 interviews over the last two summers in the Republic of Georgia to understand why Georgian troops served in Afghanistan and how their service affected the Georgian military and society. This article argues the Georgian military's capabilities have improved significantly through its participation in the wars in Iraq and Afghanistan. Yet, there are still latent Soviet structures that permeate the opinions of the Georgian military class and resist complete reform. Furthermore, this article finds that opinions on Georgia's military engagement differ between politicians, high-ranking and low-ranking military officials. While all parties seem to have a sense of pride in participating in these NATO operations, the higher the rank, the less likely the interviewee was to posit that people enlisted for reasons other than pay. However, these differences in opinion frequently do not reach outside of military matters, as most veterans and Georgian politicians hold very similar, positive opinions on the West, regardless of their status.

Abstract Name: Closing the Theory-Practice Gap in Adapted Physical Education

The Theory-Practice Gap has long been recognized as an issue in higher education as practitioners struggle to integrate knowledge learned in higher education to the PK-12 classroom (Ferraz, Vidoni, Vilas Boas, 2020; O'Learly, Wattison, Edwards, 2014; Marian, 1986). Recent research with the national Adapted Physical Education (APE) Teachers of the Year (TOY) has uncovered an APE TOY Culture. The APE TOY Culture was defined in part by a strong intrinsic drive to serve the APE/APA profession beyond the job description (Piletic, Sullivan & Hilgenbrinck, 2021). The Adapted Physical Education (APE) profession has recognized Teacher's of the Year nationally since the 1990's. However, the voices of the state APE TOY's have not been heard, collectively. The research efforts included creating a comprehensive list of awardees by state and year and inviting all awardees to complete the survey. The intent of this presentation is to provide an analysis of a recent state APE TOY survey. This session will overview the APE TOY ongoing professional

development, professional collaborations and APE service. Recommendations will address ways to close the theory-practice gap.

Abstract Name: Course-based undergraduate research experience (CURE) and Honors Program hybrid course on microplastic detection and analysis

Undergraduate research gives students an insight into the problem-solving strategies of a certain discipline. A Course-Based Undergraduate Research Experience (CURE) and Honors Program hybrid course was designed. The undergraduate course was taught as a co-disciplinary Honors and Chemistry course and included a discussion component as well as a research component. The course was designed to increase interest in chemistry through research on a currently relevant topic, and to add discussion-based curriculum to a chemistry undergraduate course.Microplastic contamination is a currently significant topic. An undergraduate course was developed to examine the extent of microplastic contamination in the environment. The class discussed social, political, and environmental implications of plastic and microplastic contamination. The lab tested multiple samples of varying matrices for microplastics and used the fluorescent dye Nile Red for detection and confirmation of microplastics.

Abstract Name: Improving Balance in Women 50 and Older Through Immersive Virtual Reality Training: A Preliminary Analysis of Balance Confidence

As adults age, the risk of falling substantially increases. For women, deficits in balance and walking speed tend to occur earlier than they do in men, increasing the risk of falls. Many falls occurring in older adults can be attributed to deficits in the somatosensory, vestibular, and visual systems that combine to provide stability during walking and standing. To study a new method to possibly improve balance in women who are 50 and older, we tested the Bertec Computerized Dynamic Posturography (CDP) Immersive Virtual Reality System as a balance training intervention for women 50 years and older. Fourteen women were randomly selected to participate in either 18 (Group A) or 9 (Group B) 20-minute balance training sessions along with going through pre, middle, and post assessments (Group B started training after the first 3 weeks). One of the assessments, delivered in an interview style format pre-, mid-, and post-intervention, was the Activities Specific Balance Confidence Scale (ABC). This validated tool assesses balance confidence, rather than fear of falling, doing a variety of everyday (non-clinical) tasks. Comparing the ABC score of the two groups

during the first 3 weeks of the study, the group doing balance training (Group A) showed a trend (p=0.22) toward a higher ABC (balance confidence) score than the control group (Group B) doing no training. When all participants (Groups A and B) were combined to see if the first 3 weeks of their balance training (9 sessions) improved ABC scores, we found a non-statistically significant trend (p=0.058) toward improved confidence in balance. Thus, our preliminary findings (small sample) show that a 3-week/9-session Immersive Virtual Reality balance training intervention has promise for improving balance confidence in women 50 years or older.

Abstract Name: Strajk Kobiet: The Evolution of Polish Laws Combating Domestic Violence from 1952 to 2023

This research project seeks to analyze the evolution of Polish domestic violence laws from 1952 to 2023. The goal of the research is to answer the question, what can be learned about contemporary Polish domestic violence policies through analyzing the evolution of domestic violence and marital laws in Poland from 1952 to 2023? Little scholarship exists on domestic violence in Eastern Europe before the fall of communism, however Eastern Europe's Soviet legal attitudes influence contemporary domestic violence laws, rates, and policies. Previous researchers have sought to close similar gaps in scholarship on domestic violence in Poland through exploring factors, causes, legal attitudes, and the Soviet period, but a significant gap still exists in Polish scholarship, especially from a legal standpoint. This project will analyze eight domestic violence and marital laws in Poland from 1952 to 2023, through two rounds of thematic coding. Coding is determined through an intersectional approach, with the first round of coding covering four sections: political, social, economic, and cultural, and the second-round further codes each of these sections into a further five subsections. The research may conclude that communist legal attitudes have influenced contemporary policies toward domestic violence, due to the negative communist view of domestic violence legal protections. The only way to effectively address contemporary Polish issues combating domestic violence is by first determining the impact of previous communist legal attitudes on contemporary domestic violence policy.

Abstract Name: Characterization of Genes Involved in Detoxification of Reactive Electrophiles that Build Up in Response to Stress in Arabidopsis thaliana

Understanding how a plant responds to stress at the molecular level is crucial for developing strategies to

enhance stress tolerance. Stress changes the cellular environment, causing major changes to metabolism and impacting protein functions and increasing enzymatic side reactions. This results in changes in the amount of canonical metabolites and increased amounts of reactive, unwanted, metabolic side products. Some particularly problematic reactive electrophile side products include formaldehyde, glyoxal, and succinyl-CoA, which accumulate in response to stress. These reactive electrophiles spontaneously react to form covalent adducts with nucleophiles such as lysine residues on proteins. These adducts can affect protein and membrane functions and can become advanced glycation end-products (AGEs). The buildup of these altered macromolecules harms cellular and physiological functions and is a major contributor to aging. In order to remove formaldehyde and glyoxal, there are highly-conserved glutathione (GSH)-dependent detoxification systems. Reactive electrophiles spontaneously react with GSH to form adducts that acyl-GSH hydrolases cleave, thus releasing a benign compound and restoring GSH. Since plant cells hold high levels of GSH, GSH effectively competes with proteins for reactive electrophiles and helps in their neutralization, thereby preventing macromolecule damage. Well-characterized and highly conserved acyl-GSH hydrolases are involved in formaldehyde and glyoxal detoxification. Additionally, the Niehaus lab recently identified a conserved acyl-GSH hydrolase involved in succinyl-CoA detoxification. Arabidopsis has homologs of these three hydrolases (At2g41530, At1g11840, and At3g10850), as well as four additional acyl-GSH hydrolase homologs (At1g53580, At2g43430, At1g06130, and At2g31350). The expression levels of these seven genes are upregulated in response to abiotic stress. We predict that the four uncharacterized acyl-GSH hydrolase homologs are involved in reactive electrophile detoxification and play important roles in mitigating harmful effects of abiotic stress. The goal of this project is to identify Arabidopsis knockout lines and test whether deleting acyl-GSH hydrolase homologs impacts stress tolerance.

Abstract Name: Analyzing the degree to which climate change has been an agent of economic malaise in African economies : Case study on Zimbabwe

This research paper seeks to examine the factors that have been significant in causing economic failure in African countries. The main focus of the paper is to explore how climate change can or has altered economic growth in African countries. However, to ensure that we maintain a holistic narrative on the factors that can impact an economy we must acknowledge other determinants by analyzing the role leadership, gender equality and technology have played in economic development. Outside of these determinants we also acknowledge orthodox measures such as FDI, population, trade and inflation that play a crucial role in shaping the stability of the economy. To further investigate how these selected variables will prove my hypothesis we will be using a time series regression model from 1980-2021, using Zimbabwe as the focus of analysis. This will be followed by a case study that will explain the correlation between the results of the regression and economic growth in Zimbabwe. Overall, the results from the empirical analysis suggest that climate change, inflation and population were more critical issues affecting the economy of Zimbabwe today. In closing this essay seeks to provide feasible solutions that Zimbabwe can harness to bring back stability, prosperity and economic growth whilst raising awareness on the impact climate change will have on African economies in the near future if preventative measures are not put in place today.

Abstract Name: Comparing Seasonal Changes in Total Phosphorus in Urban Beaver and Stormwater Ponds

Phosphorus is an essential nutrient necessary to sustain life on Earth. Its recent overuse, however, especially in urban and agricultural areas, has resulted in severe negative impacts on freshwater ecosystems. High phosphorus levels cause excessive algal growth, resulting in blooms that ultimately lead to decreased oxygen concentrations in ponds and can degrade aquatic ecosystems. In cities, green infrastructure, such as stormwater ponds, mitigate stormwater runoff by retaining sediment and phosphorus. Urban areas across the United States have seen a return of beaver populations and these beaver ponds and wetlands act as natural filtration systems, removing phosphorus and other pollutants from waterways. While there are many studies about nutrient and sediment retention in stormwater ponds and beaver ponds, there are few studies that compare these processes in urban systems and the southeastern United States. Our overall project goal is to quantify and evaluate these two types of ponds to determine which is more effective in removing phosphorus. We collected surface water from the inflow, pond, and outflow sites of 3 beaver and 3 stormwater ponds in Charlotte, NC approximately every 10 days for two years. Total phosphorus concentration was analyzed using an acid persulfate digestion method. Preliminary findings show that stormwater ponds tend to have higher total phosphorus concentrations than beaver ponds, suggesting that beaver ponds are better at retaining phosphorus. Given the negative impacts of excessive amounts of phosphorus on freshwater ecosystems, finding solutions for removing phosphorus from waterways is necessary for maintaining ecosystem health. Beaver ponds provide a low-cost nature-based solution for removing phosphorus while providing additional ecosystem services. Comparing the effectiveness of beaver and stormwater ponds at removing phosphorus from water can help us determine where to focus our efforts to prevent harmful algal blooms from endangering freshwater ecosystems.

Abstract Name: Enhancing HPGE Detector Performance Through Automated Cooling Systems

At the Sanford Underground Research Facility (SURF), advanced detectors are being used in the search for dark matter and neutrino properties. The sensitivity of these particle detectors to trace radiation amounts from their own component materials can cause background signals and overwhelm the rare signals from elusive particles. To minimize this background, the Black Hills Underground Campus (BHUC) assays construction materials for ultra-low levels of radiation before they can go underground into the detectors. These assays are performed using High Purity Germanium Detectors (HPGE).The HPGE's effectiveness relies on the ability to keep the germanium crystal at cryogenic temperatures. This requirement leads to the labor-intensive process of regularly checking and refilling the HPGE dewars with liquid nitrogen to ensure the crystal stays cool. This poster will detail our ongoing efforts to automate this process.

Abstract Name: Breakfast Skipping in College Students and its Association with Eating Behaviors.

Background: Breakfast is important in maintaining optimal diet quality and decreasing preventable diet-related disease later in life. Despite its importance, breakfast skipping is highly prevalent in the college population. Breakfast skipping may reduce one's self-regulation causing increased habits of overeating and decreased diet quality. However, eating behaviors such as eating styles and daily consumption have yet to be studied in breakfast skippers. Objective: To explore the characteristics of eating behaviors among college students who skip breakfast. Methodology: Undergraduate students participated in an observational study examining those who skipped breakfast the day prior. Participants (n=55) completed demographics, the Self-regulation of Eating Behavior Questionnaire (SREBQ), the Dutch Eating Behavior Questionnaire (DEBQ), and the Short Healthy Eating Index (sHEI). Participants were predominantly female (69%), white (58%), classified as a health professions major (40%), and the average age was 21 years old. Statistical Analysis: Descriptive statistics and bivariate correlations were analyzed using SPSS V29.0. Results: Of those who skip breakfast, students reported eating breakfast: never (20%), 1-2 days (32%), 3-4 days (42%), or 5-6 days a week (5%). Breakfast consumption frequency was positively associated with external eating (p=0.034). Additionally, lower self-regulation levels were correlated with higher levels of emotional eating (p<.001). There were 94.5% of participants who consumed added sugars above AHA recommendations (women: 24g/130kcal & men: 32g/520kcal); of this value, 47% consumed greater than or equal to 520 calories the day they skipped breakfast.Conclusion: Students who skip breakfast often skip multiple times per week, and occasional breakfast skipping may be associated with external eating. Low levels of self-regulation are related to higher levels of emotional eating. Among students who skip breakfast, added sugar consumption far surpassed recommendations. Future longitudinal studies are needed to compare variables between days with breakfast consumption vs. skipping.Funding: Support from the UCF College of Nursing.

Abstract Name: In Vitro Plant Propagation through Plant Tissue Cultures

Micropropagation (in vitro plant culture) is the practice of collecting plant tissues (explants) from a mother plant to grow identical plants in a lab using a specialized nutrient medium. A sterile environment is required to grow the plant tissue, so no contamination inhibits the plant's development and growth. The importance of micropropagation lies in the fast and cost-effective production of genetically identical plants that can replicate desirable or rare traits. These plants are also protected from pests or pathogens and can be grown in

any season using less space and time which is useful for commercial production and research. Generally, the explants should grow new shoots within 3 weeks and be well-developed with roots by six weeks as long as contamination does not interfere with this process. The plants can then be placed in soil and slowly acclimated to drier and light-intensive environmental conditions. In this experiment, we sought to establish micropropagation techniques in our lab by collecting various plant tissues from local sources and observing any growth and development under varying conditions. Two different hormones (Indole-3-acetic acid [IAA] and 6-benzylaminopurine [BAP]) were used to determine their effects on the growth and root development of each explant. The explants were carefully prepared for surface sterilization with ethanol and bleach before being placed in test tubes under grow lights for several weeks. Despite occasional contamination, many plants were able to successfully grow shoots and leaves but did not grow roots. Some IAA-treated explants showed greater pigmentation, flowering, and larger foliage while the BAP-treated plants showed smaller but more plentiful foliage, though many cultures showed no differences. The results of incomplete root development in the explants requires more research about plant growth hormones and their ideal concentrations for the explants to show proper root development.

Abstract Name: Frre the Books: Unmasking the Impact of Book Banning on Education

In the United States, the contentious issue of book banning has sparked a profound reflection on the principles of freedom of expression and the crucial role literature plays in shaping public discourse. The American Library Association's revelation of thousands of annual attempts to ban or challenge books in schools and libraries highlights a disquieting trend that has persisted for over a decade. The yearly tally has consistently hovered between 500 and 600 cases, with a significant portion targeting educational materials, revealing an ongoing clash between educational objectives and perceived sensitivities. The act of banning books, a form of restriction, raises significant concerns about hindering students' access to literature, potentially depriving them of content that resonates with their experiences or sparks their desire to share. This pervasive trend has resulted in the censorship of numerous books based on subjective claims of impropriety, palpably impacting students by stifling their freedom of expression. Teachers find themselves navigating this precarious terrain, constrained in their pedagogical approaches. If this trajectory persists, it poses a threat to the inclusion of vital discussions on controversial topics and diverse cultures. Motivations for book banning vary widely, stemming from objections to explicit content, diverse perspectives, and discussions involving race, gender, or LGBTQ+ issues. This exploration delves into the century-long evolution of book banning, identifying frequently banned books in each decade and scrutinizing the primary reasons behind their prohibition. The study investigates common rationales for banning books in U.S. schools and libraries, exploring the repercussions of removing or banning certain books from school curricula. Emerging themes include limited exposure to diverse perspectives, stigmatization of topics, impact on academic performance, and a pervasive sense of marginalization. This comprehensive analysis seeks to illuminate the complex dynamics surrounding book banning, emphasizing its far-reaching implications on education and intellectual freedom in the United States.

Abstract Name: Young Children's Ability to Represent Alternative Possibilities

One of the central capacities of human cognition is the ability to reason about alternative possibilities. Although there is evidence to suggest that this ability is fundamental for learning in the context of cognitive development, studies show that preschoolers typically fail tasks that require them to consider mutually exclusive possibilities. This could be due to (1) children holding a minimal representation of possibility before the age of four, or (2) to previous task designs which have masked children's true competence. To test these hypotheses, we designed a novel search task, in which 3- and 4-year-olds are asked to search for a target item inside two search boxes after it is dropped from either a fully transparent or opaque set of y-shaped tubes. The transparent tubes allow children visual access to the location of the object, while the opaque tubes allow for two possible locations. If children have a minimal representation of possibility, their search behavior should not differ between the opaque and transparent trials. However, if children are sensitive to the presence of multiple possibilities, they should spend less time searching the first search location in the opaque condition compared to the transparent one. Our results indicate that 3- and 4-year-olds spent significantly less searching the first location approached when the object was dropped into the opaque, compared to the transparent set of tubes. This suggests that children are able to consider alternative possibilities before the age of four.

Abstract Name: Intervention Services for Black Elementary Students and Parent Intervention Programs: Autism and Educational Reach

Equal opportunities in the classroom are crucial factors for inclusive education. Despite the increase in awareness and screening for Autism Spectrum Disorder among the Black, Asian, and Hispanic communities, racial and ethnic disparities still exist, specifically among black children with Autism Spectrum Disorder (ASD). Studies have revealed that black children with ASD have consistently been on the lower end of receiving intervention services, participating in services, and attaining a proper diagnosis of ASD. Obtaining an early diagnosis and having access to intervention services are crucial for better educational outcomes, yet black children are more likely to be placed in school special education programs because of their behavior rather than disabilities. This study aimed to understand how access to special education services may play a role in educational outcomes and how the implementation of parent mentor programs that inform black parents about ASD can empower them to create an effective foundation that could improve their child’s performance both at home and in educational settings. Using peer-reviewed sources, this research examined racial disparities among black children with ASD, focusing on delayed diagnosis among black and multiracial families and parent and healthcare provider relationships. The findings suggested that parent mentor programs for black parents can bridge the knowledge gap for black parents regarding ASD by helping

them advocate for their child's educational needs. Empowering parents through these parent mentor programs can contribute positively to the educational outcomes of black children with ASD.

Abstract Name: Does integrating poultry into organic vegetable production have an effect on biological soil health aspects?

Decades of specialization have separated livestock from crop farms in the Midwest as well as other regions of the US and internationally. Could re-integrating livestock have benefits to production, local economies, and the environment? Our project evaluates the impact of re-integrating poultry into vegetable cropping systems at three locations in the United States: California, Iowa, and Kentucky. The focus here is on how integrating poultry into these vegetable cropping systems affects soil health. We examined various aspects of the health of the soil, including physical, biological, and chemical factors, but this study will focus on the biological aspect of our measurements. At both the Iowa and Kentucky sites, we assessed the microbial biomass carbon and earthworm abundance to measure the biological health of the soil. We found that integrating chickens with vegetable cropping did not increase microbial biomass but did increase earthworm abundance by 109% compared to the control (no chickens). In the future, we will be analyzing other soil health properties and how they are affected by integrating chickens. Considering all drawbacks and benefits – including improvement in soil functioning (i.e., soil health) – is required for a holistic assessment of integrating chickens into vegetable cropping systems.

Abstract Name: The Effects of Bilateral Entorhinal Cortex Lesions on Spatial Working Memory and Septodentate Innervation in Rats

The central nervous system is capable of remarkable functional reorganization to compensate for the loss of brain tissue by neurodegeneration or injury. The entorhinal cortex (EC) is among the very first regions to show signs of deterioration in patients with Alzheimer's disease, a neurodegenerative disease characterized by significant memory loss. This study investigated how bilateral lesions of the EC impact rodent performance in a spatial working memory task and how synaptogenesis might contribute to behavioral

recovery. A delayed-alternation task conducted using a Y-maze was used to measure the rats' spatial working memory performance. Male Sprague-Dawley rats were assigned to an lesion (n = 13) or sham (n = 14) group where they either received the bilateral EC lesions or a craniotomy, respectively. Their working memory was subsequently assessed using an acquisition alternation task on the Y-maze with an intertrial interval (ITI) of 30 seconds. Their performance was evaluated based on the number of total and perseverative errors in the task across a 6-week testing period. A histological stain for acetylcholinesterase (AChE) was used to study the sprouting response from the AChE-containing, septo-dentate pathway to compensate for the loss of the EC's input to the dentate gyrus of the hippocampal formation. The AChE stain density is used as a marker for cholinergic septo-dentate sprouting. Results of these studies highlight both the significant sprouting response in the middle molecular layer of the dentate gyrus and the importance of the EC for spatial working memory.

Abstract Name: Theoretical Study of The Interaction of Select Perfluorinated Alkyl Substances (PFAS) with Transcription Factor, Nuclear Factor Kappa β

Per or polyfluoroalkyl substances (PFAS) or "forever chemicals" are a group compounds that are used for their water-resistant properties. PFAS can be classified into short or long chain compounds, based on the number of carbons they contain. Concerns for the longer chain or legacy PFAS compounds stem from their accumulation in air, soil, and water due to slow degradation in the environment. Additionally, exposure to PFAS has been linked to significant health effects and recent evidence indicates they have the potential to be neurotoxic, with the largest effect on dopamine neurons. Multiple studies show PFAS disrupt cell homeostasis by increasing oxidative stress, however the mechanism by which this occurs remains unknown. In this theoretical study, we will use computational methods to examine the potential of three PFAS chemicals (Perflouorooctanesulfonic acid (PFOS), Perfluorooctanesulfonyl flouride (POSF), and Perfluorobutanoic acid (PFBA) to interact with the transcription factor, Nuclear Factor Kappa β (NF-κβ), activation of which is important to regulation of oxidative stress and cell survival. Computational analysis included geometry optimization of PFOS, POSF, and PFBA via Avogadro using General Amber Force Field (GAFF), protein docking analysisusing Autodock Vina with Pyrx graphical user interface, and analysis of protein ligand interactions with BIOVIA Discovery Studio Visualizer. Results indicate that long chain PFAS chemicals (PFOS and POSF) had both stronger binding affinities and potential intermolecular interactions with NF Kappa B, than the short chain, PFBA. This discovery adds to our understanding of PFAS's ability to increase oxidative stress leading to neurotoxicity of dopamine neurons.

Abstract Name: Examining whether Marfan Syndrome Variants affect O-glucosylation of Fibrillin-1

Marfan Syndrome (MFS) is a heritable autosomal dominant disorder that results in connective tissue defects in the body, affecting about 1 in 7500 people. MFS is caused by missense mutations in the gene which encodes fibrillin-1 (FBN1), a protein found in the extracellular matrix required for the proper development of connective tissue found in the aorta and the lungs. These missense mutations cause variations of the FBN1 primary amino acid sequence. FBN1 contains 47 epidermal growth factor (EGF)-like domains, which can be highly O-glucosylated through biologically significant O-glucosyltransferases, POGLUT2 and POGLUT3. FBN-1 EGFs are O-glucosylated within the putative consensus sequence, C-X-N-T-X-G-S-F/Y-X-C-X-C, where 'X' denotes any amino acid, and the bolded 'S' indicates the O-glucosylated serine; some MFS variants affect these residues. Currently, the status of the O-glucose modification on MFS variant FBN1 is unknown. To assess if the level of O-glucosylation changes in MFS variant FBN1, a set of primers including an MFS missense mutation were developed and utilized in PCR-mediated mutagenesis to produce an MFS variant FBN1 plasmid. DNA sequencing showed that the developed primers successfully produced the MFS variant N1134K, which replaced the wildtype asparagine with lysine in EGF17. Currently, we are transfecting the plasmid encoding this variant FBN-1 into mammalian cells to express the protein. The purified protein will be analyzed using mass spectral glycoproteomic methods to determine whether MFS variant affects O-glucosylation of FBN1 EGF17. This work is supported by NIH grant R01HL161094.

Abstract Name: "What is Here Told:" Traditions of Irish Storytelling in Dracula

When discussing Irish influence in Dracula, critics have often focused on the contentious Irish politics of Stoker's time or on parallels between rural western Ireland and Transylvania. This paper moves away from that focus in order to consider ways in which Irish folklore and mythology impact the novel. Exploring the oral nature of these tales demonstrates how the conflict between oral storytelling and the written word appears in Dracula. Additionally, considering elements in Irish myth, from graphically violent descriptions of battles to wide-spanning journeys, leads the reader to a greater understanding of the novel's plot structure and construction of the vampire. The paper provides a slightly different lens through which to read Dracula, and its connections to orality could have greater implications for epistolary novels.

Abstract Name: Comparison of Irises in Turtles using Scanning Electron Microscopy to Identify sites Expressing Melanopsin

The source of sluggishness for the pupillary light response in turtles is thought to be due to photoreception mechanisms occurring in their irises involving melanopsin. The purpose of this investigation was to compare the anatomy of irises in different species of turtles to allow for future identification of locations expressing melanopsin. Left eyes were dissected from a red-eared slider turtle (purchased from Kons Direct), an eastern painted turtle (caught from Twin Lakes, 40.93786, -75.16199), and an eastern box turtle (provided by the North Carolina State Rescue Team), and preserved in 4% paraformaldehyde. After hemi-section, removal of lenses, and gluing onto stubs, posterior surfaces of irises were imaged by a Carl Zeiss EVO 25 SEM (Scanning Electron Microscope) using the C2D detector in variable pressure mode. Presence of radial structures were used to identify locations of dilators. Annular widths of sphincters and dilators were measured from captured images using the program, Zen 2.6 (blue edition). Widths of sphincters were 160, 120, and 168 μm, red-eared slider, eastern painted, and eastern box, respectively; widths of dilators were 669, 543, and 878 μm. Therefore, the eastern painted turtle has the smallest sphincter and smallest dilator. Normalization to the diameters of the eyes confirmed the observations: for sphincters, 3.06, 2.63, and 3.11%, for dilators, 12.8, 11.9, and 16.3%. Results show that imaging posterior surfaces of irises can be used to distinguish their components, which will assist in identifying expression sites for melanopsin. To confirm results and support with statistics, measures will be repeated using additional turtles and will compare males to females. For better ability to distinguish sphincters from dilators, images also will be attempted using the cold stage with the EVO 25's extended pressure mode to preserve surface topologies and enhance differences in sphincters and dilators.

Abstract Name: Contrasting Oak Responses to Water Stress - Osmolyte Profiling Across Species

Water represents an essential environmental factor, as it impacts plant growth, development, and structure. Drought stress induces plant acclimation to avoid tissue loss or death. Plants must adjust their physiology in response to low water conditions. One way plants acclimate to drought is by synthesizing or storing more osmolyte such as sugars, sugar-alcohols, or proline. Osmolytes are known to increase drought tolerance in plants by increasing the uptake of water by plant tissues. Oak species are well-adapted to a range of dry and well-watered environments. The objective of our research is to investigate the amount of osmolytes, specifically proline, produced by various oaks species using a common garden. This research is important because it gives us a greater understanding of how oaks and plants acclimate and are adapted to drought stress. Ultimately, this will be useful as climate change and water scarcity become more of an issue.We found that proline accounted for less than 0.05% of the total osmolyte concentration for leaf tissue. (In relative amounts, some species produce 100 times more proline than others.) The reason for this low concentration is that oaks synthesize other osmolytes and use proline in other functions (e.g., as an antioxidant). Our results motivated us to gain a greater understanding of how oaks naturally respond to drought. To serve this end, a future direction would be to research if osmolytes are dependent on soil factors (topsoil pH and organic content) that may influence nutrient availability. For example, studying the native environmental conditions of each oak will give us a greater understanding of the natural drought strategies of these oaks.

Abstract Name: An Analysis of Homocysteine and Homocysteic Acid in Bipolar Disorder

Homocysteine (HCY) is involved in methionine metabolism in the body. This chemical is also associated with the progression of neurodegenerative disorders such as bipolar disorder, schizophrenia, and Alzheimer's disease, as reported in several papers. When HCY reaches high concentrations in the body, it is believed to be converted into homocysteic acid (HCA), which contributes to cell neurotoxicity. Following analysis of our cell and media samples using liquid chromatography/mass spec (LC/MS) and high performance liquid chromatography (HPLC) with electrochemical detection (EC), we found abundances of HCY, and nitro-HCY. Other LCMS and HPLC data collected from the rat samples yielded high concentrations of what we believe to be homocysteine sulfinic acid and low concentrations of HCY. The oxidized forms of HCY, nitro-HCY, and homocysteine sulfinic acid have the potential to be either intermediates in the HCY to HCA transformation or simply alternative oxidized forms of HCY. We will continue to investigate the relationship between bipolar disorder and the presence of these compounds.

Abstract Name: Percy Jackson: The Hero Who Redefines “Troubled” Children

Rick Riordan wrote The Lightning Thief to bridge the gap between children’s literature and non-reading students by redefining fantasy fiction protagonists. Percy Jackson shares an abundance of traits with a stereotypically struggling student. Percy is a literary protagonist who does not like to read and is considered a “bad student” who bounces between specialized schools for “troubled” children. He is kicked out of school after school and comes to internalize his perceived academic shortcomings. His dyslexia, low-income household, and abusive stepfather are situational factors that contribute to the obstacles he must overcome on his hero’s journey and narrative struggle. Percy struggles to fit in at school due to the social gaps between varying degrees of “troubled” students. He is constantly anxious about his perceived academic aptitude due to the psychological self-sabotage of being labeled “troubled” and the subsequent expectations of poor academic performance. His desperation to earn the conditional respect of his mentor is tempered by his desire to give up attempting to please his authorities. At home, he feels inadequate to protect his mother from his stepfather’s cruelty. His mother is the sole figure of love and support for Percy despite her own shortcomings. Percy flees to a world of Greek mythology brought to life. However, unlike other fantasy fiction protagonists, this is no magically perfect escapist setting for Percy to claim as his new home. Instead, his personal and interpersonal struggles follow him. He is once again at odds with his authorities and his peers. Instead of academic pressures to perform, his conditional approval from his peer group hinges on his physical and magical capabilities. The Lightning Thief presents an alternative children’s literature protagonist whose relatability as a “troubled” child grounds the nuanced forces of expectations on youth in his heroic journey.

Abstract Name: Exploring Selectivity Differences in Aromatic C-H Borylations Catalyzed by Iridium Coordinated to Electron-poor 2,2'- Bipyridine Derivatives

One challenge regarding the direct functionalization of aromatic C-H bonds is borylation with ortho-directed selectivity. These catalysts typically operate under steric control making direct access to sterically hindered aryl boronate esters and acids very difficult. Nonetheless, ortho borylations have been successful with ligands that are a combination of heterocycles, which allow for iridium coordination to one nitrogen and one non-nitrogen atom rather than two nitrogen atoms like with bipyridine/phenanthroline ligands, which typically yield meta/para substitutions. Therefore, we started to consider the main structural difference between bipyridine and phenanthroline ligands, which is their aromatic connectivity, where bipyridine has a single connectivity point, and phenanthroline has an aryl group connecting the pyridine groups. We hypothesized that this differing connectivity would allow for flexibility in the bipyridine connection that's not in the phenanthroline ligand, possibly allowing the bipyridine to "rollover-metalate" to the iridium leading differences in directed selectivity. More recent developments in this area have found that electron-poor bipyridine ligands affect borylation ortho to moderate directing groups such as amides, thus we focused on ligands with carboxylate esters. We set up reactions with dimethyl benzamide where we used the ligand diethyl 2,2'-bipyridine-5,5'-dicarboxylate, where we observed strictly ortho substitutions, as well as the ligand diethyl 1,10-phenanthroline-3,8-dicarboxylate, where we saw only meta borylation with small amounts of bis-meta transformations. These findings pinpoint that this functional difference between the bipyridine and phenanthroline moieties of the compounds is making a distinct difference in selectivity as they have the same functionalized side groups.

Abstract Name: Voter Behavior and Terrorism-Related Arrests: Understanding the Electoral Successes of Far-Right Political Parties in European Parliament Elections

European countries' domestic politics are marked by threats of terrorism; meanwhile, electoral successes among far-right political parties are increasing within the European Parliament. Previous research revealed that a given European Union member country's total numbers of terrorism-related arrests and terrorist attacks in a given year are not correlated with far-right support in the country's elections for the European Parliament during the following year. Considering the effects that terrorism has on European countries, more insight is required into whether more specific variables related to terrorism, as differentiated based on motives, are correlated with the electoral success of far-right parties. Therefore, this new project seeks to reveal whether support for the far-right in the European Parliament elections of given year is correlated with variables pertaining to religiously inspired/jihadist terrorism and/or right-wing extremist terrorism during the election year and/or the previous year. These variables include the numbers of arrests related to religiously inspired/jihadist terrorism and the numbers of arrests related to right-wing terrorism in given years. As related to these variables, this project uses correlations to test the alternative hypotheses that support for far-right

parties is comparatively low in the context of a high number of arrests related to right-wing extremist terrorism and support for far-right parties is comparatively high in the context of a high number of arrests related to religiously inspired/jihadist terrorism. Relevant data is pulled from the European Parliament's election results and Europol's European Union Terrorism Situation and Trend Reports. This project seeks to uncover whether voter support for far-right parties is correlated with terrorist threats in Europe, as quantified by numbers of terrorism-related arrests in a given year, allowing for a greater understanding of voter behavior in Europe.

Abstract Name: Strengthening FDM 3D Printed Components using an Active Annealing Process

Additive manufacturing (AM) processes are an emerging group of manufacturing processes with the ability to produce products previously impossible with traditional subtractive manufacturing processes. Of the various AM processes, one of the most commonly used processes is Fused Deposition Modeling (FDM). FDM works by extruding a thin line of heated plastic, often PLA, and building up a component layer by layer. These components can be made quickly; however, they will typically fail through a process called layer delamination, where the layers of the part will peel away from each other. This fundamental flaw stands in the way of FDM's widespread adoption into mass production, and if there was a way to solve it it could lead the way for a future of more sustainable manufacturing. A common method to prevent layer delamination is to anneal FDM parts by heating them in an oven to fuse the layers together and make the parts stronger. While this method is effective at increasing strength, it could lead to distortion and reduce dimensional accuracy. In my research, I modified an FDM machine to reduce layer delamination using supplemental heating. A Prusa i3 MK3s was modified with a heater that is held precisely over a printed part to melt the previous two layers of a part together. A series of tensile test specimens based on the ASTM Standard D638-22 will be printed and then tested using an Instron tensile testing machine. Besides testing the effect of heating, the effects of dwell time and heating temperature variations will also be tested.Based on preliminary results, I predict an increase in inter-layer strength compared to unmodified parts without the dimensional changes caused by traditional annealing, with the best results predicted to be generally produced by higher temperatures and dwell times.

Abstract Name: The breast cancer genome and its association with the breast tissue bacteriome

Breast cancer (BC) is the most prevalent and fatal cancer type in women. BC forms in microenvironments in

which genes and bacteria are in close proximity. Existing research evidences gene-bacteria communication, but the relationship between the BC genome and breast tissue bacteriome is poorly understood. This investigation hypothesized that genetic variation in the top ten genes commonly linked to BC: BRCA1, BRCA2, PTEN, TP53, PALB2, CHEK2, ATM, BRIP1, BARD1, and STK11 would be associated with variations in the breast tissue bacteriome. We conducted 30X whole genome sequencing on 60 breast tissue samples (healthy, H (n=15), pre-diagnostic, PD (n=15), tumor, T (n=15), and adjacent normal, AN (n=15)) which were previously analyzed for microbiome composition and function using 16S rRNA sequencing (mSystems, 2022). Following sequence pre-processing, variant calling, and alternate allele frequency calculation by the UC Davis Bioinformatics Core, we isolated high and moderate variants for these genes with a quality score ≥ 55 for further analysis. 8 of 10 genes met these criteria within our data set: BRCA1, BRCA2, PTEN, TP53, PALB2, CHEK2, ATM, and BRIP1. Alternate allele frequencies and genotypes of variants with differences in alternate allele frequency among the tissue types were then associated with bacterial ASVs deemed differentially abundant relative to the H tissue type (mSystems, 2022) using MaAsLin2. Three BC-linked genes BRCA1, TP53, and ATM show significant associations with the taxa Muribaculaceae, Alcaligenes faecalis, Oceanobacillus, Romboutsia, Pseudomonas, and Pseudomonas fragi (p-value ≤ 0.01, q-value ≤ 0.25). These genera belong to phyla which can produce cancer-causing DNA damage or are associated with other types of cancer. The discovered associations further our understanding of the genetic and microbial determinants of BC and may highlight the breast tissue bacteriome as a biomarker of BC.

Abstract Name: Influences on Identity: How does Self-Proclaimed Cultural Identity Affect Psychological Well-being?

How does cultural identity affect psychological well-being? Varying perceptions of identity allow us to establish an understanding of it, its theory, its values, and its connections to life in a multitude of ways. Simply calling identity by its name opens up the understanding and the assumption of the thing to be vast and expansive, as identity itself is subjective to each person and entity which experiences it. While identity as we know it can emerge from scholarly settings, inter and intrapersonal settings, and as a self-established construction of acknowledgement of characteristics, personalities, and a menagerie of things that make humans feel alive, it has a plethora of subsets that makeup the entirety, grandiose umbrella that it is. Personal identity, social, intellectual, academic identity, the list goes on and on and yet they all make up someone's background or how they connect to the world and see themselves in it. One thing in particular, however, has consistently drawn my attention when I read and learn about identity studies, being the subset of cultural identity: how the social relates to the personal, and what makes up our notion of self in the environment that we are given. An analysis of published works allows the presentation of this paper to discuss the impact of disruption and instability on one's cultural identity and how that identity, however stable or insecure, affects one's psychological well-being. Through an analysis-based methodology one will find that through film and literary analysis of representation supported by published research in supporting and related fields, we can understand how a surplus of emotion, stress, or any other factors can lead to the development of effects on how secure one feels within their self-proclaimed cultural identity.

Abstract Name: Computational Study of Vocal Fold Tissue Oxygenation: Effects of Physiological Parameters

Vocal folds (VFs) are two bands of smooth muscle tissue found in the larynx. During voice production, air travels between the folds producing a biomechanical fluid-structure interaction (FSI) that causes a vibration known as phonation. Computational modeling of this FSI provides a prediction of VF dynamics and glottal flow which can lead to an improved understanding of these interactions. Our prior research studied the liquid dynamics within the VF by considering a poroelastic model for the tissue. In this current study, we aim to combine our FSI-porous VF model with a mass transport model to investigate the association of interstitial flow with oxygen transport within the VF. Previous experimental observations report contradictory relationships regarding the effects of phonation on the flow within the tissue and the associated oxygen partial pressure. It has been hypothesized that physiological conditions may influence VF oxygenation, which corresponds with dysfunctions such as hypoxia and localized lesions.To quantify key features that contribute to oxygen transport in the VFs, we developed a multiphysics computational framework of coupled mass transport-FSI methodology. The transient airflow in the larynx was described by the Navier-Stokes equations, while the oxygen transport was modeled using the advection-diffusion-reaction equation, and the interporous flow was solved via the Brinkman equation. Physiological parameters such as oxygen reaction rate, lung pressure, and tissue permeability were varied. Coupled biomechanical simulations of transient glottal aerodynamics, VF tissue dynamics, interstitial fluid dynamics, and oxygen flow were performed. The simulation results focusing on the interstitial velocity streamlines and oxygen concentration contours were analyzed.It was found that oxygenation is inversely related to reaction rate, directly related to permeability, and not noticeably affected by lung pressure. It was also found that filtration velocity is not affected by reaction rate but is linearly proportional to lung pressure and exponentially related to permeability.

Abstract Name: ISIS's Strategic Use of Human Trafficking

Since its creation in 2014, the Islamic State of Iraq and Syria (ISIS) has been proven to participate in the human trafficking of minority women. This study expands on the research related to ISIS’s use of human trafficking to uncover the extended strategic use of human trafficking by the terrorist group. Through use of government sources on human trafficking and on terrorism, primary sources as published by ISIS, and victim testimony, this research serves as an expansion on the previously understood uses of human trafficking by ISIS. In addition to trafficking women for sexual slavery, ISIS also traffics prisoners to be sold for profit, and children for forced criminality. Additionally, as the definition of human trafficking is better understood, the recruitment practices of ISIS are considered human trafficking when the recruits are exploited after joining and are persuaded to join through deception or coercion. This study serves to fill the research gap in how repatriation is affected by the designation of foreign fighters as victims of human trafficking.

Abstract Name: Adichie and African Womanism

Chimamanda Ngozi Adichie has always been a symbol for the ideals of female empowerment. An outspoken feminist Adichie is always very vocal about her ideas but has never called herself an African feminist or African Womanist believing that feminism should be universal but her writing provides diverse ways of thinking about empowerment beyond her goals. When we examine Adichie's works we see how overcoming trauma and oppression to get back to the community plays a huge role like Ifemelu overcoming her own negative self perception to find Nigerian community through her blog (Americanah), Kambili overcoming her father's trauma to relate to her aunt (Purple Hibiscus) and Akunna letting go of her old dream in order to become her fullest, most empowered self (The Thing Around Your Neck). This research examines the values of African/Black feminisms and African womanism, how those principles have been exemplified in Adichie's literary work and how her writings are useful to the African Woman. It also discusses the impact Adichie has had on African womanism, African feminism and how her writing has contributed to the movement. We look through most of her seminal pieces such as Americanah, Purple Hibiscus and The Thing ARound Your Neck and how themes such as Spiritual Connection, Connection and empowerment through community, and self reclamation have been used to exemplify the experience of the African woman. We discover how Adichie uses her own personal experience to convey a message of self empowerment and confidence in one's identity.

Abstract Name: miRNA in Ovarian Exosomes Influence Neurological Health in Mice

Aging-associated changes in motor function often leads to the development of musculoskeletal tremors. In women, the development/severity of tremors is causally related to ovarian failure at menopause. In the laboratory, mice can serve as an effective model for the development of aging-associated tremors. Based on our previous studies, ovarian somatic tissues transplanted from young mice to old mice significantly decreased the tremor amplitudes and lowered levels of gliosis in the brains of the older recipient mice, compared to age-matched control mice1. The study was carried out using both germ-cell-containing and germ-cell-depleted ovarian tissue. Neurological improvement and overall health were achieved using both types of tissue with similar results indicating that it may be a non-hormonal influence that is responsible for this phenomenon. This study is aimed to identify which properties of ovarian tissue causes these neurological health benefits to occur. Ovarian tissues excrete exosomes, vesicles that can be filled with miRNA which are transported throughout the body. We aim to isolate these exosomes from ovarian tissues using density gradient based centrifugation and have them introduced via injection intraperitoneally into mice to see if the same neurological improvements are achieved as it was done in mice with ovarian somatic tissue transplants. If such improvements are corroborated then ovarian exosomes will be sequenced to identify which miRNA sequences signal the body to undergo these health improvements.

Abstract Name: Exposure of radiation emission from cellphone in use

The impact of phone radiation on human health has been a topic of debate and research for many years. On one hand, some studies have suggested that long-term exposure to phone radiation may be associated with an increased risk of certain types of cancer, such as brain tumors. Additionally, there are concerns about the potential impact of phone radiation on male fertility and reproductive health. On the other hand, there are conflicting studies that have found no clear evidence of a link between phone radiation and adverse health effects. Furthermore, the telecommunications industry has implemented safety standards and guidelines for the emission of electromagnetic radiation from mobile phones, which are intended to minimize potential health risks. This project will compares the radiation emission from an iPhone and an android.

Abstract Name: The Impact of the Job Search Process on Young Job Seekers

Current entrants to the labor market are seeking work at a time when the economy is recovering from the COVID pandemic , when technology and automation play an increasing role in the hiring process , and in an era of economic uncertainty. How well job seekers are navigating the hiring process may depend on their previous job seeking experiences and their ability to navigate digital spaces well. Young labor market entrants are unique in that they have limited knowledge of the hiring process in general and their expectations about how it works may be more malleable than more experienced job seekers. Young entrants are also potentially more familiar with how to navigate hiring platforms and technology. These characteristics—a lack of work experience, few set expectations, and familiarity with platform technologies generally, make them an interesting group to study with respect to navigating the hiring process. How are young entrants to the labor market experiencing the job search process? To address this question, we interviewed young people living in the United States who have been actively applying to jobs. Interviewees were asked a series of open-ended questions about why they were looking for work, what sorts of jobs they aspired to, and the strategies and processes they use to locate possible employment, among other questions. These interviews were analyzed thematically using a system of open, and then systematic coding to identify common themes across interviews. This presentation will share preliminary findings from the interview data and speculate about their larger implications for job seekers more generally.

Abstract Name: Herculaneum Data Processing

Currently, EduceLab faces a challenge in processing the collection of images of around 3,500 trays of physically unwrapped Herculaneum scrolls that they have cultivated. The Herculaneum scrolls are ancient scrolls carbonized during the eruption of Mount Vesuvius in 79 A.D. Throughout history, attempts were made to physically unwrap these scrolls, which led to the vast collection of trays of physically unwrapped fragments that EduceLab has imaged. Due to the large amount of data, it has become increasingly important to have an efficient and effective post-processing pipeline for these physically unwrapped scrolls. While EduceLab has produced most of this post-processing pipeline, there are still some areas that require improvement. Specifically, within the datasets where there are a multitude of close-up images of singular trays. These multiple images complicate the study of the Herculaneum material by requiring manual stitching to obtain the complete image. This manual stitching can be incredibly time-consuming and labor-intensive due to the immense amount of images in a dataset. The goal of this project is to address this issue through the implementation of a stitching prototype program that will combine the multiple images into a singular cohesive image. This implementation will improve the post-processing pipeline by allowing the previously unstitched tray images to travel through the rest of the pipeline as a complete image. The completion of this project will provide a more efficient means of studying Herculaneum material through the elimination of the hindrance posed by fragmented imaging. Furthermore, it will advance the overall understanding of Herculaneum material and the human history associated with it.

Abstract Name: Predictive Validity of the Social Determinants of Health on Adolescent Licensure

Mobility is vital for daily tasks, including obtaining food and healthcare, attending school, and navigating one’s community. Access to such resources may impact the decision to obtain a driver’s license. Licensure rates among adolescents are declining. However, Social Determinants of Health (SDOH) variables may influence adolescent licensure decisions. This project examined the association of SDOH variables and sociodemographic factors on the odds of having a driver’s license in a sample of adolescents. Drawn from a larger, longitudinal study, adolescents (n=118) aged 16- to 18-years with and without a driver's license (Mage=16.65 years, nLicensed=50) provided demographics, family and home addresses. Various SDOH variables were gathered from the U.S. Census Bureau, geospatial software, etc. Principal Components Analysis (PCA) was conducted to assess SDOH components. Logistic regressions indicated increased neighborhood scores were associated with increased odds of licensure (OR=1.987, 95% CI=1.029-3.836), and higher built environment scores were associated with decreased licensure odds (OR = 0.350, 95%

CI=0.161-0.758). These findings suggest that the structure of adolescents' neighborhoods may influence an adolescent's decision to obtain a drivers license. Community leaders should work to improve the quality of neighborhoods to better the health and well-being of adolescents. Municipalities may target areas for additional transportation options (e.g., public transit). Future research should evaluate the impacts of SDOH variables on the odds of licensure and on driving outcomes for populations in other areas and of other ages.

Abstract Name: Queering Fairytales: A Study in Transformative Retellings

In this project I analyze a number of traditional fairy tales including Sleeping Beauty and Beauty and the Beast through a radical queer theoretical lens, drawing from theories including Jack Halberstam's concepts of queer failure and wildness, Michel Foucault's panopticism, Adrienne Rich's compulsory heterosexuality, and Judith Butler's gender performativity. The central idea of this project looks to Susan Stryker's work exploring the association between monstrosity and otherness and reclaiming the historical abjection of trans and queer bodies. These ideas, developed within the field of queer theory, reveal a great deal about the social norms we live under and how oppressive they can be for everyone, not merely for those who identify as queer or who otherwise enact forms of opposition against these norms. This project stands in the field of folklore studies and queer theory, placing an emphasis on queer cultural criticism. My work is informed by and pays homage to the tradition of queer fairy tale rewriters such as Kate Donoghue as well as scholars in the field including Kay Turner and Pauline Greenhill. The primary form of analysis is critically retelling these tales, utilizing a self-aware meta narrative voice to criticize the problematic aspects of the original versions while also exploring new, transgressive ways of valuing queer experiences.

Abstract Name: Programming and Data Training in an Undergraduate Summer Research Program: A workshop from the Molecular Sciences Software Institute

Cyberinfrastructure (CI) skills, including computer programming, computation, data analysis, and data visualization, are of increasing importance to the research enterprise in almost all STEM disciplines, including many disciplines which did not previously emphasize these skills. Students' exposure to CI skills in their standard undergraduate curriculum can vary widely by discipline and institution, ranging from no exposure at all to advanced discipline-specific computational courses. Undergraduate researchers benefit from having more CI skills, and students who already have exposure to these skills are often advantaged over students who do not. To help all our students develop these important CI skills and enhance their

undergraduate research experience, we have partnered with the The Molecular Sciences Software Institute (the MolSSI) to offer a programming and data analysis workshop at the beginning of our College's summer research program each year since 2019. The MolSSI is an institute funded by the National Science Foundation which aims to improve software, education, and training for the broad computational molecular sciences community. The workshop assumes no prior programming experience and teaches the students foundational programming and data analysis skills using the python programming language. Topics covered are intended to be immediately applicable to undergraduate research students and include basic python syntax, parsing files and searching for information, reading and writing data files, working with numerical data in the python library numpy, and data visualization using the python library matplotlib. The workshop comprises six hours of instruction, which includes live coding lessons and programming exercises. All of the workshop resources are open educational resources that are available on the MolSSI Education website (education.molssi.org), such that other institutions can easily adopt a similar workshop program. This presentation will discuss the curriculum and implementation of the workshop and examples of students using their CI skills in their summer research projects.

Abstract Name: Presidential Posters: The Power of Visual Media

In the United States, all you hear about is the politics. It's on billboards. It's on the news. It's on TV. It's flooded through your social media as you scroll down. It can even be caught in a random conversation. It's heard in all forms of media and creates propaganda to go for either politician that's in the running. Before and even during each president's run, propaganda begins to spark to the audience. But do people ever acknowledge the art that can come from these controversial topics? From early to present times in history, there have always been art for politicians that convey meanings from a bias standpoint. Whether from street artists or Congress themselves, the designs give the audience something to think about.

Abstract Name: Putting Knowledge into Action

Adolescence is a critical phase of development and a key time for laying the foundations of good health, as during this time patterns of behavior are often established. During puberty adolescent girls experience many changes in their bodies that may impact behavioral and mental health. Girls appear to be less physically active than boys, with notable drops in physical activity that begin around age nine. Within the population of adolescent girls, Latina girls are more vulnerable to poor health outcomes such as obesity and physical

inactivity. This community engaged research project is modeled after Alamance Girls in Motion and was implemented at the CityGate Dream Center, a community center serving a racially diverse population. To customize the program, the intervention was designed based on the needs obtained from parental focus groups and a survey with girls aged 9-12. Findings from the parent focus group (N=15) centered around themes of social, physical, and mental well-being and awareness of supportive community programs. The girls focus group (N=5) and survey (N=4) identified challenges to mental health, body image, and dealing with periods. Therefore, Dream Center Girls in Motion, an 8-week program for girls aged 9-12, focused on providing girls with the information, support and opportunities to engage in behaviors that improve their overall social, physical, and mental well-being. Twelve racially diverse girls from Alamance County aged 8-12 years old and 9 racially diverse Elon University female mentors participated in the program. To assess the identified needs, the girls completed the Rosenberg Self-Esteem Scale and Emotional Regulation Questionnaire for Children and Adolescents prior to the start of the program and upon conclusion. Program evaluations will be completed by the girls, mentors, and parents. Ultimately, the goal is to utilize the combined findings to ensure an effective and sustainable program.

Abstract Name: Climate Change Policy Development: A Multiple Streams Analysis of The Inflation Reduction Act 2022

Climate change has been on the national agenda since the late 1970s, yet until recently, little progress had been made because of the dominance of the fossil fuel industry within the policy subsystem. In this paper, we draw on Multiple Streams Analysis using process tracing methods to examine why significant climate policy was able to pass in 2022 when previous attempts had all failed. We examine two key case studies, the failure of Waxman-Markey and the success of the Inflation Reduction Act. In 2010 some climate organizations were hesitant about cap and trade as a policy mechanism to address climate change and failed to stimulate advocacy in their grassroots. Since then, climate groups have rallied around an alternative policy approach, which involves investing in clean technology. Activists built significant power within the Democratic party, evident in climate policy remaining prominent on the policy agenda at the beginning of Biden's presidency. Moreover, media outlets have improved their coverage of extreme weather events by tying them to climate change. In short, the political dynamics changed with climate activist building a base of power within the Democratic party, motivating citizens to elect Democratic leaders capable of passing cliamte legislation and keeping cliamte high on the policy agenda.

Abstract Name: A case morpheme or a verbal morpheme: Ho morpheme in Taiwanese Southern Min

This study analyzes the use of the "ho" morpheme in Taiwanese Southern Min (TSM). Previous literature has identified several functions of "ho" in Southern Min, including as a marker for double object construction, causative, dative, and agent (Hu, 2020). However, there is disagreement among researchers regarding whether "ho" can also function as a compound verb, preposition, or secondary predicate (Huang, 2007). Our research aims to validate these uses of "ho". To gather data, we conducted six elicitation sessions with an older male TSM speaker, resulting in 61 sentences with "ho". Our findings confirm the use of three of these markers, but indicate that "ho" cannot be used in compound verbs or as a verbal marker. Instead, our data suggests that the "ho" morpheme functions as a case marker in dative and passive constructions. Additionally, we found potential evidence suggesting that passive constructions with "ho" may carry a negative connotation. These findings indicate possible variations in the use of "ho" in double object constructions within Taiwanese Southern Min, and provide further insights into passive constructions in this dialect.

Abstract Name: Producing Datasets: Capturing Images on Multi-Camera Smartphones for Source Camera Identification

The lack of data available in the forensic science community proves to be an ongoing problem. This project’s main objective was to create a dataset with a sizeable number of images from all available cameras on multi-camera smartphones that will be publicly available, and representative of images potentially found on a person of interest's smartphone. The digital evidence team at the Center for Statistics and Applications in Forensic Evidence (CSAFE) worked with sixty recent models of multi-camera smartphones to create this dataset. Among the sixty smartphones were ten Samsung Galaxy Note 10s, ten Samsung Galaxy s20s, ten Samsung Galaxy s21s, ten iPhone 11 Pros, ten iPhone 12 Pros, and ten iPhone 14 Pros. Each of these sixty smartphones contains four individual cameras: the front selfie camera, the rear telephoto camera; the rear wide-angle camera; and the rear ultra-wide-angle camera. For each camera on each phone, the CSAFE team captured one hundred natural scene images and one hundred flatfield images. Natural scene images contain indoor and outdoor scenes but exclude all personally identifiable information. The flatfield images are photos of evenly-lit blank white walls which allow each photosite in a camera’s sensor array to be given similar information while the natural scene images provide examples of an image that could potentially be found on a person of interest’s phone. Each photo was taken with specific camera settings to ensure consistency throughout the images. While collecting data, a second sensor was found in the wide-angle camera for the Galaxy Note 10s, and so more images were captured so each sensor would have one hundred images. This dataset will be available and free for public use at some point this year and will be used by research teams at CSAFE to develop and test source camera identification methods to further forensic science research.

Abstract Name: The Integration of Te Awa Tupua (The Whanganui River Claims Settlement Bill) Into Whanganui's Local Governance, Culture, and Tourism Industry in the Context of the 2023 New Zealand Election

Internationally, several policies enumerating the rights of nature have been adopted, representing a shift towards recognizing Indigenous rights to stewardship of water within colonial legal contexts. In 2017, New Zealand implemented Te Awa Tupua, a policy which grants legal personhood to the Whanganui River. Te Awa Tupua represents a shift in Whanganui's perception from seeing the river as a resource to be used and exploited, to understanding the river as an entity that the community relates to and protects. Research surrounding Te Awa Tupua predominately relates to the philosophical foundations and historical context for the implementation of the policy, but there is a gap in research analyzing the success of the policy's implementation. This three-month transdisciplinary qualitative case study aims to analyze the extent to which Te Awa Tupua has impacted the culture, governance, and tourism industry along the Whanganui River in the context of the 2023 New Zealand election. The theoretical framework of this study is underpinned by Decolonial Theory and Kaupapa Māori, which encourage research to be conducted through the lens of an Indigenous Māori worldview, while data was obtained through participant observation, semi-structured interviews, surveys, and archival research. The findings indicate that Te Awa Tupua empowers Māori communities to share the ontologies underpinning their relationship to the awa (river) with Pākehā (non-Maori) and has provided a platform for Māori and Pākehā collaboration in protecting the awa. However, the research also showed that, in addition to specific limitations to the scope of the policy outlined in the legislation, Te Awa Tupua is limited by the constraints of the very colonial legal structure it is embedded in. Finally, within the context of New Zealand's 2023 election, the study suggested that environmental regulation and Māori rights to water stewardship are contentious political issues that affect the policy's implementation.

Abstract Name: Indigenous place names as a way to study land characteristics

Indigenous names of geographical locations and towns can grant insight into the area: whether that be the natural features or cultural significance. Due to the manner settlers from Europe interacted with Natives in the 17th-19th century, many places had their names changed to what the settlers preferred. The original Indigenous names can help us unmderstand what the area looked like before settlers arrived. For this project my collaborators and I focused on locations in Wisconsin. The primary questions being: what were the

original names of areas and their physiographic and environmental implications of the area? Many of those features have changed through time due to climate change and/or human actions: wetlands being drained or forests being cut due to urbanization.Our project involved taking names of Wisconsin locations with Indigenous names, finding probable Anishinaabe language(s) used in the name, then finding possible meaning(s) with help of a native Anishinaabe speaker. We examined if the original name is still applicable and displayed our findings via story map.Our project shows how the land features have changed throughout history and insight into our geologic past. Original Indigenous place names gave place-based knowledge: this story map can help keep this tradition alive.

Abstract Name: PERFOGRAPH: A Numerically Aware Program Graph Representation

Artificial Intelligence (AI) has revolutionized software development, creating platforms offering functionality such as code optimization, error detection, and even code suggestions. This progression has continued to include tools for code generation, advanced debugging, and modern chatbot development assistants. These tools often utilize a deep learning model to derive this functionality. However, a consistent challenge exists when using deep learning models on source code. Unlike natural text, source code has specific structures and entities that make applying the latest natural language processing techniques difficult. There are nuances to various naming conventions, function implementations, and data structures across programming languages that do not conform to a specific standard. Program representation is a process that aims to represent the programs for deep learning models for their better understanding. Several program representations have been proposed, many of which use graphs to represent programs. However, these solutions need more compile-time numerical awareness as well as insight into aggregate data structures such as arrays and vectors. When this information is not explicitly included, the performance and insights of GNNs are limited, as they cannot accurately and precisely intuit this information from current graph representations of programs. PERFOGRAPH was introduced to address this gap. It introduces a standard graph representation for programs that provides more detailed information on numbers at compile-time, aggregate data structures, and variables. This numerically aware approach to program representation provides Graph Neural Networks with this information, allowing them to better learn the features of the programs for downstream tasks.

Abstract Name: How Increases In Occurrences of Wildfires Pose a Significant Security Threat

Wildfires have the potential to harm and create significant issues for public health and safety, the

environment, and the military in the United States. This study aims to understand the impacts of wildfires and steps that can be taken to mitigate these impacts. The adverse impacts of wildfires can be studied by using tenets of fire ecology and management, and protection plans can be created to ensure the nation's security. Using ArcGIS software maintained by Esri, an investigation of wildfire patterns and adverse impacts were studied. A topographic base layer and multiple living atlas layers were used to create maps that allowed the data to be reviewed. The study found that there were relationships between wildfires and drought intensity, air quality index (AQI), and military divisions/field offices of the U.S. Army Corps of Engineers that create rising concerns for the safety and security of society. The study determined that in locations where current wildfires were occurring, the drought intensity and air quality index were high. The study also determined that the U.S. Army Corps of Engineers field offices and divisions within Alaska, California, Oregon, Texas, and Utah are at the highest risk for adverse impacts due to wildfires. These impacts include damage to property, illness, and fatalities attributable to the unpredictability of wildfires. To conclude, educational information and means of prevention and management must be implemented to ensure the safety and well-being of the people of the United States.

Abstract Name: The Rise and Fall of Safe Sex: Socio-Political Implications Preventing Comprehensive Sex Education

Sex education is often regarded as one of the best policy tools to curb STI rates. However, not all sex education curricula have the same effects. Scholars have established that comprehensive sex education (CSE) in public schools is more effective than abstinence-only programs in lowering STI cases. This literature, however, fails to address critical elements that influence STI rates beyond sex education programs, like access to broadband internet or religious identity, that mediate the efficacy and influence of these programs. Using data from the Center for Disease Control and Prevention (CDC) and the SEICUS 2022 state profiles, this project tests whether states with government-mandated inclusive or CSE programs have lower STI ratings than those having exclusive or abstinence-only sex education programs when controlling for internet access, religiosity, state party identification, and GDP. I find that religiosity is the highest predictor of STI case rates. Thus, states with higher levels of religiosity will have a higher STI rate per 100,000.

Abstract Name: Study of Different Manufacturing Processes to Minimize the Weight of a Composite beam

This undergraduate research plan is geared towards designing and constructing a beam using composite materials and focusing on the efficiency of the construction and maximizing strength to weight. The study specifically explores the impact of varying orientation and weight on the flexural behavior of composite beam structures. Each team will leverage a range of materials, including Carbon Fiber, Fiberglass, and environmentally friendly options like Bamboo and Hemp Fibers. Our testing arsenal comprises a Universal Test Machine and a Compression tester. To achieve our objectives, we are committed to fostering teamwork, capitalizing on diverse perspectives from individuals of different genders and backgrounds. Weekly in-person meetings will serve as dynamic platforms for knowledge-sharing and collaboration with our advisor. The project's significance lies in the acknowledgment of the finite resources on our planet, many of which are currently unsustainable. Composite materials present a sustainable avenue, allowing us to curtail the use of unsustainable materials and recreate products with similar or enhanced characteristics.This project is poised to deepen our understanding of composite materials beam and design principles, offering invaluable insights for future endeavors. The anticipated outcome encompasses the identification of more efficient manufacturing processes for designing and constructing beams, surpassing prevailing engineering standards. In essence, the overarching objective is to propel global sustainability through the strategic utilization of composite materials, thereby reducing resource waste and elevating engineering efficiency.

Abstract Name: Dynamics of a Helical Spring Model using Optical Laser Diffraction

Diffraction imaging is an important topic that spans across multiple educational fields. Biologists use macromolecular crystallography – a diffraction-based technique similar to coherent diffraction imaging to obtain the structure of proteins and use phase retrieval programs to reconstruct the image. In physics, diffraction imaging is used in x-ray crystallography. Perhaps the most famous example of the application of these principles to a biological problem is the use of x-ray crystallography to study the structure of DNA. Since technical challenges make it impractical to study crystalline DNA in introductory physics, the helical structures can be approached by substituting an optical laser source for x-rays and a ballpoint pen spring for DNA molecules. In this work, we introduce an advanced methodological strategy to demonstrate Hooke’s Law by using helical structure through the benefit of a novel optical diffraction imaging technique.

Abstract Name: Optical System Design for Detection of Oil Spills

This research project has been a collaborative research project between InterOcean Systems, LLC, and San Diego State University addressing the environmental & economic impact of oceanic oil spills. The primary objective of this collaboration is to develop an early detection optical system of oil spills on the ocean surface, preventing unnecessary damage done to the ecosystem and minimizing economic losses. Our proposed solution is a long-range, fluorescent-based optical system. Where the detector shines UV (ultraviolet) light onto the ocean surface, the oil-slicked surface will fluoresce back into the detector, signaling a positive reading. UV LEDs have recently become more affordable and effective, making them the prime choice for the project, as opposed to more expensive lasers used by most other similar products. Zemax OpticStudio was used to design the necessary optical components and their position to create the most practical and efficient system. Through a combination of computer modeling and experimental measurements, a UV projection and oil detection system consisting of two telescopes, a UV LED, various filters, lenses and detectors laterally attached to the telescope were created. We've rigorously tested the system with various oil samples in both well-lit and low-light environments. We were also able to successfully detect a square meter of oil from a target distance of 60 meters with remarkably high signal to noise ratios, including in daylight conditions. In this presentation, we will delve into the key features of our prototype's design while also sharing our most recent results.

Abstract Name: The Creation of Modern Logos: Family Crests and Heraldic Symbols

This essay explores the relationship between family crests and heraldic symbols and the design of modern day logos. This essay will specifically analyze the symbolism of different icons in medieval crests that led to a deeper understanding of the families that used them, linking them to logos and their ability to visually communicate a company's values. The evolution of modern logos will also be further studied as they continue to change with the ever changing dynamics of contemporary branding. By considering the history of these visual languages, a connection of these intricate histories can be made and used to further advance logo design in the present. This analysis showcases the evolution of symbolic representation from ancient heraldry to logos and contributes to the understanding of each as a separate and a whole. This essay provides a deepened overview of visual language and the evolution of symbolic representation and how they connect to culture and the design world. Family crests and their use of symbols and tradition in their designs has influenced the creation and evolution of modern logos.

Abstract Name: TRAGEDY TO TRANSFORMATION: THE ONGOING IMPACT OF SEPTEMBER 11TH

On September 11, 2001 (9/11), a coordinated Islamist terrorist attack hit the United States, consisting of four commercial airline hijackings and suicide attacks by 19 militants associated with the Islamic extremist group, Al-Qaeda. This paper identifies the significant and enduring influences of 9/11 on the United States including discrimination against people of Middle Eastern descent following the attack, a connection between the events of 9/11 and the enhanced interrogation techniques at the Abu Ghraib prison, and a surge in patriotism characterized by a sense of public solidarity and a notable rise in military enlistment in the Armed Forces. Through an examination of the historiography, government reports, and testimonials from soldiers and detainees at Abu Gharib, the collected data reveals a deeper understanding of the discrimination found within the United States and the unwarranted torturing at Abu Gharib. Furthermore, the legacy of 9/11 is enhanced by a more scientific understanding of patriotism, measured by an increase of American flags displayed outside of homes, freeway overpasses, car antennas, etc., and the profound transformation of U.S. public opinion and public unity in hopes of rebuilding a divided and broken country. Analyzing these post-9/11 outcomes supports the future development of effective strategies for counterterrorism, policy, legal reforms, international relations, combating racial discrimination, and increasing the active engagement of individuals toward their nation.

Abstract Name: Afterschool as an Antidote: How Can Afterschool Programming Play a Role in Gun Violence Prevention?

As of May 2023, one in four Baltimore gunshot victims who were 18 or under were shot near a school in the 2022-2023 academic year. In 2022, 84 shooting victims in Baltimore were victims 17 and younger; the threat of gun violence for Baltimore youth continues to rise as nearly one in three shooting victims in 2023 were high school aged or younger (Little et al., 2023). Gun violence cripples families, devastates communities, and often morphs into a deadly cycle as community members who witness violence become perpetrators in the future. Although preventing gun violence is a multifaceted issue that cannot be resolved through only one means of prevention, a powerful tool for combating youth exposure to gun violence is the implementation of afterschool programming for students. Afterschool programs provide students protection from the increased threat of victimization that occurs when youth lack parental guidance between the afterschool hours of 3-6pm. Currently, through partnerships with the city, faith-based organizations, and Chicago Public Schools, all Chicago Public School students have access to afterschool care through the “After School Matters” program that operates across the city. While Baltimore City offers numerous afterschool programs for students, the

standardized approach that is taken in Chicago is not replicated in Baltimore City. Instead, a “patchwork” of programming is created. Some students have more opportunities for afterschool care than others because afterschool care depends heavily on the success of individual community partnerships created between individual schools rather than an entire system. I propose that afterschool programming is one pillar of gun violence prevention that Baltimore City officials must consider strengthening and hypothesize that if a standardized afterschool program was implemented for all Baltimore City students to access, the striking threat of gun violence that Baltimore City youth currently face may lessen.

Abstract Name: Investigating the Role of the ESCRT Pathway During Peripheral Nerve Myelination

The endolysosome pathway is critical for the trafficking of internalized cell surface cargo required for maintaining homeostasis. Internalized cargo is sorted through a series of endosomal compartments to facilitate either it’s recycling back to the cell surface, trafficking to a specific endosome location, or degradation by the lysosome. The endosomal sorting complex required for transport (ESCRT) pathway is an essential part of the endolysosomal system and plays a key role in regulating many neuronal functions, including development and synaptic function. Components of the ESCRT pathway directly interact with proteins linked to Charcot-Marie-Tooth (CMT) disease, a type of demyelinating peripheral neuropathy. Hepatocyte growth-factor-regulated tyrosine kinase substrate (HGS) is one component of the ESCRT pathway and functions as a scaffolding protein on the endosome to identify cargo that is to be sorted by the endosome. Previous studies have shown that inactivation of HGS in Schwann cells results in motor and sensory deficits and blocks Schwann cell maturation, indicating that HGS is a key component in endosomal sorting necessary for peripheral nerve myelination. To determine how HGS may function in the endolysosomal pathway during myelination, we investigated the colocalization of HGS with markers for the early endosome, late endosome, lysosome, and recycling endosome in both wild type and P0CreHGS sciatic nerves. The findings from these studies will uncover the specific requirements of HGS along the endolysosomal pathway and provide insight into the molecular causes of demyelinating peripheral neuropathies.

Abstract Name: Fossil Fuel Money and the Fate of Climate Action in Congress

As the climate crisis worsens, environmental leaders have attempted to pass climate legislation in the United

States (US) Congress to completely decarbonize the economy and stop greenhouse gas emissions. However, lawmakers in the US have yet to take sufficient action to prevent climate change. One explanation for the failure of climate legislation in Congress is the influence of fossil fuel donations on members of Congress. This research finds that members of Congress in the House of Representatives who receive more donations from the fossil fuel industry are less likely to cosponsor environmental justice legislation. It also finds that there is no relationship between fossil fuel donations to members and their support for environmental justice legislation in more public floor votes. These relationships are analyzed using correlation and regression tests using data on fossil fuel donations to members of the 117th Congress during the 2020 campaign cycle, members' voting behavior on environmental issues, and members' cosponsoring of Green New Deal legislation. The results indicate that although members' votes are not being affected significantly, fossil fuel finance is influencing climate legislation in Congress behind the scenes and should be further investigated.

Abstract Name: Combined Inhibition of RAF, MEK, and FAK Attenuates Melanoma Brain Metastases and Prolongs Survival in Preclinical Models

Despite promising results from recent FDA-approved therapies, many advanced melanoma patients develop resistance to immunotherapy and targeted therapy. A common resistance mechanism to targeted therapy is upregulation of the PI3K/AKT signaling pathway, which has promoted the development of melanoma brain metastases. Historically, AKT inhibitors have failed in the clinic due to their limited efficacy or intolerable toxicity. Proteomic analysis comparing non-metastatic vs brain metastatic primary tumors in mice revealed focal adhesion kinase (FAK) as an AKT1 specific effector and a potential alternative therapeutic target. FAK is a non-receptor tyrosine kinase that localizes primarily to focal adhesions to regulate cell migration. To determine whether targeting FAK alone or in combination with the RAF/MEK inhibitor avutometinib reduces brain metastases and prolongs survival, we utilized autochthonous and syngeneic melanoma mouse models. Mice with either subcutaneous tumors or established brain metastases were treated with FAK inhibitor, RAF/MEK inhibitor, or the combination of both. Each cohort was assessed for tumor onset, growth, metastasis, and survival. Our results show that combined RAF/MEK/FAK inhibition significantly delays tumor onset, causes regression of established tumors, prevents brain metastases development, promotes established brain metastases regression, and prolongs survival. In addition, patient-derived BRAF-V600E melanoma xenograft mouse models resistant to the BRAF inhibitor dabrafenib and the MEK inhibitor trametinib, were sensitive to combined RAF/MEK/FAK blockade. The addition of the BRAF inhibitor encorafenib to these models further enhanced the effect on tumor growth. These results support the initiation of a clinical trial evaluating the efficacy of the RAF/MEK inhibitor avutometinib in combination with the FAK inhibitor defactinib in patients with brain metastases from cutaneous melanoma. Additionally, we are

assessing non-canonical roles of FAK in modulating the tumor microenvironment to determine whether avutometinib and defactinib also enhance the efficacy of immune checkpoint inhibition in this disease.

Abstract Name: Interventions for Multiple Adverse Childhood Experiences

This study is built on the foundation of Vincent Felitti, Robert Anda, their colleagues, and the Center for Disease Control's (CDC) study of Adverse Childhood Experiences (ACEs). The meta synthesis expands on the original 10 ACEs to include trauma types not included in the original study. The paper acknowledges the negative affect trauma can have on an individual's mental health, physical health, and likelihood to engage in risky behaviors, resulting in negative life outcomes. Current literature relating to trauma and interventions are examined and grouped into common themes across studies. Themes are also grouped by intervention types. Word coding is used to identify characteristics and results of interventions. There are currently specific interventions for specific types of ACEs. The meta-synthesis will attempt to answer, what are the most effective interventions for people with multiple ACEs? Answering this question will help professionals implement the most appropriate interventions for people with multiple ACEs to result in positive life outcomes. The paper looks through a macro level lens in addressing trauma and adversities. Findings suggest the importance of building empowered communities, especially within communities with high levels of ACE's. Results indicate the importance of healthy and positive relationships, community level interventions, and complementary and alternative medicine (CAM).

Abstract Name: Differences in Central Pain Mechanisms and Sociocultural Factors Among Older Adult Hispanic Americans and Non-Hispanic Whites

Chronic Pain is a result of alterations to the Central Nervous System, which is responsible for receiving and interpreting pain messages. When central pain mechanisms are negatively affected, pain inhibition is reduced, and pain summation is exacerbated. Evidence also considers the influence of sociocultural factors on pain

perception. Authors suggest that disparities in health outcomes exist between populations, chronic pain being more common among Hispanic Americans (HA); however, limited research has been done to compare central pain mechanisms and sociocultural factors between older adult Hispanics and Non-Hispanic Whites (NHW).The preliminary analysis included 24 participants (58.3% females), 15 Hispanic, 9 Non-Hispanic Whites (Mean age=68.12 years, SD=6.469). Validated questionnaires provided at the beginning of the sessions assessed demographic and sociocultural factors. Participants underwent quantitative sensory testing that included thermal pain threshold, tolerance, Temporal Summation (TS), and Conditioned Pain Modulation (CPM). T-tests were performed to assess differences in pain sensitivity, central pain mechanisms, and sociocultural factors between HA and NHW. Correlation analyses were also performed. Independent t-tests revealed there was not a significant difference in the level of inhibitory process [$t(21)=-1.636$, $p=0.117$] or in pain summation at 50 °C [$t(18)=1$, $p=0.331$] between HA and NHW. However, there was a significant difference in the level of optimism [$t(20.16)=3.449$, $p=0.003$], where HA had significantly higher levels of optimism (Mean=2.07, SD=0.44) than NHW (Mean=1.62, SD= 0.18). Significant correlations were found between inhibitory process and level of optimism ($r=-0.577$, $p=0.004$), and between inhibitory process and resilience ($r=-0.432$, $p=0.04$). Preliminary results on this study have demonstrated that ethnicity does not play a significant role in central pain mechanisms between HA and NHW; however, HA do seem to display greater levels of optimism. Regardless of ethnicity, one's level of optimism and resiliency seems to affect their central pain mechanisms.

Abstract Name: LGALS3 Expression in KRT13+ Hillock Cells: An Immunomodulator in Squamous Cell Lung Cancer

Lung squamous cell carcinoma (LSCC) is a subtype of non-small-cell lung cancer (NSCLC) associated with poor survival outcomes due to a lack of targeted therapies. Our laboratory previously created a genetically engineered mouse model (GEMM) of LSCC driven by SOX2, a highly overexpressed oncogene in LSCC. Recently, we analyzed single-cell RNA sequencing data from mouse tumors and identified a distinct LSCC population marked by keratin-13 (KRT13). Interestingly, KRT13+ cells are found in unique "hillock" structures in the differentiating lung epithelium that express squamous-lineage markers and are immunomodulatory. We hypothesize that KRT13+ cells in LSCC are similarly important for squamous fate and immunomodulation. We analyzed scRNA-seq and human transcriptomic data for enriched genes in KRT13+ LSCC cells, identifying Galectin-3 (encoded by Lgals3), a secreted protein that regulates myeloid recruitment and is also enriched in KRT13+ Hillock cells in the mouse lung. To test if Galectin-3 can alter myeloid infiltration in LSCC, we genetically deleted Lgals3 in tumor organoids that have KRT13+ populations, which secrete high levels of Galectin-3 by ELISA. Knocking out Lgals3 should decrease myeloid migration, which we will determine using transwell assays in vitro. In addition, we will knock out Lgals3 in GEMMs in vivo to validate the results from the tumor organoids. We expect that Lgals3 knockout will lead to a decrease in myeloid recruitment in tumors, which we will measure by immunohistochemistry (IHC) staining. To test if Galectin-3 is sufficient to alter myeloid migration, we overexpressed Lgals3 in a small-cell lung cancer GEMM that has low Galectin-3 expression and low myeloid infiltration. Here, we expect that IHC staining will reveal that Galectin-3 promotes myeloid recruitment. Together, these studies will determine if KRT13+ secretes Galectin-3 as a mechanism to alter immune populations in LSCC, which may be further developed into developing therapeutic strategies to improve patient outcomes.

Abstract Name: Physical Activity of Children with Autism Spectrum Disorder During Weekend Days versus Weekdays: A Systematic Review

The ‘Structured Days Hypothesis’ suggests during less-structured periods, such as summer months or weekend days, children’s physical activity (PA) is lower and, thus, may be detrimental to health. Exploring this hypothesis in children with autism spectrum disorder (ASD) is important, given they are less active and tend to prefer structure and routine compared to neurotypical peers. Weekend days are similar to summer days since both have reduced structure in comparison to the consistent weekday routine. The purpose of this review was to examine differences in PA levels of children with ASD during weekend days versus weekdays. Three databases (PubMed, APA PsycInfo, and ERIC) found 604 studies for screening. Seven studies met inclusion criteria (e.g., children 5-13 years, ASD diagnosis, weekend day and weekday PA outcomes). Three of the seven studies reported PA was greater on weekdays, two reported that PA was greater on weekend days, and two reported no differences. Findings provide researchers with insight into potential differences in PA of children with ASD during weekdays versus weekend days. Further studies are needed that purposefully measure PA during different environments to help inform PA interventions targeting children with ASD.

Abstract Name: Lineage-specific Overexpression of LMX1B Elicits Different Responses in the Basal and the Apical Calvaria

The calvaria, the top part of the skull, consists of the frontal, parietal, and occipital bones held together by sutures and fontanels. The supraorbital mesenchyme acts as the ossification center to form the frontal and parietal bone and coronal suture that separates them. These cranial bones are derived from embryonic cell populations that form distinct tissue lineages: neural crest-derived frontal bone and mesoderm-derived parietal bone. However, the mechanism by which sutures determine their position during development is largely unknown. The anti-osteogenic property of LMX1B has been shown to be crucial to proper calvaria formation. Here, we investigate the effect of neural crest-specific overexpression of LMX1B on calvaria formation using a Cre-loxP system on a mouse model. To label the mutant and non-mutant cells, we used ROSA26-YFP Cre reporter. We also performed microCT morphometric analysis of mutant and control calvaria to examine the relative position of the coronal suture within the frontal bone-coronal suture-parietal

bone complex. We found that the apical coronal suture shifted to the anterior in the mutant due to the reduced frontal bone. Surprisingly, the basal coronal suture shifted to the posterior in the mutant. Further lineage analysis showed that mesoderm-derived cells contributed to the frontal bone to compensate for the loss of neural crest-derived bone in the basal calvaria. The apical calvaria lacked compensation by the mesoderm bone. Thus, the basal calvaria, but not the apical calvaria, has a mechanism to resist the anterior shift of the coronal suture, which appears to have overcompensated in our mutant.

Abstract Name: The Effect of Biomechanics on Throwing Velocity and how Velocity Affects Pitcher Salaries with Reference to Pitching Output

Average fastball velocity throughout Major League Baseball has increased dramatically over the previous 15 years. This research examines the factors leading to this increase and provides a cost-benefit analysis to determine whether throwing consistently at high velocities is worth the injury risks, compared to financial benefits, from the player perspective. Additionally, this analysis examines if paying hard-throwing pitchers is worth the monetary risk from a team executive's perspective, due to increases in leaguewide throwing injury rates. The production of advanced motion capture technology to obtain real-time biomechanical data has given way to the optimization of pitchers' biomechanics, with the goals of increasing throwing velocity and injury prevention. This innovation may be the driving force behind the significant increase in average fastball velocity throughout Major League Baseball in its recent history. An empirical model was developed using multiple regression in R to analyze the average impact in which a range of "point of interest" (POI) biomechanical measurements have on fastball velocity for pitchers (via Driveline). Preliminary results show that many POI biomechanical features significantly influence fastball velocity in pitchers at all levels, most notably, energy transfer across the throwing elbow between foot plant and ball release, peak shoulder internal rotation, and peak torso axial rotation velocity. With the use of 2023 MLB pitcher salaries, this study also found that pitchers in the top 10% of the league, in terms of average fastball velocity, tend to make less money than the rest of the pitchers throughout Major League Baseball, on average. Many factors other than throwing velocity also play into this observation and are examined in the analysis. The financial benefit of consistently throwing at elite fastball velocities may not be worth the risk, due to the increasing injuries resulting from prolonged stress on the throwing arm at high throwing velocities.

Abstract Name: Examining a Wisconsin Farmers' Market SNAP Incentive Program - Using Survey Data from 2019-2023

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition

Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of a variety of chronic diseases. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity among US children which have been shown to persist into adulthood. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers' markets offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at farmers' markets. We have selected one Wisconsin farmers' market that sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the market. This presentation will show that in 2020, COVID-19 increased the number of families facing food insecurity and using SNAP. Our administrative data illustrates the increases and subsequent decreases in SNAP shoppers at the market as we moved through the pandemic. In 2023, the number of SNAP shoppers declined significantly as did the spending, but the SNAP caseload stayed constant. The remainder of this study provides more detailed results regarding the patterns in SNAP household shopping at this farmers' market using the MMP over this period. This presentation is connected to another submission analyzing a variety of data from surveys of SNAP households shopping at this farmers' market using the MMP during these years.

Abstract Name: Diversifying RNA-Based Memory Storage Devices for Studying Promoter Activities in Non-Model Bacteria

The central dogma of molecular biology states that genetic information stored in DNA is converted to RNA and then protein. Current methods to monitor the first step in individual organisms are hard to compare across non-model bacteria. A new technology called RNA Addressable Memory (RAM) was recently engineered to store transcriptional information in cells. To store information, a ribozyme (RNA-enzyme) is encoded in a plasmid that performs a trans-splicing reaction which yields 16S rRNA with a synthetic barcode. The prototype RAM design was modified to: (i) swap out the promoter that transcribes the ribozyme, and (ii) alter the barcode sequence. To compare these designs, the vectors were conjugated into Shewanella oneidensis and Pseudomonas stutzeri. Ongoing research is measuring the barcoding using quantitative PCR with the goal of improving the information storage capabilities of RAM. This new approach is expected to facilitate studies of how a given promoter functions across distantly-related non-model bacteria.

Abstract Name: Antioxidant Capacity of Raw Coffee and the Effects of Roasting on Its Change

Antioxidants, often mentioned in discussions about healthy foods and drinks, are closely linked with numerous health benefits. These substances, found abundantly in various foods, act as reducing agents that protect cells from damage by neutralizing harmful free radicals called reactive oxygen species (ROS). The antioxidants serve as electron donors and play a crucial role in stabilizing these radicals, thereby preventing cell dysfunction, which can lead to various diseases. Regularly consuming antioxidant-rich foods is believed to offer protective benefits against certain diseases. Take coffee, for instance, a beverage enjoyed by millions worldwide in various forms. Since raw coffee beans are not typically consumed, most antioxidant research has focused primarily on commercially available roasted coffee beans and particles. In this research, efforts were made to study the total antioxidant capacity of three different originated raw green coffee beans, including Ethiopian, Colombian, and Mexican beans, and how it changes during roasting. The Trolox equivalent antioxidant capacity (TEAC) method was adopted to assess and compare the total available antioxidant capacity. The preliminary experimental results confirmed that raw coffee beans possessed a significant amount of antioxidants, with more detailed information to be presented in the upcoming presentation.

Abstract Name: Disseminated Intravascular Coagulation as a Risk Factor for Bleeding in Acute Leukemia Cases

Acute leukemia, comprising acute promyelocytic leukemia (APL), acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL), is characterized by the rapid proliferation of immature blood cells, often leading to hematopoietic insufficiency and an increased risk of bleeding complications. This study aims to provide a comprehensive analysis of the risk factors associated with bleeding in patients diagnosed with acute leukemia. A retrospective observational study on newly diagnosed acute leukemia patients diagnosed between May 2012 and November 2022 was conducted using recorded International Society on Thrombosis and Hemostasis Disseminated Intravascular Coagulation profiles (including prothrombin time, D-dimer, and fibrinogen), age, and bleeding events. Patients without complete datasets were excluded. Continuous patient data was compared using Gray's test. Categorical patient data was analyzed with between-group comparisons using the chi-squared or Fisher's exact test. Univariate and multivariate predictors of hemorrhagic events were evaluated using logistic regression analysis (backward stepwise method), with results expressed as hazard ratios (HRs) and 95% confidence intervals (CIs). Multiple risk factors contributing to bleeding complications in acute leukemia were identified; DIC score was most significant and the focus of the study and emerged as a primary contributor to bleeding events. Additionally, the specific subtype of acute leukemia played a pivotal role in defining the bleeding risk profile. Patient-related factors, such as age, exhibited insignificant associations with bleeding outcomes. Furthermore, the impact of treatment modalities, including chemotherapy was highlighted as a crucial determinant of bleeding risk. This comprehensive analysis underscores the multifaceted nature of bleeding risk in acute leukemia, encompassing hematologic, genetic, patient-related, and treatment-related factors. Recognizing and understanding these risk factors are essential for optimizing therapeutic strategies, tailoring supportive care measures, and improving overall outcomes in patients with acute leukemia. Further research is warranted to refine risk stratification models and explore targeted interventions aimed at mitigating bleeding complications in this population.

Abstract Name: Meeting The Recommended Daily Step Count Does Not Alter Heart Rate Variability In Young Adults

We investigated the influence of meeting the recommended amount of daily steps on heart rate variability (HRV) in college students. Thirty-three young adults (M/W: 18/15; 23 ± 5 years) were asked to wear accelerometers at the hip for at least ten wake-time hours across seven consecutive days. On the eighth day, HRV was measured in the morning using 3-lead electrocardiography (EKG). Heart rhythms were assessed for 10-minutes during seated rest with both feet on the ground, eyes closed, and in a fasted state. The last five minutes were used for HRV analysis to determine root mean square of successive differences (RMSSD), standard deviation of NN intervals (SDNN), low-frequency power (LF), high-frequency power (HF), and LF/HF ratio. Daily steps were averaged across all seven days, and participants were categorized into two groups using the threshold of 7500 steps/day which is recommended for adults to achieve health benefits associated with a physically active lifestyle. Independent sample Student t-tests were used for group comparisons. No differences were found between adults that met the daily step threshold (active) versus those that did not (inactive) for RMSSD (active vs. inactive: 34.9 ± 18.2 vs. 38.3 ± 19.5 ms, P = 0.60), SDNN (47.2 ± 23.8 vs. 51.3 ± 20.3 ms, P = 0.60), LF (7.0 ± 1.1 vs. 7.2 ± 0.8 log ms2, P = 0.55), HF (5.9 ± 1.0 vs. 6.1 ± 1.2 log ms2, P = 0.61), or LF/HF ratio (1.9 ± 0.2 vs. 2.0 ± 0.4, P = 0.35). These results indicate that HRV in young, college-aged adults is not influenced by being physically active, as reflected by total daily steps.

Abstract Name: The Awareness, Knowledge, and Practice of Female Zayed University Students Regarding Folate or Folic Acid

Background: Adequate folic acid intake before and during early pregnancy can prevent the development of most Neural Tube Defects (NTDs). However, there is a shortage of up-to-date literature on how much childbearing-age women including university students are informed about folate or folic acid, in the United Arab Emirates.Objective: This study aimed at evaluating awareness and knowledge level of folate, and folic acid (FA) supplement usage among Zayed University female students. Further, it tried to assess the risk level of inadequate folate intake among the target population and to identify major demographic factors associated with the knowledge and FA usage while particularly emphasizing pregnancy experience.Methods: 239 female students of the two Zayed University campuses whose age was 16 to 40, from both health and non-health colleges, completed a self-administered online questionnaire. Collected data was analyzed using SPSS version 29.0.Result: 63.2% of participants heard about folate or folic acid and overall 44.8% had a good

knowledge level. Further, 77% didn’t ever regularly use folic acid. Based on the food habit analysis, 38.5% were at higher risk, 29.3% were at moderate risk and 32.3% were at lower risk of inadequate folate intake. Health science specialization, and history of folate deficiency or anemia were associated with awareness and knowledge of folate/FA. Additionally, those married or divorced were most likely knowledgeable and FA users. History of folate deficiency was also associated with FA usage; however, pregnancy experience neither had a significant association with knowledge nor use of FA.Conclusion: The findings indicate a significant gap in knowledge and folic acid intake among female young adults besides their higher risk status for inadequate folate intake. Therefore, effective education programs with the involvement of health professionals and families are required to raise knowledge and promote the consumption of folate-rich foods and FA use.

Abstract Name: Personal Experiences with Mental Health and Family Openness on the Mental Health Literacy of Undergraduate Students

Abstract: Mental health literacy—knowledge or beliefs on mental health disorders—is a prerequisite for early recognition and intervention of psychological disorders. According to Cheung et al. (2017) and Gulliver, Griffiths, & Christensen et al. (2010), early intervention and diagnosis are crucial in improving mental health—to the extent that the individual will seek help. In this context, low mental health literacy may be a barrier to seeking help. It is, therefore, essential to identify how different variables affect mental health literacy and, subsequently, remediate low mental health literacy levels in vulnerable populations. My project uses data collected from Brooklyn College undergraduate students to reveal the intricate relationship between personal variables, encompassing one’s own psychological history and family openness to discussing mental health, and the impact of these variables on an individual’s mental health literacy. Miles and colleagues (2020) found notable differences in levels of mental health literacy between men and women, younger and older age groups, those who have had previous experience with mental health versus those who have not, and those who have families open to discussing mental health issues. That study's results revealed that high performers were between the ages of 28-32, female, white, and in their fourth year of college. Those who have taken courses in psychology and majored in psychology or scientific fields have been diagnosed or treated for psychological disorders also proved to be higher performers. This thesis will further challenge the variables studied in Miles et al. (2020), specifically, the association between variables of interest (e.g., previous diagnosis, counseling experience, family openness to talking about mental health issues) and scores on a multiple-choice questionnaire of mental health literacy.

Abstract Name: You Work Like a Girl: Understanding Evaluations of Masculinity Violations in the Workplace

Previous research has discovered that men have a tendency to apply punitive measures to their peers when their behaviors deviate from established norms associated with "toughness", "anti-femininity", and "status" (Moss-Racusin, 2010). While this insight advances our understanding of gender norms in society, there exists a notable gap in research regarding these dynamics within organizational settings, and how they impact both individuals and organizations. Our study sought to address this void by providing valuable insights into the workings of male gender norms within organizational contexts and their subsequent effects on individual well-being and organizational success. Employing Experimental Vignette Methodology (EVM), we recruited 400 participants, each compensated with $1.30 for their 15-minute survey participation. Participants were randomly assigned to either the "masculine violation" or "masculine confirmation" condition in which they read a vignette about an employee in a work setting. In the masculine violation vignette, participants encountered a scenario where an employee's behavior deviated from traditional masculine norms, exemplified by a calm and empathetic demeanor. Conversely, the masculine confirmation vignette presented a scenario where an employee adhered to conventional masculine expectations, displaying a confident and bold demeanor. Post vignette presentation, participants shared their perceptions of the individuals and reported emotional experiences during the survey. Questions ranged from perceived levels of respect received by the presented employee to the extent of anger experienced while reading the stories. A notable finding of our study was that the employee in the vignette in which masculine gender norms were violated was consistently rated higher on levels of respectability, promotability, likability, approachability, and effectiveness. These findings have wide-ranging implications for understanding the interworkings of gender dynamics within organizations.

Abstract Name: Resurrecting Progressive Education: What the Revival of a 75-Year-Old Survey Reveals About the Trends of Education Philosophy in the Ozarks

Nearly a century after the height of the progressive education movement, the philosophies guiding the modern public school classroom are a far cry from the child-centered pedagogy of John Dewey. The revival of a 1928 survey of the teacher ideologies leading Springfield, Missouri public schools provides new insight into the permanence of progressive education. Previous research, including the historical analyses of Lawrence Cremin, has determined that the United States began moving away from experience-based psychology and sociology education theories in the mid- to late-20th century. Utilizing data from the original 1928 survey and the modernized 2023 version, this paper examines the social and historical contexts that are responsible for the transformation of teacher opinions on educational practices. The results of the study support the idea that the education system has shifted into a structure designed to create efficient workers rather than fostering a democratic community of diverse creatives. These findings are significant to the educational narrative of the Ozarks and the greater Midwest.

Abstract Name: Analyzing the Spatial Distribution of Lithics at Frog Bay Tribal National Park

This research focuses on the Frog Bay archaeological site (47BA60), located within Frog Bay Tribal National Park (FBTNP) in Red Cliff, WI as part of Geté Anishinaabe Izhichigéwin Community Archaeology Project (GAICAP). This project is directed by the Red Cliff Band of Lake Superior Chippewa's Tribal Historic Preservation Office (THPO) and academic archaeologists. As such, this work is done collaboratively with Red Cliff community members. Frog Bay is a multicomponent site, meaning there were several different past human occupations of the site. The oldest material dates to 3327-2931 cal BC, during the Middle Archaic period. This study examines shovel test pits (n = 469) that were excavated from 2018 to 2022 and cover an area of approximately 1.96 hectares (4.84 acres). Using maps created using ArcGIS Pro and a lithic (stone toolmaking debris) attribute analysis, this research defines artifact accumulation areas to better understand how Indigenous people used the area of Frog Bay in the past and to identify high-potential areas for future excavations. Furthermore, spatial inferential statistics are used to determine whether distributions of different size classes of lithics and raw materials are randomly distributed, clustered, or dispersed across the site. Overall, this analysis provides key information about cultural patterns in northern Wisconsin, particularly pertaining to lithic tool-making activities which Geté Anishinaabe people have participated in for more than 5,000 years.

Abstract Name: Best Practice in Teaching ESL Burmese Family Caregivers Regarding At-home Fall Prevention

Background: Falls are a huge global concern. Falls can happen to anyone, regardless of age, but they are more common in older persons aged 60 and up. The purpose of this study is to identify some risk factors for falls and to educate the Burmese community to reduce fall incidents in the home.Method: Participants will be a sample of convenience of the Burmese community that attends a local church. There will be two groups, where one (control) group will receive education regarding fall prevention and the other group (uncontrolled) will not receive any education regarding falls. Face-to-face education will be conducted for 30-60 minutes, and a semi-constructed survey will be provided after a month to evaluate the effectiveness. This study used a total of 16 literature reviews which were carried out globally.Limitations: This study is mainly for the Burmese community and participants are local church attendees only. The questionnaire used to conduct this study was developed in China, thus it may not accurately represent older persons worldwide.Discussion: This study will underline the significance of these events and the necessity for further study. Positive behavioral changes in the Burmese community are expected, leading to reduced incidence of senior falls and enhanced care delivered by family members to the elderly.Keywords: Fall prevention in the Burmese Community, Fall risk factors, Fall-related injury

Abstract Name: Celebrity Influence on UMD Students' Perception of the Death Penalty

The topic of the death penalty has been debated for many centuries. College students' attitudes have been explored. Yet, there has not been enough research regarding how the influence of a celebrity figure may play a role in shaping a young individual's perspective on the controversial topic. This research aims to answer the following questions: How influential are celebrities when it comes to spreading awareness of the death penalty? Does this differ when an expert on the topic tries to influence people's attitudes? To answer these questions, this study uses a five-group, post-test-only experimental design in which participants are randomly presented with either one of two videos challenging the death penalty (one of a celebrity and one of an expert), one of two written statements (one attributed to a celebrity and one attributed to an expert) challenging the death penalty, or the control group in which no video or statement was presented. The research revealed that celebrities influence individuals but that the delivery of information matters. Participants reported that the written statement of our selected celebrity was more persuasive and more likely to change their opinions than the video presented by that same celebrity. However, our measure of the strength of death penalty support was found to be higher for those reading the celebrity statement than those watching the celebrity video. Among death penalty supporters, experts, though seen as less persuasive, had a greater impact on actual death penalty opinion. Though support for the death penalty is often robust and resistant to change, the current study presents evidence that both celebrities and experts can have an effect on attitudes.

Abstract Name: College Students Experience With Helicopter Parents And Their Academic Self-Efficacy

Autonomy development and decision-making are the first part of becoming independent. Existing studies highlight a significant challenge within the college-aged demographic due to helicopter parenting, hindering the development of autonomy among college students. The present study explores the effect of helicopter parenting on academic self-efficacy in college students. The researcher hypothesized that perceived helicopter parenting would influence reducing academic self-efficacy in college students. In this study, helicopter parenting was measured with the Helicopter Parenting Scale (Padilla-Walker & Nelson, 2012) and Helicopter Parenting Behaviors Questionnaire (Schiffrin, 2014). Academic self-efficacy was measured with the Academic Self-Efficacy Scale (Greco et al., 2022). The sample included 103 full-time college students from a Christian university. A t-test and a simple regression analysis were conducted to analyze the data. The findings in this research revealed that perceived helicopter parenting has no significant impact on academic self-efficacy ($b1 = .094$, $p = .087$). In addition, there was no statistically significant difference in academic self-efficacy between males and females ($t = -4.34$, $p = .66$). The findings emphasize the need for society and university institutions to recognize that academic self-efficacy in college students is impacted by different types of parental support. Furthermore, future implications address the need to understand how perceived types of parental support can be studied among college students.

Abstract Name: Exploring the Correlation Between Physical Activity Levels and Depression in College Students

This study aims to explore the relationship between depression symptom levels and physical activity levels among college students. The project is a quantitative study in which data were collected from the PHQ-9 survey and QPAR Scale. In this study, the researcher analyzed the data using descriptive statistics, including frequency, mean, standard deviation, and inferential statistics, such as independent sample T-test, ANOVA, and Regression. The findings in this research revealed that there is not a statistically significant relationship between depression symptom levels and physical activity levels. The implications of this research study are that regardless of depression symptom level status, students should be involved in some type of physical activity based on the slight effect size demonstrated. Future studies should be done on the different types of depression, comparing males and females who are physically active and those who are not. Self-esteem would be a helpful variable to consider for future reference to measure depression symptom levels. Integrating anaerobic and aerobic physical activities in the study would also be beneficial in understanding if certain exercises benefit students more than others.Keywords: depression, physical activity, college students

Abstract Name: Carpathian Peaks to Miami Beach: A Phenomenological Study on the Acculturation of Ukrainian Immigrants

Armed conflict is one of the principal drivers of forced migration, an involuntary or coerced act for a person or people to move from one's home or country of origin. Whether they are internally displaced or seek asylum, immigrants acculturate to the dominant culture of their new home. The most recently displaced people in Europe have been Ukrainians, caused by political unrest and armed conflict: Euromaidan, Revolution Of Dignity, and the Russo-Ukrainian War. These periods of unrest, starting in November 2013, have displaced nearly six million Ukrainians across Europe. In this phenomenological research study, six Ukrainians who immigrated to the United States beginning on January 1, 2013, were interviewed to discover their lived experience of acculturating to American culture. The themes that connected their distinct immigration stories, challenges, coping mechanisms, employment, and relationship with their culture were documented and studied.

Abstract Name: ProACTIVE: A culturally responsive program on intimate partner violence

Intimate Partner Violence (IPV) is an ongoing issue in the United States and accounts for approximately 15% of all violent crimes, according to the National Coalition Against Domestic Violence. Individuals convicted of this offense are mandated to attend behavior change programs through the criminal justice system. However, men of color face an extreme disadvantage in the criminal justice system, which was created around racism and bias. A new community-based program, ProACTIVE, is a voluntary intervention that encourages acceptance of emotions and commitment to healing without any form of judgment. ProACTIVE is a trauma-informed and culturally responsive program that hopes to reach men of color who are at risk for IPV and to help create a healthy mindset by using Acceptance and Commitment Training (ACT). A mixed methods approach will be used to determine if ProACTIVE is effective for men who have not been mandated to attend any program, especially for men of color. We will evaluate the effectiveness and feasibility of the program through pre- and post-treatment surveys as well as follow-up interviews. If ProACTIVE is effective for men of color, these surveys should show commitment to healthy behaviors and emotional healing without involvement in the criminal justice system.

Abstract Name: Designing the Drive System Handoff Module for Lunar Crater Traversal

The lunar environment is populated with unexplored terrain, craters with up to 40 degree slopes preventing current robotic systems from successfully examining their promising unknown properties. LATTICE (Lunar Architecture for Tree Traversal In-Service of Cabled Exploration) was designed to expel these unknowns with an efficient, ever-expanding robotic system transforming the well-known cable car into lunar infrastructure. The LATTICE drive team have been designing an elevator drill system for an earth scale demonstration which will plant the stakes containing cable for the robotic shuttle to traverse. A stake handoff system was necessary to drive these stakes. The handoff system, in the form of a linear rail, was designed to hold 2 meter stakes, weighing 15 kg, close enough so that they can be drilled, but firm enough so that the stakes do not slip. The handoff was developed as a passive mechanism which releases as the drive system is driven away.

Abstract Name: Identification of previously undescribed residues in lysyl hydroxylase 1 that are predicted to influence substrate-enzyme interactions in the Fe2+ catalytic site

Lysyl hydroxylase 1 (LH1) is a homodimeric alpha-ketoglutarate-dependent hydroxylase class enzyme that catalyzes the hydroxylation of lysine residues in the triple helices of fibril-forming collagens. This process produces the hydroxylysine residues necessary for pyridinoline cross-link formation between collagen fibrils in the extracellular matrix (ECM). Ferrous iron (Fe2+), alpha-ketoglutarate (AKG), molecular oxygen (O2), and ascorbic acid (vitamin C) act as cofactors that facilitate oxidization. Previous studies have performed site-directed mutagenesis utilizing a baculovirus vector and insect cells to identify the residues that bind the Fe2+ and AKG cofactors to their corresponding binding sites. This study aims to identify additional residues not discussed in the literature that influence the binding of Fe2+ cations in LH1 via in-silico simulations that simulate in-vitro site-directed mutagenesis. A homology model of LH1 was retrieved from the SiMPLOD database. PrankWeb, a machine-learning tool that analyzes homologous proteins to identify pockets of residues that may influence the binding of a protein's cofactors, was used to identify residues of interest yet to be discussed in the literature (positions 641, 642, 645, 665, 680, 709, 719, and 724). The H656S variant was selected as a control, as previous studies have demonstrated that this mutation completely inactivates enzyme activity. An evolutionary conservation analysis was performed using ConSurf. In-silico prediction tool scores were retrieved using Ensembl Variant Effect Predictor (VEP). Molecular-dynamics simulations (MDS) were conducted in YASARA for each amino acid position of interest, with each residue replaced with glycine, to assess each variant's impact on protein movement in a simulated aqueous environment. Each variant's average carbon alpha root mean squared fluctuation (RMSF) and carbon alpha root mean squared deviation (RMSD) were graphed. The distance between each monomer and Fe2+ cation at fixed nanosecond intervals was measured and compared to the distance at the initiation of the simulation for each variant.

Abstract Name: Culturally Enriched Memory Books: Enhancing Engagement and Well-being in Individuals with Dementia

Dementia presents significant challenges in communication and emotional well-being. Providing meaningful interventions that engage individuals with dementia is crucial to improving their quality of life, Culturally enriched memory books have the potential to provide such engagement by tapping into personal and cultural memories. This research aims to investigate the effects of culturally enriched memory books on the engagement, emotional well-being, and quality of life of individuals with dementia. Memory books containing culturally relevant content, specifically focused on Ethiopia, was shared with residents in a memory care unit. The study will explore the role of meaningful interactions and cultural exposure in dementia care, and the therapeutic value of incorporating audiovisual elements, such as traditional music.

Abstract Name: How Can We Improve our Juvenile Recidivism Rates Among female Juveniles

The rise of female youth being detained as juvenile offenders is increasing. Female youth offenders have higher rates of mental illness than male youth. Delinquency rates among females have increased by 92% between 1985 and 2002. Female youth have more trauma and a history of abuse that contribute to their delinquent behavior. Female youth are committing person, property, drugs, and public order offenses. There is a rise in females committing more violent and nonviolent crimes. Girls account for the majority of arrests for certain types of crimes such as 59% in running away, and 69% in prostitution and vice. Females who participate in nonsocial behavior can directly be linked to delinquency and affect them through adulthood. Females have a higher tendency to be in an abusive relationship, drug abuse, and criminal behavior. Age, Gender, Race, and Ethnicity are factors that also play in juveniles being delinquent. As individuals get older they are more likely to engage in criminal and delinquent acts. The Uniform Crime Report shows that individuals are more likely to engage in delinquent behavior at the age of 16. Black and Brown youth are more likely to be detained than youth who are non-Hispanic and white. Since 2006, the population of female delinquent youth has not been the same until recent studies have shown these numbers are increasing. This study focuses on the impact of females being in the juvenile system and what are the risks and causes through qualitative interviews of professionals in the Midwest who have worked closely with juveniles, such as correction officers, police officers, and probation officers.

Abstract Name: Studying the Electrochemical Activity of Methanol Dehydrogenase in Lanthanide-Modified Methylobacterium extorquens

Recent studies have demonstrated that some enzymes in bacteria isolated from lanthanide-rich areas use lanthanides as metal cofactors in place of more common metals like calcium and that these lanthanide-enzymes have enhanced catalytic properties. For example, Methylobacterium extorquens is a methylotroph that conducts redox chemistry using methanol dehydrogenase (MDH). MDH is a type of quinoprotein that contains a pyrroloquinone and either a lanthanum (La3+) or calcium (Ca2+) metal cofactor. Here, the bioelectrocatalytic activity of MDH from M. extorquens grown in La3+ rich media is compared to MDH from M. extorquens grown in typical Ca2+ rich media. Biochemical assays have shown that La3+-MDH has higher activity than Ca2+-MDH. However, the bioelectrochemical activities from these bacteria have not been compared. If La3+ grown M. extorquens has higher bioelectrochemical activity than Ca2+ grown M. extorquens, then improved biofuel cells and sensors can be created. M. extorquens is grown in two separate

cultures, one with La3+-rich media and one with Ca2+-rich media. Spectrophotometric assays confirm higher activity for the bacteria grown in La3+-rich media than bacteria grown in Ca2+-rich media. The bioelectrochemical activity for oxidation of methanol to formaldehyde is measured by cyclic voltammetry and amperometric i-t curves for various concentrations of methanol in a tris-HCl buffer. In addition to comparing the bioelectrochemical activity of the La3+-MDH and Ca2+-MDH, the activity of the whole bacteria in solution versus immobilized on electrode surfaces will be compared, and an optimized bioelectrochemical electrode will be developed.

Abstract Name: Novel ACSS2 inhibitors sensitize to radiation to kill breast cancer brain metastatic cells ex vivo

Brain metastases (BMs) in breast cancer patients is considered an end-stage event, with no effective drug treatment and a median survival after diagnosis measured in months. The first line of defense against BM is radiation resulting in static tumor growth. Currently, there are no effective drug treatments for BM patients, thus there is an urgent need to develop novel treatment strategies. BMs must adapt to lack of nutrient availablity in the brain environment and become heavily dependent on Acetyl-CoA Synthease 2 (ACSS2) for the generation of acetyl-CoA for lipid and fatty acid synthesis. Here, we test the ability of novel ACSS2 inhibitors to reduce tumor growth in an orthotopic ex vivo tumor-brain slice model. Subsequently, treating these tumor-brain slides with radation syngerizes with inhibition of ACSS2. This data identifies ACSS2 as a novel therapeutic target for treatment of BMs and show promising synergy with first line of defense treatment of radation.

Abstract Name: Excavating Campus Expansions

My ongoing research initiative of the 2023-2024 academic year has been a collaborative effort with an Assistant Professor at the University of Kentucky. The research uncovers the social and racial implications that stemmed from the expansion of three higher-education institutions—the University of Colorado Denver, Metropolitan State University and Community College of Denver—into Denver's Auraria neighborhood during the city's urban renewal era in the 1970s. The establishment of the Auraria Campus entailed demolishing large sections of a predominantly Hispanic, low-income working-class neighborhood. Simultaneously, this research proposal examines Auraria Campus's uncanny connection to another controversial campus expansion thirty years prior in Chicago: the Illinois Institute of Technology (IIT) campus expansion that wiped out the predominantly Black neighborhood of Bronzeville and was designed by modernist architect Mies van der Rohe. The Auraria campus expansion was led by Jacques Brownson, a

protégé of Rohe's, who referenced planning and architectural techniques from Mies' IIT project. Employing a comparative methodology, the research meticulously analyzes historical archival materials, including but not limited to aerial maps, Sanborn maps, newspaper clippings, and drawings produced by the architect. The intent is to analyze past and present conditions of the site, map out, reconstruct, and calculate (in 2D and 3D) an index of the demolished residential and commercial buildings during the expansion, as well as tracing language tactics utilized to falsely frame the neighborhood's conditions, making the expansion seem like the best, if not only, option. Ultimately, this research seeks to contribute unique perspectives to the deeper understanding of the social and racial consequences of influential architectural projects. By tracing the parallels between Auraria and IIT expansions, the study strives to question and complicate Mies van der Rohe's legacy in America, emphasizing the need for a more critical examination that incorporates the social and racial dimensions of architecture.

Abstract Name: Magnetic Field Induced Ordering Of Block Copolymers

Poloxamers are amphiphilic ABA type triblock co-polymers that act like a surfactant in water, creating a micelle with a "B" type hydrophobic polypropylene oxide core and "A" type hydrophilic polyethylene oxide coronas. They are widely applicable as hydrogels; notably, they have been utilized in biocatalysis, drug delivery, and drug stability. In this project, we probed an atypical response of disordered poloxamer solution to ordered gel transition in response to magnetic fields. The behavior of a poloxamer solution in presence of an applied magnetic field (B = 0.5T) was investigated using magnetorheology, where the rheological characteristics of the samples were studied while exposed to an in situ magnetic field. Specifically, the time required by the poloxamers to transition from their disordered to gel state under magnetization, referred to as critical time, was tracked as a function of block ratio and molecular weight. The gels were characterized using small-angle x-ray scattering (SAXS), which revealed structural information about the gels obtained post-magnetization for 3 hours beyond the critical time. The critical time decreased exponentially and the modulus remained relatively consistent when increasing the molecular weight of the poloxamer. These results are helpful for future applications by demonstrating the tunability of magnetically-induced poloxamer gels.

Abstract Name: Design, Synthesis, and Biological Evaluation of New Multitarget-Directed Ligands for the

Treatment of Chronic Pain

Chronic pain is deteriorating quality of life of 1 in 5 of U.S. adults. Current treatments include Nonsteroidal Anti-Inflammatory Drugs, providing mild to moderate pain relief; while opioids carry a high risk of addiction, tolerance, and death by overdose. Soluble epoxide hydrolase (sEH) and fatty acid amide hydrolase (FAAH) are enzymes involved in the metabolism of lipid signaling molecules associated with arachidonic acid and are both associated with pain and inflammation processes. Co-administration of selective sEH and FAAH inhibitors produced antinociception without undesirable side effects in animals. However, the co-administration has many drawbacks, including the possibility of drug-drug interactions in vivo, which complicate preclinical/clinical studies and drug development.The long-term goal of our lab is to develop a single drug that can inhibit both sEH and FAAH simultaneously. We have previously discovered several dual sEH/FAAH inhibitors having low nanomolar range potencies at both enzymes. In this project we will perform structure-activity relationship (SAR) study of 4-phenylthiazole-phenyl moiety using a four-step synthetic route. We first optimized Hantzsch-Thiazole reaction with microwave irradiation and reducied the reaction time from 2.5 hours to 3.45 minutes. Using this reaction, we were able to obtain 12 different aniline intermediates in high yields and use them to synthesize final 4-phenylthiazole-phenyl analogs. All compounds underwent biological assessment in enzymatic assays for both sEH and FAAH inhibition. Our SAR study demonstrated that incorporating fluoro and methyl groups are well-tolerated in both enzymes, leading to the discovery of numerous potent dual inhibitors. We performed docking experiments in both enzymes to further analyze binding modes of these dual inhibitors. The most potent inhibitor will be sent to our collaborators at CSU East Bay for in vivo testing.This research is supported by the National Institute of General Medical Sciences of the National Institutes of Health under award number R16GM149204.

Abstract Name: The Use of Analytical Methods to Enhance the Marketing of Chick-fil-A

Chick-fil-A, the American fast-food chain, prides itself on fresh, delicious chicken along with fast and effective service. Although Chick-fil-A's upper management has a positive business reputation, they should use this project to assess how their business compares to Popeyes. The project aims to evaluate and improve Chick-fil-A's overall customer service and satisfaction. UWG students gathered data for the project via a questionnaire, which included both Likert and demographic questions, to get a better understanding of customers' perceptions of Chick-fil-A and Popeyes. Using an online survey called Qualtrics, the class collected 318 responses from family, friends, and colleagues around Georgia. Students analyzed the data through SPSS to provide valuable information to Chick-fil-A about one of their competitors. Approximately 84% of the surveyed respondents believe that, overall, Chick-fil-A is a better restaurant compared to Popeyes. The research concludes that the survey is representative of Georgia's population in terms of gender. The research is not representative of Georgia's population in terms of race. Independent sample T-tests showed that respondents value Chick-fil-A more than Popeyes. They strongly believe that Chick-fil-A offers a quick

meal, offers quick service in the drive-thru line, and overall is a great dining experience. Many also agree that they are a regular at Chick-fil-A, the restaurant offers healthy options, the menu offers a good variety of options, and they offer an inexpensive meal. Regression analysis showed that overall satisfaction of Chick-fil-A's service was dependent on the overall customer perception that Chick-fil-A is a great dining experience. The class recommends that Chick-fil-A should add a value menu, gather input from their male customers, expand business hours to being open 7 days a week, and expand their clientele to the African American community through advertising campaigns. Overall, our research shows that Chick-fil-A is accurately serving its Georgia customers.

Abstract Name: Selfish Shellfish: Shelter Sharing in Grass Shrimp (Palaemon pugio)

As a scientific community, we often assume that invertebrates are like mini-robots that should respond predictably to external variables and environmental cues, but their behavior is often more complex than we give them credit for. From eusocial shrimp to cultural transmission in insects to harassment and anxiety in crustaceans, a growing body of research ascribes complex behavioral patterns to invertebrates. Whether or not these are characterized as 'emotion' or 'personality' is up for debate, but it is clear that many invertebrate intra- and inter-specific interactions are more complex than previously anticipated. Our recent research involved a common Atlantic shrimp (Palaemon pugio) and investigated the link between grass shrimp claw size and shelter use in a tank that simulated their natural environment. The tank contained a high-value and a low-value shelter, as well as 5 large-clawed and 5 small-clawed shrimp that were tagged and observed with time-lapse photography. Analysis indicated that they were unlikely to share shelter and claw size controlled access to it, although the claw size and shelter use relationship actually flipped depending on the source of the shrimp (wild caught from New Jersey or aquaculture-raised). Wild caught shrimp had displayed behaviors that were expected while aquaculture shrimp would share shelter among small clawed shrimp. Results revealed dominance hierarchy formation and a possible difference in social behavior between wild-caught and aquaculture-raised shrimp, suggesting that there are many complex factors at play that affect shelter use in grass shrimp. While much is yet to be investigated to further understand shrimp dominance hierarchies and their ecological ramifications, these 'unusual' behaviors paint a complex portrait of marine invertebrate behavior.

Abstract Name: Childhood Trauma, Stress, Gender, and Depression's Impact on Suicidal Behavior

Suicide is one of the leading causes of death in young adults. Continuous prevention and intervention efforts

throughout the world have been made to reduce suicide risk in this population. Two of the biggest known risk factors for suicide is childhood trauma, a traumatic event or events that occur during youth, and depression. Researching the impact childhood trauma and depression make in conjunction with other factors will help to increase knowledge of suicidal behavior. In this study, recent stress and gender will be factored with childhood trauma and depression severity to predict suicidal ideation and attempt. Recent stress is useful to see recent life events that may be negatively affecting one's mood. Gender has shown differences that are displayed not just in the prevalence of suicidal ideation and attempt, but also in childhood trauma, depression, and stress. Young adults will make up the demographic of this study to better understand the relationship of multiple risk factors to suicidal ideation and attempts within this age group. Young adults experience stress in many ways, through transitioning to adulthood, studying, and working towards long-term career goals. The aim of this research will be to understand and address how childhood trauma, recent stress, gender, and depression severity impacts suicidal ideation and attempts. Two hypotheses will be tested in the study: (1) Childhood trauma, recent stress, gender, and depression severity predicts recent suicidal ideation. (2) Childhood trauma, recent stress, gender, and depression severity predicts suicide attempts. Research will consist of a quantitative study through an online survey consisting of self-report questionnaires that utilize multiple well-known scales. Inclusion factors for participation in the study are those enrolled in college and ages 18 to 25. This study will ask questions on past childhood events, recent stress, depression severity, recent suicidal ideation, and suicide attempts.

Abstract Name: Unmanning Richard II: The Inherited Queer Discourse of Ricardian Chronicles

In "Unmanning Richard II: The Inherited Queer Discourse of Ricardian Chronicles," I examine how fourteenth- and fifteenth-century historical chronicles portray King Richard II—who ruled England from 1377 until his deposition in 1399—as queer through the creation, deployment, and accumulation of the "unman" archetype that amalgamates the traits of youths, women, and "sodomites." Previous scholarly work has explored aspects of the queer reign and representation of Richard II, including several studies into the medieval development of anti-queer discourse, historical definitions of "manliness," and fourteenth-century associations between misrule and sodomy, as well as investigations into the "validity" of defining Richard as queer. This project seeks to elide these isolated inquiries into a cohesive, diachronic narrative of how anti-queer discourses function—in both the Middle Ages and the present. In this project, I examine contemporary Ricardian chronicles through a threefold lens that engages medieval ideas about sodomy, modern queer theory, and historical and literary criticism; I thus enact a queer historiography, rereading negative portrayals of Richard as both drawing from anti-queer discourse and serving as queer signifiers. The "unman" in Ricardian chronicles represents an accumulation and fulfillment of the many threads of medieval sodomy discourse, allowing queer portrayals of Richard to signify as castigatory propaganda and vice versa, thus intertwining manhood (and, implicitly and explicitly, personhood) with honor and dignity—and an absence of manhood, rendered as a queer state, with an absence of that same honor and dignity. This project, through the lens of José Esteban Muñoz's vision of queer utopia, seeks to reimagine the past as an empowering queer space, affirming queerness in the present and looking ahead to a future where queerness is divested of moral associations.

Abstract Name: Filling in the Blanks: A Student-Designed, Research-Based Instrumental Analysis Laboratory

Instrumental Analysis Laboratory is an excellent catapult for independent, student-drive experimental design and execution. Through the design of a viable experimental approach centered on a single piece of instrumentation students learn the ins and outs of instrument capabilities and limitations. Peer review of these experiments opens doors to essential colleague critique, honing of standard operating procedures, and enhanced discussion on experimental design, data and error analysis, and execution. Students actively engage with the experimental design process, develop methods, teach their colleagues, and gain a better understanding of the research process. I have created a curriculum that centers around the research process, to help students gain an understanding of the central role research plays in chemistry. This presentation will provide an overview of the curriculum, lessons learned, and student feedback.

Abstract Name: Engaging Academically At-Risk Student Populations in Structured Undergraduate Research as a Student Success Initiative

Regis University is enrolling an increasingly diverse student population, including academically at-risk (AAR) and underprepared students. AAR students are a diverse and challenging population of undergraduate students who are at the highest risk of not realizing their goals of attaining a college degree. In an effort to serve – not just enroll – these students, we are investing in support mechanisms to ensure their academic success. One such program is the Undergraduate Research Certificate (URC), which encourages academically underprepared students to engage in mentored research. The URC has been designed to meet the needs of populations often excluded from research by providing structured training, support services, and community-building opportunities. Many HIPs, including at Regis University, (e.g. honors programs, study abroad, internships, etc.) systematically exclude AAR students because: they do not meet the GPA requirements of these programs; students need to self-select into these programs while still in high school; or there is a financial burden that comes along with participation. We have intentionally integrated our URC into the curriculum in a way that does not increase cost to the student, does not require them to identify their affinity for research before getting to college, and does not erect barriers based on previous academic performance. This structured approach is especially critical for our AAR students who have been shown to benefit most strongly from scaffolded HIPs. Through targeted recruitment, we are actively increasing the number of AAR students enrolled in the URC and are assessing various academic success outcomes (e.g. persistence/graduation rates, GPA, credit completion rates), while controlling for affective and cognitive factors (e.g. academic self-concept, perceived social support, academic self-efficacy, achievement emotions). Intentionally leveraging HIPs, like structured independent scholarship, as tools for the retention and success of AAR students is a critical step in achieving equitable academic outcomes for diverse learners.

Abstract Name: Toward More Functional Upper Limb Prostheses: Evaluation of Organic Hand Dexterity,

Grip Strength, and Anthropometric Measurements

The design of upper limb prostheses blends mechanical performance with human-machine interfaces. Using electromyographic devices requires significant training, which can result in patients becoming discouraged and subsequent device rejection. To maximize functionality, prosthesis designers examine parameters of manual dexterity, which is a fundamental part of daily life and expression of creativity. Due to its multifaceted nature, dexterity can be challenging to benchmark for prostheses. Iterations of the Box and Block Test (BBT) are commonly used research and rehabilitation tools to establish a baseline. Past studies have utilized the tests for assessing manual dexterity in individuals training to use upper limb prostheses. This study aims to understand how dexterity, strength, and anthropometric measurements correlate for organic limbs, establishing updated baseline comparisons for future prosthesis design iterations. Data was collected from 50 collegiate participants aged 18-24 with full control of their upper extremities. Parameters collected include scores from variations of the BBT, grip strength, hand measurements, and a comparison of left vs right handedness via the Edinburgh Handedness Inventory. The results included grip strength scores for the study-collected sample, which were consistent with the national standards. Weak correlations between grip strength and dexterity scores on the BBT and modified BBT ($r = 0.268$ and $r = 0.167$, respectively) for organic hands signify a need to optimize device grip strength and dexterity. With validated equipment, the testing methods from this study will be used for comparison to prosthesis patients enrolled in an ongoing clinical trial training to use the Limbitless Solutions prosthesis. The dexterity results will serve as benchmarks for direct comparison to prosthesis patients, with biomechanical parameters correlating with performance to be used for improving prosthesis design considerations. Implementation of new design criteria from this study may enhance the overall dexterity of a prosthesis.

Abstract Name: Mindfulness, patience, and intertemporal choice: Can mindfulness increase patience?

Intertemporal choice is the process of making decisions that involve trade-offs between present and future outcomes. It is important for many aspects of life, such as health, finance, and education. However, many people are too impatient and tend to overly discount the future, preferring immediate gratification over long-term rewards. Impatience can lead to suboptimal choices and negative consequences. Therefore, finding ways to augment intertemporal choice is a valuable goal. One possible way to improve intertemporal choice is through mindfulness, which is the practice of paying attention to the present moment with openness and curiosity. Mindfulness has been shown to have various benefits for psychological and physical well-being, such as reducing stress, anxiety, and depression, and improving attention, memory, and emotion regulation. Mindfulness may also influence intertemporal choice by reducing impulsivity and the perceived temporal distance to the future. In an experiment with university students, we tested the hypothesis that mindfulness can increase patience. We randomly assigned participants to watch either a 3-minute guided meditation video or a 3-minute video on how to tie a tie. Participants then completed a time preference measure consisting of choices between smaller-sooner or larger-later financial rewards. We also measured their emotions, perception of how long 1 month, 6 months, and 1 year were from today, and risk preferences.Counter to our hypothesis, we found that the mindfulness video did not decrease patience, compared to the control video. We also found that the control group was more happy, cheerful, and relaxed, whereas the meditation group reported feelings of boredom. Finally, we surprisingly found that the control group made the overall less risky decision. Moving forward, we plan to find a better mindfulness manipulation, and hope to find valuable insights regarding the enhancement of intertemporal choice.

Abstract Name: Design and Validation of a Traffic Light Controller Utilizing 555 and 4017 ICs

This study delves into the practical application of the 555 IC, an integrated circuit renowned for its versatility across three operational modes: bistable, monostable, and astable. The bistable mode is a set/reset flip-flop, while the monostable mode is a pulse generator, yielding a single output pulse. The 555 IC acts as an electronic oscillator in the astable mode, dictating specific timing intervals. Additionally, we incorporate the 4017 IC, a decade counter well-suited for counting tasks within the lower numeric range. Operating in binary form, this counter sequentially counts from 0 to 9, providing a decimal representation of the count. To validate the practicality and functionality of our traffic light controller design, we initially constructed and tested it using Multisim, a simulation software. Subsequently, we advanced to implementing the controller on a physical breadboard. Both the simulated and hardware designs consistently exhibited the anticipated performance, thereby affirming the successful operation of our traffic light controller system. In our future work, we will employ AI technology and incorporate additional sensors to ensure reliable performance even in challenging weather conditions, such as dense fog or intense sunlight.

Abstract Name: A Caregiver Tool or an Inconvenience? How Mobile Apps Could Influence the Effectiveness of Supplemental Social-Emotional Skills Taught at Home.

The practice of recognizing emotions and using socially appropriate strategies to manage them is known as emotional regulation and develops rapidly during early childhood (Harrington et al., 2020). There is also developmental and societal value to teaching children about regulating emotions as early as preschool. Early childhood caregivers often provide these lessons about emotional regulation; however, other tools can be supplemental resources. Digital media is one example of a tool children learn from since it is accessible and delivers content in multiple formats (Barr, 2019). Using caregiver reports and a 10-day longitudinal design, this study aims to analyze the effectiveness of mobile apps with different levels of scaffolding as a supplementary social-emotional learning opportunity for preschool children. Correlational matrices will be

used to assess the associations between dependent variables: joint media engagement (DV1), likelihood of child demonstrating emotional regulation skills (DV2), and frequency of app use (DV3). In each correlational pairing of dependent variables (DV2 and DV3; DV1 and DV3; DV1 and DV2), the Embedded-Scaffolding app (Daniel Tiger for Parents) is expected to have a stronger positive correlation than the other conditions. Additionally, it is expected that the Embedded-Scaffolding (Daniel Tiger for Parents app) condition will have a stronger difference between pre and post-test DV3 scores compared to the difference between pre and post-test DV3 scores in the other conditions. The present study aims to understand potential influences when assessing the effectiveness of digital media used as a supplemental social-emotional teaching tool at home. Ultimately, maximizing accessible resources used in this population has the potential to educate children about critical social and developmental skills equitably.

Abstract Name: Adaptation of Cryptococcus deneoformans to gradual increases in temperature

Climate change poses many threats, including the potential evolution of certain environmental microbes to adapt to living at human body temperature. One of these microbes, Cryptococcus deneoformans, is an invasive human fungal pathogen that produces spores. C. deneoformans has been developed as a model for the study of human fungal pathogens. When spores are produced and inhaled, they can germinate into yeast that spread to other tissues, such as the brain. Because germination is required for disease, our lab has focused on the conditions that initiate germination and developed a quantitative germination assay (QGA) to measure it. To assess the ability of laboratory strains of C. deneoformans to adapt to growth at higher temperatures, we will slowly expose them to incrementally higher temperatures from 30°C to 37°C over time. We will then test how these strains respond to conditions that test properties associated with survival in diverse environments. We hypothesize that temperature-adapted strains will show more robust survival phenotypes than non-adapted strains and will produce spores that germinate more efficiently at high temperatures relative to non-adapted spores. If high-temperature adaptation promotes more robust survival under a variety of conditions, our data may provide information on how global temperature increases due to climate change will impact environmental fungal pathogen survival overall.

Abstract Name: Classroom Managed: Teaching and Behavior Management Strategies Implemented in Eastern Kentucky Schools

In recent years, the increase in teacher attrition has become a salient issue in schools in both Kentucky and

across the nation. In 2019, 44% of new teachers reportedly left the field within the first five years of teaching. Educators list student behavior challenges as one of their top concerns. Beginning teachers are often overwhelmed with misbehavior, causing a feeling of job dissatisfaction, and is often listed as a reason for teacher attrition. Classroom management, a necessary tool for educators to use in the classroom, reduces the number of disruptions that occur and improves productivity.Classroom management refers to different strategies teachers use to create positive and effective learning environments for students. Large amounts of instructional time are lost when teachers lack effective classroom management skills. New teachers struggle to implement classroom management, resulting in a loss of instructional time and an increase in behavior issues. The lack of experience and time leaves many new teachers struggling to implement an effective management system that supports instruction and reduces misbehavior.This research study examines data collected from educators of varying experience in Eastern Kentucky. The data results help to determine what strategies in classroom management are most successful. Using a mixed method of interviews and surveys, educators from elementary, middle, and high schools share how classroom management differs for each age group. Responses encompass various strategies regarding student behavior, parent involvement, previous classroom management training, and individual strategies implemented by beginning and experienced teachers. Evaluating classroom management strategies used in Eastern Kentucky classrooms provides direction for new teachers struggling to identify their management style, allowing for an easier shift into implementing their own classroom management techniques in the field.

Abstract Name: “Women are meant to be seen and not heard- unless they are SOE agents.”

World War II gave way to a new form of intelligence gathering; Britain created the Special Operations Executive, SOE, as a response. Their F-Section that focused specifically on France hired the most unlikely of spies, including mothers, Jewish women, a disabled American, and a Sufi Princess. In this small section, they produced vital work that aided the allies in their D-Day victory and the French Resistance in their fight against the Germans. When the war was over, the SOE dissolved, and society struggled with how or if they wanted to commemorate the work of these women. When the war ended, there was a spike the women receiving awards and recognition, but within ten years they were forgotten about by the society that once honored them. Starting in the 2000s, there has been a steady rise in scholarship about these agents, many had passed away before they could see their work celebrated. Now, they are being commemorated in a variety of ways such as having their stories told on the big screen, making their stories more assessable to future generations. My research drew from the SOE file of Virginia Hall, films about the women, and the rise in scholarship in the form of books and articles. There is a nice mix of primary and secondary sources used for this niche research topic.

Abstract Name: The Effects of Menstrual Cycle Hormones on Borderline Personality Disorder and Attention-Deficit/Hyperactivity Disorder Symptoms

Prior literature shows that attention-deficit/hyperactivity disorder (ADHD) and borderline personality disorder (BPD) interact in important ways, as people with a comorbid diagnosis tend to have higher levels of negative affect and impulsivity than those with only ADHD or BPD. However, there are few studies that examine the impact of the menstrual cycle on symptoms of ADHD or BPD, with even fewer focusing on their comorbidity. We aim to investigate the effects of reproductive hormones on this clinical population that we hypothesize is more likely to be sensitive to hormone fluctuations. Participants in this study were 46 young adults (ages 18-25) who were assigned female at birth (AFAB). Participants were divided into two groups: 1) a high BPD symptoms group if they endorsed four out of nine symptoms of BPD while also meeting diagnostic criteria for ADHD (n=14, 30.0%) and 2) other participants who did not meet this criterion (n=32, 70.0%) based on semi-structured interviews (i.e., the SCID, SCID-PD). Every participant completed four laboratory visits at targeted menstrual cycle phases (i.e., midfollicular [rising estrogen]; postovulatory [declining estrogen]; midluteal [rising progesterone]; & premenstrual [declining hormones], during which they completed self-report surveys (i.e., the DRSP; UPPS) assessing their levels of negative affect and impulsivity. Our findings did not show a significant difference in symptom severity among the ADHD-BPD participants at different points in the menstrual cycle ($p \geq 0.1$). Our findings also did not indicate a significant difference in the levels of variation in negative affect or impulsivity between the two groups ($p \geq 0.1$). However, some findings trended towards significance, with negative affect increasing during the cycle's midluteal phase more significantly in the ADHD-BPD group. Findings should be replicated with a larger sample in order to allow more powerful tests of menstrual cycle effects on negative affect and impulsivity in those with ADHD and BPD.

Abstract Name: Seeking Closure: Measuring Impact of Lesson Closure on Laboratory Students' Learning Outcomes

Although life science laboratory courses (or components) are important for student success, these courses repeatedly demonstrate a failure to meet the intended learning objectives, especially those relating to understanding theoretical concepts. Lesson closure is a strategy where students' working memory intentionally processes key points, learning objectives, and the what, why, and, how of the novel information. Facilitating lesson closure has shown to increase student comprehension and confidence in materials taught in lecture-based courses. To date, no studies report the use of lesson closure on student's performance on laboratory learning objectives. With our study, we intend to expand on the research of lesson closure and investigate closure in a life science laboratory-based course by implementing terminal closure sessions preceding the completion of labs. With this strategy, we aim to answer the question: What is the impact of utilizing terminal closure in laboratory environments on student's understanding of theoretical concepts, confidence of that understanding, and future retention of lab content? During the closure sessions, the instructor will prompt students to collaboratively discuss the purpose of the experiment, their results in context, and why each step was necessary. To assess the impact of terminal closure sessions on student learning, we will use pre and post laboratory 3-tiered multiple choice diagnostic tests. The first questions will test basic comprehension, followed by listing potential explanations for the previous questions, and finally

the third level will ask students to rate their confidence of preceding answers. Evidence collected and analyzed in this study will guide future development of laboratory-based courses by providing instructors with a strategy and instrument for gaining and assessing laboratory outcomes, in addition to better equipping students with knowledge and skills for careers in the life sciences.

Abstract Name: Spatial dynamics of foliar fungal community structure in the Pando Aspen Clone

The Pando aspen grove in Central Utah is a remarkable organism comprising a clonal colony of Quaking Aspen (Populus tremuloides) in Fishlake National Forest. While Pando has garnered plenty of attention, the role of the fungal microbiome within this clonal system remains relatively uncharted. This research project delves into the endophytic and epiphytic fungal communities inhabiting the leaves of this giant single organism, employing meta-barcoding techniques to analyze the fungal ITS2 region from both the leaf surface and interior. The clonal nature of Pando means that plant genotype is consistent across a broad area, allowing us to test hypotheses about how plant-associated fungi disperse and associate with their hosts. In particular, we are testing whether proximity to a forest edge affects foliar fungal community structure. This research will enhance our understanding of how forest patch size and location contribute to plant-fungus community formation. These findings may also have implications with the potential to affect the health and resilience of this aspen clonal colony, which could in turn inform conservation strategies and forest management in the face of environmental challenges and the shifting ranges of aspens and fungal symbionts.

Abstract Name: StRoNG Net: Undergraduate Research in Genomics.

Since the first release of a draft human genome, almost a quarter of a century ago, there has been a quiet revolution in genomics. Dramatic technological advances have made sequencing the genomes of "non-model" organisms throughout the tree of life feasible and affordable. Often, non-model genomes are sequenced in pursuit of specific scientific questions that only examine a small fraction of the overall genome, leaving the rest unstudied.Understudied genome sequences from non-model organisms are a great opportunity for undergraduate scientists to conduct original research. As a field of study, genomics is well suited to undergraduate research for several reasons:1. Genomics research projects can be granular and highly

scalable. A project can be as simple as identifying one or two genes of interest or as complex as comparative studies of genomes from multiple species.2. Genomics research is highly accessible. Data are often stored on central servers and accessed through web interfaces. Students only need a web browser to participate in research.3. Genomics provides a forum to introduce students to advanced computational topics like machine learning and artificial intelligence.4. Genomics is well suited to providing Course-based Undergraduate Research Experiences (CUREs) to large cohorts of students.StRoNG Net (STEM Research on Non-model Genomes Network) is a community of educators and researchers supporting undergraduate research in genomics. The network provides a forum to develop research opportunities and to share experience and best practices.

Abstract Name: Building the Louisiana Freshwater Sponge Project: The interdisciplinary undergraduate research hub at Baton Rouge Community College

After moving from a 4-year research University to Baton Rouge Community College in 2013, Dr. Miller quickly realized that there were no research opportunities for the students on the campus. Knowing the impact undergraduate research has on student success, in 2015 Dr. Miller set out with a mission to secure funding and change the campus experiences to include research. In this presentation, she will share her journey of how her initial implementation of Course Undergraduate Research Experiences (CUREs), evolved into a leading hub of freshwater sponge research in the United States. She will share how she and her collaborators have secured over 1.5 million dollars in Federal, State, and local grants to support student stipends and build a state-of-the-art research project, The Louisiana Freshwater Sponge Project. Since its formal development in 2019, the project has provided forty community college students with part-time employment while they gain transferrable workforce skills, resulting in a 95% retention and graduation rate. These students have participated in cutting-edge research focused on the diversity, taxonomy, and ecology of freshwater sponges in Louisiana. This research has equipped students with a wide range of skills ranging from field methods in ecology to lab-based molecular techniques and computer coding. These students have also participated in local outreach initiatives to raise public awareness of freshwater sponges. Dr. Miller will discuss the importance of collaborating with other institutions to provide the most impactful experiences and reflect on student experiences including student travel, conference presentations, and upcoming publications. She will also share mentorship advice for leading an interdisciplinary project that has provided undergraduate research experiences to computer science, general science, pre-engineering, pre-professional, and nursing majors.

Abstract Name: Toward the Development of a System to Measure Thumb-tip Movement Produced by Muscles

Thumb-tip movement impairment, often resulting from neurological injuries, leads to loss of grasp functions vital in daily activities. Understanding the specific movements produced by thumb muscles is key to improving surgical and rehabilitation interventions for grasp impairment. To date, the thumb-tip movements that muscles produce remain unclear. Our work aimed to clarify these movements. We developed an arm fixation device, along with motion tracking and actuation systems, to accurately capture thumb-tip movements that muscles produce. In our study, two cadaveric specimens were dissected to expose the extrinsic thumb muscles: the extensor pollicis longus (EPL), extensor pollicis brevis (EPB), abductor pollicis longus (APL), and flexor pollicis longus (FPL). Each muscle's tendon was pulled five times using a linear actuator to a displacement of 39 mm and at 28 mm/s. We measured the resulting thumb-tip movements. Thumb-tip trajectories ranged between 16 mm and 64 mm with FPL generating the smallest trajectory and EPB the largest trajectory. Of the four muscles, FPL exhibited the most intra-trial variability in its thumb-tip trajectory. Lastly, of the muscles tested, only EPB produced a thumb-tip trajectory consistent with its nomenclature. That is to say, EPB produced primarily an upward/dorsally-directed thumb-tip movement. The observation that muscles produced different amounts of movement than the input movement (39 mm) suggests that the thumb behaves like a variable transfer function depending on the muscle involved. The observation that most muscles produced thumb-tip movements inconsistent with how they are named points to the complexity of musculoskeletal biomechanics. Both findings agree with previously published results on muscle-produced thumb-tip forces. This work begins to provide a better understanding of muscle-produced thumb-tip movements. This has the potential to aid in enhancing models of the hand that are used to design improved interventions for grasp function following neurologic impairment.

Abstract Name: Breaking Boundaries: The Legacy of the Institut für Sexualwissenschaft in LGBTQ+ Rights and Activism

This paper delves into the influential role played by the Institut für Sexualwissenschaft (Institute of Sex Research) in the early 20th century, particularly focusing on its impact on LGBTQ+ rights and activism. Founded by Dr. Magnus Hirschfeld in Germany, the institute pioneered research into human sexuality, gender diversity, and LGBTQ+ issues during a time when societal attitudes were far from accepting. Through an analysis of the institute's groundbreaking research and educational initiatives, this paper highlights how it challenged prevailing prejudices and advocated for LGBTQ+ rights. It also explores the enduring legacy of the Institut für Sexualwissenschaft in shaping contemporary discussions on sexuality and gender diversity, emphasizing the lasting importance of its early contributions to the ongoing pursuit of LGBTQ+ equality and acceptance.

Abstract Name: NCUR Abstract

Chefs Kiss is a home for Christine Ha who is a blind chef. The main question for this project was how do you design a homey yet functional space for someone who is completely blind but also a chef who loves to cook at home and entertain people in her home? Through a lot of research and listening to guest speakers I learned that designing a home for someone who is visually impaired involves paying a lot of attention to little details that you normally might not have paid much attention to. An example of this is providing more outlets than a typical home to allow the homeowner to adequately use all of the technology they use to go about their daily lives. You also have to pay attention to things such as the contrast between walls and baseboards or walls and door frames to make it easier for the user to clearly see where they are and when they are entering new spaces. For my research, I read many different interviews Christine has had where she spoke about how she lives her life and how she navigates her world, and how she manages to cook while being completely blind. For my final design, I chose materials that contrast well with each other as well as incorporating more opportunities for technology to be integrated within the home to make the home adaptable to Christine and her husband as they age within the home. I also integrated smart appliances within the kitchen and throughout the rest of the home as well as selected furniture pieces that do not have any sharp edges, making it safer for Christine to walk throughout the home. Overall, I believe my design for her home is the perfect mix of homey and functional.

Abstract Name: Focusing Undergraduate Research on Finalizing Education of Chemistry Majors

How well prepared are BS Chemistry majors for their postgraduate endeavors? How can they be more competitive on the job market or more efficient in graduate school? In order to answer these questions, I had been interviewing the recruiters who come to Penn State in the last 10 years trying to identify which improvements can be made for the development of technical and soft skills needed to complete the education of our chemistry majors. Similar questions were addressed in communications with graduate faculty and their suggestions were considered/incorporated as well.In this presentation I will describe the recent experience in my pedagogical approach which utilizes undergraduate research for achieving the aforementioned educational goals. It utilizes modified project-based learning, and it is executed in the three-course-sequence consisting of CHEM 457 (experimental physical chemistry), CHEM 459W (advanced experimental physical chemistry), and CHEM 494 (independent research). More specifically, (a) the classical exptl. phys. chem. class (CHEM 457) was modified such that the students gain most of the necessary foundational cognitive skills and knowledge, (b) the second class entitled advanced exptl. phys. chem. (CHEM 459W) was designed such that they perform authentic research projects relatively closely guided by the professor, and (c) the independent research class (CHEM 494) was designed such that the students finalize their project (finish the manuscript to be submitted in a peer-reviewed journal) under minimal supervision of the professor. The learning goals and syllabi of all three courses will be presented as well as the corresponding justifications.

Abstract Name: Motivations of Caffeine Use amongst College Students

Caffeine is a popular substance that is oftentimes associated with college students. While research explores caffeine consumption in college students, motivations of use and differences in use by college major are yet to be explored. The objective of the current study is to investigate motivations of caffeine use in college students and explore differences by major. A validated cross-sectional survey regarding caffeine consumption habits was modified to fit study objectives and distributed via Qualtrics. Participants were CSULB undergraduate students taking a general education class that requires students to engage in experiments for class credit from the academic semester of Fall 2023; a second run will be conducted during the Spring 2024 semester.The initial sample consists of 63 participants, 33 participants indicating the pursuit of a health major (a degree option offered under CSULB College of Health and Human Services), whereas 30 participants indicated enrollment in a non-health major. Preliminary results indicated “taste” (n=22), “caffeine usage is a pleasurable/enjoyable habit” (n=17), and “it is delicious” (n=14) as primary motivators across all majors. Taste was seen as a higher motivation for health majors compared to non health majors. Habit was more prioritized for non health majors compared to health majors. Health majors selected ”it is delicious” more often than non health majors, who were more likely to select “ritual, waking up, and increased willingness to work” as motivation for use. The highest number of respondents were freshmen (76.2%), majored in nursing (n=12), female (71.4%), 18 years old (65.1%), and Hispanic/Latinx (60.3%). These results are helpful for targeting caffeine-related guidance to align with student motivations for using the substance. Continued study may provide context for exploring the relationship between caffeine use and motivations to further caffeine-related research.

Abstract Name: Viscous Biolocomotion: Simulation versus Physical Models

Marine, estuarine, and coastal regions are sensitive to disastrous human-induced environmental disasters, one such being oil spill events. Current remediation efforts involve the use of surfactants, introducing additional chemicals that may create long-term environmental damage. This has encouraged research for an effective and toxin-free way to target the containment and cleaning of oil spills through bacterial mechanisms or bio-inspired microrobotics. Naturally occurring bacteria such as Alcanivorax and Marinobacteri have been shown to break down complex hydrocarbons and assist in the oil degradation process. This project aims to advance our knowledge of biolocomotion in viscous fluids, like oil, by coupling computational models for bacterial

flagellar motion with experimental lab validation. We model flagellar motion using a motor-driven helix submerged in fluid and use particle image velocimetry (PIV) to map the velocity flow near the helix. The parameters for the helix shape, motor speed, and fluid (glycerin) were determined to match Reynolds numbers as closely as possible to those associated with observed fluid motion surrounding bacteria (Re ~ 0.1). Several different sizes of helices were used to determine which length scale of a flagella, amplitude or length, would match the 0.1 Reynolds number. Comparison between the observed flow field and the computational model is used to validate our modeling assumptions and refine both our computational model and PIV. Future goals include prototyping different flagellar configurations, including flexible filaments and robotic flagella, thus allowing for a fuller exploration of parameters, waveforms, and biomechanics that govern swimming efficiency within these environments. From this framework, we hope to investigate the remediation potential for bacteria as well as microrobots that mimic bacterial motion but could be designed to navigate complex environments and navigate oil spills more efficiently.

Abstract Name: We Must A.R.T (Articulate, Review, and Tackle) Racism in Health Care

This is a health promotion project focusing on educating the public on the correlations between racism and obesity, stress, cardiovascular disease, and hypertension. Learning is expressed and exchanged through a community arts project. “Racism and mental health and the role of mental health professionals” by M Schouler-Ocak discusses what race is, the history of racism in the United States, and how racism can affect one’s mental health. It is explained that racism occurs on every level: structural, institutional, interpersonal, and internal. This puts people with observed racial and ethnic inequities at risk of severe mental illness. A meta-analysis and systematic review determined that racism is related to poor mental and physical health. The results of this review state that racism is related to the development of affective, psychotic, and substance use disorders. After evaluating the mental health issues in the community, depression was the most common outcome. This is all a result of the stress responses being triggered by discriminatory experiences. As such our project further affirmed the correlation between racism and stress, as well as obesity and cardiovascular disease. The quantitative and qualitative research (surveys and observations) consisted of self-identification questions, experiences, and comprehension of the topics discussed during the sessions, expressed by answering a scale of strongly disagree to strongly agree. During this project, there were six sessions—three with the African American community and three with health professionals. During the sessions, different stressors and diseases and their relationship with racism were presented to the attendees. Surveys were issued to the attendees before and after the presentation. The sessions with the African American community resulted in higher knowledge and the sessions with the healthcare professionals resulted in around the same knowledge as before.

Abstract Name: Investigating the Anti-Cholinesterase Properties of Crassocephalum crepidioides in Larval Zebrafish

Acetylcholine is an essential neurotransmitter in the brain that has important functions in learning and memory. Levels of this important molecule are low in patients with dementia and Alzheimer's disease. Acetylcholine is broken down by the enzyme acetylcholinesterase. Acetylcholinesterase inhibitors such as donepezil are commonly used to treat dementia and Alzheimer's disease by increasing the levels of acetylcholine in the brain. Previous research has shown that the plant Crassocephalum crepidioides inhibits acetylcholinesterase and therefore has possible applications as a treatment for Alzheimer's. However, acetylcholinesterase may be linked to apoptosis in young individuals. This research aims to provide insight on how acetylcholine affects young, healthy brains and examines the effects of C. crepidioides as a potential dementia treatment. In this study, zebrafish embryos were treated with aqueous plant extract as they developed. After all embryos hatched, fluorescence microscopy was used to quantify apoptosis in the zebrafish larvae. Results showed that C. crepidioides does not have a significant correlation with apoptosis. However, embryos had a faster hatching rate and lower mortality, indicating possible positive effects of the plant extract on growth and development. Previous studies have demonstrated that acetylcholine has a role in embryonic development and the release of growth hormones such as IGF-1. Future experiments will investigate these mechanisms by quantifying acetylcholine and measuring the presence of growth hormone IGF-1 in larval zebrafish after treatment with C. crepidioides.

Abstract Name: How Gentrification Increases Food Insecurity: An Analysis of Pittsburgh's Hill District

In 2018, Pittsburgh was ranked the 8th most gentrified city in the United States. Through the process of gentrification, food insecurity can arise from restrictions on transportation, food options, and livable properties. Postulating a correlation between neighborhoods undergoing gentrification and increasing food insecurity, this research addresses the question: how does gentrification impact food insecurity?This paper focuses specifically on Pittsburgh's Hill District, a predominantly minority populated neighborhood undergoing gentrification since the 1950's. Once a prospering and lively neighborhood, the Hill has since lost its sense of community to corporate interest. Now considered a "food swamp," the Hill's food insecure status is a result of negligent corporate interference. Urban neighborhoods that feature more than 4 fast food, corner, or convince stores per .25 square miles are labeled "food swamps."In combating food insecurity, data collection processes and measures can misidentify many families and individuals as food secure. Current literature addresses issues with aggregate data, as macro level data does not accurately translate to micro level statistics. Although the City of Pittsburgh states 1 in 5 people are food insecure, this data does not account for differences in caloric intake across sex, gender, and age.This research paper employs mixed methodology to translate aggregate data more accurately. Beginning with secondary data analysis, this project will collect existing macro data. Then, town hall meetings where residents can share their stories and struggles invites community engaged learning and research. Following, this meso level data will proceed with one-time, semi-structured interviews to establish a research instrument for micro level food insecurity.

Finally, to gather longitudinal data on the impact of gentrification, annual mail-in surveys will use the established instrument to measure food insecurity and resident erosion rates in the Hill District.

Abstract Name: Utility Company Credit Ratings and Regulatory Environment

Credit ratings serve as a crucial classification tool for categorizing companies as risk-equivalent entities. This criterion gains paramount importance when utilities, seeking higher rates in rate cases, are typically compared to companies within a so-called proxy group. The selection of this proxy group often relies on credit ratings. In this study, we delve into various issues related to utility credit ratings over the last 20 years, including the assessment of 1. How utility credit ratings have performed during this period. 2. The extent to which utility credit ratings have mirrored the underlying financial metrics of the companies and the regulatory environment. Our focus is on data from the past two decades of U.S. gas and electric utilities. Given that utilities operate as regulated businesses, their ultimate financial conditions are significantly influenced by regulatory outcomes. The study explores the impact of several regulatory variables on credit ratings. One notable variable is the commission rating, derived from a broad measure of how each state commission manages issues related to utilities, such as utility rate case requests and commission decisions on specific utility issues. Furthermore, we scrutinize a specific regulatory decision variable – the authorized return on equity set by the commission in each rate case where a rate increase is requested. This authorized return on equity stands out as the single most crucial variable determining the overall revenue requirement for a utility. Additionally, we consider the financial metrics of the utilities when examining the influence of the regulatory environment on credit ratings.

Abstract Name: Comparative Analysis of Building Electricity Demand

Cornell University's sustainability is recognized by the Princeton Review's Green Honoral, has ranked 4th in the Sierra Magazine for its advancements in sustainability, and has received a STARS Platinum award in the national with a score of 85.12/100, AASHE endorsed, self-reporting sustainability tracker3. In 2013, the Cornell Sustainable Council undertook the 2035 vow to Carbon Neutrality. At this time, Cornell's score on STAR's "Building Energy Consumption" category is a 1.32/8.00, and a 2.60/8.00 on "Clean and Renewable

Energy.” Later, in 2014, the SACLG published a report analyzing the “Options for Achieving Carbon Neutrality by 2035.” Nonetheless, after 7 years, Cornell’s STARS has failed to improve in both the building efficiency and clean energy categories, with scores of 4/6 and 0.81/4 respectively.In response to this stagnation, the Cornell University Carbon Neutrality ESW team has decided to conduct an exploration of the most tolling emitters on the Ithaca campus. We present the methodologies and results of a comparitive analysis identifying fume hoods, ultra low freezers, data centers and centralized HVAC systems as the main loads in the most energy consuming buildings.

Abstract Name: AI-Driven Interview Coaching Platform: Enhancing Global Freelancing Opportunities for Pakistan's Technical Workforce

The global freelancing market offers many opportunities, but individuals from developing countries like Pakistan often face challenges. While many of these individuals have strong technical skills, they struggle during interviews that have international standards. This difficulty can prevent them from securing freelancing roles, highlighting a need for specialized interview training.This research presents a platform designed to train students and professionals for these interviews. Distinctively integrated with advanced technologies such as Natural Language Processing (NLP), machine learning, and data analytics, the platform offers a tailored training experience. By analyzing users' responses in real-time and utilizing predictive analytics, it delivers targeted feedback, enhancing users' grasp of industry knowledge, their ability to articulate accomplishments, and their comprehension of emerging industry trends.The research methods include a literature review and a survey. The literature review studies the challenges of freelancing interviews and the role of technology in interview training. The survey gathers feedback from users of the platform to understand its effectiveness. Results show that users of the platform are better prepared for interviews and have a higher chance of success in the international freelance market.This study is important because it addresses a gap in interview training for individuals in developing countries. It shows how technology can help these individuals improve their interview skills and access global freelancing opportunities. The use of NLP and machine learning in the platform also suggests how technology can shape future interview training tools. The research further underscores the benefits of AI-driven platforms, such as scalability, cost-effectiveness, personalization, and enhanced accessibility. However, it also draws attention to potential challenges, including technical hurdles, socio-cultural reservations, and ethical considerations. The exploration of initial initiatives like CareerTuners.ai offers glimpses of the concept's budding realization.

Abstract Name: Equal Opportunity for Invisibly Disabled Employees

The needs of employees with specifically invisible disabilities are not being met by employers. Policy makers, activists, and political scientists have long collaborated to extend civil rights for marginalized communities; one instance is the enactment of the American Disability Act (ADA). The ADA is currently insufficient, as it does not protect these employees with invisible disabilities who come to the workplace with an altogether unique set of needs. Social scientists have thoroughly documented how civil rights laws tend to be reactive measures. To argue on behalf of further protections for those with invisible disabilities, more needs to be understood about how workplace accommodations can foster the professional environment necessary to, one, protect this group and, two, set the conditions for them to flourish. This is what I intend to show. What becomes clearer is that the lack of federal regulations safeguarding invisible disability-related accommodations results in ill-prepared employers providing inadequate assistance to those who need it. To that end, I investigate patterns of cognitive disorders in working adults in their late twenties to early thirties, like depression, increased since the COVID-19 pandemic. Depression is considered a disability under the ADA but continues to remain invisible because individuals with depression are not visibly impaired. As diagnoses for the working population are on the rise, it is imperative for us to now understand why employers must also be equipped with the necessary provisions parallel to the needs of their changing workforce population. The ADA has been amended to broaden protections before, and can be again—to enforce and standardize the implementation of resources for workers whose disabilities largely remain invisible. My study can help show why it should be updated once more.

Abstract Name: Aeromicrobiology with High-Power Rocketry

Aeromicrobiology is the study of microorganisms living in the atmosphere. High-power rockets are capable of achieving impressive altitudes, even while carrying delicate payloads. For this series of experiments, our payload is the LADCAP (Launchable Automatic Device for Collecting Airborne Particles). LADCAP collects high-altitude microorganisms, called extremophiles, which can withstand low temperature, low pressure, desiccation, and increased UV flux. The data collected about extremophiles on Earth can potentially be extrapolated to extremophiles in other locations, including other celestial bodies. While the surface of Venus is extremely hostile, the cloud layer of the planet's atmosphere is much more hospitable to the possibility of life. This cloud layer has moderate temperatures of 0-60°C and pressures of 0.4 - 2 atmospheres. Extremophiles in Earth's own atmosphere would have adapted to live under similar conditions. Therefore, the samples we collect on Earth could provide insight into the types of extremophile life that exist in the Venusian cloud layer. With the LADCAP proprietary system, our research group has aspirated airborne microorganisms from the atmosphere. Through repeated launches, our group has collected and cultured numerous airborne microbes including rhizoid bacterial colonies and fungal colonies. In addition to the LADCAP system, we are developing an alternate method of sampling for airborne particles. This method would function without a flight computer and would be designed for amateur microbiology in classrooms without access to the same resources as our research lab.

Abstract Name: A Self-Love Story: Varieties of Narcissism, Attachment Dynamics, and Self-Object Needs

This study is aimed at exploring the interplay between narcissism, attachment patterns, and the formation of self-object needs, as initially interpreted by Kohut (1971). Our primary objective is to investigate the association between narcissism and attachment insecurities. Our study also seeks to shed light on how individuals develop a coherent or fragmented sense of self from infancy through adulthood, with a primary emphasis on the role of attachment figures. By dissecting the interplay between self-object needs, narcissism, and attachment, we pave the way for a deeper comprehension of these dynamic relationships. Providing newfound hope and solutions for individuals grappling with narcissistic traits and self-disorders. It is hypothesized that maladaptive covert narcissism will be predicted by positive attachment avoidance, negative attachment anxiety, positive conflicted self-efficacy, positive conflicted affiliation, and positive dismissive self-efficacy, while communal narcissism will be predicted by negative attachment avoidance, positive attachment anxiety, positive approach affiliation, positive conflicted self-efficacy, and and positive conflicted affiliation.

Abstract Name: When the Orient and the Occident Met in Israel: The Impacts of Orientalism on Ashkenazi-Mizrahi Dynamics in Israel and Beyond

In her paper “The Invention of the Mizrahim,” New York University scholar Ella Shohat illuminates the creation and evolution of a unique “Mizrahi” identity for Jews from Arab lands, who arrived in Israel after its establishment in 1948. This identity was meant to segregate Mizrahi “Oriental” Jews from European Jews, known as Ashkenazi Jews. Erasing Mizrahi’s Arabness became a national project that attempted to create a homogeneous Israeli identity founded on the Eurocentric ideals of the Occident. Mizrahi Jews have been marginalized over the years, facing neglect, oppression, and cultural assimilation. This process continues, evident in the 2018 Nation-State Law in Israel that makes Arabic a language with a “special” but not “official” status, impacting not only Arabs but also Mizrahi Jews, many of whom are Arabic speakers. Through ethnographic observations from museums and cultural institutions in New York and Israel, archival research, and immersive literature review, this research provides insight into the prevailing Orientalism and lack of adequate representation of Mizrahi Jews in historiography both before and after 1948. My research adds a contemporary layer to the Mizrahi question by analyzing various forms of expression of contemporary Mizrahi voices, revealing that Jewish history is almost thoroughly equated to Ashkenazi history. Guided by the Orientalism framework of the Palestinian-American scholar Edward Said, and relying on the collected ethnographic evidence, this paper argues that Israel developed its own type of Orientalism – Israeli Orientalism – which excluded the Mizrahi narrative from cultural and political spaces to this day.

Abstract Name: The Cytoplasmic Fragments of M-CSF Receptor Suppresses Obesity Related Bone Phenotype

Bone health is becoming a greater area of study because of its importance in multiple disease and trauma related illnesses such as osteoporosis, rheumatoid arthritis, and revision surgeries. The drug Denosumab has successfully reversed osteoporosis in many patients, but comes with significant side effects when patients taper off the medication. Patients will see their bone mass density drop suddenly below their original baseline before taking Denosumab which causes subsequent fractures and hospitalization. In what clinicians deem the rebound phenomenon. Unfortunately, Denosumab (a lifelong drug that is not covered by insurance after ten years) must be taken twice a year and costs $3000 per dose, forcing patients to choose between osteoporosis or $6000 in yearly payments. New science shows a possible explanation for such clinical presentation. While many believe osteoclasts were terminally differentiated cells, new science shows that osteoclasts can recycle themselves by fissioning and fusioning off multinucleated bodies. This recycling allows osteoclasts to fission off and enter a dormant phase and fusion into larger osteoclasts when signaled to do so. These dormant smaller osteoclasts are named osteomorph. When osteoclasts inhibitors mimicking the effects of Denosumab were given to mice, researchers were able to see osteoclasts fission into osteomorphs. However, when inhibitors were withdrawn, osteomorphs fused with each other and osteoclasts activity increased dramatically as seen through two photon microscopy and actin filament tracking software Imaris. Such phenotype is a close comparison to the rebound phenomenon seen in clinical settings and has become the targeted area of research. The A17 TACE enzyme is shown to interact with the receptor protein c-FMS and increase osteoclastogenesis in vivo. The goal is to now find if the A17, c-FMS mechanism is solely related to osteoclastogenesis. Further questions are if blocking A17, c-FMS can prevent osteomorph fusion during inhibitor withdrawals. Thus preventing the rebound phenomenon.

Abstract Name: Quantifying Water Uptake on Atmospheric Mineral Dusts in a DRIFTS Cell

Clouds influence the temperature of the Earth's surface by reflecting solar radiation. As such, accurate data regarding cloud formation is crucial for climate modeling. Particulate matter in the atmosphere can act as cloud condensation nuclei once enough monolayers of water have adhered to the solid particle. The number of monolayers is determined primarily by the relative humidity (RH) level above the particle's surface and the matter's chemical composition. Past explorations of this water uptake process used the diffusion reflectance infrared Fourier transform (DRIFTS) spectroscopy method. This research attempts to quantify monolayer uptake by mineral oxides and other types of particulate matter explored by past experiments to improve literature values. Ground solid samples (Fe_2O_3, TiO_2) were exposed to varying (20-84%) RH levels in a DRIFTS cell. Both absorbance and Kubelka-Munk spectra were taken of each RH and the area (less baseline) under the spectra was plotted relative to RH. The Brunauer-Emmett-Teller-III (BET) equation was used to determine the number of monolayers the sample could have picked up (at 100% RH). The TiO_2 sample was

found to have a maximum monolayer capacity of 2.5, which is less than that stated in the literature. Additionally, we found that absorbance data fits the BET model much more closely than data gathered using Kubelka-Munk analysis. This method and data analysis choice can be applied to other forms of particulate matter for further study.

Abstract Name: Engineering DNA Probes Delivered Through Brain-Specific Extracellular Vesicles for Targeted DNA Methylation at the FKBP5 Gene

Epigenetic changes such as DNA methylation impact gene expression and function. Previous efforts have used microRNAs that act post-transcriptionally and tend to be a lot more transient than changes in DNA methylation. We seek induce stable increase in DNA methylation at specific genomic loci at the FKBP5 gene using engineered DNA probes to normalize gene function.The FKBP5 gene acts as the primary regulator of glutocorticoid (stress-hormone) signaling with implications in several stress related diseases like depression, PTSD, and anxiety. Chronic exposure to stress leads to persistent DNA methylation loss and transcriptional upregulation at FKBP5 which impacts psychiatric disorders, stress response, and cortisol homeostasis. Our initial data is promising as we were able to use single stranded DNA probes treated with SSSI methyltransferase to increase methylation at intended targets not just in the FKBP5 gene but also in CDH1, IL6, and MAOA genes in two mammalian cell lines which facilitated robust expression changes. We are now developing the probe as well as engineering extracellular vesicles (EVs) that have a higher affinity for brain tissue and are safe relative to viral-vector methods to deliver it. The probe will be electroporated into EVs which will then be injected retro-orbitally into stress-hormone treated mice. Genomic DNA and mRNA will be extracted from brain tissue to test for methylation and gene expression changes from one group of mice followed by tests for stress-related behaviors in a second group. Mice injected with unmethylated probes will be used as negative controls. Based on the results observed in the in-vitro stage, we expect to see molecular changes in gene expression and methylation as well as behavioral changes in stress-response in treated mice. We hope to further test the probe in other non-human primates and work towards developing this as a therapeutic tool with several applications.

Abstract Name: Prenatal Cannabinoid Exposure Affects Memory through Alterations in Glutamatergic Receptor Expression

As the legalization of cannabis has increased, prenatal exposure to cannabis has also increased significantly and is expected to continue rising. Currently, no therapy is available for cognitive deficits associated with prenatal cannabinoid exposure (PCE). Glutamate, a major excitatory neurotransmitter in the brain, plays a significant role in memory formation in the hippocampus. The two major glutamate receptors in the hippocampus, N-Methyl D-Aspartate Receptors (NMDARs) and alpha-amino-3-hydroxy-5-methyl-4-isoxazole Propionic Acid Receptors (AMPARs) are required for learning and memory formation. This project hypothesizes that memory deficits observed in PCE rodents are due to the upregulation of specific subunits of AMPA and NMDA receptors. To test our hypothesis, pregnant Sprague Dawley rats were orally gavaged with 5 mg/kg of pure D9-tetrahydrocannabinol (THC) from gestational day five to post-natal day nine and examined between PND 40-50. To evaluate the learning capacity and memory deficits, behavioral experiments were performed such as an elevated plus maze (EPM), trace fear conditioning (TFC), and contextual fear conditioning (CFC). Immunoblotting of hippocampal lysates revealed that PCE significantly increased the expression of GluA2, a subunit of AMPARs, and GluN2A, a subunit of NMDA receptors. In summary, our studies demonstrate, at least in part, the molecular mechanisms of hippocampal-dependent memory deficits associated with PCE.

Abstract Name: Forecasting Fate: Analyzing Capital Punishment Trends in the US (1976-2016)

In this study, we meticulously organized and analyzed a comprehensive dataset encompassing capital punishments in the United States from 1976 to 2016. Data from the Department of Corrections in each state, as well as the NAACP Legal Defense Fund comprise the dataset. One challenge was figuring out how to extract the data for our analysis, since the majorityis categorical data rather than numerical. In addition, we measured statistics for more relevancy. Employing decision trees, we engineered a model to deduce different features of capital punishment. The model underwent severe calibration and validation phases to ascertain its predictive accuracy and reliability. Our findings unveil correlations between the data features, predict new entries, and discover hidden biases within. The predictive model crafted in this study demonstrates an exceptional ability to anticipate an offender's sex, race, and age. The insights on the criminal and the crime will show us what attributes and features lead to the death penalty most often. As a result, our model will present potential flaws in the United States Judicial process and expose needed changes.

Abstract Name: The Characterization of Neurotransmitters Following Acute Ethanol Exposure and Social Behavior Assay in Zebrafish with and Without Embryonic Ethanol Exposure

In the United States, 1 in 100 children will be born with birth defects associated with prenatal alcohol exposure; these birth defects are collectively labeled as fetal alcohol spectrum disorder (FASD). Impaired social behavior is often a devastating symptom of FASD that dramatically reduces the quality of life for patients with FASD. Thus, advancing our understanding of the mechanisms responsible for ethanol-induced social defects is paramount. Zebrafish have already begun playing a role in furthering our knowledge about potential mechanisms responsible for ethanol-induced social defects. Previous work in zebrafish has shown that embryonic ethanol exposure from 24 to 26 hours postfertilization (hpf) disrupts adult social behavior and that this social deficit is associated with, decreases in whole brain levels of dopamine and its metabolite 3,4-dihydroxyphenylacetic acid (DOPAC). While dopamine has been shown to have a role in ethanol-induced social defects other catecholamines such as norepinephrine and serotonin could also be critical given that these monoamines modulate numerous processes that can be involved in social responses such as motor control or stress. Since zebrafish brains can be easily dissected into anterior, middle, and posterior regions we propose to extend the previous results by using high-performance liquid chromatography (HPLC) with electrochemical detection to measure dopamine and other catecholamines in targeted brain regions instead of in the whole brain. We will expose zebrafish eggs to ethanol from 24 to 26 hpf and collect monoamine samples from the anterior and middle brain regions immediately after acute ethanol exposure and assay of social behavior in adult zebrafish. Our results will increase the resolution of the previous work and thus provide further mechanistic insights into one of the most devastating symptoms of FASD.

Abstract Name: Hypoxia, Platelet-Activating Factor, and Rho Kinase Inhibition in Fetal Ovine Pulmonary Vascular Smooth Muscle Cells - Insights into Signaling Pathways and Contractile Protein Expression

In fetal ovine pulmonary vascular smooth muscle cells (PVSMC), the synergy of hypoxia and Platelet-Activating Factor (PAF) induces heightened intracellular calcium flux, leading to increased pulmonary vascular tone in utero. While PAF receptor (PAFR) internalization is recognized as a method to inactivate PAF effects in PVSMC in vitro, hypoxia elevates PAFR expression. Interestingly, Rho kinase (ROCK) inhibitors decrease PAFR expression, suggesting an alternative pathway for downregulating PAFR-mediated responses. This study delves into the effects of PAF, hypoxia, and other modulators of pulmonary vascular reactivity in arterial (PA) and venous (PV) smooth muscle cells, aiming to elucidate the signaling pathways of PAFR-mediated fetal ovine pulmonary vascular reactivity. The hypothesis is that ROCK inhibitors attenuate PAFR expression in hypoxia, leading to increased expression of contractile proteins. In normoxia, PAFR density (Bmax) in PA and PV SMC was 487±37 and 624±17, respectively. This increased by 30-35% in hypoxia, higher in PV than PA in both normoxia and hypoxia. The KD for PAFR binding to PASMC was higher than for PVSMC, and hypoxia decreased the KD of PAFR binding in both cell types. ROCK inhibitors attenuated PAFR binding comparable to cycloheximide, but unlike the PAFR inhibitor CV3988, cycloheximide did not affect pre-synthesized proteins. ROCK inhibitors decreased PAFR expression but increased expression of MLCK2, Calponin, and Desmin in PASMC, especially in hypoxia, with varying effects in PVSMC. These findings highlight the intricate modulation of PAFR-mediated signaling in PVSMC by hypoxia and ROCK inhibitors, showcasing distinct effects on PA and PV cells. The increased expression of contractile proteins in hypoxia suggests their involvement in PAF-induced contractions in PVSMC. This study contributes to a deeper understanding of the complex regulatory mechanisms governing fetal ovine pulmonary vascular reactivity during the perinatal period.

Abstract Name: Titan Providence: Self-Navigation Drone Goes Where No GPS Can

The primary objective of this project is to develop an autonomous drone platform that emphasizes lateral modularity, evolving both hardware and software components. Instead of designing a specialized drone tailored for a single function, like package delivery or hazard detection, our aim is to construct a versatile AI-driven hardware platform capable of performing various tasks without significant code or hardware modifications. We intend to leverage open-source hardware and software resources, such as the Pixhawk 4 flight controller, Raspberry Pi, ArduPilot, and Dronekit, to realize this project. Currently, we have two teams dedicated to this project. The first team, known as the Hardware Engineering Team, is responsible for creating, evaluating, and maintaining the drone's hardware components. They are also focused on equipping the drone with a versatile sensor suite to ensure safety, spatial awareness, and overall robustness. The second team, the Computer Science/Engineering team, is tasked with designing, testing, and exploring autonomous functionalities like navigation, obstacle avoidance, and object recognition. Our ultimate vision is for this drone platform, with its adaptable software and robust physical capabilities, to support the seamless integration of different modules based on specific objectives. This plug-and-play approach will enable us to spend more time conducting research in real-world scenarios.

Abstract Name: Thermal Analysis of Lithium Ion Batteries using Computational Fluid Dynamics

Amidst the global transition towards renewable energy sources, lithium-ion batteries have emerged as the cornerstone of a sustainable future. Their high energy density and efficiency have made them indispensable components in diverse applications, ranging from electric vehicles to portable electronics. However, as renewable energy adoption intensifies, the need for effective Battery Thermal Management (BTM) becomes increasingly crucial.This research delves into a comprehensive thermal analysis of lithium-ion batteries, specifically focusing on effectively managing heat dissipation during battery operation. Utilizing Computational Fluid Dynamics (CFD), simulations were conducted to evaluate heat generation characteristics and volume-averaged temperatures of a lithium iron phosphate (LiFePO4) battery during 1C to 3C charging and discharging cycles. These simulations were then compared with experimental data obtained from a thermal camera.The simulations revealed that 3C discharging generated the highest heat, approximately 62 W, corroborating the hypothesis that shorter charge and discharge times lead to faster charging, increased current, and consequently, elevated heat generation. Notably, a discrepancy arose during 1C charging, where the solution failed to converge due to an oversized mesh that deviated from the actual

battery dimensions. The experimental results focused solely on measuring volume-averaged surface temperatures. Unfortunately, direct temperature comparisons with simulations were hindered by limitations of the cost-effective thermal camera setup.Future endeavors aim to elevate the quality of research by upgrading thermal camera experiments to facilitate equitable comparisons with CFD simulations. Additionally, exploring the application of phase change materials for passive cooling of lithium-ion batteries, refining and converging CFD simulations for higher accuracy, and furthering our knowledge of these critical energy storage components are key priorities. CFD improves BTM system design, reducing the reliance on physical prototypes. Enhanced correlation with experiments enhances safety validation and advances our understanding of lithium-ion battery thermal behavior.

Abstract Name: Determinants of Successful Inclusive Brand Expansions or Line Extensions

Brands today are recognizing the need to go beyond vanity tokenism to be truly inclusive and appeal to a rise in consumer consciousness and changing demographics in the USA. Brands incorporate inclusivity in all aspects of the marketing mix; from new product launches to accessible pricing and distribution, to more visibly supporting various environmental and social causes. Our focus was on the product element to determine patterns that emerge from successful inclusive brand expansions or line extensions. We chose six inclusive products by legacy brands to analyze: Lego Botanicals (for adults), Crayola Colors of the World, Ms. Monopoly, Bic for Her Pens, American Girl Doll Joss, and Bandaid Our Tone. As a starting point, we adapted some of the tools and methodology used in inclusive communications research to study inclusive products (which needs more existing literature). We conducted a case analysis on each product and then collected the relevant data (academic journals, press articles, and sentiment analysis through Amazon reviews). We then aggregated the findings from emerged patterns and developed a rubric for successful inclusive product launches. Some of our elements of success include distribution at major retailers, sales data, the product launch spawning more extensions or expansions, and imitative competitive launches. We analyzed common words and phrases by star rating using the VADER dictionary for consumer sentiment analysis, then coded Amazon reviews based on topic categories. Coding text reviews by categories such as questioning brand intent, user experience, and five others helped us better understand the rationale behind the numerical star rating. Our results suggest that the experience of interacting with the product dictates consumer sentiment more so than other topic categories. This research provides a framework for brands to represent marginalized groups authentically.

Abstract Name: Challenges and Opportunities in AI-driven financial inclusion for Arab Individuals from a

Gender perspective.

This study investigates the challenges and opportunities in AI-driven financial inclusion for Arab families, specifically examining gender dynamics. Situated within the broader context of understanding the intricate interplay between financial inclusion, economic growth, and poverty reduction, especially within regions characterized by limited access to traditional financial services, this research significantly augments our comprehension of the transformative potential of AI in addressing these socio-economic issues in the Arab world. Centering its inquiry on gender dynamics, the study keenly acknowledges and endeavors to unravel the impediments that women encounter in their quest to access financial services within the intricate fabric of Arab family structures. Through a meticulous examination of diverse AI applications within the financial sector, the research astutely accentuates the technology's capacity to augment risk detection mechanisms, alleviate information asymmetry, and furnish personalized customer support. An in-depth analysis of the prevailing state of financial inclusion in the Arab world brings to the forefront enduring challenges such as poverty and the limited adoption of electronic payment systems. Furthermore, the study delves into the nuanced gender dimensions of AI-driven financial services, delineating key determinants that influence women's participation, including income levels, age demographics, smartphone ownership, and digital literacy. These invaluable insights coalesce to advance the overarching objective of nurturing economic growth through an enriched landscape of financial inclusion in the Arab world, with a distinctive emphasis on addressing gender-specific challenges. The resultant recommendations proffered in this study are poised to serve as a roadmap for policymakers and stakeholders deeply committed to advancing both gender equality and economic development in the region.

Abstract Name: How can Personality Assessments be used to create effective and balanced groups for better learning environments in the classroom

This research explores the utilization of personality assessments, such as the Myers-Briggs Type Indicator (MBTI), to construct effective and balanced groups for enhanced learning environments in online classrooms. In this study I aim to address the importance of strategic group formation for fostering active learning and student engagement. In this research, I administered a survey which was sent to the students of 5 classes (2 online classes and 3 in- person classes). The survey had a link to the MBTI tool which was used to determine their personality types and several other questions such as group role preferences, and learning styles were also asked. Groups were then formed mainly based on MBTI profiles, with participants assigned specific roles according to literature-based guidelines. The groups engaged in various collaborative activities, such as weekly group work, discussion board assignments and a final group project for the online class. Group satisfaction and role fulfillment were then assessed through a class wrapper. The results for the summer term (online) indicate nuanced relationships between MBTI-based group composition and performance metrics. While MBTI-based groups exhibited higher satisfaction in organizer roles, they demonstrated lower performance and productivity scores in leader and communicator roles compared to non-MBTI groups. According to the results from the summer term, it suggests that while personality-based grouping enhances satisfaction in certain roles, challenges may arise in others, emphasizing the need for a balanced approach to group formation. That said, data analysis is currently in process for the fall term. This would give me a valuable insight on how the results vary for the in- person and online classroom setting. Overall, this research helps identify how MBTI personality can be used to split groups in a pedagogical setting.

Abstract Name: Influence of AMIGO2 on CAFs/MD231 Co-clusters and Extravasation of Cancer Cells

Breast cancer (BC) is the most commonly diagnosed cancer and the primary cause of cancer mortality in women because of the tumor's metastatic features. Cancer-associated fibroblasts (CAFs) promote the BC metastasis phenotypes by secreting cytokines and chemokines, and accommodating the tumor microenvironment (TME) with suitable growth conditions. These growth factors help CAF/BC cells to form co-clusters and bind to endothelial cells for extravasation. Our lab recently discovered through Single Cell RNA sequencing that CAFs induce the expression of Amphoterin-induced gene and open reading frame 2 (AMIGO2) in triple-negative breast cancer (TNBC) cell lines that may aid in extravasation of BC/CAFs co-clusters versus mono-clusters. AMIGO2 is an adhesion transmembrane protein that has been studied to promote the attachment of liver cancer cells to endothelial cells. This study aimed to observe AMIGO2 gene expression in BC cells as they bind to endothelial cells during metastasis. Through immunofluorescence staining and RT-PCR on MDA-MB-231 TNBC cells treated with AMIGO2 siRNA led to the discovery that AMIGO1 protein compensates when AMIGO2 expression decreases. Analysis of RT-PCR of MDA-MB-231 cells treated individually with AMIGO2 siRNA, AMIGO1 siRNA, and a combination of both confirmed that this compensatory effect was statistically significant (p<0.01). The percent of MDA-MB-231 cells treated with siRNA that were bound to endothelial cells during endothelial binding assay was significantly lower (p<0.01) compared to the samples not treated with AMIGO siRNA. Future directions will be to determine if the extravasation of CAF/MDA-MB-231 co-clusters and BC models is dependent on AMIGO proteins.

Abstract Name: The Effect of Differently Treated Farm Soil on the Diversity of Soil Microbiota

The existence of a healthy microbiome in soil is essential to the health and overall growth of farm plants. However, it is still unclear what effect different soil treatments have on the microbiome of the soil. Further research is needed to determine if different treatment types cause fundamental differences on the overall soil composition and microbiome. This study aims to explore the microbiome difference between four differently treated soil types; namely prairie, grazed pasture, tilled and non-tilled soil. It was hypothesized that there would be a significant difference between the prairie, and grazed soil vs tilled and non-tilled soil. Soil samples were collected, DNA was extracted, and then sent for sequencing. The sequencing data was later analyzed through NCBI's Nephele Cloud-Based Microbiome Analysis Program. Furthermore, an analysis to determine the pH, organic, and inorganic composition was done. Alpha and beta diversity were assessed to gain insight into the different species that inhabited the soil groups. The diversity results were then statistically compared alongside the soil composition to determine whether there is a significant correlation between the microbiome and composition of farm soil. A multitude of samples of each soil category were

collected to minimize the effect of confounding variables on the results from both the sequencing and the soil composition tests. Moreover, differing treatment groups were processed to analyze the individual and group differences of our samples. The results indicated a higher alpha diversity in the prairie soil group compared to the rest, while both the till and no till groups had similar beta diversity. This study showed that treatment styles do affect soil diversity. Further research into this topic could give us more insight into how to utilize soil treatment to improve farm cultivation.

Abstract Name: A Colorimetric Assay for the Quantification of Uranium in Drinking Water

Uranium (U) is a naturally occurring radioactive metal found in small amounts in soil, rocks, and water. In the context of water quality, elevated levels of uranium can pose health concerns when present in drinking water. Chronic exposure to uranium may have adverse effects on the kidneys and other organs. Monitoring uranium levels in water sources is essential to ensure compliance with safety standards and to protect public health. This study presents a newly developed colorimetric method for the determination of uranium concentrations in drinking water. By synthesizing and employing a novel ligand that generates a measurable color change proportional to uranium concentration, we quantified uranium levels through spectrophotometric analysis. The experiment involves sample collection, preparation, and analysis, with a focus on optimizing detection limits. Calibration curves are generated using standard uranium solutions to establish a quantitative relationship between absorbance and uranium concentration. The colorimetric approach offers a user-friendly and cost-effective alternative for routine monitoring, providing valuable insights into uranium exposure in drinking water sources. This research introduces a practical tool for uranium monitoring in drinking water and contributes to the broader field of water quality analysis methodologies.

Abstract Name: Examining diversity and representations of the human body in A&P textbooks

Images are essential for anatomy and physiology textbooks because they help students better understand the structure and functions of the human body. By including diverse and representational images in STEM

textbooks, we not only broaden knowledge and create awareness of many viewpoints and experiences but also foster a more inclusive environment within STEM education. In this study, we conducted a content analysis on images from three recent editions of anatomy and physiology (A&P) textbooks, including Martini 12th ed, Patton 11th ed, and Saladin 10th ed. Our objective was to assess the progress in diversity representation compared to earlier editions. We used a blinded multi-coder approach to analyze the frequency of racial identity, sex, body size, and disability in each textbook. Our analysis revealed that all three new editions have increased the number of non-white images, particularly in Black representation. Additionally, we observed an increase in images depicting disability. Representation of male bodies and average-sized bodies was significantly more frequent than in past editions. The findings of this research emphasize the importance of making A&P textbooks more diverse. This data will be used to inform changes to future A&P textbooks to increase representation across all identities.

Abstract Name: The Impact of Setting on Student Peer Evaluations in Social Work Practice with Groups

The purpose of this project is to assess the impact of setting in a social work with groups class. The settings being compared are 1) a class in the pre-Covid19 era versus a class in the post-Covid19 timeframe; and 2) a class held on the main campus class at a university versus a class held as a part of a social work degree completion program.The relevance to our research is the significantly different approach some students had to take during the pandemic. Students that could not role play group simulations had less practice before entering the field. Therefore, there is a whole group of social workers who did not get the same hands-on curriculum that provides important skills for the field. We plan to look at the effect of setting from cohort to main campus on the student-peer evaluation process.In a Group Skills class the students are required to simulate a group where the students act as facilitators. Students are required to evaluate one another on how well each person facilitated their group. While their peers are facilitating, the rest of the students are completing the evaluation forms.For this research project specifically, we are comparing the scores pre-covid students gave to each other versus post-covid students. We are also comparing the scores cohort students gave to one another versus the scores main campus students gave to each other.Students in the cohort complete their general education requirements at a community college. The cohort takes their remaining social work classes as a group over a two and a half year program.We believe the pre-covid students likely evaluated their peers harder than the post-covid students did. We have mixed opinions on how we believe the main campus students and the cohort students evaluated one another.

Abstract Name: The Influence of Art Music on Modern Composer Alan Menken

Alan Menken is a living film composer whose music is recognized by people of all ages throughout the world. In his writing for films and musicals, he takes into account many important factors, especially the accuracy of the music for the time period and location of the story being told. One noticeable example of this is in his music for the animated film Beauty and the Beast, where Classical and Romantic era influence can clearly be heard in the title song. Influence from pieces such as Frederic Chopin's Ballades pour Piano can be heard in the unique modulation technique that brings the music into a new key for the final verse by repurposing the tonic chord as the leading tone chord in another key. Influence from Romantic composer Johannes Brahms can be seen through the use of consistent motives, such as a subtle half-step interval being the base of his Clavierstücke. Menken uses this technique in the bridge that leads into the final verse of the song "Beauty and the Beast." These are examples of how he used music of the past to influence his composing and thus create extremely effective storytelling in his music that will be listened to for years to come.

Abstract Name: Trauma- Informed Care and Restorative Practices with Discipline- Involved Students

The school systems throughout the United States have relied on zero-tolerance discipline policies and punitive reactions toward maladaptive student behaviors. However, trauma-informed and restorative justice practices are starting to become normalized in place of current zero-tolerance programs. The purpose of this study is to explain why the implementation of trauma-informed care and restorative justice practices will benefit students. The researcher pays special attention to practices considering past traumas, including situational, systemic, and generational, that may impact a student's behaviors. The researcher reviewed the literature examining restorative justice practices, trauma-informed care, and Adverse Childhood Experiences. With the findings from this review, a trauma-informed afterschool support group curriculum will be created for middle school students, to teach them about the manifestations of their maladaptive behaviors and how these can be traced back to their identities, past experiences, and trauma. The implementation of programs such as these is imperative because harsh punishments in schools currently are the root of many deeper issues including the school-to-prison pipeline and can affect students throughout adulthood. Although trauma-informed care is a step in the right direction, it still does not fix the corrupt roots of the education system which is why an abolition framework is needed. The researcher hopes that by educating students and school personnel about trauma-informed and restorative practices, the likelihood of future issues as a result of maladaptive behaviors in early school years will be mitigated.

Abstract Name: Monitoring Frog Virus 3 Homology and Virulence Across the United States

Ranaviruses are large double-stranded DNA viruses (family Iridoviridae) that parasitize three taxonomic classes of poikilothermic vertebrates. They are significant wildlife pathogens, posing a substantial threat to amphibian biodiversity. Some previous phylogenetic analyses have focused on highly conserved regions which can lead to non-informative topologies at a regional scale, ultimately leading to an unclear evolutionary history and geographic distribution. Here, we report a phylogenetic analysis of the FV3-like subgroup of Ranavirus obtained from poikilothermic vertebrates throughout North America based on four genes suitable for phylogeographic construction. Phylogenetic analysis was conducted using the Markov Chain Monte Carlo simulation implemented by Bayesian evolutionary method by sampling trees. Individual analysis of the four primary gene sequences results in similar topologies suggesting well-supported relationships amongst and between members of the subgroup. Preliminary data also indicate the existence of at least two major distinct FV3 lineages circulating throughout North America. Analysis of representatives from each proposed lineage suggests the possibility of recombination events and reveals differences in coding sequences that may have implications for virulence, species designation, and phylogeographic history.

Abstract Name: Metabolomic Profiling of Texas Grapevines via Liquid Chromatography-Mass Spectrometry: An Untargeted Approach

Vitis vinifera, known as the wine grape, plays a crucial role in the global agricultural sector. The United States ranks fourth in wine production worldwide, with 87% of Vitis vinifera grapes being utilized for wine-making. According to WineAmerica, the Texas wine industry made a significant economic contribution of $13.1B to the state of Texas in 2017. Leading wine-producing nations have conducted extensive analyses of metabolites and biomarkers, aiming to reveal unique signatures associated with their respective growing regions. In contrast to other areas, Central Texas faces challenging environmental conditions, including heatwaves and drought, throughout the growing season. Despite these challenges, the wine produced in this area is recognized for its exceptional quality, experiencing a significant surge in production over the past decade. Consequently, it is crucial to investigate and pinpoint potential grapevine biomarkers specific to Central Texas.The composition and quality of wine in Texas are significantly impacted by the state's environmental conditions. There is no current research that explores the connections between physiology and metabolism in Texas grapevines throughout the growing season. This project seeks to address this gap by documenting the metabolome of seventeen grapevine varieties cultivated in five vineyards across Central Texas using liquid-chromatography mass-spectrometry based untargeted analysis. About 400+ samples,

including leaf and grape tissue, were harvested during the growing season in June, July, and August. The samples were homogenized and the metabolites were extracted using two-phase liquid-liquid extraction. An Orbitrap LC-MS/MS System was utilized for analysis and data acquisition. A comprehensive library of putative compounds was obtained based on their molecular weight and retention time given by the mass spectrometer, in addition to their characteristic ion fragmentation. The metabolomic data was analyzed using Compound Discoverer and MetaboAnalyst. These results provide insight about the correlations between grapevine varieties and metabolites, and similarities within vineyards.

Abstract Name: Staying Relevant: The Response to the Shifting Tastes and Quality of Brooks Brothers

Brooks Brothers is the oldest apparel brand in the United States, and several internal and external factors led to its bankruptcy in 2020. Being in operation for over 200 years, the brand was influential in defining and innovating American style through its luxury offerings of business and traditional wear. However, the bankruptcy signaled its failure to adapt to evolving consumer and retail trends. The brand is now working to make a comeback.The case study analyzes four key areas relating to Brooks Brothers' issues since the 1980s: its history, the changing fashion landscape, customer experiences, and potential missteps in internal strategy. Qualitative data is collected from online fashion forums to understand customer sentiment on the brand's offerings, its perceived decline, and potential solutions. It also incorporates interviews with current Brooks Brothers management for an insider perspective. The case study tries to assess these insights alongside scholarly context on fashion, marketing, and branding.Preliminary findings show the primary issues identified by customers are quality deficiencies in their apparel, fashion irrelevance from both contemporaries and traditionalists, higher prices unmatched to value, and overexpansion. However, hope remains for a turnaround by refocusing on quality, scaling back operations, reconnecting with its Americana heritage roots, and also appealing to Gen Z customers. The conclusions discusses recommendations to Brooks Brothers management on reviving the brand.The case study will help better understand how iconic brands can lose their relevance without careful stewardship and offer some observations and insights on reviving it. It will be informative for fashion brand leaders who are trying to deal with shifting consumer segments, balancing heritage with innovation, and revitalizing declining yet prestigious brands.

Abstract Name: Identifying Species of Unknown Bacteria With Antimicrobial Properties Using 16s rRNA Sequencing

The world currently faces not only a shortage of effective antibiotics to treat human pathogens, but also a rise in bacterial resistance to existing antibiotics. Most current antibiotics in use have come from antibiotic-producing bacteria in our soil. This research project aimed to identify unknown bacteria with antimicrobial properties from local compost samples, with an ultimate goal of finding novel antibiotics to help combat bacterial infections. Unknown bacteria samples were collected, cultured, and screened for antibiotic activity. Bacterial DNA was then isolated using a IBI MINI gBAC Genomic DNA Kit and amplified using a polymerase chain reaction (PCR) at the 16s rRNA gene. A DNA clean up kit was used to remove any contamination and Qubit was used to ensure concentration of DNA met sequencing guidelines before DNA samples were sequenced. Resulting sample sequences were compared to DNA sequences of known bacteria, using online databases to generate possible matches. Results suggested bacteria were most likely Bacillus

safensis. Our next steps include determining which antibiotic these bacteria are producing and searching for additional bacteria with antimicrobial properties in our compost samples.

Abstract Name: Harmonizing Horizons: Cultivating Inclusive Pedagogies for Tomorrow's Minds through the Prism of Diversity in Education

This oral presentation explores the synergistic relationship between diversity in education, culturally responsive teaching (CRT), and the multifaceted outcomes for students. Employing qualitative research and data-driven methodologies, our study elucidates the positive impact of embracing diversity in curriculum and literature. Our findings not only underscore the academic advantages linked to culturally responsive teaching but extend into the realms of professional and personal growth. Through analysis, we showcase compelling data highlighting the enhanced performance of students who have experienced culturally responsive teaching, revealing marked improvements in academic achievement. Moreover, we delve into the broader spectrum of outcomes, shedding light on the professional trajectories of these students, demonstrating increased readiness for diverse workplaces and career success. Beyond the professional domain, our research examines the personal development of students, emphasizing the acquisition of crucial life skills such as empathy, cultural competence, and effective communication. By weaving together these strands, our presentation positions diversity and culturally responsive teaching as pivotal components for fostering a holistic and inclusive educational experience. Our presentation is a nuanced narrative supported by data and research, emphasizing the imperative role of diversity and culturally responsive teaching in shaping a well-rounded, successful, and empowered student body, as they contribute to our society.

Abstract Name: Exploring Differences in Health Behaviors Between Black and White Patients with MS in the Deep South

Introduction: Multiple Sclerosis (MS) was always believed to be a disease that primarily impacted White females. Recently, there has been an increase in diagnoses in Black adults with MS. These patients often have

high comorbidities including type 2 diabetes and hypertension. Although the reason for these disparities is not yet understood, we hypothesize that they may be due, in part, to higher levels of behavioral risk factors including poor diet quality and low levels of physical activity. The purposes of the study are: 1. to explore differences in health behaviors between Black and White patients with MS in the Deep South, and 2. to determine if these behavioral differences impact health outcome disparities between Black and White patients.Methods: We will invite 300 patients from the UAB MS clinics to participate. Participants will complete a phone interview that will include questionnaires on dietary intake, physical activity, smoking, and sleep. Questionnaire responses will be matched with the participants' medical records to determine health outcomes. Differences in health outcomes will be explored based on self-reported behavior, race, and biological sex. We will then conduct multivariate regression to determine if health behaviors significantly impact the differences in health outcomes between black and white participants.Discussion: As of December 2023, twenty-seven participants have been recruited to the study. By April 2024, we anticipate having one hundred or greater participant responses. If our hypotheses are supported, this would add to our understanding of the differences seen in disease presentation and progression in black adults. These results could indicate that different racial groups could benefit from tailored lifestyle interventions to increase adherence to health behaviors.

Abstract Name: Improving Exoplanet Detection by Predicting Stellar Variability in Low-Mass M Dwarfs

Identifying small, potentially habitable exoplanets orbiting low-mass M dwarfs is a critical step in pursuing the exploration of life beyond our solar system. We employ the Radial Velocity (RV) technique to search for exoplanets. Despite the precision of our spectrographs, the presence of stellar surface variability introduces noise that obscures the expected planet signals. It is imperative for us to address this obstacle in our data analysis.The Transiting Exoplanet Survey Satellite (TESS) provides a valuable asset of high-precision photometry, capturing brightness measurements and providing us with an abundance of photometric data for our target stars. Previous studies illustrated the efficacy of photometry for predicting activity-induced RV noise in Sunlike stars, enabling enhanced data modeling and extraction of small planetary signals. However, it remains uncertain whether this method extends to low-mass M dwarfs, which is the focus of our investigation.Our study harnesses the RV measurements obtained from the Habitable-zone Planet Finder (HPF) instrument alongside TESS photometry data for a curated sample of M dwarfs. By examining the correlation between TESS photometry and RV noise, we validate whether TESS data can reliably predict noise levels in HPF observationsThrough our research, we pave the way for enhanced data analysis methods that utilize TESS satellite's photometry to mitigate stellar variability-induced noise, thus improving the detection of small exoplanets orbiting low-mass M dwarfs. Our findings make significant strides toward a more comprehensive understanding of exoplanets and their potential habitability.

Abstract Name: Examining Differential Effects of Sugar Diets on Hepatic Gene Expression in Female Mice

Obesity is a significant risk factor in the development of nonalcoholic fatty liver disease (NAFLD). The increased liver adiposity is often linked to high sugar consumption. This study examined the correlation between the consumption of various sugars and the development of NAFLD. Female C57Bl/6 mice were given ad libitum access to 30% sucrose (SUC), glucose (GLC), or fructose (FRT) solutions in place of water (CTR) for 27 weeks. At the termination of the study, liver triglyceride levels were significantly elevated in all groups in comparison to (CTR) groups. Oil Red O staining confirmed these results, showing observable lipid droplet accumulation in the livers of all experimental groups. This lipid accumulation was most pronounced in SUC and GLC groups while the FRT mice had a more limited increase. Two-step RT-qPCR on liver tissue indicated changes in the regulation of genes in glycolysis, fructolysis, and fatty acid synthesis pathways. Genes involved in fatty acid synthesis were upregulated in all three sugar groups. GLC mice showed upregulation in both glycolysis and fructolysis. FRT mice showed upregulation in fructolysis. While the SUC mice did not show upregulation in either glycolysis or fructolysis, there was an upregulation in GAPDH, an enzyme that is utilized after glycolysis and fructolysis converge, which may indicate a possible utilization of both pathways for the dimer SUC. The results highlight glucose as the main contributor to upregulation in metabolic pathways, with a synergistic effect in sucrose on mouse physiology and gene expression.

Abstract Name: The Biotoxin BMAA Promotes Mesenchymal-Like Phenotype and Chemotherapy Resistance In Neuroblastoma Cells

Neruoblastoma is the most frequently occurring extracranial childhood tumor. This cancer is difficult to treat due to its high metastasis rate and 40-50% of children that enter remission after initial diagnosis will suffer relapse within their lifetime. Mesenchymal-like cancer cells are an indicator of malignant tumors as they exhibit several tumorigenic properties including downregulation of differentiation markers, and increased colony-forming potential, motility, and chemoresistance. Evidence suggests that environmental factors may play a role in cancer cell mesenchymal transition and relapse. We have previously demonstrated that the cyanobacterial biotoxin beta-methylamino-L-alanine (BMAA), often found in algae blooms, is capable of influencing neural cell differentiation state through mechanisms involving the Wnt signaling pathway suggesting the possibility that BMAA may play a role in influencing other differentiation processes involving Wnt including mesenchymal transition in neuroblastoma. In this study we present evidence that BMAA promotes mesenchymal transition in a human neuroblastoma cell line and provide support for the hypothesis that the biotoxin can promote this process in these cells resulting in changes in gene expression and cellular function in manners consistent with cellular mesenchymal transition. We also present evidence that effects

induced by BMAA can be mitigated using small molecule inhibitors of Wnt/Myc signaling. Overall, our results support a mechanism by which BMAA promotes mesenchymal transition in neuroblastoma and may drive relapse. Importantly we also provide evidence of the efficacy of Wnt pathway inhibitors in reverting this process, potentially leading to more favorable clinical outcomes in neuroblastoma patients.

Abstract Name: Applying the StarCraft Multi-Agent Challenge to Adversarial Training of Neural Networks

In Multi-Agent Reinforcement Learning (MARL) the use of training environments such as the StarCraft Multi Agent Challenge (SMAC) have shown great promise in training effective proximal policy networks to approach the optimal policy. This training environment offers some limitations, however, in the very restricted training space of predefined scenarios and opposing agent behavior. We propose modifying SMAC to allow multiple teams, called M-SMAC our new environment allows for a more dynamic training space. This new environment expands the previous training space be more dynamic, by replacing predefined opponent behavior with actively learning opposing agents. Such a training environment allows for simultaneous adversarial training of proximal policy networks, as well as a near infinite training space through the use of modular model deployment. Preliminary results and other research suggest that our proposed modified environment M-SMAC does show promise for the use of both adversarial training of proximal policies, as well as use in generating a population of policies to be trained similar to a genetic model.

Abstract Name: Using Technician Statistics For Productive Animal Care

Animal care technicians for research labs have many responsibilities in order to maintain the integrity of a research project. However, it is difficult to determine what tasks will require most of a technician's time and effort. Thus, it is proposed that tracking what each individual does during a given shift can allow supervisors and technicians to create an efficient schedule of how they will work and provide a standard for individuals to meet every day. This project consists of tracking in detail what an animal care technician does in a given "shift", including observation hours, handling and restraining, working in different biosafety levels, cleaning and prepping caging, and changing the caging. This data collection, over several months of work, finds relationships between tasks, the frequencies of being completed, and the time they take. The key tasks of an animal care technician are observing, providing nourishment, maintaining clean environments for both the researchers and the subjects, and maintaining supplies and accurate records. Additionally, many hours are dedicated solely to observing the animals to ensure their health and safety. Moreover, cleaning and prepping of caging or supplies are completed more than half of the time during a given shift. Finally, working with a given species may require more time to complete a task (such as cage changing or cage preparation) compared to another species despite the task being the same. If each technician were to track their tasks and create a profile of personal statistics, they would be able to easily determine how long a task should take. Moreover, a supervisor would be able to determine if a technician is working more efficiently or even falling behind during daily tasks. Overall, these findings could be used to incorporate better time management and help maintain a safe environment for the subjects.

Abstract Name: Neuroanatomical Differences in Developmental versus Acquired Reading Impairment

Reading is an important part of communication that allows us to share ideas with one another daily. Structures like the supramarginal gyrus (SMG) and the middle temporal gyrus (MTG), support phonological decoding and word recognition, respectively. Impairment of the primary left hemisphere reading network, either reduced activation in developmental dyslexia (DD) or structural damage in pure alexia (PA), often causes reading mechanisms to rely more heavily on the right hemisphere (Murphy et al., 2013). Little research has been done to examine the structural characteristics of the right hemisphere in people with DD versus PA. Although not much is known anatomically about PA, research on the anatomical differences in children with DD has shown reduced gray matter volume in brain regions like the left SMG and MTG, correlating with the reading disability (Raschley et al., 2010). The current study aims to examine anatomical differences in the right SMG and MTG between different reader groups. Data are from an ongoing study of adults with DD and PA. Data was extracted using FreeSurfer which allows for anatomical analysis based on brain structure volume and thickness (McCarthy et al., 2015). Participants (mean age =51.2) were divided

into three groups: typical readers (n=14), DD (n=18), and PA (n=7). A one-way ANOVA for each region of interest was conducted using SPSS. It was hypothesized that individuals with DD and PA would show greater gray matter volume in the right SMG and MTG compared to typical readers. There was a statistically significant difference, F (2) =5.115, p<0.01, for the cortical thickness of the right SMG. Tukey's HSD found DD to have a significantly lower SMG cortical thickness compared to controls and PA. Our results suggest that DD and PA may have different neuroanatomical adaptions related to reading disability.

Abstract Name: Gender Differences in Central Pain Mechanisms and Sociocultural Factors Between Older Adults from the U.S.- Mexican Border Region

Chronic pain is a complex facet of the human experience, that extends beyond its physiological manifestations and remains prevalent among the elderly. Research indicates that men and women perceive and process pain differently, women often showing greater sensitivity to pain. Evidence has also considered the influence of sociocultural factors on pain perception. However, research is lacking examining differences in central pain mechanisms and sociocultural factors between genders in older adults from the border region.Preliminary analysis included 24 participants (58.3% females), 15 Hispanic, 9 Non-Hispanic Whites (Mean age = 68.12 years, SD=6.469). Validated questionnaires provided at the beginning of the sessions assessed demographic, and sociocultural factors among participants. Participants underwent quantitative sensory testing that included thermal pain threshold and tolerance, Temporal Summation (TS), and Conditioned Pain Modulation (CPM). T-tests were performed to assess differences in pain sensitivity, central pain mechanisms, and sociocultural factors between genders. Independent t-tests revealed there was not a significant difference in the level of inhibitory process [t(21)=0.09; p=0.92] between males and females. However, there was a significant difference in pain tolerance [t(14.64)=-2.47, p=.026] where males (Mean pain rating=82.69, SD=9.95) had a significantly lower pain tolerance than females (Mean pain rating =52.82, SD=37.03). Additionally, there was a significant difference in pain catastrophizing [t(15.76)=2.862, p=0.011] where females (Mean=13.46, SD=12.11) had significantly higher levels of pain catastrophizing than males (Mean=4.7, SD=3.59). Preliminary results have demonstrated that gender does not play a significant role in central pain mechanisms; however, males have a lower pain tolerance than females. Additionally, females have higher levels of pain catastrophizing.While a larger sample size is needed to draw stronger conclusions, considering gender could better assist clinicians in a patient-centered approach to pain management in the border region.

Abstract Name: Comparative Analysis of the Power Outputs of Microbial Fuel Cells under Various Cathode Treatments

In 2022, Fossil fuels produced 60% of the electricity used in the USA. A total of 422 billion metric tons of carbon dioxide has been emitted by the US since 1800 because of fossil fuel burning, hastening global warming, and climate change. With increasing demand for energy and the alarming environmental concerns of burning fossil fuels, a clean alternative energy source is critical. Microbial fuel cells (MFCs) are a clean renewable source of energy that harnesses electrons released by certain species of soil bacteria (e.g. Shewanelle and Geobacter) that are electrogenic in nature. In this project, the mud was collected from the Lake across the Loop Road West and poured into each of the fuel cells. The anode was put at the bottom of the fuel cell under anaerobic condition while the cathode was put on the surface under aerobic condition. While same anode treatment i.e. glucose plus potassium acetate was given to all microbial fuel cells, three different cathode treatments i.e. Ammonium persulfate (APS), Potassium periodate (KIO4) and Potassium permanganate KMnO4 were given in triplicates. Bioelectricity generation was monitored posttreatment of anode treatment, cathode treatment, and controls with no treatment were set up. The experiment was conducted for a total of 30 days yielding a total power output of 343W/m^3. A cumulative power output of 1102W/m^3 was produced in two semesters. Further tests need to be conducted to optimize the cathode and anode treatments.

Abstract Name: Investigating the Effects of GABA Agonist Drug Exposure on Sensitive Period Timing and Language Development in Infants

In the first year of life, infants undergo perceptual tuning during experience-expectant mechanisms known as sensitive periods. The onset of sensitive periods involves a coordinated symphony of biological mechanisms that operate jointly to establish a balanced excitatory-inhibitory (E-I) neural circuitry, with maturation of gamma-amino butyric acid (GABA) circuits assuming a pivotal role. Recent literature using animal models suggests that GABA agonist drugs accelerate sensitive period timing. While it is well-known that the developmental milestones achieved during these periods have cascading effects on subsequent behavioral and cognitive abilities, there is a paucity of research regarding the possible modulatory effects of precocious GABA agonist inhibition on sensitive period timing and language development in humans. The present study compares infants who underwent general anesthesia (GA) prior to 2 months with a control group unexposed to GA, examining the effects of precocious maturation on auditory sensitive period timing and language outcomes. To do so, we propose a novel method for assessing early brain maturation, utilizing resting-state and task-evoked electroencephalographic (EEG) data collected at 2-, 4-, and 10-months to derive a spontaneous/evoked (S-E) ratio that is representative of the E-I circuitry. Preliminary results indicate that the S-E ratio at 4 months is predictive of language skills at 10 months, with no across-group differences. This 4-month ratio occurs during the window of transition during the sensitive period for perceptual narrowing. Thus, while GA exposure has no significant effect on auditory sensitive period timing, the S-E ratio offers a promising avenue for mapping the trajectory of sensitive periods in developing populations.

Abstract Name: Advancing the Precise Mapping of Dendritic mRNA Localization Patterns through Neuron Linearization

mRNA localization is a process by which messenger RNA (mRNA) molecules are selectively transported and localized within a cell to allow specific protein synthesis and function. In neurons, its polarized structure utilizes RNA localization to modify synaptic features, therefore affecting synaptic plasticity, the cellular basis of learning and memory. However, wrongful localization can cause cognitive impairments. Prior studies aimed to investigate dendritic mRNA localization patterns in mouse neurons using standard neuron growth culture. Nevertheless, the visualization of mRNA localization using this method lacked the precision required for a detailed examination of dendritically-based RNA. To address this limitation and gain more insights, we sought to investigate the impact of patterned growth neurons on mRNA localization patterns. By employing hybridization chain reaction fluorescence in situ hybridization (HCR FISH), we were able to detect and visualize Shank1, a dendrite-based gene involved in the organization and function of synaptic stability, within photolithographically linearized mouse neurons. We observed that by cultivating neurons in a linear orientation, we successfully attained high-resolution capture of Shank1 localization within the dendrites of linear neurons. This study demonstrates that culturing neurons in linearized patterned coverslips allows unprecedented capture resolution for subcellular sequencing experiments and effectively details spatial measurements utilizing single molecule RNA FISH (smFISH) technologies. Based on this information, automated quantification software will be used to compare mRNA abundance between linearized and control neurons to further investigate any differences introduced by patterned culture conditions.

Abstract Name: Navigating Selfhood Through Chess: A Lacanian Analysis of The Queen’s Gambit

In the game of chess calculated moves and strategic precision define success. In The Queen's Gambit by Walter Tevis, the game helps unravel the impact of childhood trauma on talented, yet emotionally wounded, protagonist Beth Harmon. Published in 1983 and set in the 1960s, The Queen's Gambit follows the life of Beth, an orphaned child prodigy who, after discovering her chess skills in the basement of her orphanage, Methuen, goes on to conquer the male-dominated world of competitive chess.Before both of her parents passed away, Beth endured a neglectful upbringing, which continues as she navigates the challenges of abuse and adolescence within the confines of Methuen. Even after Beth is adopted, and later rises through the competitive world of chess, she struggles to cope with the lingering traumas of her past, often resorting to substance abuse as a crutch. Chess becomes Beth's source of control, providing a pathway for healing from the wounds of her childhood. In Lacanian theory, most individuals are anchored by linguistic systems in their attempt to control the chaos of the unconscious. In her childhood, however, Beth does not successfully navigate Lacan’s developmental trajectory—the Real, the Imaginary, and the Symbolic. This necessitates her unconventional use of chess as an anchor, revealing alternate pathways to stability and selfhood as she heals from childhood trauma.

Abstract Name: Holography: A Tool for Preserving Heritage in Colombia

Colombia, a distinguished member of the world's 17 megadiverse nations, stands as a repository of unparalleled biodiversity and cultural wealth. Despite this, inadequate outreach strategies have hindered the preservation of its historical and biological treasures. Ongoing archaeological discoveries continually augment our understanding of pre-Columbian art pieces, revealing the rich history left by indigenous cultures like the Muisca, Tayrona, and Sinú. Sites such as San Agustín, Tierradentro, and Ciudad Perdida offer glimpses into sculptures, pottery, and other artifacts. Additionally, researchers actively study Colombia's fauna to understand their ecological roles and behaviors, contributing to various fields. Unfortunetly, much of this knowledge is concentrated in Bogotá's museums, neglecting cultural information in other regions. This raises a critical question: How can tools be developed to facilitate cultural outreach while enhancing preservation?Holography, an interferometric technique enabling realistic three-dimensional imaging without affecting originals, emerges as a promising solution. The holography research group at Universidad EAFIT focuses on optical holographic techniques to capture the essence of Colombia’s cultural objects, such as pre-Columbian gold pieces, botanical fossils and arthropods. These holographic records aim to improve public engagement and cultural appropriation.The research methodology centers on holographic techniques, particularly reflection and transmission photosensitive recordings. Years of development within this domain are comprehensively analyzed, with student-led investigations contributing new findings. This approach considers inherent challenges posed by different subjects, ensuring a nuanced understanding of the holographic process.A notable accomplishment is the creation of holograms of sculptures, culminating in a dedicated art exposition. This project serves as an exemplary integration of holographic techniques into cultural preservation efforts, showcasing the impact on both scientific research and public engagement. It emphasizes the significance of combining technological prowess with cultural and biological preservation, fostering societal appreciation for Colombia's rich heritage.

Abstract Name: Does Providing Short Context Information Meet Communication Needs Among Neuro ICU Nurses?

Nurses want to remain up to date, although this has become increasingly difficult for many reasons. In 2022, over > 6,000 medical journals were publishing new content that is relevant yet may be long or repetitive. This can include information on new medications, new indications, new assessment tools, and new procedures that are discovered every week. Governing bodies may generate new laws, rules, and education requirements. Hospitals are also constantly changing policies and procedures and requiring nurses to complete online education modules. The problem is that nurses have limited time to spend resolving this information overload. This study seeks to explore the acceptability and efficacy of implementing a new

information dissemination method. The study team developed a communication tool “The NKD ICU” which is shared as an email (not an email attachment) sent out every week. The NKD ICU uses limited text. It relies on hyperlinks to allow nurses to see all the information immediately and then select a hyperlink for content that they want to examine more deeply. The outcome will align with implementation research outcomes and use the Intervention Appropriateness Measure (IAM) and Feasibility of Intervention Measure (FIM). The NKD ICU was first distributed in August 2023 and is being continually refined through the reader's feedback. The number of nurses responding is increasing and helping to keep nurses actively engaged in wanting to learn and be involved in research. Currently at NKD ICU #12, with about 83 recipients, and 58% opening the email on average. The NKD ICU has the potential to supplement nursing huddles and promote active change within the neuro unit through increased awareness. Based on AIM and FIM scores collected after the data collection phase, the project will roll out to additional areas of the hospital or undergo further refinement for future use.

Abstract Name: Impostorism and Family Achievement Guilt in College Students

Previous research shows how psychological barriers such as impostorism increase the likelihood of First-Generation College students (FGCs) leaving college before finishing their degree (Jury et al., 2017). Since studies have also seen a proneness of this phenomenon in students who feel a sense of guilt towards their role as a student (Stone-Sabali et al., 2023), the goal of this study was to examine relationships between impostorism and family achievement guilt and how these relate to a student’s sense of belonging and well-being. It was hypothesized that feelings of impostorism and family achievement guilt would be stronger in FGCs than in Continuing-Generation College Students (CGCs). The study sample consisted of 47 college students, with 20 (42.6%) FGCs and 27 (57.4%) CGCs. Participants completed online questionnaires to assess Family Achievement Guilt, Impostorism, Sense of Belonging, and Well-Being. Independent t-tests show FGCs experience more guilt (t (47) = 2.060, p=0.045), especially about having more privileges than other family members, than CGCs (t (47) = 3.965, p=<.001). Correlations showed that impostorism was positively related to guilt and negatively related to belonging and well-being. Also, guilt, particularly due to leaving family and experiencing pressures, negatively relates to well-being. These findings provide further evidence to institutions that FGCs experience various psychological struggles in higher education and that protective factors must be implemented to increase college retention and graduation rates in this population.

Abstract Name: A connection beyond mountains: Tourism as a bond between the Antioquia and Yamanashi regions.

Despite being approximately 14,000 kilometers apart, the Japanese prefecture of Yamanashi and the Colombian department of Antioquia can behold astonishing similarities. Two communities separated by a great geographical and cultural distance, with barriers such as language, customs, prejudice and misinformation, prevent the two regions, with great potential for collaboration, to interact with each other. So then, what makes these far-flung communities suitable for a beneficial, bilateral link? From the geography of both being regions surrounded by mountains, to its economic activities, there is a list of similarities between the two, that showed the immense possibilities of understanding and possible innovative cooperations. Through this comparative study, it was possible to break down the intangible barriers in order to generate a connection between these two communities through the systematic collection and analysis of qualitative data focused on tourism elements of each region. This way not only new opportunities for cooperation, promotion, and creation. of strategic alliances not previously imagined are created, but also the exchange of knowledge between both cultures allows to expands the horizons and break with biases so ingrained in Western culture towards Asian communities, and viceversa, that sometimes limit the development and effective cooperation between the two. The result of this extensive research is a multilingual website, available in spanish, english and japanese, where both regions can benefit from getting to know each other, working together,and form strategic alliances that increase the flow of tourism and knowledge exchange between the two. The webpage created serves also as a as a platform for companies and organizations to show their activities there and gain contacts. Ignorance is the greatest poison, and this study has shown that biases based on ignorance limit exponencially the horizon of unimaginable possibilities of growth, cooperation, innovation and development between two communities.

Abstract Name: By Invitation Only: Anti-Americanism in Stoker's "Dracula"

In this paper, I focus and build upon the work of scholars Stephen Arata, Carol Senf, and James Simmons to explore xenophobia within Bram Stoker’s Dracula. More specifically, this paper explores Stoker’s othering treatment of his characters of various nationalities who speak non-standard English dialects. Characters focused upon include Van Helsing, Dracula, and Quincy Morris, with a primary focus on Quincy Morris. This paper analyzes Stoker’s treatment of Quincy Morris, an American Southerner, in comparison to the novel’s other non-English characters. Looking particularly at Stoker’s introduction of Quincy to the novel; Quincy’s use of a broadly stereotypical southern dialect; Quincy’s behavior; and Stoker’s choice to kill Quincy at the end of the novel, I establish Stoker’s xenophobia towards Americans by building upon arguments presented by Arata, Senf, and Simmons about Stoker’s treatment of his American characters across his works. Furthermore, through analysis of Stoker’s treatment of Quincy in comparison to his treatment of other non-English characters in Dracula, I surface the discovery that within Dracula, it is not non-English characters who receive Stoker’s harshest treatment, but rather international characters who enter England without invitation. Building particularly upon Arata’s work, I posit that Stoker’s choice to kill-off Quincy at the end of the novel is not mere coincidence, but a manifestation of Stoker’s anxieties about potential reverse-colonization of England by Americans. I conclude that “the real fight of Dracula is not over vampire invasion, but rather imaginary reverse colonization.”

Abstract Name: Analyzing the interaction between proteins Bma-AGE-1 and Bma-AAP-1 in the parasitic nematode Brugia malayi

Brugia malayi is a parasitic nematode that causes lymphatic filariasis in humans. It is hypothesized that the iL3 infective stage in B. malayi is similar to the dauer stage in the well studied model organism Caenorhabditis elegans. The insulin/IGF-1 signaling (IIS) pathway is important in regulating the dauer stage. We are studying the proteins AGE-1 and AAP-1, which are essential in the IIS pathway. We hypothesize that Bma-AGE-1 and Bma-AAP-1 work similarly in B. malayi during the iL3 stage. We have confirmed the predicted gene structure of Bma-aap-1 and Bma-age-1 using Reverse Transcription Polymerase Chain Reaction (RT-PCR). We are currently constructing an expression plasmid for Bma-age-1 and will follow with Bma-aap-1. We plan to express the proteins in cultured cells and use pulldown assays to determine whether they are able to interact with each other. In the future, if we can successfully show this works in cell culture, we can then use that system to test other aspects of their function (like kinase activity). Understanding the function of the IIS pathway in B. malayi may lead to ideas for drug or vaccine targets.

Abstract Name: The Unethical Representation of Native Americans in Twilight

The Twilight series by Stephenie Meyer was a massive pop culture phenomenon in the early 2000s. The question of who Bella should end up with became a passionate, even comical, debate between fans who were ‘team Edward’ and ‘team Jacob’, although Jacob never had a chance with Bella when in competition with his counterpart. Jacob and, more broadly, the representation of Native American culture in the series has been heavily scrutinized for misrepresenting the Quileute tribe. Reflecting on the process of writing the first book of the Twilight series, Meyer reveals that the inclusion of Natives into the narrative came as an almost accidental result of the setting. The desired setting of Forks, Washington, just so happened to be situated by the La Push reservation, where the Quileute live, and so Native characters and themes were included into the narrative. The Native American men in Twilight have been turned into hyper-sexualized, animalistic, beasts, whereas the vampires have been represented as wealthy, sophisticated, and very white. Meyer also revealed that she had included aspects of her Mormon beliefs into the narrative, a religion with a historically discriminative relationship with Natives. When examining the representation that Meyer had cultivated, my paper will show how the novels are riddled with stereotypes and common discriminatory tropes of Native American culture and how those stereotypes mirror problematic Mormon views of Native Americans, or as they are called in the Book of Mormon, Lamanites. Furthermore, this paper will then look at how the

Twilight series' controversial representation has impacted the Quileute tribe and examine the ethical complications of Meyer, a white Mormon, writing about Native Americans and their culture in a discriminatory way.

Abstract Name: (Eco)llage: From Modernist Medium to Contemporary Ecocritical Methodology

In modern and contemporary art history, collage has been discussed in terms of how its formal and visual qualities make the medium political. This is apparent from analyses of the satirical feminist collages of Dadaist Hannah Höch to the contemporary ecofeminist and postcolonial collages of Wangechi Mutu. What these artists and others demonstrate is that the material and discursive nature of collage can overlap, layer, expose and obscure dominant ideologies. This active power of collage transforms it from merely a medium into a methodology. A shift is happening where some scholars are turning away from the visual analysis of collage as a fine art towards understanding how collage operates as a political methodology. Feminist researchers like Blanca Ortiga and Saara Sarma reinterpret collage as a generative method of reimagination that sidesteps traditional ways of accessing and sharing knowledge. Similarly, Katie Hamill and David Lubin advocate for using the juxtaposing, narrative, and playful elements of collage making as a model for redefining academic standards and practices. Building on these arguments, my research explores a relationship between the act of collaging as resistance and the emergence of ecocritical art history. A community-based ecocritical collage methodology uses the conscious act of cutting, layering, pasting, and attention to materiality to resist normative ways of representing human and nature relationships. Collage as a community-based method can be used as a political ecocritical practice, and simultaneously offers the opportunity to expand art historical analyses of how ecocriticism functions in visual art.

Abstract Name: Left out: Chronic Absenteeism in Elementary Schools

In Massachusetts in 2022, approximately 33,000 students were chronically absent (missing ten percent of the 180-day school year) students (Buyinza, 2022). The purpose of this research project was to learn what strategies and programs work to support elementary students who are chronically absent, and why students are missing school. Chronic absenteeism impacts all academics but particularly reading levels; social skills and future career opportunities are also negatively impacted (DESE, 2022). Having resources to support educators and their students during these trying times is important for the success of a child's educational future. As part of this project, teachers, administrators, school counselors, and attendance officers were

interviewed to understand how they ensure chronically absent children receive academic and social-emotional support. It was discovered during this research that communication is a key task, between families and teachers and between teachers and administrators. Attendance should be a number one priority to schools because without children in the classrooms, who are educators going to prepare for the future?

Abstract Name: Microbes, It's Their Word We Just Live in It

Currently, we are experiencing a rapid emergence of antibiotic-resistant bacteria, a crisis attributed to the abuse of antimicrobial medications, and a lack of new drug development. Since their introduction, antimicrobials have been inappropriately dispensed and over-prescribed. We are now seeing the consequences of these actions, resulting in bacteria that have mutated to be resistant to most available antibiotics. Pharmaceutical companies are not working to research and develop new antibiotics due to reduced economic incentives and challenging regulatory requirements. Tiny Earth is an organization focused on tackling antimicrobial resistance while also diversifying the scientific community by enlisting the help of undergraduate students who can take research courses that focus on soil health and antibiotic discovery. Thanks to this organization, we could focus on developing our skills in our microbiology lab while also searching for new antimicrobial drugs. We collected soil samples and plated them to determine the potential antibiotic-producing isolates. The initial approach involved employing colony morphology to assess the various colonies' characteristics, including their edge, elevation, shape, and surface on the plate. Each colony was plated as a patch on a lawn of E.coli, B.subtilis, and S. epidermidis to detect potential inhibition zones and study its antimicrobial efficacy. Four colonies showed promising results. Subsequently, DNA extraction from these colonies was conducted, and the 16srRNA gene was amplified by PCR and sent to sequencing. The results from our sequencing showed that the bacteria belonged to genera from Serratia, Glutamicibacter, Bacillus, and Pseudomonas. TheBacillus sample identified as Bacillus toyonensis originated from Easting Park in San Diego. It may be unique given its large zone of inhibition against E.coli and warrants future testing to characterize its antimicrobial properties.

Abstract Name: Navigating the tenure track: The relationship between stress, anxiety, and retention in university professors

The tenure process in higher education is a complex and multifaceted process. While offering job security, prestige, and academic freedom in research and teaching (Batterbury, 2008), it can also be a source of stress and anxiety due to its competitive nature and demanding evaluation process (Jacobs & Winslow, 2004). Competition can be intense due to a high number of qualified candidates for a limited number of tenure-track positions. Once such a position is secured, tenure-track candidates experience sustained scrutiny of their performance during their probationary period. This stress can impact work-life balance and overall job satisfaction (Hellsten et al., 2011), potentially leading to the loss of high-quality faculty. Our proposed longitudinal study aims to address this issue by identifying factors that increase anxiety and stress during the probationary period of tenure-track faculty. We aim to provide a comprehensive analysis of these trends, with a particular emphasis on gender-based differences. By understanding and addressing the sources of stress during the tenure process, we hope to offer solutions for fostering supportive environments that encourage the retention of a diverse body of high-quality faculty through the award of tenure. This study, as the first of its kind, endeavors to bridge a significant gap in existing research by focusing on the identifying challenges faculty face on their journey toward tenure and generating effective solutions to help retain them.

Abstract Name: Adapting to Change: An Examination of Centers for Teaching Excellence Programming in Response to Evolving Educational Needs in Utah

The prevailing assumption in academia has been that outstanding researchers would naturally be outstanding teachers. However, this notion began to face scrutiny in the late 1950s and early 1960s (Cruz et al., 2023). The societal upheavals of the 1960s had a profound impact on American colleges and universities, leading to students demanding and obtaining a more significant role in campus life. One notable change was the introduction of student evaluations of teaching, which were virtually non-existent before the 1960s but became standard practice by the late 1970s. In response to these shifts and faculty requests for support to enhance teaching, Centers for Teaching Excellence (CTEs) were born, with the inaugural centers established at the University of Michigan and Michigan State University (Bakutes, 1998; Miller, 2002). This marked the beginning of a nationwide initiative to strengthen teaching in higher education, culminating in the formation of over 1,000 such centers by the mid-1970s and general coverage across the United States by 2020 (Wright, 2023).Today, CTEs play an instrumental, mission-driven role in enhancing learning and teaching. The primary mission of most CTEs is to improve student learning, support faculty, encourage innovation, and support scholarly and creative work (Wright, 2023). While there is a wealth of literature on CTE organization, function, and impact, there is a noticeable gap in knowledge regarding the most frequently utilized programming and services offered by CTEs. Post-pandemic, the educational landscape has undergone significant changes, necessitating a shift in the learning and teaching needs of students and faculty. This research seeks to address this evolving dynamic within Utah by examining the prevalent programming and services provided by CTEs across the state. The findings from this research will provide valuable insights into these changing needs and will inform future programming and strategic directions for CTEs in Utah.

Abstract Name: Investigating the Roles of the SAC1 Gene in the TTG2-Dependent Epidermal Traits in Arabidopsis

Basic research, like studying the epidermal traits in Arabidopsis, increases our biological knowledge and paves the way for applied research approaches. Some of the epidermal traits that our laboratory studies in Arabidopsis are trichome development, development of outer seed coat epidermal cells, and the inner seed coat Proanthocyanidin-Accumulating cells. In applied research settings, these epidermal traits can have a major impact on the development of crops as well as the ability of a crop species to protect against predators. In previously conducted research, our laboratory researched the role of AtPLC1 in the PI Lipid Signaling pathway using a process of creating a promoter-reporter gene construct and a gene overexpression construct, and subsequently plant lines containing these constructs. A similar process was used to work with the SAC1 gene that was being studied for its role in the epidermal traits of Arabidopsis. To gain a full picture of the role of the SAC1 gene, a promoter- reporter gene construct with plant lines needs to be created along with a hyperactive promoter and gene construct with plant lines. These constructs are important to potentially provide a clear picture of where the gene is active in the plant and how important the individual gene's role is in the development of the various epidermal traits in A. thaliana.

Abstract Name: Relational Density and Willingness to Engage with International Students in a United States Sample

Universities in America are some of the most diverse areas in the country, offering ample opportunities for intercultural interaction. Positive cross-cultural interaction provides students with invaluable skill development and being culturally literate that will benefit them in school and their future career, but also benefit the building of a more inclusive society (Fozdar 2016). Relational Density Theory (RDT; Belisle & Dixon, 2020) may allow for modeling of relational perspectives of US college students towards international students from countries that frequently send students to study in the US. In the present study, participants completed a multidimensional scaling procedure relating individuals from those countries with positive and negative approachability characteristics. Participants then completed a willingness scale, rating their willingness to engage in interaction with individuals from each of the countries. Results showed strong preference to engage with other domestic students than international students. Amongst the countries that frequently send international students to the US, countries geographically close to the US rated higher on willingness and closest to positive approachability characteristics. Furthermore, countries that send the most international students to the US are amongst the lowest rated in terms of willingness and approachability. Results suggest higher density towards countries geographically located in North America, and higher density among countries located outside of North America. These findings show a good baseline for future research on relational networks involving intercultural interaction. Results also provide insight to how individuals

relate different countries to positive and negative approachability characteristics, showing up potential risk groups amongst international students for non-interaction.

Abstract Name: Relational Volume and Resistance to Change within Complex Networks

Relational Density Theory (Belisle & Dixon, 2020) provides a quantitative extension of Relational Frame Theory that attempts to model or describe higher-order interactions within relational behavior. RDT has been used in multiple studies to the examine complex relational networks involved with gender stereotyping (Sickman et al, 2023), consumer behavior and climate (Hutchenson et al, 2023), and racial prejudice (Belile et al, 2023). RDT describes these higher-order interactions by using terms such as density (strength of relationship) and volume (size of relational class, or nodal distance). The current study extended upon results reported by Belisle and Dixon (2020) and Cotter and Stewart (2023) by training 3- and 6-member coordinated classes differing in nodal distance. The relative strength of relations in the network was measured using a metric multidimensional scaling procedure that included time-based responding. Results showed that class size and nodal distance differentially influenced the response strength of multiple network relations and allowed for the prediction of resistance to change following counterconditioning. These results have implications for understanding the concept of volume within an RDT extension of Relational Frame Theory.

Abstract Name: "For My People:" A Mirror of The Great Migration

The Great Migration changed the landscape of both the American North and South, and the lives of millions. It brought culture and presence through poetry, dance, and song. The life of Black people is told through our experiences and the experiences of the people closest to us. By exploring the migration of Black people, I am learning about myself and my family. My project focuses on the migration of Margaret Walker from Alabama to Chicago, my grandmother’s migration from Mississippi to Wisconsin, and my migration from Wisconsin to New York. Our experiences weave stories that interrogate themes of community, racism, class, and revolution. My goal is to explore the violence of white supremacy in even our mundanities. I am sharing a deeper dive into the impact of the Chicago Black Renaissance. Understudied in the literature on the Great Migration, the Chicago Black Renaissance produced figures such as Margaret Walker, Gwendolyn Brooks, and Richard Wright. It was an explosion of art, literature, community organizing, and social activity within the African American community from the 1930s through the 1950s.This period is exceptionally fascinating because of global turmoil created by the Great Depression, World War II, and Jim Crow. Amid these

developments, Margaret Walker wrote the 1942 poem, “For My People.” Though over seventy years old, the poem’s commentary remains fresh and pertinent. It grabbed my attention because it symbolized a longing for freedom and prospects of a new and better world—a world Black people imagined. My project explores how “For My People” anthologized the figurative and literal movement of African American people, mirroring the movement of The Great Migration.

Abstract Name: Emotional Suppression Correlation Between Ethnicities

Objectives: Racial discrimination is a shared experience for many minority groups. Previous research has supported the idea that many Black adults and students have felt that they were treated unfairly based on race. The present study aimed to investigate the relationship between emotional suppression and perception of discrimination among Black and non-Hispanic White participants. The objectives of this study were to measure the perception and expression of emotional suppression between racial and ethnic groups.Methods: This study included 80 participants in total. Participants self-identified their race as Black (n=35), non-Hispanic White (n=40), and other race or ethnicity (n=5). Participants of this study completed one questionnaire comprised of five sections. Questions included a mixture of created scenarios, thoughts on attitudes and perception of emotion and perception, and the Emotional Regulation Questionnaire (EQR).Results: Cronbach's Alpha was used to determine the reliability of questions (α= .820), and independent t-tests were used to calculate results of emotional suppression. Higher numerical values indicated higher levels of suppression. Black participants reported that they were more likely to suppress emotions ($\mu = 4.17, SD = .98$) than non-Hispanic White participants ($\mu = 3.11, SD = .81$), $t(73) = 5.16, p < .001$, 95% CI [.656, 1.48]. A t-test was used for discrimination perception. Higher numerical values increase as perception of discrimination increases. Black participants had higher levels of discrimination perception ($\mu = 3.41, SD = .53$) than non-Hispanic White participants ($\mu = 2.92, SD = .73$), $t(73) = 3.318, p < 0.001$, 95% CI [.197, .791].Conclusions: Results supported in this study are consistent with previous research. To conclude, Black students are more likely to suppress emotions compared to non-Hispanic White counterparts, as well as perceive that other Black individuals experience emotional suppression at higher rates than non-Hispanic White participants perceived.

Abstract Name: Extractive Economic Activities and Displacement Dynamics: A Deep Dive into the Afro-Colombian Communities of Chocó

Late capitalism and forced displacement in Colombia represent a complex and enduring crisis, particularly affecting Afro-Colombian communities. This study examines the relationship between extractive economic activities, their impact on the environment, and forced displacement, with a focus on the exacerbating effects of illegal mining, logging, and contentious land ownership in Colombia's Chocó region. Historically, Afro-Colombian communities have faced systemic challenges due to lack of political representation, lack of state presence in the region, and internal armed conflict in the area. These adversities have been magnified by extractive economic activities and land disputes, resulting in a forced displacement of Afro-Colombian households. The central research question asks: What are the effects of extractive economic activities, and land ownership disputes on the displacement of Afro- Colombian communities? By using information from the Consultoría para los Derechos Humanos y el Desplazamiento (CODHES), United Nations High Commissioner for Refugees (UNHCR) and El Departamento Administrativo Nacional de Estadistica (DANE), this study explores the roots of forced displacement in the Colombian region of Chocó for the last two decades (from 2000 to 2023). This research also uses an extensive literature review, official government sources, and descriptive statistics, to provide an analysis of the role of late capitalism in creating forced displacement and dispossession of the Afro-Colombian rural population from their lands. Understanding the factors contributing to forced displacement is a crucial step toward developing effective policies to prevent future displacement and promote economic and social justice for the prosperity of the rural communities in Colombia.

Abstract Name: The Economic Importance of Early American Mills

This paper explores the role played by early American mills, with a specific focus on the Marietta Paper Company and Concord Woolen Mill, in shaping the economic landscape of their respective localities during the 19th century. The research delves into three key aspects that underscore the economic importance of these mills: the robust construction of the mills, their strategic proximity to transportation networks, and their adaptability in usage. The study begins by examining the substantial construction of these mills, highlighting the meticulous engineering and durable materials employed in their design. The structural integrity of these industrial complexes not only facilitated efficient production processes but also contributed to their longevity, ensuring sustained economic impact over the years. Furthermore, the paper scrutinizes the strategic location of these mills in relation to transportation infrastructure. This geographical proximity not only streams the transportation of raw materials and finished goods but also amplified the mills' accessibility to wider markets, fostering economic growth in the surrounding areas. An essential aspect of the mills' economic significance lies in their versatility of use. The Marietta Paper Company and Concord Woolen Mill exemplify how adaptability became a hallmark of successful industrial establishments. Their ability to diversify production based on market demands or technological advancements ensured continued relevance and economic contribution to their communities. In conclusion, this paper asserts that the Marietta Paper Company and Concord Woolen Mill serve as compelling case studies in understanding the economic importance of early American mills. By examining their robust construction, strategic locations, and adaptability, the research sheds light on the enduring impact these industrial entities had on the economic development of their local areas, underscoring their role as economic pillars in the growth of 19th-century America.

Abstract Name: Making Abstract Philosophy Concrete Through Collaborative Art

Philosophy and art overlap and entwine throughout history. Existentialist philosopher Albert Camus suggests artistic creation as an answer to existing in an absurd world. Chicana feminist philosopher Gloria Anzaldúa used hand drawn illustrations called "glifos" during her lectures to aid attendees in better understanding her philosophy. The late thirteenth century ink painting "The Pleasures of Fishes" by Zhou Dongqing depicts a passage from the book "Zhuangzi," an important Daoist text. In each of these examples, art is a means to better understand philosophy. I am a visual artist, and I intend to use one of my own chosen artforms, collaborative art, to accomplish the same end. As a collaborative artist, I gather many people together to realize one artistic vision. I have staged over twenty collaborative art events over the past three years, and have used research methods from Rita Irwin’s essay “Communities of A/r/tographic Practice” and concepts from Allan Kaprow’s essay “Manifesto” to better understand how participants are impacted by collaborative art. My research has led me to believe that collaborative art will excel at making abstract philosophical concepts accessible to a larger audience. To explore this belief, I intend to stage three collaborative art events, each one designed to introduce a philosophical movement in a concrete and accessible way. The first event will be inspired by Albert Camus' "The Myth of Sisyphus," and will demonstrate existentialist philosophy. The second event will be inspired by Gloria E. Anzaldúa's "Light in the Dark/Luz en Lo Oscuro: Rewriting Identity, Spirituality, Reality," and will demonstrate Chicana feminist philosophy. The third event will be inspired by Laozi's "Daodejing" and Zhuangzi's "Zhuangzi," and will demonstrate Daoist philosophy. My presentation of these three events will demonstrate the value of using collaborative art as a means of teaching difficult philosophical concepts.

Abstract Name: Temporal Gaussian Processes for Dynamic Modeling of Implied Volatility

The accurate modeling of the implied volatility surface holds great significance in option pricing, trading, and hedging. Significant research has been devoted to this task, ranging from mathematical models to machine-learning solutions. However, these approaches generate point estimates based on imperfect market data, which can lead to inaccurate and misleading models. Gaussian Processes, which are a a Bayesian nonparametric method, have addressed this challenge. They generate posterior distributions of implied volatility functions, producing confidence intervals and quantifiable measures of model uncertainty. We improve upon this approach by incorporating temporal dynamics into a Gaussian Process to capture trends in changing implied volatility surfaces over time. Our model is then applied to end-of-day option quotes, showing high accuracy that can outperform traditional parametric models in implied volatility estimation and option pricing. Our findings could significantly impact hedging strategies, as the distribution that our model derives accounts for a spectrum of scenarios, enabling a more nuanced assessment of risk. Using our model's output, we will further validate this application by conducting empirical tests and simulating hedging strategies under various market conditions. We expect this to demonstrate the effectiveness of our approach in reducing risk exposure compared to traditional methods, thereby providing a tangible measure of the practical benefits of incorporating our Gaussian Process method in the real world.

Abstract Name: Using Congruent Communication Skills at the Beside: A Guide for Student and Graduate Nurses

The aim is to modify Haim Ginott’s congruent communication techniques to be used by nursing students and

graduate nurses to increase ease of communication at the beside. Haim Ginott taught his principles of congruent communication to parents and teachers as a means of interaction with children, resulting in children who feel seen, heard, and empowered. The relationship between nurse and patient is also one of power inequality, and many studies posit that good communication is the nurse's responsibility. From a patient perspective, lack of communication, lack of empathy and authoritarian attitudes are points of dissatisfaction. Nurses attending communication training report that patient self-management and compliance with treatment are improved. Congruent communication provides a blueprint for nurses to handle not only patient's strong emotions but their own as well. This in turn fosters a relationship in which the power differential is more balanced, and the client is much more likely to receive education and implement change in behavior. A poster and a handout will be created that will be distributed to student nurses in a nursing program. It will describe three techniques from Haim Ginott's method that can be understood and implemented immediately. A link to a survey will be provided and data from the survey will be collected and analyzed to determine effectiveness and ease of implementation of the skills outlined in the poster. Insight will be used for creation of a comprehensive program in the future. Nurses inherently want the best for their clients and are unsatisfied, stressed, and self-doubting when unable to communicate in ways that have positive outcomes and protect the dignity of both parties. Giving nurses tools to create authentic, powerful connections with clients is a way to create lasting impact.

Abstract Name: Shifting Perspectives: Exploring Translanguaging and Teacher Education

ithin the U.S. education system, a historical inclination towards English-only ideologies have marginalized the voices, cultures, and languages of bilingual students. Students labeled as English Language Learners Students labeled as English Language Learners confront a significant achievement gap, scoring approximately 15% lower on standardized tests than their non-ELL counterparts, underscoring the shortcomings of the English-only classroom approach for bilingual students. Consequently, the educational field endorses bilingual education with translanguaging pedagogy as a more efficacious alternative to redress this discrepancy.This research advocates for a transformative shift from a monoglossic view of language learning to a heteroglossic paradigm, emphasizing the crucial role of translanguaging pedagogy in supporting bilingual learners in the education setting. Translanguaging, as an inclusive approach, enables bilingual students to bring their authentic selves and languages into the classroom, utilizing their entire language repertoires in the classroom learning environment. This poster presentation delves into the bilingual way of knowing and learning, highlighting the necessity for heteroglossic ideologies and creativity within educational frameworks. This study employs an autobiographical narrative inquiry approach involving a pre-service teacher at a U.S. midwestern University, showcasing the successful implementation of translanguaging pedagogy in teacher education programs. The findings underscore the pivotal role of teacher education in driving the integration of translanguaging pedagogy, positioning it as a transformative force to empower bilingual learners in the U.S. schooling environment. This presentation argues for the need to restructure teacher education programs to incorporate translanguaging as a fundamental and transformative pedagogy in the education of all pre-service teachers for fostering inclusivity and maximizing the potential of bilingual learners in contemporary educational settings.

Abstract Name: Doing Being Nonbinary: The Sociophonetics of Coming Out

This paper functions as one of the first examinations of the sociophonetic characteristics of non-binary speakers as measured across their gender journey and coming out. As widely recorded as gender differences in speech patterns (e.g. pitch, intonation, g-dropping) are among binary (and most often, cisgender) speakers, there is little research on how people who identify as neither woman nor man fit into this model. In this paper, I examine twelve public figures who have come out as nonbinary in the past decade. Through variables of g-dropping, pitch, and segment duration, I establish the differences in each speaker's voice from before and since their identification as nonbinary. A preliminary hypothesis poses that each speaker will exhibit a departure from their "before" way of speaking and towards an overall "after" voice outside a male-female binary. Preliminary results of ten speakers for their average segment durations and g-dropping suggest that changes in gendered speech patterns do indeed shift away from what they were before. For example, speakers assigned male at birth significantly decreased their use of g-dropping. Additionally, a variety of speakers across sex assigned at birth significantly altered the duration of aspiration following a word-initial or stressed syllable-initial voiceless velar plosive. The understanding that speakers' gendered linguistic features do change as they explore and come to identify with a gender identity separate from the one assigned to them at birth supports the intuitive hypothesis that a group of people whose gender identity falls outside a binary would also exhibit speech patterns that fall outside the binary. Ongoing analyses include fundamental frequency and pitch range, further features that are highly gendered and may vary across stages of gender expression.

Abstract Name: Using Deep Learning Models to Detect Brain Tumors from MRI Images

In the medical diagnostics field, a major challenge is accurately and promptly detecting brain tumors in MRI images. Integrating image classification models has the potential to enhance diagnostic practices, reduce errors, and expedite tumor identification. This research utilized deep learning algorithms to create an automated system for reliable brain tumor identification from MRI scans aligning with the broader goal of advancing medical technology. Additionally, investigating various classification model types contributes to improved healthcare diagnostics, aiding early detection for better patient care.The research utilized a dataset comprising two folders of brain MRI images—one with tumor-free images and the other with images featuring tumors—gathered from Kaggle. Four pre-trained models were applied, and the same dataset was used for testing different image classification models and frameworks. Data preprocessing steps, such as resizing, augmentations, segmentation, normalization, and contrast enhancement, were standardized across models to authenticate accuracies.Validation tests assessed the accuracy and precision of the models, involving the saving of models in H5 format for seamless reuse and evaluation. A graphical user interface (GUI) was developed using the 'ipywidgets' library, offering an interactive platform for testing model performance. Testing involved four distinct brain images from outside the dataset to evaluate the model's generalization capabilities. Results indicated accuracy rates ranging from 75% to 90%, reflecting the model's

ability to identify brain tumors. Variability in accuracy was attributed to factors like image diversity, dataset size, model complexity, and sensitivity to different tumor types and sizes.The research's short-term goal was to develop a deep learning model for accurate brain tumor detection, while the long-term objective involves refining detection algorithms for broader medical applications. Future work includes incorporating diverse datasets to assess how accuracy percentages evolve in detecting brain tumors and experimenting with popular continuous learning algorithms.

Abstract Name: Unveiling the Blueprint: Mentor-Student Co-Creation of Journal Guidelines for Undergraduate Research

Participatory design and reflections on co-creating a journal Our work delves into the pivotal role of journal guidelines within the context of Research Experience for Undergraduates (REU) programs in STEM education, with a specific focus on the collaborative creation process between mentors and students. The establishment of comprehensive journal guidelines is crucial to the success of undergraduate research endeavors, offering a structured framework for scholars to articulate and disseminate their findings effectively. The central research question for the write-up is: How does the collaborative co-creation of journal guidelines between mentors and undergraduate students within the Research Experience for Undergraduates (REU) programs impact the quality, publication success, and overall trajectory of STEM research conducted by participating scholars? The research methodology involved a comprehensive exploration of collaborative processes in creating journal guidelines within STEM-focused Research Experience for Undergraduates (REU) programs. Qualitative research methods, including in-depth discussions and observations, captured mentor-student dynamics. Participants were purposefully selected for expertise, and a systematic review of IEEE standards informed guideline criteria. Analysis of published REU research offered insights into guideline impact. This multifaceted approach aimed to unravel mentor-student collaboration intricacies, providing a holistic understanding of co-creation and its implications for undergraduate STEM research. These guidelines serve various purposes, equipping participants with tools for effective publication navigation, fostering scholar-led peer feedback, and facilitating successful research dissemination. Moreover, adherence to these guidelines is shown to influence participants' career trajectories, providing a transformative experience in the broader STEM education landscape. In essence, the collaborative creation of journal guidelines emerges as a cornerstone, optimizing the impact and quality of undergraduate research within the REU framework.

Abstract Name: New insights on the mechanisms of active avoidance behavior during signaled threat: Prefrontal contributions and behavioral differences across sex and age groups.

Flexible adaptation of behavior during imminent threat is critical for safety and survival. A type of behavioral adaptation that is typically implemented during environmental threat is active avoidance in which specific actions or behavioral sequences are dynamically engaged to prevent harm from threat. While previous studies suggest that the medial prefrontal cortex (mPFC) is implicated in the learning of active avoidance responses, the role of discrete subregions of the mPFC – known in rodents as the prelimbic (PL-PFC) and infralimbic (IL-PFC) cortices – still remain unclear. In this project, we are implementing a novel behavioral paradigm in which mice are capable of developing flexible avoidance responses during a tone cue that predicts electric shock punishment, by stepping onto a small non-electrified platform that is dynamically presented into the behavioral chamber during tone-shock trials. Our results have so far revealed that over the course of five daily training sessions (20 trials/day), a large proportion of young-adult mice can develop robust active avoidance responses to avoid incoming shocks. However, optogenetic-mediated silencing of principal glutamatergic neurons in the IL-PFC subregion led to a significant impairment in the development of active avoidance responses, whereas neuronal silencing in the PL-PFC subregion produced no significant effects. In addition, our results suggest that female mice can learn active avoidance in more optimal manners than male mice, however there were no significant differences between aged groups (16 months old). Although potential differences in IL-PFC signaling across sexes and ages still remain to be elucidated, we hypothesize that IL-PFC signaling could be an important factor that promotes better avoidance learning in certain groups and/or individuals.

Abstract Name: Low-Iridium Catalyst for Proton Exchange Membrane Water Electrolysis (PEMWE)

As the energy sector transitions from fossil fuels to hydrogen for a clean fuel alternative in order to preserve our environment, research into green hydrogen production has become of growing interest. Proton exchange membrane water electrolysis (PEMWE) can be used to produce hydrogen, but its dependence on the scarce element iridium poses a challenge. Therefore, for this study, a minimal amount of iridium was determined to facilitate effective PEM water electrolysis in conjunction with ruthenium. Research, configuration, and synthesis of ruthenium-iridium oxide at different ratios revealed a degree of stability/instability that could potentially be used in PEM water electrolysis. The results indicate that the ratio of 90% ruthenium and 10% iridium were considered stable. By discovering and developing a new material for lower iridium loading for PEM water electrolysis, we can uncover novel results that contribute to the metamorphosis of the energy sector and a cleaner environment.

Abstract Name: Exploring meteoritic fragments with microscopy and spectroscopy techniques

Carbonaceous chondritic meteorites are ancient materials from the earliest times of our Solar System, and thus, these objects can provide valuable information about how planets formed. These meteorites are composed of micro/millimeter-sized inclusions surrounded by a matrix of microparticles. The study of the physical properties (e.g., structure, composition and morphology) of these constituents can give evidence of the conditions (e.g., thermal, temporal and barometric) in which the materials found in the meteoritic samples developed in our Solar System. These physical properties can be studied using different experimental and analytical methods. In this work, we use microscopy and spectroscopy techniques, such as Raman spectroscopy, optical microscopy and atomic force microscopy, to study several properties of carbonaceous meteorites (e.g., mineralogical composition and topography at the micro and nanoscale). In particular, we analyze two meteoritic fragments: Northwest Africa (NWA) 7184 and Aguas Zarcas. We explore numerous regions of individual inclusions, surrounding matrix and inclusion-matrix interface. We correlate our results to look for clues about the origin of these extraterrestrial materials.

Abstract Name: Sociocultural Influences on Digital Parenting Strategies: A Statistical Analysis of the Effects of Familism, Latinidad, and Income on Active and Restrictive Mediation

This study explores how parents' beliefs and attitudes about mediating their child's digital technology usage (referred to as digital parenting) are influenced by three sociocultural factors: Latino identity, family income, and familism. Familism is a value that encompasses a sense of duty to support, respect, lean on, and prioritize family members and family cohesion. The concept originated from research with Latin American families, but the values of familism are also commonly found in low-income families of all ethnicities in the United States. Although familism is an important cultural value that has complex interrelations with childrearing values (e.g., autonomy-supporting vs. controlling), little research has yet been published that addresses the intersection of ethnicity, income, and familism as specfically related to digital parenting. In addition, the influences of Latino identitiy and family income (used as a proxy for socioeconomic status in the current study) on parenting are difficult to disentangle due to sociohistorical systems of oppression and marginalization that have limited the accumulation of wealth and capital in Latino communities in the United States. Existing research has either depended on qualitative studies with small sample sizes or statistically controlled for income or ethnicity (or both) in larger quantitative studies. Rather than controlling for income or ethnicity, the current study "controls in" these important variables through multiple linear regression in a multi-group model to examine how they synergistically influence digital parenting strategies among Latino

and non-Latino parents in the U.S. Preliminary results show that familism accounts for a large portion of the variance in digital parenting, and that Latino parents with high familism scores tend to rely more upon restrictive mediation strategies (e.g., content filtering, screen time limits, etc.). These results will be discussed in terms of the emergent "protective parenting" style among Latino families in the U.S. and the need for culturally-responsive social services.

Abstract Name: The Romance and Destruction of Monsoons: An Analysis of Monsoon Portrayal Over Time in Indian Films

Globally, popular notions of Indian films such as Monsoon Wedding and Lagaan include elaborate songs and dances, rollercoasters of emotion and plot, and, most importantly, rain. Are these stereotypes, or does the Indian film industry repeatedly use rain, and specifically monsoons, in films across time and genre? If so, how does this symbolic pattern in which intimacy and emotion are frequently tied to the presence of monsoon rains relate to broader contexts? Using a discourse analysis of 27 films selected for their cultural relevance or box office success from the 1930s-2010s, this paper asks how monsoons are written into Indian film across time and genre and how that is related to Indian culture including the impacts of colonialism, globalization, and climate change in India. This analysis finds that monsoons and rain are overwhelmingly present in important romantic scenes or sad and emotional scenes–especially in the 90s romance genre. Additionally, because the analysis is focused on films across time and genre, relations between global politics, genre of film, and manner of monsoon portrayal are highlighted. As India is impacted by globalization, monsoon portrayal becomes more monolithic in films. English also is spoken increasingly, plot structure and character arcs shifted from underdog stories to more high-class characters, and in the 2000s a shift towards social commentary–feminism, religious conflict, caste system, climate change–emerge as a theme in the larger plots of films. Indian film is a commonly studied area for its cultural influence, but analysis tends to focus on individual films, rather than systematically analyze trends. The cross-genre and chronological approach of this paper identifies trends in India which showcase both the continuing importance of monsoons as a cultural keystone in India and how their representation is evolving as India becomes ever more important in global economies and cultures.

Abstract Name: Character Building in Undergraduate Researchers

A substantial body of empirical research has confirmed the positive impact of Undergraduate Research (UR) on students. However, there is a noticeable gap in our understanding regarding the developmental trajectories of character-building outcomes stemming from UR experiences. The aim of this presentation is to share

insights into the character-building outcomes observed among undergraduate researchers, which I have both researched and encountered in my role as a research mentor. Existing literature highlights the favorable influence of Undergraduate Research Experiences (URE) on self-efficacy (Martin et al., 2021). This led me to wonder about the potential for additional character development resulting from engagement in research activities. To address this inquiry, I collected quantitative data through a survey specifically designed to gauge students' perceptions of character development. Undergraduate students were asked to report the extent to which their UR experiences contributed to their personal growth in various character dimensions, including Humility, Courage, Industriousness, Responsibility, Creativity, Honesty, Tolerance for obstacles, Patience, and Caring. In addition to the survey, qualitative data was gathered through four open-ended questions to capture students' perspectives on character development. The findings from this comprehensive study, coupled with personal observations and reflective insights, will be presented in this discussion. It is anticipated that this research will enrich the existing literature on the benefits of undergraduate research and offer valuable insights to mentors and undergraduate researchers keen on fostering character development through research endeavors.

Abstract Name: Space Rocket

Star Base was a youth science program that was related to spaceships and space travel. This is a department of science where little kids from elementary school could learn about the solar system and the galaxy, we live in. To learn how to build a rocket and visited the cockpit of a space shuttle. To see the different types of meteoroids and learn how they burn on the earth's atmosphere. This study helps gain a new perspective to study the earth and the solar system. To find out if there is life in other worlds and seek ways of improving a new generation. For a new generation to be better than us in all the aspects and to build a greater society. Methodology is a particular area of study. The materials are needed to build a rocket where cardboard and a plastic bottle just modify and cut pieces and give them an aerodynamic shape. Paper to used has a small parachute once you launch it will make sure the rocket lands safely. The weight, lift, drag, and thrust need to be checked once you finish building so that the force of the launch can make the rocket fly. Findings will indicate how this rocket will have an impact on future generations and could increase their potential of making their own experiments. This is because this is just a model of a rocket, and we want to understand and determine how spaceships work and how they are launch. This is important to know because it opens a reality to whole new different worlds. To the possibility that one day we could travel to another world and be up in space and see our own planet.

Abstract Name: Stimulating Kids with Autism through the Sensory Room Experience- Under The Sea

Sensory rooms are used for kids with autism in school because they are often overstimulated. A sensory room is an area that gives the students the sensory materials they need to self-regulate and be ready to learn and socialize. Students need a space where they can decompress, have different sensory stimuli, and a better learning environment. Varying amounts of equipment and materials need to be used for a sensory room to be effective. Different textures, toys or fidgets will allow them to choose the activity they want to engage with. Our goal for this service-learning project was to improve the atmosphere of a sensory room for children with autism in an elementary school from El Paso, Tx. The participants of this service-learning project consisted of two aides and 9 teachers who constantly used the sensory room for their students. Participants were

assessed about the needs of the sensory room. The improvement of the sensory room took two months to finish. During this time equipment and material such as; Christmas lights, a trampoline, a sensory swing, a balance beam, a crawl tunnel, and a board with fish drawings were added. Teachers and aids were given a pre/post survey to assess the sensory room and the impact it had on the students. T-test was performed to assess the pre and post-survey. Results from the t-test revealed statistically significant improvements in questions #2 [t(9)=5.308;p<0.001], question #3 [t(9)=-38.895=<0.001], and question #4 [t(9)=4.946;p<0.001]. No significant differences on question # 5. The sensory room improvements not only led to immediate positive changes in the students behavior, but also established a foundation for sustained, long-term benefits. These findings highlight the effectiveness of implementing more activities and visual decorations in the sensory room for students' with sensory needs.

Abstract Name: Maintenance Plan for Solar Energy Technologies and its Implementation in Rural Communities

In Colombia, there are still numerous communities that do not have access to electricity (non-interconnected zones, NIZ). The government and other entities are making efforts to provide this resource to those communities, nowadays they are implementing Photovoltaic solar systems. This research contributes to the eradication of energy poverty making the communities able to sustain the energy projects over time. We are working with Amazon Conservation Team, conducting research to study the implemented photovoltaic technologies in the NIZ, specifically in the region of “Amazonas” to study their culture, and life styling, help them understand the way that solar photovoltaic systems work, and build a closer relationship between the community and the photovoltaic systems. We realized that the success of the energy projects in the NIZ relies on the need of the communities to be part of the project. We noticed that these communities do not have the essential knowledge to sustain these systems and there is a lack of investment and management in Operation and Maintenance (O&M). If we can offer them a maintenance plan and help them take ownership of the technology, with a methodology to share the knowledge, energy poverty will be reduced. The initial results we have had are the construction of a children's story, as a teaching and learning tool for the transfer of knowledge to indigenous communities. This is how this research will help the energy projects to be more sustainable over time, because we are providing a replicable methodology that integrates the communities with the project, bringing solutions to the O&M problem. Engaging the community as part of the project will provide them new opportunities in education and allow them to improve their living conditions.

Abstract Name: Is sexual pleasure a human right? An important gap in the sexual and reproductive rights of Peruvian women

Historically, policies on women's sexual health in Perú have ignored the element of pleasure, focusing almost exclusively on reproduction. Perú's sexual health policy has been shaped by strong Catholic ideas focused on the patriarchal control over women's bodies. A clear indication of this is the fact that abortion is only legal in cases of extreme danger to the life of the pregnant woman. Given the importance of the Peruvian Society of Obstetrics and Gynecology (SPOG by its name in Spanish) in the development of sexual health policies and sexual education guidelines in Perú, this paper analyzes the content of 16 articles published by the SPOG from 1975 to 2023 to understand how recent medical discourse elides pleasure and perpetuates the attitudes that sexuality should be limited to reproduction. Only the articles that included "sexual and reproductive rights," "sexual and reproductive health" or "sexuality" in their titles were included in this study. Findings included that only 31% and 12.5% of the articles mentioned sexual pleasure or "well-being" as part of sexual health, respectively. Nonetheless, only one article maintained a sex-positive position in its entirety while the rest maintained a reproductive focus through most of its content. However, as it was shown in sexual education campaigns in other countries like Senegal, a sexual pleasure focus can lead to a higher rate of condom use. Thus, the purpose of this study is to pursue further avenues of research on sexual pleasure considering Perú's specific historical and sociocultural conditions. As the SPOG stated, between 25% to 40% of maternal mortality could be eliminated if unwanted pregnancies are prevented so a focus on sexual pleasure could be beneficial as it could increase the rate of contraceptive use. Ultimately, a focus on sexual pleasure could open new paths to improve women's sexual health in Perú.

Abstract Name: Hyflex Modality: Comparison of Engineering and Social Sciences Student and Professor Perspectives

The challenges brought on by the COVID-19 pandemic have led universities to introduce technology-rich pedagogies that support students facing barriers to in-person attendance. Hyflex is one approach that may benefit students and allows students three options for attending class which are in-person, synchronously, and asynchronously. However, a small body of literature on its efficacy creates the need for additional research to determine the overall benefits of Hyflex. Our current study implements a mixed methods approach using survey data and focus groups to examine the perceived impact of Hyflex on students and faculty in social science courses compared to STEM courses. Analysis of the surveys and focus groups revealed that both STEM and social science students appreciated the flexibility that Hyflex offered. Some faculty were also noted appreciating the flexibility for students and grade similarities or improvement in STEM courses, but were discouraged by the lack of attendance and discussion in person. Discussions were prominent within the chat box feature on Zoom, during office hours, and in group settings outside of class. An implication of our

research is that Faculty teaching a Hyflex course should not expect students to attend class-wide discussion in person without incentive and structure. Future research should include quantitative data concerning student grades for STEM and social science classes to discern if certain courses may be better suited than others for the Hyflex modality.

Grace Murphy

Abstract Name: Exoskeletons - Designing for Social Justice

Many engineering professionals believe that discussions surrounding diversity, equity, and inclusion (DEI), and social justice do not belong in engineering because engineering is supposed to be a neutral or objective field. Through an extensive review of literature and a survey sent out to potential users, the need for DEI in engineering was examined, specifically within a project aimed to equitably design an upper limb tensegrity-based exoskeleton. Many current engineering projects do not take into consideration social justice principles which leaves certain groups further marginalized and disempowered while empowering a select few. Engineering has the opportunity to be a field of service, but first risks and benefits must be weighed and the outcome of enhancing human capacities must be valued over monetary gain. In order to equitably design our exoskeleton we considered user needs from the very beginning through empathy mapping and surveying potential users. The results that we have gathered thus far suggest that potential users care foremost about cost and secondly about the comfort and fit of the device. Moving forward it is crucial that we implement design choices that reflect the value so the potential users to ensure that the device we create is usable and offers a sustainable solution to users.

Abstract Name: Unveiling Celtic Women: How Ancient Tales Shaped Gender Roles and Power Dynamics in 5th Century Ireland

This study examines the impact of legendary Celtic women on the views and treatment of women in Celtic pagan society after its Christianization in the fifth century. By exploring the lives of Queen Medb, Saint Christine, and Brigid of Kildare, we seek to understand how these tales, filled with miracles, magic, war, and desire, altered or enforced societal perspectives on gender roles. The research begins by providing a synopsis of Celtic life and gender roles before and during the first decades after the official Christianization of Irish Celts around 431 CE, followed by an exploration of Catholic and pagan religious beliefs and practices, thus introducing these legendary women. The central question of this study has a dual focus: How and when were the tales about these women constructed, and how were these tales used to enforce power dynamics and societal gender roles around 500 CE before and after the Christianization of pagan Celts? This study analyzes ancient documentation, legends, and varying interpretations of the lives of these women. There is little to no

documentation of ancient Celtic pagans that is not written by Catholics, meaning that this research must examine these written sources critically. By considering power dynamics and how men utilized legendary tales to maintain control over women, we aim to shed light on the role of influential female figures and their impact on societal norms. The expected results of this study are multifaceted: the tales surrounding these women reveal how men used these stories to promote silent obedience among women and how women were uplifted or punished based on archetypes of female people and spaces. These conclusions will be discussed within the context of Celtic society during pagan and Christian periods, offering insights into the treatment and perception of Celtic women, building upon minimal research on the topic.

Abstract Name: Using Intelligent Industrial Robots for Formation of Lipid Bilayer Membrane

Medium to small-sized Industrial robots have the ability to carry payloads that can be as high as several kilograms at Tool Center Point (TCP) speeds that can reach 11,000 mm/s with an astonishing precision repeatability of as low as 10 micrometers. Recent advances in industrial robots have enabled them to be collaborative, compact, and equipped with vision systems at continuousely reduced costs. In this work, we present the use of intelligent industrial robotics for the deposition of black lipid bilayer membrane across an aperture. The Montel-Mueller method is employed, in which a two-chamber apparatus with a 0.1 mm aperture is used for the deposition. A monolayer of a combination of phosopholipids is first deposited on a surface of 10 mM NaCl solution in both compartments of the apparatus using the intelligent robot, then the solution level is raised gradually, as the level approaches and passes the aperture level, a lipid bilayer is formed across the aperture. Electrochemical Impednce Spectroscopy is then used to investigate the electrochemical properties of different lipids. The robot with its vision system is then used to deposit a lipid bilyer membrane on a silicon slide using the Langmuir-Blodgett and Langmuir-Shaeffer techniques. Preliminary results show a significant improvement in the deposition compared to manual techniques.

Abstract Name: The Role of Trauma and Love in Beloved by Toni Morrison

This paper frames a close reading of Toni Morrison's Beloved through the lens of trauma and love being prevailing forces among every character, but most importantly, in the main character Sethe. Even though every character in this novel suffers from some kind of trauma, Sethe is the character that actually confronts and somewhat overcomes her trauma. She does this through the immense love that she feels for her four children. Specifically, this paper uses three very important secondary sources to illustrate this idea of love

prevailing over the badas well using direct quotes from teh novel. The frist being Dimitrij Jelovcan-Bulatovic's "Love as a Leading Force in Beloved by Toni Morrison" in whihc Jelovcan-Bulatovic discusses this love phenomenon. The secnes in whihc Morrison depicts in her novel help readers to discern that Sethe is one of the sole charcters that worked through their trauma throughout the entirety of the novel. THe second being Janeen Selfridge's "Beloved: The Physical Embodiment of Psychological Trauma" where she examins the role of slavery and the psychological trauam that is a direct result of slavery and how it affects the characters of the novel. The last being "Slavery and American Gothic: The Ghost of the Future" by Jason Haslam in which Haslam analyzes the connection between themes of slavery in novels like Beloved and the gothic genre as a whole. Reading novels like Beloved that do not shy away from themes of slavery and psychological trauma allow readers to gain a new perspective on teh long term effects of slavery on those who were enslaved.

Abstract Name: Aesthetic Attachments for Infant Cranial Orthotics

Parents all over the world take care when dressing their babies. When infants between five and twelve months old have developmental issues with their skull and head shape, also known as plagiocephaly, pediatricians recommend cranial remolding orthosis to assist with painlessly reshaping the skull for both medical and aesthetic purposes. While parents are motivated to purchase these medically valuable orthotics, they are expensive, have little aesthetic appeal, and only come in limited colors and styles. While helmets can be printed with a color or pattern, the fabricated design is permanent. Further, the helmet must be worn 23 hours of the day in order to be effective. This means that any choice of dress for an infant – either day-to-day or for the regular photo shoots that come along with the period of infancy – must either match the helmet's specific color scheme or clash, further making the orthotic stand out. By developing a way that could make the aesthetic of the helmet temporarily customizable, it will encourage parents to get the orthotic for their child, make it more aesthetic, and accommodate the changing interests of a family. Through a process of shadowing at clinics, connecting with patients and fabrication manufacturers, and designing prototypes, a product was developed with the intended goal of being marketable to families impacted by infant plagiocephaly. Through research, it was determined that parents are primarily concerned with discretion, ease of use, interchangeability, and safety, all of which were considered in the iterations of the final form. Ultimately, the product developed is a customized hat, designed specifically to cover the cranial orthosis, keeping in mind the safety of the infant, breathability, and aesthetics. Further, product branding – including name, logo, tag, color scheme, and photography – was designed for marketing and patenting purposes.

Abstract Name: Student Pathways, Barriers and Outcomes in Environmental Studies

Spurred by a desire to improve undergraduate retention and performance, student data from St. Olaf College was used to answer department-level questions about students' decisions to major or concentrate—minor—in Environmental Studies. These decisions were explored through trajectories in student coursework. Students majoring in Environmental Studies must also declare one of three areas of emphasis—Natural Science, Social Science, or Arts & Humanities—which modifies their major requirements. An exploration of major, emphasis, and concentration pathways identified barrier courses (challenging or hidden prerequisite courses) both inside and outside the department. Of particular interest were instances where student demographics and academic performance impact these trajectories. Institutional data from 2013 to 2022 included seven four-year cohorts of majors, a total of 7,602 students. Raw data from yearly transcripts was joined with records of student demographics, major and concentration declarations and withdrawals, and degrees awarded. This comprehensive dataset was then used to identify trends and create visualizations to communicate information to stakeholders. For example, 76% of students who graduate with an Environmental Studies major took their first Environmental Studies course in their first year. Of those, over half participated in the Environmental Conservation program, a first-year program that partners with Environmental Studies. Results are used to inform the Environmental Studies department about student progression through the major and concentration, and areas where improvements might support student success. These strategies for visualizing student pathways in Environmental Studies and other disciplines are generalizable to programs at similar residential liberal arts colleges.

Abstract Name: Emergency Room Nurses' Perceptions of Medication Errors in the Emergency Department

Medication errors (MEs) remain a pervasive issue in United States emergency departments, where emergency room (ER) nurses play a central role in the medication process. The medication process involves a series of steps, including transcribing, prescribing, dispensing, administering, and monitoring. Proper adherence to the process ensures that the right medication is given to the right patient in the correct dose, route, and time. It also allows consideration of potential interactions, contraindications, and side effects, with the goal of achieving safe and efficacious therapeutic outcomes. The most prevalent types of MEs encountered during the various stages of the medication process include wrong dose, wrong drug, wrong time, wrong rate or technique, and omission. Given the potential life-altering consequences of MEs, it is imperative to harness the unique insights and experiences of ER nurses who are on the frontlines of patient care. ER nurses witness firsthand the intricacies and challenges of the medication process, making their perspective invaluable in identifying the root causes and contributing factors of MEs. Recognizing the paramount importance of comprehending MEs from the perspective of nurses, this study aims to tackle prevailing constraints that often marginalize their insights and are plagued by underreporting issues. Utilizing convenience sampling, willing participants from Colorado completed an online survey. The study utilized open-ended questions to gather insights into the factors that either impede or facilitate successful practices within the medication process, as perceived by ER nurses. The subsequent application of thematic analysis to this dataset aims to unravel key themes and patterns that can inform target interventions. By integrating these perspectives into the ongoing

improvement process, this study hopes to pinpoint actionable steps that can be taken in the field to mitigate MEs; these could include better documentation, enhanced training, or the implementation of more fail-safe measures.

Abstract Name: Echoes of Innovation: Black Jazz Musicians and the Contemporary Musical Landscape

The struggle for recognition of African-American intellectual property has been fraught with discrimination and limited artistic expression. This issue is particularly evident in the context of early 20th-century New York City, where Black jazz musicians faced significant obstacles in gaining credit for innovations that are still used today. Despite their immense influence on diverse musical traditions, icons such as Ella Fitzgerald, Thelonius Monk, and Miles Davis are often overlooked in our modern consumption of music. My project aims to explore how the legacy of these jazz musicians continues to impact contemporary music globally, including in popular American musical pieces, and visualize these connections through a concept web--a new rendition of the musical timeline that allows me to expand on existing literature by influence of these icons across several genres. By examining broader musical identities, including backbeat and polyrhythm, my study aims to provide a comprehensive understanding of the profound impact of Black jazz musicians on the global musical landscape. It will delve into the historical background of African-Americans, drawing connections between the music of the West African coast and the syncopation found in innovative Black music like jazz and reggae. This will be supplemented by contributions of the Harlem Renaissance, a pivotal cultural movement that celebrated Black artistry and identity in the early 20th century. It will emphasize the inclusive nature of jazz with the discrimination that fostered it, and how its elements such as fusion, call and response, and improvisation have shaped contemporary Black music, including the evolution of hip-hop and international pop. All this occurred against the acknowledged limitations of analyzing these contributions, highlighting the loss of potential musical innovation due to the lack of recognition and appreciation of these artists during their lifetimes.

Abstract Name: Healthcare Accessibility: Bridging the Gaps Towards Better Health

Despite significant advancements, healthcare accessibility remains a critical issue in the United States, with disparities that persist across socioeconomic, demographic, and geographic lines. My study delves into the experiences of individuals who are facing barriers to healthcare access while identifying potential solutions for enhancing equity in the healthcare system, drawing inspiration from the works of prominent researchers like Dr. Camara Phyllis Jones and Dr. David Satcher, who have dedicated their careers to understanding and

addressing health inequities. Utilizing the Amazon Mechanical Turk Platform, a 17-question survey was conducted sampling 198 adults across the United States. The study explores the perceived barriers to care and the impact that socioeconomic factors and gender play in healthcare access. Findings reveal that transportation, affordability, and lack of insurance emerged as the most prevalent barriers, with lower-income individuals disproportionately affected by transportation limitations. In addition, women viewed health disparities and prioritized affordability as a barrier, while men highlighted the lack of public health insurance programs. These findings highlight the need for a versatile approach that addresses the gap in access to health care. Policy interventions should focus on expanding access to affordable health care, improving public transportation systems, and implementing gender-sensitive strategies to address the unique challenges of women and men alike. By addressing these disparities through multilateral policy interventions, the United States can strive to provide equitable and accessible health care for all its citizens, regardless of what they cannot control. This study provides valuable insights for policymakers and healthcare providers to work towards a more inclusive and equitable healthcare system for all.

Abstract Name: CougarStats: An R Shiny App for Statistical Data Analysis

CougarStats is a free, and open-source R Shiny application designed to conduct statistical data analysis. CougarStats aims to simplify statistical concepts and foster learning with a user-friendly browser-based interface. In the context of statistical education, there is a need for intuitive and comprehensive tools that are accessible to a wide range of users, from students to instructors. CougarStats is designed to address this need, providing a platform to conduct statistical data analysis across a growing list of topics while presenting detailed calculations. Current pedagogical topics include Descriptive Statistics, Probability Distributions, Statistical Inference, Simple Linear Regression, and Correlation Analysis. CougarStats is developed as a web application in the R programming language using the Shiny framework, and is currently hosted at https://www.cougarstats.ca. The application is designed using education principles to balance simplicity with analytical depth, and uses an Agile approach in its development to consistently refine functionality and incorporate user feedback. The current stage of its development involves incorporating advanced statistical concepts, such as Analysis of Variance (ANOVA), Nonparametric Statistics, Time-Series Analysis, Multiple Linear Regression and Logistic Regression. In addition, the goal is to start distributing the application to a wider audience to gather feedback on future functionality as well as ways of optimizing the current suite of tools. As a result of these continued efforts, CougarStats will be presented to the educational community as the preeminent open-source statistical analysis tool in Statistics and Data Science courses. In conclusion, CougarStats represents a significant step towards empowering students in understanding and critically evaluating statistical results.

Abstract Name: Why the UK? Undergraduate Research Students Pursuing Graduate Studies Abroad

Students pursuing undergraduate research are high-achieving and academically advanced individuals who are excellent candidates for postgraduate study in the UK. So, why study in the UK? Throughout the presentation, research advisors and students will learn about the differences in the US vs. UK higher education system as well as graduate research opportunities at UK institutions. Additionally, attendees will gain an understanding of multiple funding opportunities for graduate studies, student life in the UK, and professional options after graduation from their program.

Abstract Name: Investigating the effect of biodegradable and non-biodegradable solvents on fabricating polylactic acid (PLA) membranes via nonsolvent induced phase separation (NIPS) for air filtration application

Global industrialization has led to declining air quality, resulting in an increased need for effective air purification solutions. For critical applications such as healthcare, high efficiency particulate air (HEPA) filters capable of capturing over 99% of particulate matter 0.3 μm or smaller (PM0.3) are recommended by the Centers for Disease Control and Prevention (CDC). While conventional HEPA filters are effective at trapping fine particulate matter, they have some limitations including decreased filtration efficiency over time due to charge depletion and non-biodegradability leading to environmental concerns. Recent studies have focused on developing biodegradable HEPA flat sheet polymeric membranes via electrospinning using polylactic acid (PLA), a biodegradable polymer. However, the solvents used in the fabrication process are usually toxic. In addition, membranes fabricated by electrospinning also have the limitation of compromised filtration efficiency post cleaning due to their reliance on electrostatic charges for high particle filtration efficiency of PM0.3. This study investigated the effect of substituting commonly used hazardous solvents, n-methylpyrrolidone (NMP) and dimethylacetamide (DMAc), with more sustainable alternatives, and ethyl acetate (ETAc), for fabricating biodegradable flat sheet PLA membranes via non-solvent induced phase separation (NIPS). All fabricated membranes showed high particle filtration for PM0.3 ($\geq$ 99%) which meets the performance criteria for HEPA filters. Fourier transform infrared spectroscopy (FTIR) showed similar surface chemical compositions for all fabricated membranes and pristine PLA, indicating an insignificant effect on the membranes' chemical compositions by the different solvents. Additionally, contact angle measurements showed that the membrane fabricated using ETAc was the most hydrophobic (125 ± 3o), an important feature for air filters which prevents colonization of microorganism due to water accumulation. The results of this study suggest that high-performing flat sheet PLA membranes can be fabricated via NIPS using more sustainable solvents without compromising performance and chemical properties.

Abstract Name: Reducing Chemotherapeutic Resistance in Leukemic Cells Exposed to Asparaginase by Limiting Glutamine Concentrations

Acute lymphoblastic leukemia (ALL) is a cancer with a 5-year survival rate of 85% when treated with chemotherapy. However, in patients who develop resistance to chemotherapy, the survival rate drops to approximately 20%. Asparaginase (ASNase) is a commonly used chemotherapeutic for patients with ALL. It functions by breaking down asparagine, an amino acid that is essential for cancer cell division, resulting in increased rates of cell death. Asparagine is typically present in an individual's diet, but it can also be synthesized by cells through the enzyme asparagine synthetase (ASNS) converting glutamine into asparagine. HL60 (acute myelogenous leukemia) and Jurkat (acute T-cell leukemia) lines were separated into six different treatment groups and exposed to various concentrations of asparaginase for 24 hours (0, 1, 5, 10, 20, and 50IU/mL). To test the influence of glutamine, an asparagine precursor, upon asparagine availability and subsequent ASNase efficacy, HL60 cells were maintained in media with various concentrations of glutamine (0, .2, .8, 2, 4, and 8mM). The cells with lower concentrations of glutamine had a fourfold increase in mortality when exposed to 10IU/mL ASNase (60% compared to 15%). These results suggest that glutamine concentrations modulate ASNase efficacy and therefore could be targeted to raise mortality in resistant cell lines. A protocol to induce chemotherapeutic resistance will be developed through increased ASNS upregulation and production, which other studies have shown is a significant indicator of resistance. In the resistant cells, new EC50s will be calculated with additional treatments (such as enzyme inhibitors) to reduce resistance and heighten mortality rates. These preliminary experiments provide the baseline for future investigation into ASNase resistance and suggest that glutamine concentration is an important factor in ASNase sensitivity in leukemic cells.

Abstract Name: Physical Acts and Perceived Romance Across Mixed- and Same-Gender Pairs

We examine whether physical acts differ in terms of perceived romantic intimacy depending on the gender of the couple. Gendered friendship intimacy expectations show that same-gender women friendships tend to be more physically intimate than same-gender men friendships (Monsour, 1992). We predict that this tendency combined with heterosexist bias (i.e. belief that heterosexuality is normal or superior) will lead to acts by women-women couples to be rated as less romantic compared to men-women and men-men couples. Participants (n = 225) will be recruited online and randomly assigned to one of three conditions where they will rate different physical acts (e.g., holding hands, kissing on the cheek) performed by two men, two women, or a man/woman in terms of how romantic, sexual and flirtatious they are. We hypothesize that physical acts between two women will be rated less romantic than acts done by two men or a man and woman. Future research will examine the effects of these assumptions, the reasons people have these assumptions, and how to alter them.

Abstract Name: The Sesame Street Project

Educators are always looking for ways of optimizing classroom learning, and themed classes have been slowly gaining popularity as an option. One barrier to incorporating themes (or testing their effectiveness) is the time and energy it takes to develop a themed course. The Thematic Instruction Consortium has developed 21 Sesame Street themed course modules (centered around psychology) in an effort to reduce this barrier. The use of Sesame Street was intentional as it covers a broad range of topics and has been shown to reduce the learning gap between low and high income children. This project focused on creating two additional modules- Depression and Anxiety and Substance Use Disorders. Each module is made up of articles, videos, and activities. Articles and videos related to the module topics were found primarily using Google Scholar and YouTube. Both modules separate articles into categories- risk/protective factors, attitudes, and treatment (the Substance Use Disorders module also has a 'family impact' category). Activities utilize articles and videos to help students better understand the topics. For example, an activity in the Substance Use Disorders Module has students watch two Sesame Street videos that discuss parental substance use, and then write a script of a possible conversation between an adult and a child whose parent(s) have substance use disorders. The project provided opportunities to build skills in article comprehension and creating course curriculum. Future steps include further research on the impact of themed classes on student learning and engagement, and developing additional modules.

Abstract Name: Identifying the Weather Misconceptions of USAF Academy Cadets: Implications for Curricular Reform

Misconceptions are inaccurate conceptual understandings rooted in students' thinking that deviate from the conceptions described by experts in a discipline. These misconceptions are born from a combination of folk "knowledge," personal misperceptions, family interactions, and teachers who are not scientifically literate themselves.Weather-related crashes continue to account for a considerable proportion of aircraft accidents. Due to the nature of their service, it is important for Air Force pilots to have as few meteorology misconceptions as possible and an enhanced weather literacy. Consequently, correcting weather misconceptions must begin at the cadet level in military postsecondary institutions.The purpose of this study was to use the Survey of Meteorology Concepts (SMC) to identify weather misconceptions among forty-one cadets enrolled in an Aviation Weather class at the US Air Force Academy. Psychometrics and cadets'

responses supported the SMC's validation. The research questions were (a) Which questions in the SMC are, statistically, the best suited to measure weather-related misconceptions among Air Force cadets? (b) What were the topics in which cadets showed limited content knowledge? and (c) What were the topics in which cadets showed significant misconceptions?Participants completed the SMC as a pre-survey in August 2023 and as a post-survey in December 2023. A second group will complete the SMC in the Spring 2024 semester. Preliminary data suggests that, on average, 40% of the questions were answered correctly, but half were guesses. Of the 60% of the questions answered incorrectly, about one-third of the cadets showed actual misconceptions. By far, two of the most common misconceptions were (a) that water vapor makes clouds, fog, and dew and (b) that 0° C is always the freezing/melting point of water, regardless of other atmospheric conditions.

Abstract Name: A Machine Learning Approach to Identify Impactful Research Areas in Near Future

There has been an immense number of papers published per year. Currently, it is difficult to sort through all published works to find the most impactful works. There have been various metrics defined to identify and quantify impactful research including Journal Impact Factor, h index, and even just the number of citations. However, each of these have drawbacks including the fact that they are all citation-based metrics. The goal of this study is to identify the relationship between a research paper's metrics and the potential impact it could have in the advancements of science/engineering. Once this is understood, it would greatly benefit both academia and industries. It would significantly optimize and reduce the time and resources needed to find the most innovative, impactful, and profitable research areas. Furthermore, it would allow effective allocation of time and resources towards the research areas that are more likely to be impactful.The proposed method utilizes a normalized citation-based metric compiled using publications of impactful researchers with significant breakthroughs. A multinomial model is implemented to analyze the relationship between a publication's impact and its numeric characteristics, such as the number of authors, citation count, and age. The relation is explored through the analysis of the model's coefficients, odds ratio, and p-values. Additionally, the study demonstrates the effectiveness of holdout validation in assessing the performance on unseen data, achieving a classification accuracy above 75%. The proposed method demonstrates that the process of identifying high-impact research could be automated using machine learning techniques, thus facilitating progression of society through utilization of the most impactful research.Our ongoing research is focused on extending the proposed method by implementing a deep learning algorithm, more specifically a graph neural network, to add a new analytical dimension and provide deeper insights to discover latent criteria for identifying impactful research.

Abstract Name: Characterization of Usutu Virus Replication, Immune Response, and Blood Brain Barrier Integrity in Vitro

Flaviviruses are a global health threat causing diseases varying from mild flu like symptoms to hemorrhagic diseases and severe neurological defects. These viruses are spread by ticks or mosquito bites. Usutu virus (USUV) is a flavivirus currently circulating in Europe and has the potential to enter the central nervous system in humans. Even though USUV rarely causes neuroinvasive disease, when it does, it can lead to encephalitis, meningitis, encephalomeningitis. There is very little understanding about USUV replication, neuropathogenesis and innate and adaptive immune response. The primary host of USUV are migratory black birds, humans, are an incidental dead-end host. The goal of this study is to characterize USUV replication from the peripheries through the central nervous system in vitro. We used primary cells derived from our in vivo mouse model C57BL/6, as well as human cells lines to evaluate viral replication kinetics and the proinflammatory immune response. Viral burden was measured through plaque assay. Immune response was evaluated through qRT-PCR as well as Luminex to observe transcriptional and translation changes following USUV infection. To further understand the events leading to neuroinvasion we implemented an in vitro blood brain barrier (BBB) model using human brain microvascular endothelial cells seeded on a fibronectin insert. We measured trans endothelial electrical resistance to detect any changes in BBB integrity. We also implemented qRT-PCR to detect any changes in tight-junction proteins. The data obtained from this study will help shed light on viral replication kinetics and immune response following USUV infection in vitro.

Abstract Name: Menstruation vs. Mental Health: Validating the Experiences of Adolescents with Periods

In adolescence, girls begin to navigate the effects of womanhood but are not informed on how to differentiate menstrual health from mental health to properly validate both experiences. The hormonal shifts that occur in women’s lives, transgender included, voice a need for psychological practice that acknowledges all factors that impact mental wellbeing, including intersectionality. Menstruation is easily dismissed when assessing possible mental health issues. Mental health refers to the broad set of diagnoses offered in psychological assessments; menstruation is not factored in as a potential indicator of these mental health issues. Established research in the field of psychology is limited in understanding these connections, lacking reliability between measurements and generalization to different age and cultural groups. This literature review seeks to compile the necessary research to understand the link between mental health issues and menstruation by examining the historical context, cultural variation, and depictions of menstrual health in media that can call for future research projects.

Abstract Name: Ahead of the Field: Biochemical Alternatives to Opium Poppy Farming

Natural opiates are refined from the flowering opium poppy plant Papaver somniferum, which is grown across several countries, primarily in South Asia. To keep up with the growing need for pharmaceutical opiates, the production of compounds such as morphine, codeine, heroin, and oxycodone have become increasingly difficult to control. Opium fields are difficult to secure, with natural factors such as droughts, blights, and irregular temperature endangering an entire year's supply of these highly effective painkillers. Current methods of opium poppy harvesting can lead to unknown concentrations of additives, impure APIs, and difficulty regulating the product as it is refined. One way to combat these issues is to find methods of opiate creation that do not involve poppy fields.Scientists have managed to develop a form of opiate synthesis that is viable for large-scale production utilizing yeast-based cloning. Research into opiate biosynthesis has been ongoing for over a decade after structural studies of opium alkaloids proved chemical synthesis unachievable due to the natural complexity of the molecular structure. The three-dimensional ring structure, constructed with an alkaloid known as tetrahydroisoquinoline, is technically feasible to clone in bacteria but requires four engineered pathways which make synthesis incredibly difficult to reproduce. Yeast cell biosynthesis operates with mechanisms much closer to the poppy plant that opiate alkaloids develop in, which allows for a single-step synthesis. This makes yeast cell cloning a more viable option than the traditionally cheaper bacterial cloning methods. Funding this biosynthesis process and shifting to a hybrid model of opiate production will allow for more control over production and a reduced demand on opiate farmers.
