Natural transformation (NT) is a form of horizontal gene transfer, in which extracellular DNA is taken up in chromosomes by induced bacterial competence and homologous recombination. For many marine bacteria, environmental chitin induces the expression of the tfox protein to begin natural transformation. Interestingly, little is known about the frequency or efficiency this occurs in environmental bacteria, particularly those affiliated with a eukaryotic host. In this project, we examined the response of tfoX transformation under several treatments using two different tfoX-Kan expression vectors: (1) solely tfoX and (2) tfoX plus CRISPRi repression of the DNS exonuclease gene. Specific combinations of natural and artificial environmental conditions, such as low media pH and artificial tfoX protein expression were used to induce NT of exogenously added fluorescently labeled extracellular DNA in Vibrio fischeri strains ES114 (from the Hawaiian bobtail squid Euprymna scolopes) and ETBB1-C from the Australian dumpling squid E.tasmanica. Lowered media pH, high levels of cell culture density, and the expression of tfoX/CRISPRi significantly increased the frequency or efficiency of NT in V. fischeri. Determining the mechanisms of natural transformation in the environment with respect to symbiosis provides insight as to whether beneficial associations and horizontal gene transfer are impacted by abiotic changes in the surrounding seawater.

Abstract Name: Financial Websites: Made for One Gender?

Only about 46% of employees in the finance sector are women; however, only 15% occupy executive roles (D'Souza et al 2021). There's a clear disconnect between women entering the industry, and the cause of this consists of several deep-rooted factors that deter women from this field. Obstacles ranging from inaccessible mentors and role models to gender expectations result in this industry being largely male-dominated. Another obstacle in the way may be financial websites that cater to males, leaving females to feel unwelcome, which is the focus of this study. Past research has shown that males and females have preferences when it comes to visual aesthetics, and therefore many articles have been published around the well-known topics of font, images, layout, and color preferences in several different fields. When importing these design preferences into a digital context, other design features come into play like symmetry, button placement, and logos. While existing research points out engaging patterns of websites, no articles describe the relationship between the design elements on financial websites and gender. Thus, this paper examines this research gap. Using a multi-method design including a content analysis, survey, and focus group, I find that financial websites use design elements (like San-serif fonts and blue shades of color) that cater to males. By adding masculine design elements, these websites do not create a good fit for females and leave them feeling unwelcome on the homepage.

Abstract Name: Probing Interactions Between A2AAR and CaM using Fluorescence Resonance Energy Transfer

G-protein-coupled receptors (GPCRs) are membrane proteins that regulate physiological processes from extracellular signals to cause an intracellular response. The A2A Adenosine Receptor (A2AAR) is a class A GPCR that has a role in many human diseases, including cardiovascular diseases, neurological disorders, and cancer. It has been proposed that Calmodulin (CaM), a calcium-binding protein, binds to A2AAR on the intracellular side, causing changes to the receptor structure that affect the interactions of downstream signaling processes. This project aims to determine how the interactions between CaM and A2AAR affect the activation of the receptor. To study the interactions between A2AAR and CaM, we use the Förster Resonance Energy Transfer (FRET) technique in combination with single-molecule microscopy. We purified both proteins, labeling A2AAR with a donor fluorophore, Alexa 555, and CaM with an acceptor fluorophore, Cy5. Upon excitation of the donor fluorophore, emissions should be transferred from the donor to the acceptor depending upon the molecular proximity between the two labeled proteins. The emissions from the donor and acceptor can then be used to calculate the FRET efficiency or the binding interactions between A2AAR and

CaM. Once evidence of binding is established, we can determine how the interactions of these proteins affect the activation of A2AAR.

Abstract Name: Optimizing Heart Failure Prediction Through AI Machine Learning

According to WHO, cardiovascular issues are the leading cause of death around the world, and in recent years, more people have been afflicted with heart issues, leading to many more cases of heart failure. However, it is hard to know what exactly led to a person's heart collapsing. We hypothesize that by incorporating AI/Machine Learning techniques, heart failure predictions can be made to improve healthcare by detecting a person's chances of heart failure earlier so that it can be prevented. In this work, data from Kaggle was used to develop machine learning models. The data includes 12 features: age, anemia, diabetes, ejection fraction, high blood pressure, platelets, sex, serum sodium, serum creatinine, smoking, follow-up period, and creatinine phosphokinase. 299 patients from several hospitals were analyzed, and the availability of the IBM platform made it possible to use multiple algorithms to develop predictive models. In this work, Random Forest Classifier, LGBM classifier, and XGB classifier with and without enhancements were employed. The accuracy of various models was found at high levels, all above 80 percent. In each algorithm, significant features' percentage contribution to model predictions were noted. For instance, time (100%) and platelets (76%) were identified to be features with the most correlation to the LGBM classifier. The significance of these features from the medical perspective is also included. Similar results from the other two algorithms were obtained with slight deviation. ROC curves, F1 score, and confusions matrices were obtained for a comparative discussion. A full discussion on machine learning results including methods to improve the accuracies will be included in the presentation. This model in future will be applied to a larger dataset from various sources to investigate the significance of applying machine learning to develop predictive models that can conduct early diagnosis to save patients lives.

Abstract Name: Artificial Intelligence in the Diagnosis and Prevention of Multi-Stage Colorectal Cancer: Potential Algorithmic Bias and Systematic Mitigation

In the United States, colorectal cancer (CRC) rates reported from 2015-2019 revealed that CRC was the 3rd most commonly diagnosed cancer among men and women and 2nd highest in terms of cancer-related deaths among men 50 years of age or younger. Artificial intelligence (AI), through the mode of machine learning (ML) models, is a novel approach for screening and diagnosis of CRC that requires further study to determine

its appropriate mode of application. This study implemented a meta-analytic review of: (1) the role of etiological factors in disproportionate incidence of CRC across racial lines in the United States population, (2) the use of race and ethnicity as predictors in CRC ML models, (3) the use of glandular segmentation and manipulation of prediction thresholds in CRC ML models, in order to understand the potential consequences of biases in artificial intelligence implementation in the United States. It was found that the Black and African American (BAA) population had a higher incidence of CRC due to etiological factors including higher rates of non-insulin dependent diabetes (NIDDM), obesity, smoking, and a limitation of resources. Such etiological factors negatively impacted ML models, where inconsistencies in data acquisition led to poor model performance for this population. Modifications to ML models in the form of the usage of race and ethnicity as predictors increased model viability. Glandular segmentation and manipulation of prediction thresholds of CRC histopathological or whole slide imaging (WSI) in region and subsite-specific identification allowed for more accurate diagnosis of CRC imaging among the BAA population, revealing that such modifications may improve diagnostic ML model outputs across racial lines. Further research should continue to explore the implementation of race-based prediction for ML models diagnosing for CRC due to its novel nature, demonstrated biases, and improvement given technical modifications.

Abstract Name: Minimally Invasive Deep Brain Stimulation through Temporal Interference

Past research has proposed that non-invasive treatments for neurological disorders can be developed by incorporating temporal interference deep brain stimulation (TI DBS). This method involves offsetting two high frequencies by a low frequency. High frequencies trigger minimal firing in the cortical layer, whereas stimulation in deeper tissue is triggered by the lower frequency at the overlapping point of the EM waves. An important preliminary step to achieving TI DBS is running experiments with a phantom model of the human brain. The phantom model consists of an 18 cm Petri dish that is filled with head tissue simulating liquid. Along with this, custom-designed patch antenna arrays generate electric fields, which are then measured at points throughout the phantom model. The initial tests concluded that the areas of overlap achieved higher focality and field strength with arrays of four antennas versus two. Additionally, the requirement for destructive interference was determined because the magnitude of the EM field coming from one array has a sufficient amount of strength in specific non-target areas to potentially cause stimulation.

Abstract Name: The Tragedy of Chapecoense

In 2016, the soccer club of Chapecoense F.C was participating in the South American soccer tournament named “Copa Sudamericana” one of the most prestigious international tournaments of the continent. Chapecoense is a soccer club founded in 1973 in the city of Chapecó, Brazil. Chapecoense was considered a “little” team due their economic situation and because most of their time existing as a soccer club they played in the 3rd and 4th categories of Brazilian soccer. In 2015 they were admitted into the Copa Sudamericana of 2016. Against all odds, Chapecoense made their way through the cup defeating international champions and making it into the final round of the tournament against Atletico Nacional from Colombia. In order to attend the first game of the final, the team took a flight from Brazil to Bolivia and from Bolivia to Colombia. The plane which transported the team ran out of fuel 10 miles away from the airport crashing against a little hill killing 71 out 77 people who were on board. The world of soccer put aside their differences and joined together paying tribute to the small team with big dreams who gained the hearts of all soccer fans. Atletico Nacional requested CONMEBOL, the organizers of the championship, to name Chapecoense as the winners of the tournament. The organizers unanimously agreed to declare them the winners. The legacy and memory of Chapecoense is still alive in South American soccer and this event reminds us that no matter our skin color, team loyalty, nationality, or language, we all have the potential to speak the language of love and empathy.

Abstract Name: Creating and Analyzing Dietary Baseline Data to Measure Nutritional Adequacy of Indian Household Contacts of Diagnosed Tuberculosis Patients

Tuberculosis (TB) is a severe bacteria-caused illness with India contributing to nearly a quarter of the prevalence. Although malnutrition has been shown to impact diagnosed TB, there is a lack of research on the diets of TB-exposed adults. The Tuberculosis: Learning the Impact of Nutrition study investigates nutritional supplementation and parasitic infections' effects on TB immune response among household contacts (HHCs) of TB cases in Tamil Nadu, India. We created and analyzed a dataset with "baseline recalls," (dietary intake surveys of the last 24 hours) conducted before intervention from January, 2019, to October, 2023 where 153 HHCs completed at least 2 recalls. Food groups based on the Minimum Dietary Diversity for Women (MDD-W), an international indicator of dietary diversity, were created using SAS and Excel and compared to recommended dietary intake (RDI) levels in India. We analyzed macronutrient intake, and zinc, iron, calcium, vitamin A, vitamin D and vitamin E as some micronutrients essential to the immune system. Our analysis found, on average, the MDD-W food group “Grains, Roots and Tubers” contributed the majority of kilocalories to participant dietary recalls. This food group features foods such as most breads and potatoes. Vitamin A rich fruits and vegetables, such as mangos, contributed the least kilocalories. All micronutrients were on average under-consumed compared to the RDI and vitamin E was the most ingested vitamin at 2.16 milligrams with vitamin A the least at 189.03 micrograms. We found adult HHCs of TB patients are deficient in several key nutrients while meeting caloric expectations through consuming a disproportionate amount of the Grains, Roots and Tubers food group among all MDD-W food groups. As this longitudinal study continues, the data from this study will enable us to assess how diets of participants in 4 enrollment groups change as recalls with supplementation are completed.

Abstract Name: Companies Financial Risk Predictions using Multiple Machine Learning Algorithms

The information on financial risks associated with companies is vital for their survival and is equally required for investors who are trying to maximize their financial gains by investing in these companies. The enormous amount of financial risk data accessible by the public, needs AI/machine learning techniques to develop predictive models that can be used for future assessments. In this work, IBM machine learning Cloud-based platform called IBM Watson was employed to develop algorithm-based predictive models by incorporating data from Kaggle, an open source available for AI/machine learning-based analysis. The algorithms used were the LGBM Classifier and Snap Boosting Machine Classifier with and without enhancements. The LGBM classifier with HPO-1, FE, and HPO-2 appeared as the best model with a prediction accuracy of about 85% with a processing time as small as 21 seconds. Our model accuracies varied between 82 to 85% for all possible combinations of enhancements for both classifiers. In all cases, the ROC curve with a larger area under its graph is seen as having a higher true positive to false positive ratio. The features that played a significant role in making predictions include, but are not limited to, external audit scores, the Fin scores, and internal audit scores. Overall, a higher score on all of the factors resulted in a lower probability of financial risk and may help prevent future risks. Surprisingly, the factor “past results” appeared to be negligible as it did not affect the predictions of our models. In the proposed presentation, a detailed discussion on the confusion matrix and the overall summary based on two algorithms will be included. Statistical analysis of the data will be presented and the overall findings especially the model accuracies and the identified significant features will be compared with the research available in the current literature.

Abstract Name: College Students’ Perceptions of Sexual Consent

Sexual assault is oftentimes justified as a miscommunication, typically entailing a man's over-interpretation of a woman’s sexual interests. Despite a plethora of research having debunked this myth, the miscommunication hypothesis continues to be applied in the court of law and lingers among the public, perpetrators and victims themselves. The “miscommunication” label imposes a level of victim responsibility and is more frequently used to excuse sexual assault that falls outside of the stereotypical rape script (i.e., violent assault committed by a stranger, in a secluded area). Considering that college students are most vulnerable to sexual assault victimization perpetrated by an acquaintance; they are more likely to assume victim responsibility for inadequately communicating sexual interest. The current study tests the validity of the miscommunication hypothesis by analyzing how college students conceptualize and apply sexual consent in hypothetical sexual scenarios. Data was collected from a sample of 200 undergraduate students taking PSY 100 at the California State University of Long Beach. Participants read through 13 sexual vignettes differentiating in communication modality, consent cues and type of consent (consent, acquiescence and non-consent). Findings revealed that students were most likely to correctly identify non-consent (98.75%)

followed by consent (89%). Acquiescence was least likely to be correctly identified as consent (8.13%) and most likely to be conflated with non-consent (67%). These findings suggest that, for the most part, college students do have a comprehensive and accurate understanding of consent. Interestingly, acquiescence, the act of giving in to consent, may not be considered an acceptable form of consent amongst college students. Acquiescence typically involves consensual but unwanted sexual activity and therefore may elicit similar trauma responses to sexual assault. Researchers should examine the impact of unwanted sexual activity among consenting versus non-consenting individuals and consider developing a more inclusive label to validate all unwanted sexual experiences.

Abstract Name: Monitoring Metabolic Correlation in the Gut-Brain Axis During Ulcerative Colitis with Raman Spectroscopy and Metabolomics

Ulcerative colitis is a chronic disease in which abnormal reactions of the immune system cause inflammation and ulcers on the inner lining of your large intestine. The study aims to explore the complex relationship between the gut and the brain through metabolomic analysis using Raman Spectroscopy. Raman Spectroscopy is highlighted as a fast non-invasive diagnostic tool for detecting and identifying metabolites in both control and DSS-induced groups. The gut, often referred to as the "Second brain," is noted for its significant correlation with the brain, indicating disruptions in gut homeostasis may impact brain metabolites. The primary objective is to identify metabolites and pathways involved in gut-brain communication in colitis-induced mice. Colitis is induced in C57BL/6 mice by mixing dextran sulfate sodium (DSS) in their drinking water. Comprehensive Raman Spectroscopy scans are conducted on serum, brain, and caecum samples from both colitis-induced and healthy (control) groups. Peak identification in Raman spectra is performed to detect key metabolites related to the gut-brain axis and colitis. The study addresses a gap in knowledge by elucidating the correlation between colitis-induced disruptions in the gut and changes in brain metabolites. Previous studies have suggested a connection between gut and brain health during disease states, but the specific relationship with colitis-induced disruptions remains insufficiently explored. These experiments that are being conducted in murine models can be used as a reference to get a better understanding of the gut-brain axis in humans during colitis. By validating the hypothesis that colitis induces changes in the brain activity of mice, the study offers insights for potential extrapolation to the human context. In summary, the research contributes valuable insights into the intricate interplay between gut and brain function, which has been studied by taking multiple Raman scans of the serum, brain, and caecum samples providing implications for human health.

Abstract Name: Remote Network Effects of Post-Traumatic Lesions and Risk of Post-Traumatic Epilepsy

Title: Remote Network Effects of Post-Traumatic Lesions and Risk of Post-Traumatic Epilepsy Shivek Narang, Carly Zhao, Meghana Vasireddy, Ipek Obek, Alfredo Lucas, James J Gugger Department of Neurology, University of Pennsylvania, Philadelphia, PA Objective To assess epilepsy risk in a cohort of patients with post-traumatic contusions identified on MRI two-weeks post-injury using functional MRI to map the remote network effects of lesions. Background Traumatic brain injury (TBI) is one of the leading causes of acquired epilepsy. Neuroimaging acquired after neurotrauma and prior to the onset of seizures may be used to develop predictive models of epilepsy risk. Prior studies offer mixed results on post-traumatic lesion localization and epilepsy risk; however, no study has evaluated the effect of post-traumatic lesions on remote neural networks on post-traumatic epilepsy risk. Design/Methods We performed manual lesion (contusion) segmentation on two-week post-injury MRI of participants enrolled in phase one of the Transforming Research and Clinical Knowledge in TBI (TRACK-TBI) study. Lesion core and edema were segmented using coregistered T1 and FLAIR contrasts. Each participant's T1 image and lesion masks were then normalized to standard space where the lesion will be used as a seed in a seed-based connectivity analysis. For this analysis, we will use normative functional connectomes from the Human Connectome Project and compare lesion network maps of participants who later develop seizures to those with TBI who do not develop seizures. Group analysis will be carried out using the generalized linear model and threshold free cluster enhancement as implemented in FSL. Results: Of 606 TBI participants enrolled in phase one of TRACK-TBI, we identified 100 with at least one contusion identified on two-week post-injury MRI. Average core lesion volume was 2.2 mL and average edema volume was 128 mLs. Further results of the connectivity analyses are forthcoming

Abstract Name: Intergenerational Effects of Mental Health Stigma in Latinx College Students: An Exploration of Familial Influence

It is well known that mental health difficulties in minority communities, including the Latino community, are quite prevalent. However, research has demonstrated that few seek the mental health assistance they need. Latinos overall have lower regard for mental health services. For those that do use mental health services, families are usually viewed as the "gatekeepers" to seeking professional help, since their opinions and suggestions are a big influence on the chances that students seek help. The main purpose for this research project is to find out whether family's perceptions of mental health and treatment influences Latino students' regard for mental health and the stigma that exists in the community. This study will also find out if gender plays a role in college students' approach to mental health and help seeking behaviors. The number of participants for this study will be about 65-70 undergraduate college students that come from a Latinx background. This study will utilize a mixed methods approach, using the Familial Perspective Questionnaire and Demographics Questionnaire to obtain qualitative information from participants about their family of origin's behavior regarding mental health, while the Stigma Consciousness Scale and the Mental Health Seeking Attitudes Scale will be used to obtain quantitative assessments. Although this study has not yet been conducted and the data collection process is currently in progress, findings will likely show that Latinx college students' perception of mental health, mental health related stigmas, and help seeking behaviors will be heavily influenced by their family of origin's perceptions.

Abstract Name: Student Self Assessment of Clinical Judgement Model Through Simulation

Clinical judgment is the cognitive framework that encompasses critical thinking, decision making, and knowledge application, making it an essential domain of nursing, Lassiter (2007). Lasater's Clinical Judgment Rubric (LCJR) (2007) is a tool used by faculty for measuring students' clinical judgment and for creating educational interventions, in order to teach this vital skill. Evidence shows new nurses lack clinical judgment and the ability to effectively prioritize cases in the clinical setting, Kavanagh (2017). A new simulation educational experience was developed for undergraduate nursing students that taught clinical judgment in accordance with AACN Essentials (2021) and NCSBN Clinical Judgement Measurement Model (2019). An obstetric simulation experience was developed, in order to teach clinical judgment using INACSL 2016 guidelines. Based on the Lasater Clinical Judgment Rubric (2007), we developed a self-assessment tool to measure clinical judgment among students participating in the project. The simulation experience was tested for efficacy and effectiveness in improving clinical judgment competency among undergraduate nursing students in their obstetric course. T-tests were used for analysis. The project is designed to evaluate the efficacy of a specific educational intervention by using simulation as an evidence-based teaching method to develop competency in clinical judgment skills. This pilot study has a convenience sample of junior level students in one school of nursing located in the northeastern region of the U.S. and the results may not be generalizable. The goal of this simulation experience is to improve the development of clinical judgment skills among undergraduate obstetric nursing students and to provide educators with an evidence-based educational tool that ensures graduate nursing students have competent clinical judgment skills and are able to implement them through nursing care.

Abstract Name: Matrix Mechanics Dictate Odontoblast Responsiveness to Photobiomodulation Treatments

Objectives: Regenerative dentistry promotes the directed differentiation of stem cells. While the predominant focus of these efforts has been genetic manipulations, the critical epigenetic role of extracellular matrix (ECM) mechanics has been poorly investigated. This project aims to dissect the cellular responses of odontoblasts to matrix mechanics by replicating a wound-like environment. Methods: Polydimethylsiloxane (SYLGARD 184) matrices, composed of a 10:1 ratio (base: curing agent) were poured into 12-well polystyrene plates. Mechanical stiffness was then assessed using a Shore A Durometer (Insize). Following

sterilization with 70% ethanol, UV treatments, and serum coating, odontoblasts (MDPC-23) were seeded (100,000 cells/well) in hypoxic (1µg/mL CoCl2 + DMEM 10% FBS) and serum-deficient (0.2% FBS DMEM) to simulate wound-like environment. Alamar blue assay was performed at 24 hours to assess cell viability, and fluorescence was assessed with a Spectrophotometer (i3Max, Molecular Devices). An adhesion assay was performed to observe cell-substrate interaction 5 hours after cell seeding. Signaling pathways for TGF- β1 and FAK were investigated using small molecule inhibitors and recombinant protein. Results: The shore stiffness assessment noted the ratio 10:1 had a stiffness of 1.14 ± 1.65 MPa, 2:1 of 1.16 ± 0.48 MPa, and 40:1 of 0.57 ± 0.27 MPa. These stiffnesses were significantly (n = 3, p < 0.05) lower compared to the polystyrene culture dish control of 5.41 ± 0.96 MPa. Statistically significant changes were observed in cell proliferation with varying matrix stiffness. TGF-β1 and FAK1 signaling was noted to modulate these responses. Ongoing studies are examining the role of PBM activation of these discrete pathways in mediating odontoblast adhesion and survival. Further, direct activation of these molecular pathways is being assessed with Western Blotting for pSmad2/3, pFAK, pAKT, and pPI3K.

Abstract Name: How has the rise of African women artists impacted gender complementarity and depictions of the Black female form in West African art?

The West African art canon remains largely overshadowed by its European/American counterpart, despite being lush with centuries' worth of cross-cultural contact and ethnolinguistic diversity. My project seeks to illuminate the rich history of art in this region, emphasizing depictions of the Black female form, which remains a popular subject of art in West Africa. Drawing from anthropological resources and ethnographic case studies, I intend to analyze artistic representations of African women in both historical and contemporary contexts. Portrayals of the Black female form will be compared between colonial and indigenous artworks, with the latter divided between male and female artists. African men traditionally portray Black women in a more celebratory fashion than 19th century Europeans and Americans, who viewed Black womanhood through an anthropometric lens. But there are distinct differences in how African women portray themselves. This is reflected in the genderization of specific mediums such as sculpture and pottery (Thompson, 2008). This project will argue that the rising prominence of African women artists, particularly in male-dominated fields, disrupts gender complementarity in West African art, and grants women greater personal autonomy. This is supported by the fact that, after achieving economic independence in the mid-1970s to 1980s, African women began pursuing art full-time, and explored controversial topics such as female submission, the male gaze, war, and rape (Fall, 2007). Although monumental, this is not the first instance of female self-representation in African art. Through a synthesis of art-based research, I aim to uncover how this burgeoning feminist movement is rooted in historical examples of women-centered art, such as Bambara pottery and the Mende Sowo masquerade. My current research focuses mainly on Ghana, Nigeria, and Sierra Leone, but will be juxtaposed with literature surrounding women artists from elsewhere in Africa.

Abstract Name: Relationship Between Financial Stress and Loneliness

As discussed in Elbogen et al. (2021), financial stress is negatively linked to loneliness. The relationship between loneliness and financial stress has grown in recent years, specifically after the Covid-19 pandemic, and has been a contributing factor to suicidal ideation (Stevenson & Stevenson, 2021). As further research demonstrates, financial stress has negative consequences on one's mental and physical health and can contribute to the feelings of loneliness (Refaeli & Achdut, 2021). Understanding the relationship between these factors is important because both can impair an individual's life through things such as; their physical health, an increase in depression, energy levels, self-esteem, and sleep issues. Not much research has been conducted on these factors outside their relationship to Covid-19. The purpose of this study is to determine how loneliness and financial stress relate to one another. In the current study we hypothesize that loneliness and financial stress have a negative relationship. The data is being collected from participants across the United States. The Financial Worry and Rumination Questionnaire (de Bruijn & Antonides, 2020) was used to measure financial stress and includes four subscales: financial rumination-related emotions, financial rumination-related cognitions, financial worry-related emotions, and financial worry-related cognitions. The Loneliness Deprivation Scale (de Jong-Gierveld, 1987) was used to measure loneliness, consisting of three subscales: longing for a very close friend or confidant, emptiness feelings, and feelings of abandonment. Multiple regression analyses will be performed to investigate what aspects of financial stress impact loneliness. Some factors such as type of job and gender will be included in this analysis. Findings will be presented in terms of practical implications these relationships could have on an individual. Findings from this research will be important for individuals experiencing financial distress to understand how it impacts other important aspects of their life.

Abstract Name: Unlocking Success: Examination of Relationship Between Mindset and Academic Success

The purpose of the study was to examine the relationships among growth mindset and various outcomes in college, including grit, psychological hardiness, overall college grade point average, perception of success in college, and perception of success in general. The research delves into how these mindsets influence academic performance, shedding light on the protective mechanisms characteristic of the fixed mindset, such as self-handicapping. This avoidance of challenges proves detrimental, hindering the ability to learn from mistakes and obstructing the realization of goals.Five hypotheses were posed. First it was expected that a growth mindset is positively related to grit. Second, it was expected that a growth mindset is positively related to psychological hardiness. Third, it was expected that the growth mindset is positively related to the overall college grade point average, students perception of success in college, and students perception of success in general. Eighteen college students from southern California completed an online study that took 20 minutes to complete. Results showed support for two hypotheses only- that is, there were strong positive relationships among growth mindset and grit, and growth mindset and college grade point average. These findings underscore the advantages of nurturing a growth mindset, advocating for resilience, persistence, and

academic triumph. However, the study acknowledges limitations tied to its location-specific context and reliance on self-report measures. In conclusion, this research accentuates the transformative capacity of a growth mindset, not only in the realm of academics but also in fostering resilience and a commitment to lifelong learning.

Abstract Name: Optimizing NO and Sirolimus-Releasing Drug Coated Balloons

Cardiovascular disease is the leading cause of death worldwide. In femoropopliteal peripheral artery disease (PAD), balloon angioplasty is the most common medical intervention. In medical practice, balloon angioplasty is conducted with uncoated balloons or drug-coated balloons (DCB). Uncoated balloons frequently lead to restenosis and neointimal hyperplasia. Paclitaxel, the clinical standard for DCB, faces efficacy concerns because of the possible increased risk of death. Therefore, sirolimus has been explored as a replacement drug for its effectiveness in drug-eluting stents and overall safety compared to paclitaxel. However, while Sirolimus may suppress neointimal hyperplasia, it damages the endothelium, possibly leading to late restenosis. We propose the dual-action DCB coating with sustained release of liposome-encapsulated sirolimus to prevent neointimal hyperplasia and sustained release of NO from the bionanomatrix to promote re-endothelialization. This study aims to optimize the DCB to improve drug transfer and retention of the drugs in the artery walls. Our preliminary study aimed to measure the transfer of NO-releasing bionanomatrix and sirolimus by deploying the balloon within an agarose gel vessel mimicking model to model an actual balloon angioplasty. The bionanomatrix was conjugated with IR dye to allow for quantification. Our preliminary transfer study indicates ~30% of the bionanomatrix can be transferred to the vessel walls. Future studies will include IR-dye conjugated bionanomatrix along with fluorescently labeled sirolimus encapsulated into liposomes coated onto balloons and transferred into pig coronary arteries. Then the arteries will be mounted into a bioreactor system subjected to physiological flow conditions for up to 14 days. These studies will be critical to assess drug transfer and retention in the artery wall over time. Our dual-action DCB shows promising drug transfer to artery walls. With more aggressive in-vivo study, this novel dual-action DCB coating can significantly better cardiac patient outcomes.

Abstract Name: Utilizing ArcGIS StoryMaps for the Representation of Honor Trees Across Signal Mountain

The research project embarked on a collaboration with Dr. Boyd and the Signal Mountain Tree Board to delve into the exploration and documentation of honor trees using ArcGIS StoryMaps. These honor trees serve as a way for Signal Mountain residents to commemorate or cherish individuals by acquiring native trees, subsequently planted in designated areas on Signal Mountain. The project unfolded through a series of planned steps, starting with engaging with the Signal Mountain Tree Board to assess the existing information within the organization. Upon gathering information, we delved into the fieldwork phase, where we systematically gathered data points. This encompassed employing GPS technology to pinpoint precise locations, assessing the overall health of the trees, and considering various factors contributing to the vitality of these honor trees. The collection of this data laid the groundwork for a comprehensive understanding of the trees but also formed the basis for future analyses and interpretations. With the data in hand, the project transitioned into digital storytelling using the ArcGIS StoryMaps platform. The StoryMap served a dual purpose – not only as a promotional website for the honor tree program but also as an informative resource for Signal Mountain residents, potential donors seeking to contribute, current donors wanting to check on their tree(s), as well as furthering the legacy of Signal Mountain's Tree City USA status. In essence, this research project transcended the conventional boundaries of tree documentation by weaving together technological innovation, community engagement, and environmental stewardship.

Abstract Name: Investigating the Importance of LXR Activation in C1q Modulation of Macrophage Foam Cell Responses

C1q (complement component 1q) is an innate immune protein that plays a protective role in early atherosclerosis by enhancing removal and reducing the accumulation of cholesterol in macrophages. This leads to increased macrophage foam cell survival. Cholesterol metabolism and survival are often linked with the activation of the liver X receptor (LXR) pathway in macrophages. The LXR is a nuclear hormone receptor that is divided into two isoforms, a and b, which respond to oxysterol ligands. Studies suggest that oxysterols and a few cholesterol synthesis intermediates are important bioactive metabolites in activating LXR, regulating efflux, and maintaining cholesterol homeostasis. We have previously shown that C1q increases certain oxysterols in macrophages under conditions of high cholesterol. This project aims to investigate whether LXR activation is important in the C1q-mediated macrophage protective responses in atherosclerosis such as increased foam cell survival and decreased inflammatory responses. We hypothesize that macrophages with knocked-down LXR will no longer show increased survival in the presence of C1q. For our methods, LXR a and b mRNA were knocked down in THP-1 macrophages via transfection with siRNA. The efficiency of knockdown was investigated by QPCR. Our preliminary results showed that 48 hours after transfection we were able to reduce expression of LXRa by 86%, and LXRb by 21%. Now that methods for LXR knockdown are optimized, we will investigate the importance of the LXR receptor in C1q-mediated macrophage survival and inflammatory responses. Understanding the mechanisms involved in macrophage cholesterol metabolism may be important in identifying novel therapies for atherosclerosis.

Abstract Name: Quantification of Water-Soluble Polyphenols in Citrus Fruit Peels

Carefully designed experiments were performed to measure the amount of polyphenols present in citrus fruit peels. Citrus fruits are renowned for their vibrant colors, enticing aromas, and substantial vitamin C and polyphenol content. Previous scientific investigations have primarily emphasized the role of vitamin C in mitigating oxidative stress, often surpassing the significance of polyphenols, particularly flavonoids. Our research aimed to address this gap by quantifying the water-soluble polyphenols in various citrus fruit peels. Utilizing the Folin-Ciocalteu assay, the concentration of the polyphenols was measured, expressing the results in terms of an epicatechin equivalent reference scale. The experimental findings indicated a substantial presence of water-soluble polyphenols in the peels of different citrus fruits. This underscores the potential of citrus peels as a valuable source of antioxidants, which are crucial in neutralizing reactive oxygen species (ROS) and enhancing the body's natural antioxidative defenses. The study highlighted the nutritional value of often discarded citrus peels and contributed to a broader understanding of the health benefits of citrus fruits beyond their vitamin C content.

Abstract Name: A Scoping Review of Perceptions of Higher Education Personnel on Prevention and Response to Sexual Violence at University Campuses

Sexual violence is defined as any type of unwanted sexual contact or behavior that happens without the explicit and informed consent of the victim. Many students are being impacted by this problem, especially female first-year college students and LGBT students. While many efforts exist with students to address sexual violence, less is known about how the perceptions and behaviors of campus administrators and personnel influence the campus climate and sexual violence. A scoping review was conducted to answer the question, “What is the current state of research pertaining to campus sexual violence from the perspective of campus personnel, with an emphasis on those in administrative leadership positions?" A team of three undergraduate students, a research librarian, and a faculty member collaborated to design the study protocol following PRISMA-ScR guidelines. Three undergraduates reviewed 1853 publications for inclusion using the RAYYAN program, read included articles, and pulled key themes for the review from 27 peer-reviewed journal articles. The scoping review found that most research focuses on reporting and intervention, with less emphasis on prevention. Themes indicate that personnel are generally aware of sexual violence as a problem and recognize broad reporting requirements but lack an in-depth understanding of procedures and protocols. Essential actions include clearer policies, enhanced training for staff and students, and further research on the

topic. The issue of sexual assault should be taken seriously by the leadership teams in all higher education institutions, with clear actions taken for prevention and intervention.

Abstract Name: Comparisons of Performance and Efficiency of Biodiesel and No. 2 Diesel in a 4.5L Diesel Engine

This study seeks to evaluate the comparative efficiency between standard diesel and biodiesel fuel. The investigation focuses on the impact of these fuels on parameters such as cylinder mean effective pressure, brake-specific fuel consumption (BSFC), and energy release rate, with the goal of discerning any significant disparities between the two fuel types. This work contributes to the research on alternative fuels and biodiesel engine efficiency domain, and the effect of biofuels on rate of energy release, combustion characteristics and thermal efficiency. The research will provide information to improve engine efficiency and manage emissions. The study integrates findings from various sources, offering a comprehensive grasp of biodiesel's potential as a sustainable alternative. Specifically, it explores how fuel blends influence pressure, energy, and temperature dynamics. This research provides information to optimize biodiesel engine performance and increase the adoption of alternative renewable fuels. The fuel properties will be determined utilizing ASTM D975 Standard Test Procedures, of essential fuel parameters such as flash point, heating value, and cloud point. After the engine has reached standard operating conditions, the engine will be tested at different speeds and load torques. The following measurements will be recorded: internal cylinder pressures, fuel consumption rates, engine torque, and speed, intake air pressure and temperatures, turbocharged boost pressure and temperature, and crank angle using a rotary encoder (720 pulses per revolution). The combination of measured pressures and crank angle facilitates the determination of the heat release rate. Anticipated results indicate a difference in the energy release rate, with the ensuing analysis focusing on the effects of the fuels on BSFC and Brake Thermal Efficiency. The expectation is that biofuels may contribute to an increase in BSFC. The discussion surrounding these outcomes aims to deepen our understanding of biodiesel engine performance's intricate dynamics, guiding future advancements in this critical area.

Abstract Name: A New Look at the "October Surprise"

There has long been discussion over the validity of the 1980 "October Surprise" allegations, namely that Ronald Reagan’s campaign made a deal with the new radical Iranian government to hold fifty-two American hostages until after the presidential election, securing Reagan’s landslide victory as well as having the hostages released within minutes of his inauguration to increase his popular support. After a congressional

hearing on the matter after the publishing of Gary Sick's October Surprise found the theory to be without basis, most mainstream institutions and journalists rejected the theory and moved on. Now over forty years later, Mr. Ben Barnes has claimed in the press that he as well as his mentor John B. Connally Jr. traveled to the Middle East in order to deliver the message to the Iranians; do not release the hostages and the Republicans will give you a better deal. This new testimony from a highly respected and reliable source coupled with the decades of investigative journalism in and around the October Surprise forces even the most skeptical among us to reexamine the claims and evidence surrounding that fall in 1980. Taking into account the testimony of several figures who claim knowledge of the October Surprise, not all of whom can be trusted, the highly unusual series of events leading up to the election, and the known conspiracy of Iran-Contra along with other past transgressions by the Republican party, and the realities of the political situation within Washington at the time, the possibility, if not the certainty, of the October Surprise will become apparent.

Abstract Name: Healing and Indigenous Ecofeminism in Solar Storms by Linda Hogan

This paper examines the intertwining of Indigenous feminist and ecological themes in Linda Hogan's 1997 novel, Solar Storms. Hogan crafts a narrative that revolves around the displacement and exploitation of indigenous lands and peoples. The story follows Angela Johnson, a young Native American woman, as she returns from white foster families to her grandmothers and birthplace on a journey of self-discovery and introspection with her ecological and cultural roots. Hogan weaves the themes of reconnection and reclamation to illuminate the deeply rooted intimate relations between women and the natural world. Analyzing Solar Storms from an Indigenous ecofeminist perspective allows us to uncover the connectivity that binds the contemporary and historical subjugation of both women and the environment. Indigenous ecofeminism is an intersectional theory that recognizes the kinship and intricate relationships between indigenous women and their land. Hogan explores how displacement, stemming from settler colonialism, alienates Indigenous communities and individuals from their lands and cultural traditions. The novel continues to develop this idea as it unravels Angela's alienated, complex relationship with her mother, grandmothers, and her Indigenous culture and community. This paper seeks to show how Angela's search for her roots and fight for her future mirrors the broader themes of ecofeminism from an Indigenous perspective. In my analysis, I delve into the profound ongoing impact of entangled setter colonial violence against the natural world and indigenous peoples, whose trauma is both physical and psychological. Angela's journey in Solar Storms encompasses not only the healing of the environment but also the healing of individuals, families, and communities through Native American traditional ecological wisdom that intervenes in the prevailing environmental degradation. This paper seeks to demonstrate how Solar Storms uses indigenous experiences and wisdom to underscore the inseparable connection between women and the environment.

Abstract Name: Assessing the Prevalence of Key Risk Factors Impacting Bone Health in Adult Population in the UAE

Osteoporosis, a condition characterized by decreased bone mass is a global health concern affecting more than 200 million individuals worldwide. This chronic bone disease, often called silent disease leads to fractures, particularly in individuals aged 50 and above. This study aims to evaluate the prevalence of certain risk factors for osteoporosis among the adult population in the UAE and analyze these factors based on sociodemographic characteristics. A cross-sectional study was conducted involving 214 participants from the UAE using snowball sampling for data collection. The survey was administered online, and information was collected on sociodemographic factors, anthropometric measurements, medical history, medication use, lifestyle choices, physical activity, dairy consumption, and exposure to sunlight. Based on calculated scores the levels of osteoporosis risk were categorized as low, medium, or high. Statistical analyses were performed

using Chi-Square on IBM SPSS version 29 software. Most participants fell into the medium-risk category (77.8%) while 22.2% were classified as high risk with a higher proportion being females in the high-risk category. Females also demonstrated vulnerability to risk factors such as back pain incidence and lifestyle decisions. Associations were observed between gender, age groups, marital status, education level, and income with specific risk factors. Older age groups exhibited higher rates of tobacco use, alcohol consumption and increased body mass index (BMI). The research highlights the importance of tailored interventions considering sociodemographic variations. Public health campaigns focusing on lifestyle modifications, especially in older age groups, are crucial to mitigate osteoporosis risk.

Abstract Name: Exploring the Relationship between Migraines, Blood-flow, and Oculomotor Dysfunction

BACKGROUND: Migraines are a neurovascular disorder that causes extreme headaches, autonomic nervous system dysfunction, and sometimes aura. The purpose of this study is to assess how migraines, with and without visual aura, affect blood flow in the brain as well as oculomotor controls. METHODS: Healthy Participants (H, N=13), migraines without aura (MO, n=14), and migraines with auras (MA, n=13) (completed two trials of oculomotor tests while simultaneously recording oxyhemoglobin and deoxyhemoglobin levels through an fNIRS system. The fNIRS data was filtered with a lowpass filter of 0.1 and obtained through Oxysoft. Visual motor control, including horizontal, vertical, and circular smooth pursuit, was assessed with a RightEye system. An univariate analysis (p<.05) was conducted to examine differences between groups for both fNIR and eye data. RESULTS: There were no significant findings in the frontal lobes between groups. However, the right and left temporal lobes showed a significant difference in total hemoglobin (mg/dL) between the H and the MA group (p = .0045,). There was no difference between the MO and MA groups in the temporal lobes. Significant difference in efficiency error (≥7 mm off from the target location) in both the vertical and circular smooth pursuit between the H and MA groups (p = 0.034; p = 0.012, respectively).CONCLUSIONS: People who suffer from migraines with aura presented decreased efficiency in 2 out of the 5 oculomotor tasks when compared to a healthy group as well, and a group of migraine suffers with no aura. Additionally, the MA group presented decreased blood flow in the temporal regions of the brain when compared to the other groups.

Abstract Name: Buckling Behavior of Thin Cylindrical Shells Under Uniaxial Compression

Hollow cylindrical structures are prevalent and critical in industries like aeronautics, space, automotive, defense, and more. The capacity for cylinders to withstand compression is a major point of interest, as in practice, they are observed to buckle under lower stress than theoretically predicted. However, when a thin-walled cylinder is wrapped around a rigid core and vertically compressed, it buckles into a regular pattern of closed-packed diamonds determined by geometrical parameters of the system. This study focuses on the formation of the bucking pattern. We aim to understand the process by which buckles are locally formed, with particular focus on how repeated compressions impact buckling behavior, and to what extent these patterns are reproducible. Through the simultaneous measurement of resistive force, buckling sound, and video capture of the buckling shell, our analysis reveals that although different shells display a unique force response, a shell with a known force response will closely reproduce the same buckling steps on repeat trials. Notably, we find that the first compression of different shells produces drastically different force distributions, while 10 compressions of the same shell yield roughly the same force distributions. Although less definitive, audio traces also appear to demonstrate replicability between repeat compressions, implying buckling memory.

Abstract Name: Predicting Income Based on Health-Related Variables

Understanding the intricate interplay between an individual's health and socioeconomic status is pivotal in public health and policy-making. This research endeavors to explore the predictive relationship between health-related metrics and income levels, leveraging a comprehensive dataset encompassing diverse personal health parameters and demographic information.The study dataset comprises multifaceted attributes, including average heart rate, activity levels (such as steps, active minutes), sleep patterns (deep, light, REM sleep), and demographic descriptors (gender, race, ethnicity). By harnessing machine learning techniques, particularly regression modeling, this research aims to construct predictive models to estimate income levels based on these health-related variables. The approach involves robust data preprocessing techniques, handling missing values, outlier detection, and feature engineering to extract meaningful insights from the dataset. Various regression models, such as multiple regression and possibly advanced ensemble methods, will be trained and evaluated to predict income brackets or levels.The outcomes of this research extend beyond predictive accuracy. It uncovers potential correlations and significance between specific health indicators and income, shedding light on the complex relationship between health status and socioeconomic factors. Additionally, the study identifies key health determinants that significantly influence income variations. The findings from this research hold promise in informing public health initiatives and policies, emphasizing the importance of holistic health in socioeconomic mobility and advocating for interventions that bridge health disparities to foster economic equity. Furthermore, this investigation provided insights specifically tailored to benefit African American communities, contributing to efforts aimed at addressing health disparities and fostering economic empowerment within this historically marginalized group. This investigation stood as a crucial step toward elucidating the connections between health metrics and income,

fostering a deeper comprehension of the multidimensional nature of individual well-being and economic outcomes.

Abstract Name: The Effects of Technology and Invention on the Future of Creative Work, A Literature Study

Over the past few years, a significant amount of literature has emerged on the future of creative work and changes in the creative industry caused by technological advancement and the effects of technologies on the gendered gap in labour and the environment. There are a few major changes in the creative workforce. Firstly, one critical shift would be the change in work culture and organization of labor due to the technological substitution of human tasks. Secondly, changes to the nature of creative work and work intensity have also occurred due to a shift from manual labor to digitalized labor and automation. Lastly, technological advancement has also affected skills and requirements for the creative industries' labor force. Understanding the impact of technological advancement on the labor force of critical historical eras for industrialization is significant for forecasting changes in the work organization of creative industries that will occur in the near future and their effect on the gendered division of labour and the status of the environment. It is hypothesized that changes to the creative workforce driven by technological advancement during the 19th century may predict shifts for creative work in the near future, such as increased productivity, division of labor, and degradation of work. Thus, the purpose of this review is to examine the effects that technological advancement and early inventions have had on the creative industry. The review seeks to answer the research question: How have technological innovation and early invention affected the work organization of the creative industry? This research aim will be achieved by reviewing pre-existing literature examining the potential technologically driven shifts of work organization in the labor force from various periods to determine whether or not there is a historical influence on this growing trend.

Abstract Name: Role of BATF3 in Human T cells

Basic leucine zipper transcriptional factor 3 (BATF3) belongs to the family of transcription factors called Activator protein 1 or AP-1. During infection, T-cells multiply to achieve the numbers required to fight infection followed by contraction. A small portion of these T-cells are retained to make memory T-cells. BATF3 was originally discovered in human T-cells, however, our knowledge is limited to murine studies. In murine models, it was shown that when BATF3 is repressed, not as many cells make it out of the naive stage and into central memory. Cells expressing BATF3 live longer and proliferate more. This study aims to

determine the function of BATF3 in human T-cells. Interestingly, single-cell sequencing on human T-cells revealed that BATF3 was significantly upregulated in activated CD4 and CD8 T-cells. To study BATF3 in human T-cells, we will look at the proliferation marker Ki-67 to measure proliferation, and cytokine production to determine effector responses in BATF3 positive and negative T-cells. To do this we have stimulated human T-cells in three groups; unstimulated, stimulated with anti-CD3, or anti-CD3+anti-CD28. The cells were stained with fluorescently conjugated anti-CD4, anti-CD8, anti-BATF3, and anti-Ki-67. Anti-TNF-a, anti-IFN-y, and anti-Granzyme-B fluorescence will be used to determine effector responses. The data was acquired on Cytoflex and analyzed using FloJo software. Our results show that BATF3 is upregulated in T-cells upon activation. Further, there's greater upregulation of BATF3 in cells stimulated with anti-CD3+CD28 compared to anti-CD3 alone. Finally, BATF3 was upregulated at a higher level in activated CD8 T-cells as compared to CD4 T-cells. Interestingly, cells that express BATF3 have greater proliferation, suggesting that BATF3 may play a role in T-cell proliferation. Experiments are being performed to determine effector responses in BATF3+ve vs. BATF3-ve T-cells. Discovering BATF3 function in human T-cells may help develop a better understanding of memory T-cells.

Abstract Name: Decolonizing JANE EYRE with the Wisconsin First Nations Fusion Pedagogy Project

Informed by the Wisconsin First Nations Fusion Project ("Fusion") at the University of Wisconsin, Green Bay, I worked to "undiscipline" my teaching of Charlotte Brontë's Jane Eyre, An Autobiography (1847) to enable British Literature students to perform original research on the intersection between this novel and the cultural genocide that has long been perpetrated against Indigenous people through the pretense of formal education -- but can also be confronted in educational contexts. Rosemary Christensen and Lisa Poupart's Fusion project infuses Indigenous knowledge, history, and ethics into the curriculum, enhancing it with long-suppressed Indigenous world views. After attending Fusion dialogues in 2022-3, I refocused my teaching of Jane Eyre to enable students to utilize primary and secondary sources to explore connections between Brontë''s critique of Cowan Bridge School, where her sisters died, and residential school genocide in this continent. The first such school encountered in Jane Eyre is the hellish Lowood, which recalls not only workhouses and prisons but the deadly missionary schools of the imperial contact zones. In 1840, British colonists founded schools at Lucknow and Calcutta. Meanwhile, British missionaries in Canada founded mission schools such as the Mohawk Institute in Brantford, Ontario. Opened as a day school in 1786, the "largely church-run and funded" Mohawk Institute began boarding indigenous children in 1834, and continuing until 1970, became the longest-operating of the country's genocidal residential schools. Brontë did not know the horrific details of the imperial world's practices, but could her experience have made her sceptical? To conduct this experiment, students compare Jane Eyre's Lowood episodes with testimony by missionary, residential, and 'Indian' school 'students'/inmates from the open-access digital archive One More Voice (https://onemorevoice.org). This allows them to interpret primary sources in original ways and thereby lead the process of decolonizing our curriculum.

Abstract Name: Galectins 1, 3, and 9: Role in Pregnancy Immune Suppression and Parallels in Cancer

Immunosuppression is vital in pathophysiology of cancer, pregnancy, and related pregnancy complications. Pregnancy is a normal, biological process that can be studied as a model which mimics the immunosuppressive pathways of cancer. Pregnancy complications like Villitis of Unknown Etiology (VUE) and Chronic Histiocytic Intervillositis (CHI) consist of the breakdown of immunotolerance which can help identify mechanisms of cancer immune evasion and targets of immunotherapy.Cancer systemically shifts the immune response to an immunosuppressive tumor-supportive microenvironment. This is analogous to pregnancy in the sense that it is unfavorable for the immune system to attack the fetus. In pregnancy complications, we see a shift from TH2/M2 to an induced immune activation response, TH1/M1.Galectins, part of the lectin superfamily, extensively studied in pregnancy, play a role in the immune suppression of cancer. These proteins decipher information encoded by glycosylation machinery via a conserved carbohydrate recognition domain (CRD) which translates to proper cellular function. Dependent on the cancer, and tumor microenvironment, upregulation of certain galectins is associated with both immune activation and suppression. In pregnancy, galectins are recognized as an important factor in establishing immune tolerance at the feto-maternal interface and successful pregnancy.To understand the microenvironment in pregnancy and cancer, multi-plex immunofluorescence (MxIF) was utilized on pregnancy and tumor slides. Multiple tumor and trophoblast cell lines were cultured and treated with galectins with various in vitro assays. ELISA and flow cytometry were utilized to measure cytokines and cell surface markers, respectively.MxIF demonstrates that immune tolerance pathways at the feto-maternal interface and tumor microenvironment are similar in the upregulation of galectins and CD206 in both normal pregnancy and cancer as opposed to Th1/M1 upregulation in pregnancy complications and lymph nodes without tumors. In vitro assays suggest that galectins promote Th2 and M2 upregulation in T-cells and macrophages, respectively.

Abstract Name: Simulation and Evaluation of Flow-Induced Shear in a Microfluidic Slide via Computational Fluid Dynamics

This study focuses on the development and validation of a computational framework to leverage a computational fluid dynamics (CFD) methodology into an in vitro platform that allows for quantifying the flow-induced wall shear stress on cultured cells in a microfluidic device and systematic investigation into the influence of scaffold permeability and perfusion flowrate. Previous literature shows that using CFD in microfluidic cell culture system studies is key, as fluid flow processes have direct implications on cellular

response. A coupled fluid-porous mathematical model of the scaffold of a microfluidic cell culture slide (ibidi GmbH, Germany) filled with hydrogel is developed to determine the fluid perfusion and resulting shear stresses within its boundaries. The Brinkman equation is applied for the characterization of fluid flow and transport in the porous model. The ANSYS CFX Workbench software is used to carry out numerical simulations that determine the fluid forces and flow mechanics produced within the hydrogel scaffold. Fluid is perfused at defined rates as experimentally derived properties for culture media and computer simulations are performed to obtain physiologically relevant values for shear stress as well as the extent to which porous media flow and the resulting stresses affect filtration velocity in the scaffold.The computational solver provides a prediction of filtration velocity within the porous channel, as well as the local shear stress fields. Moreover, the sensitivity of the model predictions to physical parameters such as hydrogel scaffold permeability and perfusion flow rate are explored. Whilst CFD model predictions are performed, laboratory experimental data is collected from cell culture experiments and the results are validated. These findings will help researchers to optimize the mean pore size of scaffolds and perfusion operating conditions to manage cell proliferation when mechanically simulating cells via flow perfusion.

Abstract Name: Kantian Moral Anti-Theodicy

Theodicy is a philosophical/theological practice reconciling the Western standard conception of God with the existence of suffering. Though there have been critiques of particular theodicies, moral anti-theodicy is a ‘metacritique’ of theodicies generally: it aims to critique the practice itself on moral grounds. Current arguments for moral anti-theodicy, given by Kenneth Surin, Grace Jantzen, Nick Trakakis, Samuel Shearn, John Culp, Toby Betenson, and others, show that theodicy is a practice of detachment and instrumentalization of suffering. Relying on these arguments, the aim of this essay is to consolidate moral anti-theodicy into a Kantian critique. If detachment and instrumentalization of suffering are necessary maxims of theodicy, and both maxims contradict the categorical imperative, then theodicy is immoral within a Kantian framework. Later, I will consider “The Doctor Analogy” as an objection, and my response will suggest that, if theodicy is to continue and be a moral practice, then it should model a therapeutic approach resembling Viktor Frankl’s Man’s Search for Meaning.

Abstract Name: Empowering undergraduates in laboratory courses to make research decisions and discover their science identity.

Traditional Molecular Biology laboratory courses use simple DNA digestion and ligation to construct a dual antibiotic resistant recombinant DNA plasmid, with no use other than as an educational tool. I transformed

this “cookie cutter” laboratory into a “Course-based Undergraduate Research Experience” (CURE) to empower students to make research decisions and discover their science identity. Here I show how to incorporate research involving protein interactions into a one semester Molecular Biology course for undergraduate STEM majors. My laboratory studies protein interactions of influenza virus, but this CURE can be modified to study any protein-protein interaction of interest. To start, students search the literature for information on influenza nucleoprotein (NP) interactions and decide which interaction to research. Next, sequence databases are accessed to retrieve NP protein sequences from human, swine, and avian hosts and analyze amino acid conservation, highlighting conserved residues across all isolates. Students then examine protein crystal structure to visualize the location of conserved residues. Based on this research, students select conserved and accessible residue(s) they hypothesize are involved in the NP interaction of focus and decide how to change the amino acid to alter interaction possibilities. Typical molecular biology techniques are then used to construct the recombinant DNA plasmid, including designing primers to amplify the altered NP gene using polymerase chain reaction (PCR), ligating DNAs together into an expression plasmid using Gibson Assembly, and transforming DNA into bacteria to amplify and isolate constructed recombinant DNA plasmids. Students send the plasmid for sequencing and analyze the sequence to confirm the desired coding change. Successful plasmids will be used to express altered NP proteins and assess function in my laboratory, or (in the future) as another CURE course, “Advanced Molecular Techniques”, expanding this CURE into a one year-long project to empower students to make research decisions and discover their science identity.

Abstract Name: Psychology in Rick and Morty: Character, Trauma, and Grief

Using Rick Sanchez C-137 from the show Rick and Morty as a character study, the paper dissects the relationship between personality, action, trauma, and grief and seeks to answer the question: What are the effects of trauma and grief on a character’s personality and actions? Through qualitative analysis, Rick’s character is divided up and each important area of his psychology is discussed; from the big five personality traits he displays and his autism to the traumatic loss of his wife and daughter and the subsequent grief that consumes him, Rick Sanchez C-137 as a character is understood through the lens of his psychology. After analyzing the application of psychology in Rick Sanchez C-137’s character, this project asks and answers the question: How can creative writers be taught to apply psychology to their own characters? Learning from one popular example of a psychologically complex character, this independent study seeks to teach creative writers how to analyze a character’s psychology and identify how the psychology of the character influences the actions they make. The curriculum made from the research of the independent study spans over six lessons, which teach students how to analyze behavior and conduct research. Over the course of these lessons, writers are given the opportunity to apply what they are learning about character and psychology to their own work. This research-driven curriculum demonstrates how the accurate and authentic application of psychology can elevate writers’ craft and create characters that resonate with their audience. Teaching creative writers about this tool at the university level lays the foundation for powerful stories that resonate with their audiences to be made in the future.

Abstract Name: Examining Lifestyle Behaviors and Fitness in ROTC Cadets

The U.S. Army's Holistic Health and Fitness (H2F) program represents a significant paradigm shift in the assessment of soldiers' health and operational readiness, moving away from fitness testing as the main indicator. This shift acknowledges that suboptimal modifiable lifestyle behaviors (mLB), particularly physical activity (PA), diet, and sleep, are vital for overall wellbeing. PURPOSE: To examine mLB and fitness of Reserve Officers Training Corps (ROTC) cadets. METHODS: Eighty-four ROTC cadets (63 male) took an online survey consisting of the Pittsburgh Sleep Quality Index (PSQI), Rapid Eating Assessment for Participants short form (REAPs), and the International Physical Activity Questionnaire (IPAQ). Fitness was assessed via the Army Combat Fitness Test (ACFT). Descriptive statistics were calculated and reported as median (interquartile range). Spearman correlation coefficients were calculated for mLB and ACFT scores, with alpha level set at 0.05. RESULTS: Cadets' PSQI scores were 6.0 (4.0, 7.0) with 56 cadets reporting poor sleep (PSQI score≥5). REAPs score were 29.0 (26.0, 31.0) with 8 cadets reporting poor dietary habits (REAPs flags≥5). Cadets self-reported PA (min/week) was 90 (66,120) and 70 (60,120) of moderate and vigorous PA, respectively, with 1680 (900,2400) mins/week of sitting time. ACFT total scores were 502 ([469,545]; 82 passed). There were no significant correlations between mLB and ACFT total scores. CONCLUSION: The lack of correlation between mLB and ACFT scores was unexpected but supports the H2F framework not solely relying on fitness testing to evaluate health and wellbeing. Due to prevalent poor sleep among cadets, interventions are recommended, as suboptimal sleep may cause impaired performance and chronic health issues. Notably, ROTC cadets are full-time students and findings should not be generalized to active-duty military populations. Thus future research should explore the H2F framework in active-duty military populations.

Abstract Name: Novel Carbazole Porphyrin as an Extended Chromophore used as a Photocatalyst in the oxidative formation of Amide Bonds

Synthesis of a novel carbazole-porphyrin was done to extend the absorption spectra and optimize the molecules effectiveness as a photocatalyst. Porphyrins are a chromophore that are commonly found in nature. Chlorophyll-b in mitochondria and heme in red blood cells are both porphyrin derivatives found in nature which showcase the versatility of function this class of molecules exhibits. Chlorophyll-b is a photocatalyst helping plants to synthesize glucose from CO2 and H2O while heme binds and transfers oxygen around the body in the blood. Out of all the visible light, porphyrins primarily absorb violet light. Carbazole, another chromophore, absorbs light in the ultraviolet spectrum. A new molecule made up of these two chromophores was synthesized to make an extended chromophore. This extended the absorption spectra and enabled it to act as an electron acceptor and donor. The carbazole porphyrin has an extended pi-system due to the conjugation of the porphyrin being extended to the carbazole via ethynyl groups at the meso-positions. Due to this extended conjugation electrons can be transferred throughout the entire molecule. The application for this molecule is as a photocatalyst for oxidation methods. Currently research is being done into the carbazole

porphyrin's ability to act as a photocatalyst in the oxidative amidation of aromatic aldehydes. This reaction was chosen due to the importance of amide bond formation in many fields including chemistry, pharmacy, biochemistry, and bioengineering. Previous work has been done using tetraphenyl porphyrin as a photocatalyst in this reaction and will be used as a baseline when compared to the carbazole porphyrin. This will give insights into whether the carbazole porphyrin is more reactive due to its larger absorption spectra and extended conjugation.

Abstract Name: Electrochemical routes of biomass derivative oxidation to produce hydrogen gas and useful by products on gold, silver, and copper catalysts

An electrochemical oxidation process was used to convert biomass waste products into energy and useful byproducts such as hydrogen gas. Electrochemistry was used to oxidize the aldehyde functional group to a carboxylate group in basic conditions. This reaction was chosen due to the production of hydrogen gas at both the anode where hydrogen is produced from the aldehyde hydrogen and at the cathode where the hydrogen evolution reaction takes place from water. Additionally, the electrochemical cell operates at lower cell potentials using less energy to create the hydrogen gas and the other useful by products formed during the reaction. Using benzaldehyde, a simpler model for the biomass derivative furfural, the kinetics of the oxidation process was studied on the catalyst surfaces of gold, silver, and copper. This was done by using a rotating disk electrode to perform a Koutecky-Levich study on the reaction. The Koutecky-Levich study does linear sweep voltammetry at varying rotation rates. The study provided a better understanding of the kinetics of the reaction, how mass transfer effects the rate at which the reaction proceeds, and insight into the average number of electrons that gets transferred per reactant molecule at various potentials. Due to the Koutecky-Levich study a better idea of what conditions are needed for the optimal production of hydrogen gas as well as the highest rate of reaction was found. Gold reaches a higher current density and mass transport limiting current at high potentials. Benzaldehyde oxidation occurs at earlier potentials on silver but has lower peak current due to earlier oxide formation. Copper has the lowest peak current but has the earliest onset potential for the reaction. Gold and silver transition from production of hydrogen gas at lower potentials to the formation of water at higher potentials.

Abstract Name: Fast Fashion

Poverty, persistence, and pollution, in a single industry. With a crisis staring at you in the face, it can be difficult to ignore, especially when it is reflected in the mirror. The current climate of the fashion industry requires, or rather, begs, for it to exploit the rapid shifting of trends, the availability of materials to support the trend—as well as the wage-slavery of people—for a quick profit. On average, a single shirt in the United States is only worn several times until it is thrown out, and a great deal of clothes never get worn in the first place before they are donated, and after being donated, are more likely than not to be placed in a landfill. Many materials used in clothing manufacturing are non-biodegradable and contribute to the mark of the human age, microplastics, leaving a layer of plastic in earth that is not too dissimilar from the layer of ash and debris found around the globe that marked the end of the dinosaurs. Fast Fashion, as a typographic poster, aims to show the fleeting nature of the industry by constructing an image of a shirt created out of many lines of text, with each row of text's gap allowing for a see-through quality indicative of haste in its construction. Each line of text is warped, with many lines of text displaying a facet of the industry that is less-than-ideal, yet persistent throughout. The blue pants and the human character are the only objects solid in color, indicative of their propensity to last. Although there are many parts of the fashion process working against us, there needs to be an initiative—and from there—the gall to continue that momentum towards positive change, change that can affect much more than what you look like, but what you leave behind.

Abstract Name: AI Impact on Form and Shape of Architectural Design

Background: This study aims to compare the form and shape in the building designs by AI and those by architects and to find out which design is superior to the other.Purpose: The study seeks to find out if the architects, who have received formal architectural education and training, can design buildings with better form and shape than those created by AI.Method: This study uses a survey to find out the opinions of Utah Valley University students regarding the comparison of the form and shape in the designs by AI and architects. To contact the potential respondents, a flyer will be posted with a QR code to the online survey in all classrooms. In the online survey, four sets of images created by AI and four sets of images designed by architects will be provided for the respondents to select the ones with better form and shape. The respondents will then decide whether the images are designed by AI or architects. The images are Gothic and modern Catholic cathedrals and churches. After receiving the responses, the data and summarized result regarding the preference of the respondents and their ability to distinguish whether the design is by AI or by architects would be provided.Result: As expected, most of the students can tell the designs by AI and which designs may have better form and shape. Further, the results from the architectural and non-architectural students may have some differences.Conclusion: AI is one of the tools in architectural designs. Nevertheless, it cannot take over the works from architects who have received years of training on learning architectural elements such as form and shape. As an architecture student, this research will help architectural students to value the education and training more.

Abstract Name: Life Habits and Practices Among Vulnerable Youths in Family Reunification Care

Family-level involvement can positively impact the outcomes for vulnerable children, implying that policies and practices designed to engage kinship networks should be further prioritized in child welfare. Since the COVID-19 pandemic, some orphanage systems in developing countries started shifting towards family-based orphan care through reunification. This research project partnered with an NGO, which serves vulnerable youths in Southeast Asia. The NGO's family-based care program has the goals of holistic restoration, discipleship, and education continuation. This study analyzes in-depth interview data from 37 children who have transitioned from the orphanage program to kinship care for the last three years. This study created the interview instrument for the organization to conduct the interviews in their respective non-English languages. My research goal is to understand the children's retention of habits and practices into transitioning to kinship care. The interview findings are that most children implemented and continued success-building life habits like studying, time management, and household work. Some children mention the change in their discipline and character from the program and expressed hopes to take care of their families through educational attainment. This study has ran chi-square cross tabulations to detect correlation between variables within the in-depth interviews. One limitation would be the interviewer effect and possibly some meanings of the interview content lost in translation. Given the context of the interview setting, the children might have felt obligated to give a correct answer instead of an honest answer. For further studies, this study proposes making this a longitudinal study to examine the progress of this cohort of children.

Abstract Name: Enhancing Hydrophobic Interactions in Sorafenib for Improved Binding Affinity to Target Enzymes in Modern Enzyme-Substrate Modeling Software

Sorafenib is a pivotal targeted therapy in treating late-stage kidney, liver, and thyroid cancers, acting through the inhibition of c-Raf-1, a serine/threonine Raf kinase, effectively suppressing tumor-promoting gene transcription. While it stands as a primary treatment option for hepatocellular carcinoma, its commendable 10-month median overall survival is counterbalanced by substantial side effects and the common development of drug resistance. Consequently, the research focus has been directed toward the development of Sorafenib analogs with improved efficacy and safety. The emergence of modern and advanced molecular docking software has expedited the screening process by detecting cavities and simulating molecular interactions. Our research strategically employed CB-Dock 2.0 (Liu et al. 2022); an automated docking tool designed to calculate Vina scores—a weighted sum of molecular interactions—with lower scores indicative of stronger binding. We modified Sorafenib analog side chains to increase hydrophobic interactions with amino acid residues composing the c-Raf-1 cavity and generated Vina score using crystal structure of c-Raf-1 (3OMV) (Hatzivassiliou et al. 2010) and the crystal structure of the general kinase domain 4ASD (McTigue et al. 2012), yielding a Vina score 3 kJ/mol lower than the original. More significantly, the modified drug adhered to all of Lipinski's Rule of Five, suggesting a potential for oral bioavailability. There was an observed direct correlation between Vina scores from post-model and published IC50 values (Lowinger et al. 2002), suggesting the potential for a mathematical formula linking these parameters. Our next step involves refining and empirically validating this formula with our redesigned drug candidate.

Abstract Name: The Legacies of Neighborhood Segregation in St. Paul, Minnesota's Independent School District 625

During the 1970s, federal government efforts to desegregate schools began in the Northern United States. Desegregating schools was especially challenging in the North because school segregation was often the result of neighborhood segregation. Our research proposes an initial answer to the question: how did school desegregation efforts in St. Paul, Minnesota address the problem of neighborhood segregation in the 1970s? St. Paul's Independent School District 625 (ISD 625) implemented school desegregation through the creation of the Learning Centers Program, an alternative strategy to simply bussing students to new schools. The Learning Centers program, started in the early 1970s, created clusters of schools in an effort to allow students to attend more diverse schools for part of their school day while still preserving neighborhood schools. Within each cluster, there were several Learning Centers a student could go to and learn a specialized skill, such as music or languages. Students would spend the first part of their day learning the basics at their neighborhood school and the other half at the Learning Centers. Examining the records of ISD 625 from 1970-1977, including intradistrict communication, correspondence with parents, and communication with the Minnesota Board of Education, reveals tension from all sides about the impact of the Learning Centers program. The cluster program placed students in a desegregated environment for part of the day, but without undoing neighborhood segregation, schools remained fundamentally segregated. As a result, the end of the Learning Centers program brought a return to segregated neighborhood schools. This research shows the ways that neighborhood segregation creates a persistent structural barrier to desegregation efforts.

Abstract Name: Trends in Long-term Dissolved Oxygen in Mid-western Lakes in Response to Climate Change

Long-term dissolved oxygen (DO) trends in lakes are an important metric to assess the well-being of lakes under the effects of climate change. Along with temperature, other climate change signals such as higher frequency of floods and severe weather also impact lake DO, negatively leading to harmful algal blooms and fish kills. Land use change is another essential factor associated with nutrient pollution in lakes and surface temperature increase. Urbanization is one of the most accountable anthropogenic adjustments in the natural world, particularly in metropolitan cities such as the Twin Cities, Minnesota. This area is a hot spot of land use change and has high lake density. Lakes are culturally indispensable to Midwestern people because they

bring influential values to people (e.g., water resources, recreation, economy, etc.). However, a study of the long-term DO trends in this area is still limited due to data sufficiency and the complexity of climate change. In this study, we will analyze data collected in lakes across the Twin Cities, Minnesota in terms of DO, temperature, and land use change over the past two decades. Our goal is to assess trends in DO and better understand how lakes have responded to climate change.

Abstract Name: HarmonicThreads: A Smart Elastic Display to Support Musical Interactions

Our research revolves around HarmonicThreads, a novel, smart musical interface designed to foster the social and emotional development of children, particularly those facing differences in motor, sensory and attention skills. Currently, HarmonicThreads leverages an elastic display embedded with conductive threads and Arduino circuitry, enabling users to produce music by touching a fabric surface. Previous research has prompted the need for personalization in music therapy. Hence, we focus on the use of AI, specifically deep learning, to generate music according to the user's unique interactions with the fabric. We explore two deep learning approaches in HarmonicThreads, musical accompaniment with Google's AI Duet, and musical continuation with Magenta. The first approach takes notes played by the user and runs them through AI Duet's trained neural network, which produces a new set of complementary notes. The second approach utilizes Magenta's ImprovRNN model to play an arpeggiated pattern around a single note or chord held down by the user. We find that the first approach with AI Duet promotes more seamless musical interactions. Particularly, the algorithm allows the user to continue playing notes simultaneously with AI, instead of holding down a note and waiting for the response to complete. Therefore, we adopt the musical accompaniment method to enhance the engagement and creativity in HarmonicThreads. In our future work, we will conduct user studies to gather feedback from individuals of diverse contexts, and build upon HarmonicThreads to personalize towards the needs of these individuals. Through this exploration, we aim to contribute a unique and impactful perspective to the intersection of music, technology, and inclusive education.

Abstract Name: Agar's Dye Adsorption Capabilities, and the Effects of Amino Acids on Adsorption

With the increase in human population, the demand for clothing and textiles is also increasing, leading to an increase of wastewater released into rivers and creeks. Agar plates generally have a short life span and are

often discarded as waste in the lab regardless of them being contaminated or not. The purpose of this study is to investigate the ability of recycled agar, a substance derived from seaweed, to adsorb methylene blue, a dye used in textile industries, and to explore the effects of amino acid tryptophan plays in the adsorption. Adsorption is a phenomenon in which particles stick to the surface of the adsorbent. We focused on synthetic dextrose minimal agar base containing tryptophan, adenine, and histidine compared to agar containing just histidine and adenine. We tested the adsorption of agar by monitoring spectroscopically the amount of methylene blue remaining in solution. After testing, the agar changed from clear beige to dark purple meaning that methylene blue is being adsorbed on agar. The percent removal for agar containing tryptophan was much higher than without tryptophan, 12% vs 22% after 60 minutes. This suggests that the presence of tryptophan greatly increased the adsorption of methylene blue. This preliminary investigation of lab waste as a bioadsorbent warrant further studies regarding the effect of agar on creeks and rivers' water environment and the effect of different amino acids to improve the removal of contaminate dyes like methylene blue.

Abstract Name: Fostering Body Positivity and Cultural Inclusivity – TIGRESS AND RABBIT as a Case Study

This project focuses on integrating biophilic design and creating a comprehensive environment in women's gyms, as demonstrated by TIGRESS AND RABBIT. The purpose is to examine how to establish a distinctive and empowering environment designed to create a safe space for women to embrace their bodies and beauty.Inspired by the diversity of a rainforest, TIGRESS AND RABBIT seek to contribute space for a supportive community in fitness that celebrates all types of backgrounds of women (particularly addressing the beauty standards) especially in minority communities. Using surveys and interviews during research, this study aims to analyze the effectiveness of TIGRESS AND RABBIT's design by comparing it with existing women's gyms. The design focuses on understanding how biophilic design elements impact the user experience and well-being and creating a safe and inclusive space for women. Case studies are also used to identify design principles and their implications for fostering body positivity.The project's significance lies in understanding how this design approach positively influences the fitness journey of women, fostering a profound sense of balance, serenity, and personal growth. The overarching goal is to contribute valuable design principles that can be applied broadly in interior design for fitness spaces, emphasizing inclusivity and body positivity. By incorporating different types of activities for women to participate in such as sports (pickleball, volleyball, swimming, track, martial arts, and boxing), classes (meditation, pilates, cooking, and dance), and lounge/relaxing spaces (cafe, courtyard, pool, and rooftop lounge) this research project provides a comprehensive approach to women’s health using biophilic design inspired by the rainforest.

Abstract Name: Synthesis of biodegradable polymers from furan-protected maleimide compounds

In recent years, the Son laboratory has developed several types of degradable polymers. More recently, N-(2-hydroxyethyl)maleimide, or HEMI, has been found to be a key starting material for degradable polymers that can be formed by simple Diels-Alder reactions between furan and maleimide derivatives. One of our goals is to develop alternative syntheses to prepare degradable polymers more cheaply and on a larger scale. Specifically, an alternative reaction similar to the Gabriel synthesis is used to eliminate a ring opening step in forming HEMI and related derivatives. The key starting material is a furan-protected maleimide. To explore this proposed alternative route, different ratios of reagents and solvents will be examined, and reaction conditions will be varied. The final products will be characterized by NMR spectroscopy. Once optimized, we hope the synthesis will have broad applicability to prepare structurally diverse maleimide derivates for incorporation into degradable polymers and networks.

Abstract Name: SPR-5 and MET-2 maternal reprogramming cooperates with DREAM and MEC complexes to regulate developmental cell fates

At fertilization, histone methylation must undergo maternal reprogramming to reset the epigenetic landscape in the new zygote. During maternal reprogramming of histone methylation in the nematode, C. elegans, H3K4me is removed by the H3K4 demethylase, SPR-5, and H3K9me is subsequently added by the histone methyltransferase, MET-2. Recently, it was demonstrated that SPR-5; MET-2 maternal reprogramming antagonizes the H3K36 methyltransferase, MES-4, which maintains a transcriptional memory of a subset of germline genes between generations. Maternal loss of SPR-5 and MET-2 results in ectopic expression of MES-4 germline genes in somatic tissues and a severe developmental delay. Data from the Petrella and Ahringer Labs demonstrates that members of the DREAM Complex, a transcriptional repressor complex that regulates cell cycle, also represses germline genes in somatic tissues through H3K9me2 promoter marking. Furthermore, preliminary data from our lab shows that the histone deacetylation, MEC Complex, is also required to prevent a soma-to-germline transition. These data suggest that the DREAM complex, MEC complex, and SPR-5; MET-2 maternal reprogramming work together to prevent ectopic expression of germline genes in somatic tissues and developmental delay. To test this hypothesis, we knocked down Dream complex and MEC complex members in spr-5; met-2 mutants using RNAi and found that knocking down either complex exacerbates the severe developmental delay that we normally observe in spr-5; met-2. Using RNA-seq, we further demonstrate that knocking down Dream and MEC complex members exacerbates the ectopic expression of MES-4 germline genes in spr-5; met-2 mutant somas. Our findings provide mechanistic insight into how evolutionary conserved transcriptional repressor complexes and reprogramming of histone methylation synergize to ensure proper germline versus somatic cell fates during development.

Abstract Name: A major regulator of germline transcription, LSL-1, contributes to developmental defects when histone methylation is inappropriately inherited

Histone methylation is a post-transcriptional modification to the N-terminal tails of histone core proteins that regulates DNA accessibility, and consequently, gene expression. Like DNA, histone methylation can be inherited between generations, and is highly regulated during embryonic development. At fertilization, histone methylation must undergo maternal reprogramming to reset the epigenetic landscape in the new zygote. During maternal reprogramming of histone methylation in the nematode, C. elegans, H3K4me (a modification associated with active transcription) is removed by the H3K4 demethylase, SPR-5, and H3K9me (a modification associated with transcriptional repression) is subsequently added by the histone methyltransferase, MET-2. Maternal loss of SPR-5 and MET-2 results in ectopic expression of germline genes in somatic tissues and a range of developmental phenotypes, including a severe developmental delay. Using a combination of RNA-seq and ChIP-seq experiments, a recent study identified a major regulator of germline transcription, LSL-1, that binds and turns on germline genes in the germline during development. From our own transcriptional analysis performed on C. elegans lacking SPR-5 and MET-2, we find that lsl-1 is significantly upregulated in somatic tissues. Together these data suggest that LSL-1 may be turning on germline genes aberrantly in somatic tissue and contributing to developmental delay. To test this hypothesis, we knocked down lsl-1 using RNA interference (RNAi) and found that the developmental delay in spr-5; met-2 mutants is significantly rescued. Using RNA-seq, we further demonstrate that knocking down LSL-1 in spr-5; met-2 mutant rescues ectopic expression of MES-4 germline genes. Together, our findings provide mechanistic insight into how inappropriate inheritance of epigenetic states perturb germline versus somatic cell fates specification during development and how this perturbation contributes to developmental phenotypes.

Abstract Name: Exploring Industry 4.0 through PLC Smart Factory Integration

This research delves into the transformative influence of Industry 4.0 on manufacturing, with a particular focus on the integration of Programmable Logic Controllers (PLCs) within smart factories. Industry 4.0 signifies a paradigm shift, uniting digital technologies and physical systems to revolutionize manufacturing through intelligent decision-making, automation, and enhanced efficiency. PLCs are pivotal in this transformation, enabling real-time data analysis, predictive maintenance, and seamless machine communication. Nonetheless, challenges like interoperability and security need to be addressed for successful implementation. The research aims to comprehensively analyze the implications of PLC-driven Industry 4.0, offering insights for manufacturers and policymakers while contributing to academic discourse on manufacturing's future. Additionally, it explores the integration of PLCs, IoT, and cloud computing in smart manufacturing. Practical validation is provided through an innovative 3D printing system, demonstrating cost reduction, waste minimization, and enhanced efficiency. The automation of post-printing processes improves productivity and reduces labor while contributing to sustainability. In conclusion, this study underscores the

potential benefits and challenges of Industry 4.0 and PLC automation, emphasizing the importance of meticulous analysis for successful implementation, ultimately fostering productivity, sustainability, and global competitiveness in manufacturing. In addition to its immediate implications, this research holds the promise of catalyzing broader transformative impacts, spurring innovation, and setting a precedent for the widespread adoption of PLC-driven automation, thereby shaping the future landscape of Industry 4.0 across diverse industries.

Abstract Name: Taking ‘L’s in Mie Resonator Arrays for the Colorimetric Differentiation of Chiral Light

On-chip imaging platforms can be designed using two-dimensional arrangements of nanoscale structures to create a nano-optical array. Breaking the symmetry of the nanoscale structure shape allows for selective interactions with varying polarizations of incident light. Symmetry-breaking can result in chiral shapes whose mirror image cannot be superimposed onto the original image through rotation or translation operations. Circularly polarized light is chiral and can be assigned a clockwise or counterclockwise orientation according to its space-time traversal. The ideal chiral nanostructure will produce maximally different interactions between clockwise and counterclockwise circularly polarized light. However, the ideal design of a chiral nanoscale structure has yet to be discovered. In this work, we identify a methodology to guide us toward creating an ideal chiral structure by systematically altering the geometric parameters of two-dimensional chiral, L-shaped nanoscale structures comprising a nano-optical array. The merit of each geometric alteration to gain the ideal structure is determined by analyzing the near-field and far-field responses of illuminating the chiral structure with clockwise or counterclockwise light. This work provides insight into design guidelines for engineering L-shaped chiral nanostructures to differentiate between chiral orientations of circularly polarized light. The problem is constrained to the visible light regime, allowing our nano-optical arrays to be used as a differential colorimetric sensor for clockwise and counterclockwise circularly polarized light. These arrays have sensing applications in high-precision imaging to detect chemicals, gases, or biomolecules, ultimately improving diagnostic technologies.

Abstract Name: The Cultural Significance of Design in Japan

The reflection of traditional and innovative design is found in the craftsmanship of Japanese design. Graphic design in Japan has rich history rooted in their works of calligraphy, woodblock printing, and art forms such as ukiyo-e. Usage of these works can be found in the Edo period of Japan as they were focused on telling historical tales and depicting beautiful scenes of life with various subjects. Their art embraces the idea of minimalism and harmony while also serving to showcase certain societal viewpoints in the culture of Japan.

This analysis will dive into the historical evolution, influences, how it shaped the cultural identity of Japan today, and how their graphic design differs from the Western take of graphic design.

Abstract Name: Phocrastination: A Game-Based Approach to Assessing and Classifying Academic Procrastination In College Students

Academic procrastination, a pervasive issue among college students, significantly impacts students' academic performance and overall well-being. Current research accredit the phenomenon to personality traits and characteristics that define each individual student. This research explores two crucial constructs related to academic procrastination: conscientiousness and self-regulation. To gain a deeper understanding of higher-order cognitive behaviors, researchers are exploring innovative approaches that can measure such complex phenomena. This study employs Game-Based Assessments (GBAs) and Evidence-Based Game Design (EBGD), which have the potential and capability to measure academic procrastination. Introducing Phocrastination, a 2D cooking video game that simulates a student’s natural learning environment and analyzes their procrastination tendencies through interactions and decisions made within the game. We aim to uncover potential connections between procrastination tendencies and the domains of time management, perfectionism, distractibility, emotional regulation, and self-discipline. The design of Phocrastination was an iterative agile design process validated through extensive review of the current literature on academic procrastination and its ability to accurately measure the intended constructs. The study was conducted over summer 2023 with 77 college students enrolled in higher education in Southern California. The raw data was collected through Firebase logs and wrangled into six usable variables. Descriptive statistics and machine learning models, including Support Machine Vector, were used to achieve convergent and predictive validity. Through Phocrastination, we seek to broaden our understanding of academic procrastination as a personality trait and demonstrate the effectiveness of game-based assessments. It provides valuable directions for future studies aiming to enhance learning outcomes and student achievement.

Abstract Name: Remotely Controlled Capsule for Faster, Low Risk Brachytherapy for Cancer Treatment

The current problem with brachytherapy is that there are only two possible choices, High Dose Radiation (HDR) and Low Dose Radiation (LDR) brachytherapy. HDR uses radiation sources with very high energy

levels with a high dose rate that has a shorter treatment time but a higher risk of radiation. LDR uses radiation sources with low energy levels and low dose rates, that has lower risk of radiation but a long treatment period. In this research, a new implantable device is proposed that can control the release of radiation so that when closed, there is no radiation being emitted, and when opened can release the radiation with directivity towards the tumor to minimize the risk of radiation to the surrounding healthy cells, tissue, and organs. The frequency and duration of the release of radiation can be remotely controlled from outside the body, thereby enabling the optimization of the radiation therapy based on the size, type, and location of the tumor. The research methodology includes design of the capsule dimensions, type of metal, and thickness of metal based on the radiation source and energy level used. A circuit with inductive coils and electromagnet is designed to control the opening and closing of the radiation capsule remotely using inductive coupling via magnetic fields of the coil outside of the body and the implanted coil. Conclusions show that gold is the optimal candidate for the capsule metal, and the calculations show reasonable thickness of around 1mm to attenuate the radiation level within the safety level. Circuit designs showed it is feasible to use a single diode to convert AC current to DC current to control the electromagnet to push or pull the capsule cylinder. Overall, this is a first attempt in controlling the radiation for brachytherapy in the range between LDR and HDR.

Abstract Name: Development of UCE markers for phylogenomics in Caridean shrimps

Eusociality has evolved multiple times in the Caridean (infraorder) shrimp, especially in the genus Synalpheus from the West Atlantic. This genus is the only group known to have evolved eusociality in the marine ecosystem. The comparative analysis of the ecological and genomic underpinning of the eusocial evolution in Synalpheus has been limited by having phylogenies based on a small number of genetic markers and with a geographic breadth restricted to the West Atlantic. However, Synalpheus and potentially other origins of eusociality, can be found globally. This research aims to develop and design phylogenomic markers that can be used in Synalpheus and across the Caridean infraorder. We used the program PHYLUCE to develop ultraconserved element (UCE) markers using genome assemblies of four Caridean shrimp species (Pandalus platyceros, Caridina multidentata, Palaemon carinicauda and Macrobrachium nipponense) and one outgroup (Eriocheir sinensis). We designed baits to target these loci and evaluated these baits using an in silico approach. We identified over 6,000 markers and generated over 25,000 baits. We tested these baits using simulated Illumina reads from the four Caridean genomes and a preliminary genome assembly of Synalpheus chacei, and reconstructed a maximum-likelihood phylogenetic tree. Our tree is similar to published trees based on whole mitochondrial genomes and has better bootstrap support. Our research supports the utilities of UCE markers for phylogenetic inference across Caridean shrimps and the possibility within Synalpheus shrimps.

Abstract Name: Adenosine A2A receptors in the rostral ventrolateral medulla participate in blood pressure decrease with electroacupuncture in hypertensive rats

Acupuncture is increasingly used to manage high blood pressure (BP) as a complementary therapy. However, the mechanisms underlying its hypotensive effects remain unclear. Our previous studies have shown that electroacupuncture (EA) at ST36-37 acupoints, overlying the deep peroneal nerve, attenuates pressor responses through adenosine A2A receptors (A2AR) in rostral ventrolateral medulla (rVLM). However, it is uncertain whether rVLM A2AR contributes to EA's BP-lowering effect in sustained hypertension. We hypothesized that EA treatment lowers BP, in part, through activation of adenosine A2AR in the rVLM in hypertensive rats. To mimic essential hypertension in the clinic, we performed EA in conscious Dahl salt-sensitive hypertensive rats (DSHRs). EA (0.1–0.4 mA, 2 Hz) was applied at ST36-37 for 30 min twice weekly for four weeks, while sham-EA was conducted in a similar manner but without electrical input. In hypertensive rats, BP was reduced by EA (n = 14) but neither by sham-EA (n = 14) nor in the absence of needling (n = 8). Following four weeks of eight treatments and then under anesthesia, EA's modulatory effect on elevated BP was reversed by unilateral rVLM microinjection of SCH 58261 (1 mM in 50 nl; an A2AR antagonist; n = 7; P < 0.05) but not the vehicle (n = 5) in EA-treated DSHRs. Activation of rVLM A2AR in DSHRs treated with sham-EA by an A2AR agonist, CGS-21680 (0.4 mM in 50 nl; n = 8), decreased BP. Unilateral administration of SCH 58261 or CGS-21680 into the rVLM did not alter basal BP in salt-sensitive rats fed a regular diet with normal BP. The A2AR level in the rVLM after EA was increased compared to sham-EA and untreated DSHRs (n =5 in each group; all P < 0.05). These data suggest that a 4-week twice weekly EA treatment reduced BP in salt-sensitive hypertensive rats likely through adenosine-mediated A2AR in the rVLM.

Abstract Name: The Hazel Green Academy Revitalization Project

The Hazel Green Academy Revitalization Project is a community service-based project focused around restoring and repurposing the Hazel Green Academy (HGA). HGA was a private, college preparatory high school in Wolfe County, KY, that opened in 1880. At its height, HGA served not only as a school, but also as a source of education and community events. However, HGA closed in 1983 due to a rise in public schools in the area.The HGA Revitalization Project has three strategic priorities: create a community engagement event called Music on the Green; place all campus buildings on the National Register of Historic Places; and use the administration building for educational outreach by holding college courses on HGA's campus.These

strategic priorities will serve the community socially, academically, and holistically as HGA once did. Service-learning projects have been conducted to achieve the three strategic priorities. Students from the Craft Academy at Morehead State University have taken service-learning trips to HGA to maintain campus upkeep. This special project offers students the opportunity to engage in STEM education as well as serve the community. It is the hope of the HGA Revitalization Project to share this innovative project with other STEM-focused students throughout the state of Kentucky and beyond.

Abstract Name: Critiquing Fukuyama: Unraveling the Complexities of 21st-Century Challenges Through Deconstruction and Hauntology

In 1992, Francis Fukuyama declared in his book, 'The End of History and the Last Man,' that Western liberal democracy and capitalism were the final unfolding of history. Margaret Thatcher's slogan, "There is no alternative" reflects this general consensus in the geopolitcal West that the old ideological wars of the USSR and the United States were over, and what remained was Western liberal democracy and capitalism. However, the 21st century elucidated that this can no longer be the case. Impoverished countries, including in West Africa, Middle East, and South America, have revealed that productive forces of capitalism are heavily reliant on the mass colonial exploitation of labor. Additionally, the ongoing economic crisis and instability demonstrated through the recessions of 2008, the contradictions of the free market, and foreign debt. Lastly, the abundant evidence of ecological degradation on a global scale, most notably observed in climate change, is a significant concern. In this presentation, I explore the field of phenomenology within academic philosophy and its political implications. I draw on Jacques Derrida's book, "Specters of Marx," specifically examining his neologism of 'hauntology', which demonstrates that Neoliberal capitalist discourse, embodied by figures such as Ronald Reagan and Margaret Thatcher, still finds itself 'haunted' by the 'specters of Marxist' thought. Through this exploration, I aim to demonstrate and offer a critique of Fukuyama's ideas. Finally, to contribute to how we can revitalize the notions of what freedom, democracy and action can be understood within the 21st century as an urgent call for collective action. Only by confronting our reality can we effectively address these pressing concerns.

Abstract Name: Student Success Classification in Higher Education

Higher education is a required prerequisite for most professions in the STEM field. However, STEM fields

are inherently difficult, and some higher education students may find themselves lacking the necessary support or resources to succeed, currently resulting in an alarming 40% dropout rate. The objective of this research project is to bring awareness to early predicting factors that lead to increased student dropout, so that those students can be provided with help and resources early. This project involved developing a machine learning classification model to predict student success using early academic performance and various socioeconomic and macroeconomic factors. After trying various machine learning techniques, a Random Forest model was selected and trained on the dataset “Predict students' dropout and academic success” from UCI's machine learning repository, successfully achieving a test set accuracy of over 90%.

Abstract Name: Probing Electrochemical CO2 Reduction with a Bidentate N-heterocyclic Carbene Nickel Complex: (tBuNHC2Me)Ni(COD)

Chemistry plays an important role in CO2 reduction as well as closing the carbon cycle. Using nickel catalyst to reduce CO2 is the main goal of this research to be able to use CO2 as a chemical feedstock. Bidentate N-heterocyclic carbene nickel complexes (RNHC2R1)Ni (R, R1 = alkyl, aryl) have been reported for cross coupling reactions and can be readily synthesized from bis(imidazolium) salt ligand precursors. [tBuNHC2Me][Br]2 was deprotonated with 2 equivalents of potassium bis(trimethylsilyl)amide (KHMDS), generating two carbenes. After that, Ni(COD)2 was added resulting in formation of (tBuNHC2Me)Ni(COD), which was characterized by 1H NMR. Stoichiometric experiments with NHC carboxylates showed some reactivity with captured CO2 sources, and additional electrochemical reactivity studies are in progress.

Abstract Name: A study of machine learning processes to guide domain scientists using TIMSS education data.

Motivated by a growing interest within the education community, in this research we employ machine learning models to study students’ math and science achievements of Singapore students using non-cognitive factors. This study comprises three pivotal components: data balancer, feature selectors, and machine learners. To address the dataset's pronounced class bias challenge, the data balancer component evaluates the SMOTE and Random Undersampling methods to alleviate data imbalances. The feature selector comprises multiple feature selection algorithms that collectively vote to select the top features (out of several non-cognitive factors) for machine learning. This process reduces the data dimensionality, allowing ML models to learn and predict effectively. The machine learners consist of a suite of classifiers and regressors. The

classifiers comprise popular machine learning models to classify student achievement into five performance categories. The regressors use the selected features to predict the math and science scores. In our evaluation of machine learning models, we employ the Trends in International Mathematics and Science Study (TIMSS) data focusing on Singapore students. Our tested ML models demonstrate commendable classification and prediction capabilities. We also demonstrate an ML model selection algorithm that leverages machine learning performance metrics and user analysis preferences to select effective ML models for classification and prediction. Our study outlines an effective machine learning process, creating an effective guide for non-computer science researchers who wish to employ machine learning for their studies.

Abstract Name: Sex Differences in Response to Extracellular Matrix Nanoparticles in LPS-Induced Lung Injury

Acute Respiratory Distress Syndrome (ARDS) is a severe form of lung injury with a high mortality rate and no cure. ARDS is characterized by fluid accumulation in the lung and an exaggerated immune response, leading to poor gas exchange. Current treatments include mechanical ventilation and inhaled treatments. These treatments merely work to subdue ARDS symptoms or attempt to prevent further injury. The current inhaled treatments have a particle size on the microscale; however, it has been suggested that particles should be between 100-500nm to enter and remain in the distal alveolar regions of the lung. By utilizing electrosprayed nanoparticles of a decellularized porcine lung, we expect to see increased deposition of particles and higher biocompatibility due to organ-specific components of the ECM. We hypothesize that a higher dose will have a more positive effect on LPS-induced lung injury. For this study, a porcine lung was decellularized, lyophilized, cryomilled, and electrosprayed to form nanoparticles with a diameter of 225nm. Afterward, mice were injured with LPS to mimic the conditions of ARDS, then treated with ECM nanoparticles. Following a 24-hour recovery period, lung mechanics, bronchoalveolar lavage fluid, fixed lung tissue, and plasma were collected from the mice. In female mice, the most significant decrease in cell infiltration occurs with 0.125 mg/mL (1x) of ECM nanoparticles administered. In male mice, however, a lower dose (0.0625 mg/mL, 0.5x) of ECM nanoparticles trends toward a greater decrease in cell infiltration. While we hypothesized that higher doses of ECM nanoparticles would have a more positive effect on lung injury, our recent data has shown increased cell infiltration with the highest dose of nanoparticles. To further explore these findings, our future studies will include detailed protein and cytology analysis in BAL fluid, as well as analyzing lung histology, gene expression, and plasma proteins.

Abstract Name: The Cuban Revolution: Its' End & Beginning for Graphic Recognition

Cuban graphic design emerges as a vibrant and politically charged art form, reflecting the resilience and creativity of designers amidst challenging circumstances. Through a comprehensive analysis of the evolution of Cuban posters, this research illuminates the innovative techniques, visual languages, and ideological foundations that characterize the era's influence on graphic design. The study not only sheds light on the intricate interplay of art, politics, and culture in Cuba but also highlights the far-reaching influence of Cuban designers on global visual communication. By unraveling the threads of history, politics, and creativity within Cuban graphic design, this paper offers valuable insights into the impacts it had on a worldwide scale. Additionally, I examine Cuban poster design's transformative power of graphic communication with its messaging—shaping societal narratives and challenging established norms. Ultimately, this exploration of Cuban graphic design serves as a compelling case study, enriching our understanding of the intricate connections between design, society, and cultural evolution.

Abstract Name: Post-Impressionism in the East

Through a review of relevant literature and analysis of primary sources, this research demonstrates that post-impressionism had a profound impact on Eastern cultures. The movement inspired artists in Japan, China, and other Eastern countries to adopt new techniques and styles that blended traditional techniques with post-impressionist principles. For instance, the rapid emergence of techniques in Japan and the Shanghai School in China were a direct result of post-impressionism influence. The research also highlights that post-impressionism's impact went beyond just art styles, as it challenged traditional notions of beauty and representation in Eastern cultures. This led to a more diverse and inclusive artistic discourse, which allowed artists to explore their individuality and creativity. Additionally, I examine how the adoption of Post-impressionist techniques by Eastern artists helped to create a new visual language that blended traditional Eastern art forms with Western influences. Ultimately, my research highlights how Post-impressionism shaped the artistic and cultural landscape of the East in the early 20th century.

Abstract Name: Investigating the role of Hoxb13 in castration-resistant prostate cancer

Prostate cancer is the second most lethal cancer in men, whose ten to twenty percent are classified as castrate-resistant prostate cancer (CRPC), which makes special cases when patients receive hormone treatments. Although disease risk is most closely associated with age, a few cases linked to hereditary gene variants contribute to disease initiation and progression. HOXB13 is a homeobox protein that plays a role in prostate

epithelium development and expresses normal levels in an androgen deficiency context. At the same time, Hoxb13 has been shown to modify the Androgen-Receptor(AR)--binding gene expression responsible for tumorigenesis in either upregulation or downregulation. Using the transgenic HMKO mouse prostate cancer model, which overexpresses the human oncogene MYC in a prostate-specific manner, along with Hoxb13 loss-of-function, we study the impact of the Hoxb13 in prostatic carcinogenesis. At first glance from histology of different Hoxb13 genotypes, we observed a significant decrease in tumor initiations in mice carrying the deleted Hoxb13 allele compared to the Hoxb13 wildtype and Hi-Myc. The results suggest that Hoxb13 contributes to the transcriptome changes that permit transformation in MYC-driven prostate cancer, and one of those is the Androgen Receptor (AR) transcriptome. To confirm that loss-of-function Hoxb13 will downregulate proto-oncogene and upregulate the tumor-suppressing gene that under the regulation of AR, we analyze the mRNA and protein expression in HMKO. Understanding the role of HOXB13 eventually specialized drug development treating prostate cancer by targeting HOXB13 mRNA or protein,

Abstract Name: Exploring the Effect of Heteroatom Doping on Optoelectronic Properties of Nanographynes vs Nanographenes

Graphene-like 2D materials have been a subject of great interest due to their potential applications in photonics and electronics. Yet, achieving efficient bandgap tuning in these materials to render them semiconducting remains a challenge: graphene, in its pristine form, lacks a bandgap. Various methods, from exploiting quantum confinement and creating nanostructures to chemical modifications, have been explored to open the bandgap in graphene—all with limited success. Recently, a novel material called graphyne, which resembles graphene, but contains a mix of sp2 and sp-hybridized carbons, has been discovered. Early studies suggest this material may offer a more easily tunable bandgap, positioning it as a promising alternative to graphene.In this computational study we have investigated the effect of single dopants (e.g., Si and Ge) and co-dopants (e.g., B-N and B-P) on the optoelectronic properties of nanographene and nanographyne using density functional theory. Our results show that nanographyne, in comparision to nanographene, exhibits higher sensitivity to bandgap tuning and has a more stable electronic structure. In particular, doping nanographyne with Ge and Si induced a red shift in absorption wavelength, while B-N and B-P substitutions resulted in a blue shift of absorption. Among the various substitution patterns explored, heteroatoms incorporated within the central ring had the most pronounced impact on the bandgap of nanographyne.The results of this project advance our understanding of the factors governing optoelectronic properties in nanographynes, paving the way for the creation of well-defined nanostructures with desired characteristics. Moreover, it provides critical insights for the controlled design of 2D graphyne-based materials applicable in organic field-effect transistors, organic photovoltaics, and organic light-emitting diodes.

Abstract Name: Arts and Crafts: Is it Art?

The Arts and Crafts period started around 1876 and ended around 1916. This period consisted of very floral designs, borders, blackletter typefaces, and new technology. This movement was the response to the Industrial Revolution and the effects of mass-produced art and design. The most prominent design that affected graphic design would be typography, the evolution of printing, and wood carvings. William Morris had an immense amount of impact on the arts and crafts and influenced many other designers as well. He kept the handcrafted arts alive as well as designed multiple books that would also become very popular. The connection between typography, printing, and wood carvings conveys the impact the arts and crafts movement had on graphic design.

Abstract Name: Trust, Transparency, and Technology: Building Digital Equity Through a Civic Digital Commons

This research project involves designing and deploying a digital rights platform that operationalizes the City of Long Beach's data privacy guidelines and its Framework for Reconciliation. The researchers are mounting "data privacy notices" in three Long Beach neighborhoods, physically adjacent to or digitally embedded within civic technologies, e.g., surveillance cameras, mobile payment kiosks, public WiFi routers, the City's parking app. The notices feature a QR code that, when scanned, takes users to an online platform that details how the City uses and stores data from that device, and who can access those data. Users can also share comments/concerns with local government officials. By providing transparency and accountability, the digital rights platform has the potential to promote greater trust between residents and local government. This mixed methods study utilized focus groups, data walks, and surveys to collect qualitative and quantitative data to answer the research questions. Transcripts of comments gathered from these data collection efforts were coded and analyzed using the constant comparative method of Glaser & Strauss (1967). The research findings will inform the digital rights platform design and ensure it is aligned with the priorities and needs of Long Beach residents.

Abstract Name: Insular Cortex Perineuronal Net and Parvalbumin Intensity Throughout the Mouse Estrous Cycle

Perineuronal nets (PNNs) are extracellular matrix structures that stabilize synapses of parvalbumin (PV) interneurons in the insular cortex and play a crucial role in the brain's adaptive response to drugs and alcohol. Studies indicate higher PNN intensities in the insular cortex in female mice, which is associated with increased aversion-resistant alcohol drinking. As alcohol use disorder (AUD) has increased in women over the past few decades, understanding the mechanisms that mediate this condition is vital for the development of new biological targets and sex-specific treatments. While previous research has linked estrogen levels to elevated hippocampus PNNs, the relationship between 17β-estradiol fluctuations during the estrous cycle and insular cortex PNNs remains unexplored. This study tracked the estrous cycle stages in female mice and compared PNN intensities in the insula, assessing associations with estrogen and progesterone levels. Using fluorescently labeled Wisteria floribunda agglutinin (WFA) to visualize PNNs and a fluorescent antibody to parvalbumin for PV neurons, we show here that PNN intensity was highest in the insular cortex during estrus, indicating an association with low estradiol levels. In contrast, the estrous cycle had a limited impact on PV intensity. These findings suggest a complex relationship between hormone fluctuations, particularly 17β-estradiol levels, and PNN dynamics in the insular cortex. This knowledge may provide a greater understanding of sex-specific mechanisms underlying AUD.

Abstract Name: Lifetime Discrimination, Perceived Stress, and Social Support as Predictors of Depression.

Depression, or major depressive disorder, is the most common psychiatric diagnosis, and is a leading cause of disability worldwide (NAMI, 2022). As depression becomes more widespread, many studies are being conducted to analyze its etiology. The study aimed to identify whether social factors, such as lifetime discrimination, perceived stress, and social support predict depression. The study hypothesized that higher levels of both lifetime discrimination and perceived stress would predict depression. Additionally, the study hypothesized that lower levels of social support would predict depression. For the study, the target demographic was young adults, ranging from 18 to 24 years of age. The participants consisted of 113 undergraduate students recruited from the psychology department at California State University, Long Beach. The participants completed an online survey that consisted of questions regarding the discrimination they have experienced throughout their lifetime, their perceptions of stress, their levels of social support, and their symptoms of depression. A multiple regression was conducted such that lifetime discrimination, perceived stress, and social support were regressed onto depression. The result indicated that the regression model was statistically significant ($F(3,109) = 6.07$, $p < 0.001$, $R^2 = 0.14$). The findings indicated that perceived stress ($\beta = 0.35$, $t(109) = 3.98$, $p < 0.001$) was a statistically significant predictor of depression. Moreover, greater perceived stress would significantly predict greater depression in participants. Therefore, it is plausible that perceived stress may predict depression. However, the findings indicated that lifetime discrimination ($\beta = 0.15$, $t(109) = 1.68$, $p = 0.097$) and social support ($\beta = -0.003$, $t(109) = -0.03$, $p = 0.977$) were not statistically significant predictors of depression. Thus, it is plausible that neither lifetime discrimination nor social support would predict depression. Nonetheless, further extensive research is necessary to learn more about lifetime discrimination, perceived stress, and social support as predictors of depression.

Abstract Name: Does cognitive behavioral therapy for insomnia (CBT-I) improve insomnia and anxiety symptoms in college students?

Introduction: Insomnia disorder is prevalent in college students and commonly co-occurs with mental health conditions such as anxiety. Cognitive behavioral therapy for insomnia (CBT-I) is the first line recommended treatment for insomnia, typically for patients that are middle aged or older, but less is known about its performance in college students, which this study aims to investigate. Methods: 34 college students (Mage = 19.71 years, 58.8% Female) from Denton, Texas, and diagnosed with insomnia disorder were randomized into in-person CBT-I or waitlist control (WLC) groups. At both pre- and post-treatment, participants completed the State-Trait Anxiety Inventory (Spielberger et al., 1983) and the Consensus Sleep Diary (Carney et al., 2012), from which sleep efficiency (SE) and wake after sleep onset (WASO) were derived. One-Way Analyses of Variance (ANOVA) assessed group differences in pre- to post- treatment changes in SE, WASO, and anxiety symptom severity.Results: One-Way ANOVAs revealed significant group differences in pre-to post-treatment changes in SE ($F(1, 26) = 9.57$, $p = 0.005$) and WASO ($F(1, 26) = 10.54$, $p = 0.003$) but non-significant group differences in anxiety symptom severity ($F(1, 27) = .045$, $p = 0.834$) between CBT-I and WLC groups. Specifically, those who completed CBT-I reported more improvements in SE ($M = 0.14$, $SD = 0.09$) and WASO ($M = -23.90$, $SD = 19.06$) than controls ($M = -0.01$, $SD = 0.16$; $M = -2.04$, $SD = 15.46$, respectively).Conclusion: Our results demonstrate CBT-I improves sleep, specifically SE and WASO, in college students. However, results suggest CBT-I does not significantly impact anxiety symptoms. The literature on CBT-I and anxiety remains mixed which warrants further investigation into the transdiagnostic effects of CBT-I on secondary mental health outcomes in college students. Future research should also investigate the specific conditions that CBT-I should be perform under that could produce effective improvement on secondary mental health symptons, such as anxiety.

Abstract Name: Assessing toxicity of the potential nitrogen carriers for nano-enabled fertilizers, hydroxyapatites, in Caenorhabditis elegans.

The growing global population has increased the demand for crop production, leading to an increased usage of nitrogen-based fertilizers. However, less than 50% of the applied nitrogen is bioavailable for the plants due to being leached out in the form of nitrates and emitted into the air as greenhouse gas, thus contributing to climate change. Nano-enabled fertilizers that can be employed for more efficient targeted nitrogen delivery with slow release are being developed. In this study safety-by-design approach has been utilized to evaluate potential toxicity of such candidate nanomaterials, Zn- or Fe-dopped Hydroxyapatite (ZnHAP and FeHAP) in a soil nematode, Caenorhabditis elegans. To aid in delivery of nanomaterials into the plant's stomata by reducing surface tension, surfactant is being added. Thus, we have examined toxicity of Zn- and FeHAP alone and in the presence of surfactant Silwet L-77. Mortality, reproduction, and growth endpoints were assessed to determine toxicity of Zn- and FeHAP to C. elegans. With ZnHAP, on average 24% to 34% mortality was observed from 100 mg/L to 275 mg/L potentially due to Zn dissolution after uptake. We have not observed the release of Zn from the materials before the uptake in the media. FeHAP showed lower toxicity and did not cause mortality above 10% up to 300 mg/L and reached 25% only at 700 mg/L . Reproduction was not affected at the tested lower concentrations of both Zn- and FeHAP. However, surfactant Silwet L-77 at 0.1% and 0.2% alone and when combined with the Zn- or FeHAP caused significant toxicity to the nematodes. Our results indicate that FeHAP has lower toxicity and might be a better candidate for nitrogen-enabled fertilizers. [TV1] We are also exploring toxicity and behavior of other surfactants in the presence of Zn- and FeHAP. Please re-check these results according to your poster data. [TV1]

Abstract Name: Ultrasound Forcing: Device Design and Applications in Neuromodulation

Focused ultrasound, a cutting-edge technology, has emerged as a powerful tool in the field of medical science for noninvasively targeting and manipulating biological systems within the human body. Neuromodulation, the manipulation of neural activity using low-intensity focused ultrasound, is a growing interdisciplinary field with a major goal of noninvasively treating disorders in the brain such as epilepsy, chronic pain, and migraines. In order to advance towards these goals, it is crucial to study neural systems in isolation, as this allows for direct observation of the neuromodulation's impact. For this reason, an acoustic forcing device that can create focused ultrasound waves was designed and assembled. This square-shaped device fits inside a petri dish, and the vibration of its piezoelectric ceramic plates when connected to a function generator creates waves that propagate through the medium. To test the device, we patterned microbeads in a petri dish of water in order to characterize the strength and spatial pattern of the acoustic forcing. This acoustic forcing

device was then used in experiments attempting to stimulate calcium activity in human neural progenitor cells. In future experiments, this device can be used to conduct further experimentation on neural networks. The results of this acoustic forcing research provide further information on the impact of focused ultrasound on neural cells, and future research will expand upon the characteristics of the acoustic forcing device.

Abstract Name: Identifying Geographic Disparities in Suicide Rates and Survey Data Involving Risk Factors

The purpose of this project is to identify geographic disparities in suicide data and known risk factors using publicly accessible data. The state of Oklahoma has been in the top fifteen states reporting suicide mortality for the past ten years, usually falling within the top ten. Within Oklahoma, we will attempt to identify factors that contribute to disparity using BRFSS survey data. Our community campus is located within Tulsa County, second only to Oklahoma county in population. Data from the National Violent Death Reporting System will be compared to self-reported survey data involving the risk factors related to cause of death. Public Health initiatives regarding suicide are relevant and significant. In 2020 suicide was the twelfth leading cause of US death overall (45,979). This number is almost twice the size of homicides (24,576) reported in the US during the same year. Provisional CDC data indicates that both the number and the rate of suicides in the US increased 4 percent from 2020 to 2021, after two consecutive years of decline (2019-2020). The Oklahoma Violent Death Reporting System (OKVDRS) is a statewide surveillance system for monitoring suicides, homicides, undetermined manner deaths, unintentional firearm injury deaths and legal intervention deaths that collates data from medical examiner reports, death certificates, and law enforcement reports. Medical examiner suicide data for the state's two most populous counties (Oklahoma and Tulsa) will be compared to collated data. Adults reporting a health care professional diagnosis of any depressive disorder will be compared between counties, and adults reporting 14 or more days during the past 30 days during which their mental health was not good. Geographic disparities exist and can help leverage public support for protective factors, education, and intervention strategies. The goal of this project is illumination of potential solutions for our campus community.

Abstract Name: Willingness and Reluctance to Communicate with Police

The study aims to understand social psychological scales and create a data set that properly assesses the relationship between populations and their communication with police. There is a high level of aversion to communicating with police throughout the United States between individuals and communities. There needs

to be more knowledge of the degree of willingness of citizens to communicate with police. Many minority communities consider "snitching" a highly infamous offense with a particularly negative connotation. An examination of the phenomenon of snitching is carried out in this study by using a survey to examine and analyze the willingness/reluctance of individuals to communicate with police. The survey scales individuals' trust, loyalty, and connection to the police. The measure more directly addresses the matter than traditional measures of "trust in police" and also looks at key potential correlates. Some of these probably are indicators of criminal risk, but others might be seen as positive attributes, such as distrust of authority or loyalty to groups and friends. Many studies on this issue have problems because reluctance to work with police is correlated with distrust of police and criminal thinking and behavior, which are not shared widely in general population samples and may not be studied in enough numbers. After a small pilot study, we attempt to remedy that by targeting the study toward a more at-risk and economically disadvantaged U.S. population.

Abstract Name: Creating a Ten Legged Spider: Using CRISPR Technology to Produce a Transgenic Arachnid

Transgenic animal models have been used for a variety of different species to show how DNA can be modified to enhance specific mutations and showcase gene function. For example, Dr. Frank Ruddle figured out stable inheritance by inserting foreign genes into a transgenic mouse and seeing how it transferred to its offspring. However, there is not a successful completion of a transgenic arachnid yet to be completed. By using a CRISPR-Cas9 system, it is believed that creating a transgenic arachnid is possible. CRISPR-Cas9 technology can be used to edit genes by creating an RNA complex that attaches to DNA strands, cutting them in half, and then inserting programmed DNA into the cut section. By using this technology, we hypothesize that arachnid DNA can be modified to remove the segmentation between the head/thorax and abdomen, and instead generate a fifth pair of legs, making this the first transgenic arachnid. Parasteatoda tepidariorum, the common house spider, is injected with the Cas9 sequence into the ovaries. Once the parasteatoda tepidariorum lays eggs and then hatches, the clutch is separated into multiple containers. At this time, the spiderlings are highly observed through microscopes to determine if any physical characteristics of the mutation are present. After about two weeks, one group of ~10 parasteatoda tepidariorum undergoes DNA extraction, which is then used to run PCR tests to determine if the clutch carries the DNA to generate a fifth pair of legs. The PCR results are observed through gel electrophoresis, and then interpreted through the present alleles. The process is then repeated with all future clutches from the offspring of the originally injected parasteatoda tepidariorum until results are shown. If succeeded, this will be the first transgenic arachnid, and can be used to study future regeneration and evolution of segmented invertebrates.

Abstract Name: Satire in the Magical World

The research collected in this essay provides new insights into Harry Potter and The Order of the Phoenix revealing J.K Rowling's hidden social criticism. In Harry Potter and the Order of the Phoenix, J.K. Rowling uses satirical elements, such as parody, hyperbole, and mockery, to call out and expose the dangers of government interference with the education system. Whether or not this was her intention, Rowling uses the teachers in her novels to represent good versus evil, good education versus American education. This paper highlights stumbling blocks that American Education has had to overcome, such as the No Child Left Behind Act. The NCLBA is the basis for the mockery shown in Harry Potter and the Order of the Phoenix through Professor Umbridge neglecting active learning and solely focusing on the education pushed by the Ministry. Professor Umbridge and The Ministry of Magic can be read as a mimicry of the American Education system suffering through the rules of the NCLBA. My analysis is shaped by Victoria Scholz's paper "Other Muggles' Children: Power and Oppression in Harry Potter," and John McNally's article regarding the NCLBA: "Many Children Left Behind: How the No Child Left Behind Act Is Damaging our Children and Our Schools." This interpretation of The Order of the Phoenix helps us to recognize and spread awareness about how America's education system is suffering. Rowling's novel is trying to help us through the means of parody: showing our education system how things can go terribly wrong when government interferes, using the allegorical interference of the magical government in the wizarding school. This paper hopes to humble us and show that even our neighbors in the UK are noticing what is wrong with our education system and that they are trying to show us what's right and wrong.

Abstract Name: Cutting Costs on Campus: Early In-Person Voting and Voter Turnout

National voter turnout rates reveal that young Americans are consistently underrepresented at the polls. With millions of the nation's youngest voters obtaining their right to vote amidst the transition from high school to college, this period highlights an opportunity to instill patterns of habitual voting within the nation's newest voting bloc. Relatedly, it is recognized that college students may face unique barriers to casting a ballot. One potential reform that may increase access to voting for undergraduate students is the convenience of on-campus early in-person (EIP) voting locations. Accordingly, this study investigates the impact of on-campus EIP voting on undergraduate voter turnout in North Carolina poised around the question, "Does the presence of on-campus EIP voting yield a higher turnout of undergraduate voters?" Drawing on theories of voting behavior and civic education, I expect that the convenience of on-campus EIP voting sites could increase voter turnout amongst undergraduates. To test this hypothesis, the study uses a mixed-method approach, combining voter turnout data from 2018, 2020, and 2022 general elections at North Carolina universities with interviews of collegiate professionals to identify cross-institutional patterns. The ultimate findings of this study will contribute to a more nuanced understanding of the role that convenience voting methods play in enhancing youth engagement in the democratic process. Ultimately, this study provides insight into youth voter turnout with broader implications for policymakers, educators, and public administrators seeking to implement effective strategies that promote youth voter engagement in the United States.

Abstract Name: The History and Evolution of Traffic Signs

AbstractThis paper will cover the design history and evolution of traffic and street signs in the United States from the 1900s to the present day. It will include the importance of easy recognition within street signs. As well as how certain design elements can have an impact on how quickly a driver can react to a sign. The use of color, typography, shape, and reflectivity play an important role in traffic signs. In addition, there have been multiple changes to increase legibility and driver safety through acts of standardization and material changes.

Abstract Name: Inclusive Playful Learning Spaces: A Guide to Intergenerational and Diverse Learning Environments

The Disability Rights Movement established the United States' first civil rights guidelines for people of various abilities in public spaces and education. However, since then, limited progress has occurred in creating socially equitable environments for all to experience. Inclusive design considers the age, identity, race, abilities, location, and economic demographic of the people in a space. By investigating how to make these spaces inclusive, designers can create more diverse and accessible learning tools for children and communities. Therefore, what if inclusive design could be incorporated into playful learning practices to alleviate this problem? Playful learning is a design concept meant to create educational opportunities for children that allow self-exploration and expand social, emotional, physical, cognitive, and academic skills. Reviewing existing literature on inclusive design and playful learning spaces, I have developed guidelines and learning tools to educate designers and community members on what these environments consider. These learning tools will inspire awareness of designing for inclusivity while encouraging learning through play.

Abstract Name: Weight Stigma Toward Pregnant Patients: An Experimental Study of Medical Students

People who are overweight and obese commonly experience weight-related stigmatization, including within the healthcare system. Weight stigma from healthcare providers can lead to negative psychological and physiological outcomes for patients. This is particularly important in pregnancy care, as weight stigma is associated with pregnancy complications, even when controlling for actual weight. Previous research indicates that many medical providers harbor biases towards individuals with obesity, but few studies have explored the prevalence of weight stigma specific to pregnant patients. The current study investigates the presence of implicit and explicit weight bias in a sample of pre-service healthcare professionals (i.e., medical students). Using a between-subjects experimental design, participants are randomly assigned to either read a vignette about a normal weight or an obese pregnant patient. Participants then complete a number of questionnaires related to medical decision-making, perceptions of and liking of the patient, explicit attitudes about people with obesity (the Anti-Fat Attitudes Questionnaire), and knowledge about weight gain guidelines during pregnancy. We are currently collecting data at one Midwestern medical school (n=47 to date), with plans to recruit additional participants in January, 2024. Independent samples t-tests and Cohen's d effect sizes will be used to compare medical students' perceptions and attitudes towards obese versus normal weight patients. We hypothesize that medical students will report more negative attitudes toward caring for obese pregnant patients, and perceive obese pregnant patients as having poorer self-management. We also predict that few students will have accurate knowledge of official pregnancy weight gain recommendations. The results of this study will be useful in understanding current trends in medical students' weight biases, which can then inform curriculum decisions.

Abstract Name: Dietary Adaptations to Fertilizer Use. Exploring Short-term Dietary Change from Stable Isotope Analysis of Mummy Hair and Archaeobotanical Remains in Pre-Hispanic Chincha, Peru

While stable carbon and nitrogen isotope analysis are the pillars of paleodietary reconstruction, we know that climatic aridity and agricultural additives live bat guano or manure fertilizers can alter stable isotope values from those expected based on the presumed food web consumed by a community at a particular time. Therefore, before attributing isotopic change in human tissues to dietary change, we must first rule out changing fertilizer usage and understand the contributions to altered isotope ratio values from periods of intense desertification—dependent of human practices. This study conducts stable isotope analysis of human mummy hair from a drought period prior to the Inca Empire's rise, relative to modern and ancient plants from excavated and AMS-dated contests in the Kingdom of Chinch (South Coastal Peru). Together with published comparative SIA data from hair and plants, results will show how similar maize agricultural practices and maize consumption were In Chincha to other sites and region to identify the outcomes of human intervention in this case.

Abstract Name: Understanding trends in political issue framing through innovative statistical processes

Understanding political discourse requires analyzing how candidates frame issues differently even if they agree, called issue frames. This research analyzes the issue frames used by congressional candidates from 2008-2022, utilizing a dataset of about 55,000 issue positions pulled from candidate's websites. Our research gives recommendations on finding the right number of issues to analyze and how to identify issue frames by using diagnostic statistics.We first employed BERTopic, an algorithm developed by Grootendorst (2022), to analyze all statements together and identify the primary political issues being discussed. This gave us a list of primary issues and keywords that signify a specific issue, but requires us to specify standards to find the right number of issues and when to combine or separate issues as needed.We then find a discrete snippet of words surrounding BERT keywords for a given issue, and compile these words for each candidate in a year. This yields a data frame, where each row has a candidate, a year, and all of the words they used discussing that issue that year. Next, we used structural topic models (STMs), as outlined by Roberts et al. (2013), to find issue frames based on candidate's word choices. We use topic coherence and uniqueness measurements to find the right way bandwidth of words to analyze and number of topic frames to look for. STMs can take into account various covariates such as political affiliation and year while analyzing word choice clusters. This gives an understanding of how political parties have separated, how time has impacted issue frame choices, and what trends we may expect to continue in the future.

Abstract Name: THE FEASIBILITY OF BIODEGRADABLE PACKAGING IN GHANA

Research Question What is the feasibility of biodegradable packaging in Ghana? Research Context This research would be solely focused on Ghana. Ghana is committed to achieving the Sustainable Development Goals of the UN, especially Goal 12 on responsible consumption and production and Goal 13 on life below water, which is supported by this study. Using sustainable packaging may decrease plastic pollution, which will help Ghana progressively get closer to meeting these goals. The use of biodegradable packaging will assist Ghana in protecting public health, marine life, and economic growth. Research Methodology The research methodology for exploring the feasibility of biodegradable packaging in Ghana is meticulously outlined. The research philosophy employed is pragmatism, emphasizing practical problem-solving rather than adhering to a specific philosophical stance. The reasoning approach is inductive, aligning with the exploratory and qualitative nature of the study. The research design adopts an exploratory case study with a qualitative approach, allowing for a detailed investigation into the complexities of biodegradable packaging within the Ghanaian context. The scope involves purposive and convenience sampling of key stakeholders such as manufacturers, food vendors, and consumers. Data will be collected through semi-structured interviews and focus group discussions, employing thematic analysis for qualitative data interpretation. The study acknowledges limitations in generalizability and potential oversights in stakeholder representation. Validity is reinforced through member checking and peer debriefing, ensuring the trustworthiness of findings. Ethical considerations encompass informed consent, confidentiality, voluntary participation, and respectful

treatment of participants, ensuring the study upholds ethical standards in its exploration of biodegradable packaging's feasibility in Ghana. Conclusion Biodegradable packaging has various advantages and can significantly reduce Ghana's plastic waste problems. This study would bring economic benefits to businesses using greener packaging, which might lead to cost savings and enhanced corporate social responsibility.

Abstract Name: Do Voters Turnout for Black Women?

The United States Congress is meant to be an establishment that represents the US population within our government. With 7.7% of the population being Black women, why do they make up less than 1% of our congressional branch? Previous scholarship on voter turnout and congressional representation focus on the overall representation of a minority population without reference to the potential impact gender might also play. I leverage election data from the 89th Congress to the 118th as well as voter turnout records to answer the following questions: What is the differential impact of gender on voter turnout for Black candidates for the United States Congress? Is there a racialized gender differential between Black men and women within Congressional elections? Through an ordinary least squares statistical analysis, I aim to determine the difference in voter turnout when there is a Black woman on a Congressional ballot versus a Black man to better understand the impacts of race and gender on voter turnout.

Abstract Name: Challenges in Post-Processing of Fused-Deposition Modeled Parts

This work explored possible improvement in the Post-Processing of Additively Manufactured Acrylonitrile-Butadiene-Styrene (ABS) parts from the Stratasys F370 Fused Deposition Modeling (FDM) 3D Printer. The printed support material was dissolved in a Sodium Hydroxide solution at a pH of 10; previous research found that blisters/voids were formed in ABS parts when placed in an ultrasonic tank for cleaning. To eliminate or minimize these formations, a flow method was employed using the same ultrasonic tank but leaving the frequency off and incorporating circulation within the solution. This method used a steel paddle attached to a synchronous motor with an Revolutions Per Minute (RPM) of 60-70. Five 1x1x1in blocks were printed and tested for the first test of experiments. Another set of experiments looked at the dissolving rate of support material. Four 3x2in cylinders with a depth of ⅛ in were printed using ABS that had soluble support inside the hollowed-out area. This was to determine the dissolving rate by both ultrasonic method and the flow method. It was found that in the flow method void experiment no voids were found. In the support removal experiment, it was found that each method was more optimal for specific design formats. Nevertheless, both methods were successful and effective for removal of support in all four experimental

trials.Keywords: Fused-Deposition Modeling, Flow Method, Ultrasonic Tank, Support Material, Blisters, Post-Processing

Abstract Name: Opinions on the Necessity of a Carbon Tax

Daily activities including transportation, production of goods, electricity generation, and waste all add to humans' overall carbon footprint. One way to incentivize people to produce less carbon is to apply a tax to those who over-emit. The target of these taxes generally are corporations who contribute greatly to our carbon footprint, but there are often misunderstandings about how these taxes work. This study attempts to measure the opinion of students at the University of Wisconsin-Stout about carbon taxes when they are levied on an individual versus when they are levied on corporations. We find that most respondents wanted corporations to pay the tax if they over-emit. Leveraging Chi-square analyses, evidence supporting several relationships were determined. Much like the US population broadly, partisanship was an important influence. Ninety-seven percent of UW-Stout students that identify as Democrats stated that society would receive benefits if corporations paid more in taxes to lower emissions. Alternatively, only thirty-five Republican identifying students at UW-Stout stated that corporations paying more in taxes to lower emissions would be a benefit. There were a substantial number of neutral opinions about carbon taxes, which was a surprising finding considering past literature showing that the respondents would be more unanimous feeling more positively about having the tax be placed on corporations. Perhaps our results indicate that students have a certain level of distrust towards the government. There could also be a lack of knowledge overall when it comes to the carbon tax policy. Alternatively, it could be that they don't care what happens in their community if it doesn't affect them personally. We suggest that future studies further explore the relationship between trust in government and environmental policy knowledge and their effects on opinions on carbon taxes.

Abstract Name: Evita: The Unassuming Rise of Argentina's Most Beloved First Lady

Born in the rural town of Los Toldos, Argentina, Eva María Duarte was not the heiress to great wealth, fame, or success. The illegitimate daughter of a wealthy farmer, Eva was often overlooked and shunned by siblings and citizens of her town. Her rise to fame as one of Argentina's most renowned historic figures was unprecedented, and it did not follow the acceptable patterns of her time nor those of other great Latin American heroes. From rumors of a romantic relationship with a dashing guitarist to her fateful move to the

city of Buenos Aires and her marriage to the low-ranking Minister of War, Juan Domingo Perón, who would become President of Argentina, the life of the now-iconic Eva Perón is shrouded in mystery. This research explores the myths, presuppositions, and assumptions made about Eva Perón's life and influence, and separates fact from fiction and speculation. It is a study of the charismatic leadership of one of Latin America's most famous ruling couples and an exposition of the origins of many long-perpetuated rumors regarding Eva Perón's rise to fame. Known charmingly as "Evita," a nickname that garnered international renown with Andrew Lloyd Webber's musical of the same name, Perón is often viewed as a sleazy, over-sexualized female powerhouse rather than a charismatic, adoring, and calculated leader who sought to accomplish what she perceived as best for her nation. Using Evita's memoir, primary sources from those affected by her policies, and modern praises of her work, the research seeks to provide an accurate portrait of Argentina's most loved First Lady, Eva Perón.

Abstract Name: The Impact of Zoom on Smartphone Camera Identification

Feature-based forensic science involves the process of identification, where experts attempt to determine whether a questioned object is of the same origin as a known item. In camera identification, this typically means a photo of unknown origin is compared to a camera fingerprint from a suspect's camera. By using the Peak-to-Correlation Energy (PCE) score to measure the similarity between a questioned image and a camera fingerprint, it is often possible to determine with a high level of accuracy whether the questioned image was taken by the suspect's camera, i.e., whether the image and fingerprint 'match.' This project expands on camera identification by testing whether zooming in affects the reliability of identification on various smartphones. The Center for Statistics and Applications in Forensic Evidence (CSAFE) purchased sixty phones for camera identification research. This project began by testing ten iPhone 14 Pro's-- a phone with a dedicated telephoto (zooming) camera. Photos were collected with the telephoto camera on each phone at five different zoom levels (3x, 6x, 9x, 12x, and 15x). Two hundred images were taken at each zoom level, one hundred of which were of a blank wall and one hundred were of natural scenes. The blank wall images are used to calculate the phone's fingerprint, an average of the blank wall image noise residuals. The natural scene images are then compared to the blank image fingerprints. Our initial results show that camera identification for 3x zoom magnification is fairly accurate but unreliable for magnification greater than 3x. Further trials are being conducted to evaluate this result over a range of phones and to see if anything can be done to improve the reliability of identification.

Abstract Name: Portable Weather Prediction Device

Abstract— The U.S. military currently relies on the Defense Meteorological Satellite Program to predict weather around the world. In some situations, communication with satellites is dangerous or difficult, if not impossible, a localized system for predicting severe weather is therefore beneficial to soldiers. To address this problem, the team has developed a portable low-cost weather detection system and algorithm to make predictions of extreme localized weather. The small-footprint microcontroller-based system measures pressure, temperature, and humidity over time and provides a real-time extreme weather assessment without reliance on satellite data or any communications. Though current devices are capable of collecting localized data, none of these predict incoming weather. Using data for Charleston, SC, the most significant indicators for predicting incoming weather are pressure, temperature, and humidity. In assessing storm risk, the pressure must be above 1009 mb for no storms, 1000-1008 for mild storms to thunderstorms, and any pressure of 1000 or under can result in Hurricanes, cyclones, and typhoons. Heat and water vapor are required for precipitation. As temperature increases so does humidity leading to a storm formation.

Abstract Name: The Art of Communication with AI: Unlocking the Power of Generative Language Models

The increasing popularity of generative AI models has led to a new research trend focused on improving collaboration with these models and optimizing their results. In other words, now that generative models are capable of solving problems, how should we interact with their applications, such as ChatGPT and Bard, in order to get the best result? In our research, we focused on Prompt Engineering, one of the trends in this area. We used a systematic literature review framework to gather and analyze the newest papers, introducing Prompt Engineering methods and how they can improve human interaction with language models in the form of prompts and lead to accurate and applicable results. In addition to a brief description of the logic behind each of these methodologies, we will present a number of examples to show how to apply these methods in our daily use cases of Language Models. This research aims to provide a guideline for understanding and using prompting methodologies for different use cases, including but not limited to Few-Shot Prompting, Chain-of-Thought Prompting, and Generated Knowledge Prompting, in addition to understanding the general attributes of a successful prompt. We are looking forward to a comprehensive literature review that includes test cases and identifies research gaps in this developing area.

Abstract Name: Anti-Racist and Inclusive Arts Education in Secondary Schools

My project aimed and succeeded in creating a website that hosts a curriculum framework that is inclusive to

artists all over the world. In our education system, there is a serious lack of diversity in the artists we learn about. In middle schools, some kids don't even really learn specific artists, just different art styles, but what good are the styles if we know nothing about their stories! I researched and focused on artists who are Black, LGBTQ+, and disabled, but organized the project resources so that educators can use the template to include endless possibilities of other cultures and/or groups of people. Along with the groups of artists, the website contains a page full of resources for teachers to make diversifying their classrooms more simple in hopes to take anxiety out of an often heavy subject. Not only will this educate our educators, but it will allow students (especially students belonging to a minoritized group) to get an understanding of how they want to develop their own personal art styles and see themselves as artists because they have someone whom they can look up to. Owning my positionality is important here because as a white woman I will never understand the struggles and complexities of what it means to be minoritized, but I just hope that I can use my voice to help, and I am always open to learning from diverse groups on how to improve and become the best version I can be for all my future students!

Abstract Name: An Investigation of Water Quality Surrounding Environmental Justice on the Waterways of Southeast Raleigh, NC

Walnut Creek Wetland Center located in downtown Raleigh, North Carolina is rich in history of injustice resulting from a lack of environmental stewardship over several years. Many homes built in this southeast area of Raleigh where known floodplain issues occurred were forced on historically black families. Over the years, the waterways in this vicinity were known for trash dumping grounds and resting areas for waste coming from the upstream flow of Walnut Creek. In the mid 1990s, the surrounding community took action and began focusing on improving the issues of flooding and poor water quality. Working with Partners for Environmental Justice (PEJ), we began a study to monitor the waterways as a result of the years of environmental justice issues. The aim of this project is to investigate the possible point sources that could be the main cause for contamination in the Little Rock Creek. Weekly measurements of basic water quality parameters such as pH, dissolved oxygen, conductivity, turbidity, and nutrients, along with monthly biological testing, have shown significant concerns. The preliminary data findings will be used for community outreach and assessing wetland ecosystem services. This monitoring of various locations will lead to vital information to share with stakeholders in making future decisions regarding environmental stressors and their impact on this community.

Abstract Name: The Influence of Historically Contextual Video Game Franchises Towards an Individual's Perception of Historical Knowledge

Video games are a form of interactive entertainment which encourages further engagement from players. Billions of people have incorporated video games into their lives, with many playing daily. This has led many to consider the potential video games have as instructional tools in education. Past research has focused on analyzing the educational potential of incorporating video games into social studies courses. While findings are mixed, a sizable group of researchers support the incorporation of video games into the classroom. Outside of the debate on whether they should be used or not, the literature hasn't focused as much on how video games are related to an individual's perception of their knowledge, and specifically how historically contextual videogames can effect one's perceived rating of historical knowledge. In order to fill this gap, I distributed a unique online survey to 1500 students at a regional public school in Wisconsin and separately to a community Facebook group for the town the University is located in. The results indicate that there is a significant relationship between those who are interested in playing historically contextual video game franchises and their perceived knowledge of world history, with those who were interested in historical video games rating their historical knowledge higher. Even when controlling for demographics like gender, marital status, and the amount a person reads, there still is a significant relationship between one's perceived knowledge of world history and their interest in playing historically contextual video game franchises. This study thus provides further information about what influences our perception of historical knowledge.

Abstract Name: What do Americans Know?: A Study on the Relationship between Students US Civic Knowledge and their Demographics

Civic knowledge is pivotal for creating informed citizens who participate in government and understand how their country operates. A lack of education in this area could be diminishing our abilities to understand complex issues and participate in democracy. Thus, this project centers on assessing the amount and type of knowledge amongst college students as measured by their performance on the US citizenship test. Acknowledging the differential effect that culture, education, and experience can have on civic knowledge, this research examines the relationship between test scores and age, race, gender, and economic status. Which segments of American college students tend to have more civic knowledge than others? Who could be targeted to foster a more informed public? To answer these questions, I created and administered a unique survey with questions from the US citizenship test, demographic questions, and a state identification quiz. Tests were administered in person to students in general education courses at a regional public college in Wisconsin, with a total of 122 completed. The average score on the citizenship test section was 81%, while the average for state identification was 72%. Thus, at the coarsest level, college students are knowledgeable in these areas. In addition, on average, males scored 6% higher, students studying in the Human and Social Science career cluster scored 10% higher, and people who identify as white scored 7% higher. Other demographics had no effect on students' test scores. Students thus displayed a high level of civic knowledge, suggesting that current education of history is working in Wisconsin. However, the map section data shows a need for more emphasis on geography. Further research on this topic will allow for finer-grade identification of knowledge gaps, allowing for a more precise application of policy in the current civic education system.

Abstract Name: Our Children Need Us

This essay delves into the challenges and injustices surrounding the protection of children's rights in the United States despite the foundational principles in the Constitution. Despite children being granted the same rights as adults, this essay highlights the prevalence of child abuse and the inadequacies of the justice system, leading to thousands of children facing adult consequences for their actions. Limitations on children's First Amendment rights are explored, focusing on cases of restricted freedom of assembly within the school environment. The Eighth Amendment is scrutinized for failing to protect children from cruel and unusual punishment, exemplified by the practice of incarcerating children in adult facilities. The Fourteenth Amendment's promise of equal protection is also found to fail the youth, particularly when it comes to children facing dangers in adult prisons or the foster care system. This essay concludes by advocating for solutions and systemic changes that include educational initiatives, separate institutions for juvenile offenders, improved support for mental health, and more access to rehabilitation programs. It calls for a collective effort to raise awareness, enact reforms, and safeguard the well-being and rights of the youth, emphasizing that the protection of children's rights is crucial for the future of society.

Abstract Name: Exploring Dual Inhibition of D2 Dopamine and A2A Adenosine Receptors

D2 Dopamine and A2A Adenosine are Class A GPCRS that are implicated in the onset of neurodegenerative diseases like Parkinson's disease. Alternatively, these receptors are also capable of decreasing the symptoms of the disease. GPCRs are considered excellent drug targets, because of their involvement in several integral functions within the body, like hormone regulation and cell recognition. The aim of this research is to identify potential dual inhibitors that target A2A and D2 receptors that can down regulate Parkinson's disease. To achieve this, we employed virtual screening tools, such as HTVS, SP, and XP and the stability of the screened compounds were validated through long range molecular dynamic simulations. The MD results revealed GLU-169, ASN-253 interactions are important, and other analyses support our findings.

Abstract Name: The Impact of a Palliative Care Nursing Elective Course on Baccalaureate Nursing Students' Knowledge and Confidence/Self-Efficacy

Purpose: This study aims to assess the impact of a newly developed Palliative Care elective nursing course on baccalaureate nursing students' knowledge and confidence/self-efficacy in providing care for patients with chronic illnesses. Approximately 45% of Americans suffer from chronic diseases, which are the most prevalent and costly health conditions in America. The new 2021 American Association of Colleges of Nursing (AACN) Essentials identified palliative care as one of the four spheres of care. Schools of nursing need to incorporate new teaching strategies to ensure that nursing students are equipped to care for populations with chronic illnesses. Study findings will be used to make data-driven curriculum changes, that will incorporate student feedback. Methodology: Quasi-experimental design (pre-test and post-test) utilizing purposeful sampling of undergraduate nursing students enrolled in the Palliative Care elective course in the Fall 2023 semester. The Undergraduate Nursing Palliative Care Knowledge Survey 2.0 (UNPCKS 2.0) measured knowledge and the CARES Perceived Competence Measure 2.0 (CARES-PC 2.0) survey measured confidence/self-efficacy. Results: Data collection is completed. Using SPSS, pre- and post-scores will be analyzed in December 2023.Implications: We predict an increase in participants' knowledge and confidence/self-efficacy in providing care to patients with chronic illnesses. These findings will be utilized to better understand how to implement palliative care nursing education in undergraduate nursing curricula, as recommended by the AACN (2021). These results will provide students with insight on their clinical reasoning and empower them to apply this knowledge confidently into their professional practice.

Abstract Name: Cultural Stigma and Health Behaviour: A Case Study of Mexican Americans in the U.S.

One of the fastest-growing demographics in the United States is the Hispanic population. Historically, many underserved groups, such as Mexican Americans, have faced health inequalities; thus, more research is required to serve this growing population. This research project aimed to measure if stigma within the Mexican American population existed towards certain illnesses and if stigma affected the health behaviors of individuals in the community. The review process found that many existing articles assumed that stigma existed, but there was a lack of research into what different forms of stigma existed, and potentially why. This study will begin by conducting 12 cross-generation interviews to gather relevant information on the individual-level impact of stigma. There will have been three generations of Mexican Americans interviewed, with each having four individuals. The interviews will then be analyzed through several rounds of qualitative coding to identify similarities and differences in respondents' views. The presentation will showcase the preliminary results, which primarily aim to illustrate how perceptions of health stigma have evolved across generations within the Mexican American community. These initial findings will also explore whether beliefs associated with stigma persist among younger generations. The overall study aims to highlight the need for community-based interventions that tackle disparities originating and existing within communities. Most funded interventions are focused on addressing external disparities, but this study aims to emphasize the importance of addressing internal disparities to improve health outcomes for the Mexican American population.

Abstract Name: A Survey of Teachers of High School Students with Visual Impairment to Explore Enrollment in Secondary Mathematics

The objective of the presentation will be to inform others about the current trends in the mathematics course-taking patterns of secondary high school students with visual impairment nationally including but not limited to Advanced Placement and Dual Enrollment course-taking patterns and the highest level mathematics courses taken by graduating secondary students. The data was collected using a Qualtrics survey divided into four sections. In the first section, the respondents provided consent, confirmed themselves as a teacher of at least one high school student with visual impairment in the 2022-2023 academic year, and provided basic demographic information. The second section asked about the amount of hours respondents and paraprofessionals dedicated to attending class with secondary students with visual impairment and assisting secondary students with visual impairment with completing mathematics assignments. In the third section, respondents answered three questions regarding each secondary student on their caseload taking at least one general education mathematics course: the preferred media type (audio, braille, dual media, or print), grade level, and mathematics courses taken during the 2022-2023 academic year. In the fourth section, respondents discussed the challenges currently faced by secondary students with visual impairment and potential aids. The results of the survey were compared to the 2009 National Assessment of Educational Progress as reported by the National Center for Education Statistics in 2018, the 2019 National Assessment of Educational Progress High School Transcript Study, and a study analyzing the status of secondary mathematics for students with visual impairment in 1988 conducted by Rapp and Rapp. An analysis of the data revealed significant progress in the past few decades: secondary students with visual impairment were performing at a similar level to all secondary students nationally. However, with the increasing use of technology in secondary education, new challenges and concerns were also identified.

Abstract Name: Revolutionizing Venture Capital: Unveiling the Impact of Emotional Intelligence and Financial Literacy on Portfolio Selection in Ghana's Dynamic Investment Landscape

This research unravels the intricate interplay between financial literacy and emotional intelligence, exploring how they redefine the very fabric of portfolio selection strategies. By dissecting the uncharted potentials within the venture capital landscape, this study unveils novel strategies, challenges traditional investment paradigms, and propels a paradigm shift in fostering entrepreneurial ecosystems in the African context.

Research on the venture capital space has been largely on the evolution of the industry in Africa and the benefits it offers the African context. However, this study seeks to explore the influence of emotional intelligence and financial literacy on decision-making in the venture capital space. The study delves into understanding these dynamics using homophily and heterophily theories, offering insights into market interactions based on emotional intelligence and financial literacy. Departing from conventional quantitative methodologies, based on an exploratory research design, the research employs interviews to explore the varying perceptions and experiences of different venture capitalists. The anticipated results aim to provide a comprehensive understanding of how financial literacy and emotional intelligence inform investor decisions, suggesting whether or not venture capitalists prefer portfolio companies whose management teams exhibit comparable or higher levels of these variables, aligning with the homophily theory. These findings would foster an understanding of a more holistic approach to portfolio selection, combining emotional intelligence and financial acumen for enhanced decision-making in Ghana's dynamic venture capital investment landscape. Overall, this research contributes to a crisp understanding of the Ghanaian venture capital, addressing decision-making, risk, and relationship dynamics.

Abstract Name: Measuring Emotion Bias in Large Language Models

Large language models (LLMs) are continuously being adopted into the lives of everyday people, increasing the need to understand biased text generated by these models. Recent studies show LLMs have societal bias in domains such as gender, race, and religion, but there is lack of knowledge of whether or not LLMs have the potential to resonate with human emotion. To address this gap, we create a dataset from many online communites on reddit for emotion detection. Using theories of emotion and word embeddings of LLMs, we measure emotional emotional bias in LLMs. We also begin to investigate ways to mitigate this bias and control generated output by prompting LLMs and controlling input data based on physchological literature.

Abstract Name: The Role of Isolated Facial Cues in Perceiver's Judgments of Speech Onset Times.

Talkers' facial cues are known to aid speech perception and signal social turn-taking conventions. Less is understood about how they affect specific temporal coordination between partners. We tasked participants with timing keypresses to coincide with the beginnings of recorded utterances. In our experiments, audiovisual recordings of talkers initiating utterances were drawn from a corpus of natural conversations. Final audiovisual stimuli were animations of isolated facial features, created using Python scripts operating over face-tracking data. Stimuli were presented in three counterbalanced conditions (within participants). In one experiment we had: talker's lips animated over a black background with sound, talker's head tilt animated over a black background with sound, and with the face completely invisible with sound. In another experiment, we had: talker's lips animated over a black background with sound, talker's lips animated over a black background without sound, and with the face completely invisible with sound. In our former experiment, key press RTs were the shortest with lips only. The no visibility and head tilt conditions had the same reaction times. In our subsequent experiment, keypress RTs were shortest in the lips-only condition, followed by lips and sound and then sound only. Other implications for models of turn-taking, and possible future directions, will be discussed.

Abstract Name: A Comprehensive Analysis of the Sentiments of ChatGPT on Social Media

Since November 30, 2022, ChatGPT has seen a rise in popularity, going viral across several social media platforms. ChatGPT is an artificial intelligence chatbot developed to enable users to engage in human-like conversations and much more with a chatbot. We look to focus on understanding the global impact of ChatGPT and the influence it is had across the world. Reddit is a social media platform, where users can post and share different content. Twitter (currently X) as well, is another social media platform, where users can express their thoughts and ideas, sparking conversations among a larger audience. Both platforms offer a variety of data containing valuable information into the sentiments and perceptions surrounding ChatGPT. The primary objective of this research paper is to gain insight into the sentiments of ChatGPT to provide useful information about the product. We will analyze Reddit and Twitter data using natural language processing tools: Textblob, Vader, NRC Lexicon, and Word2Vec. Using the sentiment analysis tools, Textblob and Vader, we found an overall neutral sentiment within the 52, 416 comments gathered from Reddit and 478, 265 tweets from Twitter. This suggested that the sentiments expressed on social media were balanced and did not significantly lean towards positive or negative. From NRC Lexicon, we found more positivity and optimism in the data. Additionally, we looked into the topics of ChatGPT in different contexts such as social, academic, and economic aspects in Reddit posts and communities. From Word2Vec, we discovered 50 of the different topics that were frequently discussed. It is important to note that human interpretation plays a crucial role in understanding the sentiment analysis. Our findings shed light and contribute to a deeper understanding of the impact of ChatGPT and the discussions surrounding this technology.

Abstract Name: The Effect of Age and Race on Prevalence of Preeclampsia

Preeclampsia is a disorder of hypertension in pregnant women, after their 20th week of pregnancy, which causes a reduced blood supply of oxygen and nutrients to their fetus. Both genetic and environmental factors have been previously shown to contribute to the development of preeclampsia. The goal of this research project is to compare women from a diverse population who have been pregnant and investigate the factors that may contribute to preeclampsia. Data from participants in the All of Us Research Program were analyzed using R in a Jupyter Notebook environment. Genomic analysis was performed using Hail. The average age at diagnosis for preeclampsia was 31. It was found that pregnant women who had preeclampsia were significantly younger than pregnant women without preeclampsia (p-value =1.56 e-4). There was no statistical significance between age at diagnosis and pregnant women with preeclampsia (p-value = 0.9306). Also, white women developed preeclampsia significantly more than black women (24.3% vs 10.4%, p-value < 2.2e-16). These findings suggest more demographic, socioeconomic, and genetic factors need to be investigated to provide a better understanding of the development of preeclampsia, which may lead to precision preventive care for pregnant women.

Abstract Name: Identifying the effects of adult-phase suppression of CVD- and insomnia-related genes on cardiac and sleep phenotypes

Cardiovascular disease (CVD) remains the leading cause of death world-wide, while insomnia is the most common form of sleep disorder. Recent genome-wide association studies have identified several loci for insomnia with links to CVD. Despite the impact these two diseases have on society and their genetic links, the mechanistic connections between CVD and insomnia remain relatively unknown. Our previous research using Drosophila melanogaster has shown that 4 genes near this locus show compromised sleep and cardiovascular phenotypes when suppressed throughout development and adulthood. We hypothesized that adult-phase-specific suppression of CVD- and insomnia-related genes will also compromise sleep and cardiac function. To test this, we used the drug-inducible UAS-Gal4 GeneSwitch system to suppress gene expression only in the adult phase in a tissue-specific manner. RNAi lines of CVD- and insomnia-related genes with fly orthologs were crossed with the cardiac-specific driver Hand-GS-Gal4 and the neuronal-specific driver Elav-GS-Gal4 to determine the roles of genes in cardiac and sleep physiology, respectively. Once progeny reached adulthood, the flies were transferred to food drugged with 200 or 500 μM of RU486, initiating adult-phase knockdown of the gene of interest. To quantify cardiac physiological parameters, 3- and 7-week-old Drosophila hearts were prepared in a semi-intact manner and imaged using high-speed videography. To assess the genes of interest's roles in sleep, sleep and locomotor activity of 3- and 7-week-old flies were then measured using Drosophila Activity Monitor (DAM). Data collection is currently underway. Overall, this

study will establish the importance of four CVD- and insomnia-related genes in development, thus enhancing our understanding of their role in each disease.

Abstract Name: Perceptions of Femininity and Masculinity as Presented by Hamlet

This piece will explore the main character of Hamlet by Shakespeare, Hamlet's perceptions of femininity and masculinity based upon his inability to grieve and his relationships with his mother, Gertrude, and his supposed lover, Ophelia, and their own femininity in relation to Greek tragedy characters Niobe and Hecuba. In the wake of his father's death, Hamlet struggles immensely with the idea of grieving as a man, especially after his uncle calls his grief "unmanly". Hamlet is forced into a position in which his intense need to grieve is viewed as a weak sign of femininity and places him at odds with his desire to portray his manliness in lieu of the power vacuum that will take place after the death of his father. As Hamlet denies his own need to grieve, he simultaneously rages at the women in his life, drawing unfavorable comparisons between his mother, Gertrude, and the Greek tragedy character, Niobe, and between his lover, Ophelia, and a prostitute. Hamlet's own desire to present himself as a hyper-masculine being comes at the cost of many things, including his relationship with Ophelia. As Hamlet feigns madness, his lack of love and empathy for Ophelia drives her to suicide by way of true madness. This work will be supported by Shakespeare's intricate use of puns, metonymy, and parallelism, as well as imagery of sex and prostitution. Author Tanya Pollard and Lynn Enterline's works will also be included as a means to discuss boys' education during the 15th and 16th centuries in which boys were asked to perform female roles in order to learn how to feel deep emotion and to perform it because it was believed that boys lacked this ability while it was an intuitive gift for women.

Abstract Name: Flight Data Telemetry Device with Data Logging using Customized Off-The-Shelf Modules for Experimental Radio Control Aircraft

Radio Controlled (RC) airplane models are important for developing innovations in aircraft. Live telemetry data such as aircraft orientation, power system status, and kinematics are useful for both flying the aircraft

through remote control and for evaluating performance. Proprietary telemetry systems for RC planes are not easily customized, and do not offer local data back up in case of failure of the radio link. In this work, an RC plane telemetry device was built using off-the-shelf sensor modules interfaced to a Raspberry Pi Pico microcontroller board that was programmed in MicroPython. The system was designed to be low cost, use widely available components, and be easily customized. The completed device incorporated, a Global Positioning System sensor, barometer, current sensor, a 6-axis acceleration sensor, and a micro flash memory card. A pair of NRF24L01 wireless modules with whip antennas were used for data transmission, one mounted on the aircraft and the other on the ground station. The completed device had a mass of 46g and was 30mmx100mmx30mm in size. Software for displaying the received data was developed in Java using Processing software. Details of the construction of the system will be presented together with data from the planned evaluation of the system on a 120cm wingspan RC plane in terms of verifying basic operation, communication reliability, effective sampling frequency, range, crash survivability, and assessing its interference on RC transmitter signals

Abstract Name: Addressing the Overdose Problem in Orlando, Florida: An Anthropological Exploration of Overdose Prevention Perceptions Among People Who Use Drugs

The ongoing overdose problem in the United States, particularly exacerbated by the widespread use of the synthetic opioid, fentanyl, and polydrug use, represents a critical public health challenge. This project explores how people who use drugs (PWUD) in Orlando, Florida, are responding to overdose in their community. Drawing on ethnographic research conducted at a syringe services program in Summer 2023, I argue that PWUD in Orlando actively take measures to prevent overdose and overdose deaths but are faced with many obstacles that challenge their overdose prevention efforts. I examine overdose narratives of PWUD to show how factors preventing effective overdose prevention are not just systemic but also cultural. In particular, the prevailing stigma of opioid use hinders the creation of a supportive environment for preventing overdoses and perpetuates the ostracization of PWUD in Orlando. Recognizing the profound influence of stigma towards the PWUD with whom I conducted research, I make the case for comprehensive overdose prevention training in Orlando to equip PWUD, their families, first responders, and the broader community with the knowledge, skills, and tools to address overdose. Such training also has the potential to recalibrate cultural misconceptions and biases toward PWUD. As Florida and the nation continue to experience an overdose problem, understanding local cultural and structural challenges remains pivotal. This project demonstrates that by integrating comprehensive training and combating stigmatization of PWUD, Orlando communities can prevent overdose and save lives more effectively. Moreover, this project aims to contribute to the anthropological literature on drug use and overdose to understand how these topics are perceived and framed in the US. Furthermore, this project addresses the broader lack of representation of PWUD in the literature of overdose prevention, which has tended to focus on public health experts and other stakeholders rather than those directly affected by overdose.

Abstract Name: Impact of Social and Physical Activities on Balance and Quality of Life in Displaced Elderly Women

In the United States, nearly 600,000 individuals face displacement, with 40% of this population navigating the challenges of unsheltered living. Therefore, addressing this community's necessities will impact the health, mental health, and overall quality of life. This service-learning project aims to improve motor and cognitive skills to mitigate the risk of falls by enhancing these individuals' overall quality of life.The preliminary analysis included seven female participants aged 62 to 77 from La Casa de las Abuelitas (Shelter for displaced elderly women). The modified Quality of Life questionnaire and the Timed-up-and-go were assessed pre- and post- intervention. The intervention consisted of one weekly session for over eight weeks.T-test revealed no significant difference between the pre- and post- level of quality of life [T(2)=1.89; P= 0.199] and no significant difference in the participant's balance [t(2)= -1.144; p=0.371]. Despite the absence of statistically significant findings, this project brought qualitative data on social happiness and a heightened sense of connectivity among the Abuelitas.While recognizing the need for a larger sample size to establish statistical significance, the project underscores the transformative potential of community-driven interventions. The project's broader impact demonstrated how simple acts of community engagement can positively influence the lives of displaced elderly individuals. Ultimately, the project demonstrates the importance of recognizing and addressing the unique challenges faced by this vulnerable community, offering insights into the potential for positive changes through targeted interventions and community support.

Abstract Name: Impaired Neurogenesis Following Simulated Microgravity

As NASA strives to advance the reach of human space exploration, astronauts are spending longer durations exposed to microgravity. Astronauts returning from space show cognitive deficits, like attention lapse and lower reaction times. With commercial spaceflight becoming more common and soon accessible to the public (via private ventures like SpaceX) understanding the mechanism of such deficits is imperative. Space exploration presents novel challenges to biological systems, often precipitated by micro-gravitational conditions. For example, data from NASA's Lifetime Surveillance of Astronaut health program indicates that the cognitive deficits seen in astronauts following spaceflight are accompanied by changes in brain structure. The mechanism for this remains unclear, however, one possibility is that microgravity causes the loss of cells in the brain. We studied whether microgravity could lead to cell loss by testing the ability of neural stem cells to produce astrocytes and neurons, the main cell types in the brain. We found that simulated microgravity compared to control gravity decreased the production of neurons, the communication cells of the brain, without changing the production of astrocytes. To investigate the underlying mechanism associated with

neuron loss, we performed quantitative polymerase chain reaction (qPCR) on neural stem cells exposed to simulated microgravity compared to control gravity, to test for changes in gene expression of proteins known to drive neurogenesis. Of particular interest from our results was a protein important for neural development and neuron production, MASH1, whose expression was significantly lower in microgravity-exposed cells. This could explain the loss of neurons seen in our study and provide a target to counteract the microgravity-mediated effects on neural differentiation, hence reducing complications associated with spaceflight.

Abstract Name: History & Community: The Work in Progress of the Pullman National Historic Park

The Pullman Palace Car Company of Chicago was established in Chicago at a time of great economic expansion. Located about twelve miles south of Downtown Chicago the company mainly manufactured top-of-the-line rail sleeper cars. The product ultimately made travel more comfortable and luxurious. As demand grew for its product, a company town was established to allow workers to live and produce in the same space. The town included high-end amenities such as plumbing, electricity, and gas heating along with recreational amenities such as theaters, saloons, and sports facilities. At the time many saw this as revolutionary both for the worker and company. This dynamic ultimately came into question when the U.S. experienced the Panic of 1893, which resulted in the company lowering wages while maintaining high rents in the company town. The strike led to about 200,000 walkouts nationwide, yet ultimately failed. The legacy of the PPCC is now a memorial site, established by the National Parks Service in 2022. The site was established to preserve what is left of the PPCC to allow for further interpretation of the company's legacy. Through primary sources and other scholarly articles, questions arise about whose history is effectively portrayed. Narratives favoring the corporate version of history appeal to most visitors, yet the narratives of the community of Pullman are underrepresented even though they establish a significant part of the current interpretation.

Abstract Name: Hear the People, Heal the People: Community and Provider Perceptions of Pre-Hospital Emergency Services in Mas, Bali, Indonesia.

This transdisciplinary qualitative case study, conducted in situ in Bali, Indonesia, from September to November 2023, explores the perspectives of local community members and emergency care providers regarding the pre-hospital services available in the Mas area. The research contributes to the literature on the implementation of emergency medical systems in lower- and middle-income countries (LMICs), in recognition of the fact that emergency medical care is of paramount importance to individual and community health but remains under-addressed in much of the world. Drawing on Participatory Action Research and

Decolonial Theory methodologies, the study utilized participant observation, surveys, and semi-structured interviews to capture an illustrative and informative range of perspectives. Participants included community members who may or may not have utilized pre-hospital transportation and care as well as healthcare providers responsible for delivering those services. The findings of this study support much of the existing literature regarding the difficulties LMICs face when developing emergency medical services, such as incompatible infrastructure, traffic, and a lack of local engagement with, and understanding of, the ambulance system. In addition, the focus on Mas, a peri-urban Balinese village, provides unique insights, such as how cultural and social norms influence a person's decision to call an ambulance, and how emergency care information campaigns could utilize Balinese community structures to better reach locals. The research also discusses broader systemic issues, such as the impacts of economic inequalities on access to care and corruption in the Indonesian healthcare system. This case study may serve as a resource for policymakers, healthcare providers, and community members to better understand the existing challenges of, and potential improvements to, pre-hospital services in Mas. Moreover, it contributes to a wider discussion on emergency medical care in challenging settings and emphasizes the importance of cultural awareness and community involvement in shaping emergency services.

Abstract Name: Machine Learning in Forensics: Footwear Impression Analysis

Footwear Impression Analysis is a discipline of forensics where one tries to determine if shoeprints left at a crime scene can be reliably linked to a suspect's shoe. Recent developments in this field have led to the design of quantitative and algorithmic approaches to compare shoeprints, which involve applying ideas from statistics and machine learning.However, machine learning requires large amounts of labelled high-quality data. In our case, this means a dataset of shoeprints where features relevant for comparison have been marked accurately. A recent paper by Park and Carriquiry used interest points on the shoeprint image (such as corners or centers of circles) as relevant features for comparison, but such interest points are difficult to extract

automatically from shoeprint images.We present a graphical tool designed to assist in the markup of interest points in shoeprint images. We use this tool to create a dataset for training deep neural networks. The trained networks are to be tested on shoeprints of varying levels of quality, with a focus on accurate extraction, speed, and explainability. We hope to provide the markup tool and the best performing model to help forensic examiners in their work.

Abstract Name: Polk Directory Indicators as Factors of Transiency in Lafayette, IN, Neighborhoods

The city of Lafayette, Indiana, has identified above-average levels of transiency in the neighborhoods of Lincoln, Hanna, Vinton, Monon, St. Lawrence McAllister, and Historic Jefferson. Despite the availability of funding for community development projects, the city lacks consistent and updated data to inform its proper usage. The Polk Directory is an online database housing demographic and socioeconomic data on the residents of Lafayette, which can be used to provide the city with information on where its funding can be best spent. Data contained in the Polk Directory provides the city of Lafayette with important context surrounding the well-being and lifestyle of its citizens including spending habits, income, and assets and liabilities. By combining this data with US Census data and student-collected property condition surveys, a clear image of Lafayette's socioeconomic diversity can be revealed. Through the use of Tableau, a data visualization software, this study aims to visualize the distribution of socioeconomic statuses of the residents living in the seven neighborhoods identified by the city of Lafayette. This study aims to examine demographic and socioeconomic data from the Polk Directory and US Census data, housing condition data from property condition surveys, and the high levels of transiency in the neighborhoods for potential correlations. A summary of findings will be presented using a heat map. The heat map aims to show the property condition of houses in each neighborhood and individual and group socioeconomic indicators as factors of the neighborhood transience level. Lawmakers would be able to use this map to identify and isolate leading factors that lead to high levels of transience in the city of Lafayette.

Abstract Name: Molecular Analysis of Root Fungal Communities in a Truffle Orchard Chronosequence

Truffle fungi form a mutualistic relationship with their host tree, relying on it entirely for carbon while helping the tree acquire limiting nutrients. In North Carolina, farmers are attempting to cultivate these fungi in orchard settings. Many ectomycorrhizal fungi in the soil compete with the truffle fungi for the tree roots,

therefore truffle farmers look to control conditions to favor the truffle fungi. Shifting soil conditions due to orchard succession and orchard treatments therefore can alter the competitive landscape in a fungal community. This study looked at fungal community development as orchards age at Burwell Farms in Warrenton, North Carolina. Growing Tuber borchii, a desirable white truffle species, has been their specialty and their farm has orchards at multiple stages of development. The oldest and most profitable orchard is around 8 years old, the middle-aged orchard is 3-4 years old and the youngest orchard is 1-2 years old. It was hypothesized that the fungal community would shift as the orchard ages. We took advantage of the different orchard development stages to study the fungal root community change as the orchard ages. Because ectomycorrhizal fungi - including the truffle - cannot be cultured, we used molecular approaches (DNA community fingerprinting of the total fungi through T-RFLP) to analyze the fungi on the roots. Root samples were collected in May of 2023, and a bulk DNA isolation was done on the ectomycorrhizal root tips found in each sample. DNA sequencing was also performed to determine what was on the roots to the genus level. T-RFLP community fingerprinting results support that fungal communities within each stage are more similar than they are between stages. Bulk sequencing data shows that abundance of Tuber borchii decreases as the orchards age. These results can be used to start to project trends as competition for tree roots increases.

Abstract Name: A Median Estimator for Three-Dimensional Rotations

The median is a way of measuring the center of a data set that is robust to outlying values. While the median has been studied extensively for traditional 1-dimensional data sets, it has received less attention for 3-dimensional rotation data. Bingham and Fischer (2014) develop a median estimator for 3-D rotation data through minimization, but this process relies on optimization search algorithms and does not have a closed form solution. As such, this minimization technique does not always compute the same result for the median rotation when applied to the same data set.In this poster, a different approach for computing a median rotation that does not depend on minimization techniques is explored. This newly developed median rotation is compared to the pre-existing notation of the mean rotation under various conditions through a simulation study to investigate whether the median rotation outperforms the mean rotation.The newly established median is also compared to the approach of Bingham and Fischer (2014) to verify that the new approach keeps the desirable properties of the median but is computed in a more efficient manner.

Abstract Name: Examining Waiting Time, Charting Language, and Evaluation of Black/African American Patients in Emergency Departments in Virginia: Refining DEI Training with Implicit Bias Recognition and

Management

Patient satisfaction is dependent on the patient's waiting time, provider evaluation, and overall treatment. 47% of African Americans believe that health inequities stem from hospitals and medical centers prioritizing their well-being less than other patients (Funk, 2022). Only 47% of African Americans believe that health outcomes have improved for them over the past 20 years (Funk, 2022). This dissertation examines patient waiting time, physician language used in medical charting, and the evaluation of Black/African American patients at Emergency Departments (ED) in Virginia teaching hospitals in order to determine the nature of implicit bias in treating Black/African American patients. There are currently six teaching hospitals in Virginia and only four hospitals that have an ED. This literature review aims to understand the need to incorporate Implicit Bias Recognition and Management (IBRM) curriculum in diversity, equity, and inclusion (DEI) training given to ED faculty and staff. Peer reviewed articles were cross examined to analyze DEI initiatives seen in teaching hospitals in different locations to understand the limitations within each program. Based on current literature, implicit bias training is imperative to patient satisfaction among racial and ethnic minorities; yet, there is a lack of transparency and delineation of training in teaching hospitals located in Virginia.

Abstract Name: An LCMS-Guided Bioanalytical Approach for Rational Natural Product Library Design and Optimization

Natural Products play a pivotal role in the field of drug discovery, accounting for a significant portion of approved pharmaceuticals. These natural products are derived from various sources, including fungi, bacteria, and plants. While these sources offer a rich supply of potential medicinal compounds, discovering and developing new drugs from them is not without resource constraints, high costs, and time-intensive efforts. Fungi, due to their ubiquity and adaptability, stand out as an up-and-coming source to produce metabolites and antibiotics. To harness the full potential of natural products, the creation and maintenance of comprehensive Natural Product libraries are indispensable. Screening these natural product libraries against infectious diseases is a key part of the drug- pipeline. However, the construction of these compound libraries is troubled with difficulties arising from the slow production of diverse natural product samples and the associated financial burden. Our overarching objective is to employ evidence-based methodologies to reduce the size of the design of natural product libraries, thereby bolstering the efficacy of new drug development processes. To achieve this, we used untargeted metabolomics techniques, allowing us to achieve equivalent chemical diversity while reducing the number of samples required. This approach not only enhances the proportion of identified chemical features but also diminishes the need for extensive extraction procedures, producing significant cost and time savings. Building upon our findings, considerable progress has been made in advancing our novel approach to drug optimization. We are actively exploring new sample selection methodologies and assessing the significance of diversifying natural product families within our libraries. We will be applying publicly available datasets to our new method to verify our process. Moving forward, percent hit rate analyses will be run through RStudio to determine if our library-building method is effective enough to reduce the number of biota samples needed for testing.

Abstract Name: Design and Synthesis of Peroxisome Import Moieties

Peroxisomes are membrane-enclosed organelles in eukaryotic cells that are involved in cellular lipid metabolisms such as long chain fatty acid β-oxidation and synthesis of myelin sheath lipids, as well as the metabolism of potentially harmful Reactive Oxygen Species (ROS) including hydrogen peroxide. The study of peroxisomes is particularly important to human health because their dysfunction plays a role in the pathogenesis of various disorders including obesity, cancer, and certain neurological abnormalities like neuronal migration defects and demyelination. Despite the known role of peroxisomes in various metabolic processes, peroxisomes remain understudied compared to other organelles. We believe developing chemical tools that can be used to examine peroxisomal cellular functions would lead to a better understanding of the origin of these metabolic disorders. Current approaches to target chemical tools to the peroxisomes utilize Peroxisome Targeting Signal 1 (PTS 1) amino acid sequences. Polar sequences limit the types of molecules that can be directed into peroxisomes to very nonpolar cargos, which balances overall polarity to enable passive diffusion into cells. Our approach is to synthesize Peroxisome Import Moieties (PIMs) that are more nonpolar than current PTS 1-based sequences. This will enable the import of more polar cargos into the peroxisomes. Overall, our PIMs will allow for the production of chemical tools that can be used to study the peroxisomes in live cells.

Abstract Name: Exploring the Relationship between Igbo Language Proficiency and Sense of Belonging to Igbo Culture among Igbo People Living in North America and Nigeria

Language is an important aspect of how members in a community cement their bonds with one another, and it is often the foundation of any community. Community members can communicate their identity, cultural history, background, and opinions through the use of language. In Nigeria, there are three major languages and culture groups–Igbo, Hausa and Yoruba. Existing literature highlights that the Igbo language is not yet endangered, but is nearing the line and programs need to be implemented to prevent its endangerment and possible extinction. However, Hausa and Yoruba are not at risk of endangerment. Using a mixed-methods approach, this study explores the relationship between the level of an Igbo person's proficiency in the Igbo language and their sense of belonging to their culture. The data source for this study includes students from North American and Nigerian tertiary institutions, as well as members of Umu Igbo Unite chapters in various cities across North America. This research highlights the effects of being unable to speak one’s native language, and assesses the importance of language transmission across generations for the preservation of cultures.

Abstract Name: Campus Cultural Promotion Groups: Exploring their Effects on Belonging and Achievement Scores for African College Students

Students from racial/ethnic minority backgrounds are known to face decreased belonging and academic achievement. Studies have shown the protective factors of cultural promotion groups for Asian-immigrant and African-American students. However, the experiences of African students remain unstudied. This research project aims to explore the relationship between awareness and participation in cultural promotion groups within higher institutions and the campus sense of belonging and achievement scores of African students. This study utilizes a mixed-methods approach: 150 surveys and 5 focus groups. The survey measures academic scores and awareness and participation levels in cultural promotion groups. The focus groups employ the photovoice methodology to delve deeper into the experiences and perceptions of participants. It is hypothesized that greater participation in cultural promotion groups will correlate with enhanced campus belonging and academic scores for African students. The study holds potential implications for institutional policies, aiming to foster a more inclusive environment, emphasizing the empowerment of African students in higher education settings.

Abstract Name: Biochemical characterization of a new Microbacterium species isolated from a contaminated Chlamydomonas culture plate that is a vitamin B auxotroph

One of the side research interests of our research lab is to identify antibiotics that kills bacterial strains that contaminate Tris Acetate Phosphate (TAP) medium plates of the green micro-alga Chlamydomonas reinhardtii without affecting the algal growth. We isolated one yellow-pigmented bacterial strain from a contaminated Chlamydomonas TAP plate that we named as Clip185, based on the Chlamydomonas strain it contaminated. Partial 16S rRNA gene sequencing and whole genome sequencing revealed that Clip185 is a new Microbacterium species.We found that Clip185 cannot grow on TAP-agar plate solo, although it was isolated from a contaminated TAP plate. Clip185 can grow very slowly when it is co-cultured with Chlamydomonas on a TAP plate. We found that Clip185 can grow well in Chlamydomonas-grown TAP liquid culture filtrate, when supplemented with a carbon source. Clip185 can also grow in TAP liquid/agar medium solo when supplemented with a minimum concentration of 0.01% of yeast extract or Tryptone. Clip185 grows well in Lysogeny broth medium which contains both yeast extract and Tryptone. Yeast extract/Tryptone in bacterial growth medium provides nitrogen, amino acids and vitamins to bacteria. Clip185 can only grow in a minimal medium that contains vitamin B and a carbon source.Whole genome sequence analyses revealed that Clip185 is an auxotroph for four types of vitamin B and has a high requirement for branched chain amino acids. Our results show that Chlamydomonas is providing vitamin B and probably three branched chain amino acids to Clip185, when it is co-cultured with Chlamydomonas in TAP medium. Additionally, our research has created a new growth medium recipe based on TAP to screen vitamin B auxotrophs for their capabilities to utilize different organic compounds as the sole carbon source.

Abstract Name: Leveraging Generative Model to Protect Machine Learning Frameworks

With its countless applications, machine learning has become an integral part of our lives. Moreover, our increasing dependency on machine learning applications presents a growing need to safeguard sensitive data. Machine learning models, dependent on large datasets, can inadvertently memorize training data, making them vulnerable to threats like model inversion and membership inference attacks. For example, in model inversion attacks, even with only public API access, attackers can potentially reconstruct training samples. This research aims to propose a privacy preservation approach from a different perspective that is to protect the privacy of training data samples from the source. We investigate the feasibility of training machine learning models using only synthetic data produced by Generative Adversarial Networks (GANs),

eliminating the use of real data samples. Given the sensitivity of medical data, we employ the MedMNIST dataset, a standard collection of 2D and 3D biomedical images such as chest X-rays, breast ultrasounds, and abdominal CTs. By utilizing GANs to generate synthetic data for training, we aim to bypass the use of real medical data, thus safeguarding the patient's private information. In the experiments, we will evaluate the efficacy of synthetic data against MedMNIST data in training machine learning models and gauge the protective capabilities of GANs. Through risk assessments derived from empirical evaluations, we'll employ various inference attack models, such as membership inference and model inversion attacks, to measure the model's security when integrating GANs. Using the MedMNIST dataset, we will also examine the potential trade-offs between privacy preservation and the robustness of a machine learning model.

Abstract Name: Revolutionizing Recycling: A Low-Cost Smart Trash Can with Computer Vision and CNN Integration for Enhanced Sustainability Awareness

The increasing volume of waste and the environmental impact of improper waste disposal practices have emerged as critical global concerns, necessitating innovative solutions. Inefficient recycling practices and inadequate awareness regarding appropriate recycling methods significantly exacerbate this issue. This study employs cutting-edge Computer Vision and Machine Learning techniques, integrating them into a user-friendly Graphical User Interface (GUI) rich with educational content on recycling practices. Leveraging the VGG-16 model, our system adeptly categorizes waste into four distinct classes: glass, plastic, metal, and general waste, streamlining the recycling process.Furthermore, our innovation extends beyond software solutions. Incorporating an array of hardware components such as Raspberry Pi and Arduino-based LEDs and fans, we developed an affordable smart trash can. This technologically advanced system delivers not only real-time feedback but also engages users proactively by offering educational content. This fosters a culture of proper waste segregation, aligning with sustainable practices. The remarkable achievement of our machine learning model is reflected in its impressive accuracy of 91%, underscoring the efficiency and reliability of waste categorization within the system.By launching this initiative, our primary goal is to inspire and cultivate sustainable recycling practices. We aim to empower individuals by providing them with the knowledge and tools needed to make environmentally conscious decisions. Ultimately, this undertaking aspires to mitigate the adverse environmental impact of improper waste disposal, fostering a greener and healthier planet for generations to come.

Abstract Name: EFFICACY OF ULTRAVIOLET RADIATION DISINFECTION TECHNIQUE IN ELIMINATING PATHOGENIC MICROORGANISM FROM AQUAPONIC SYSTEMS.

The study aim is to investigating UV radiation's efficacy in purifying aquaponic wastewater, this study addresses sustainability, environmental safety, and water access. Objectives include assessing UV efficiency and optimal duration for eradicating harmful bacteria. The experiment utilized the spread plate method on samples from various water sources, exposed to UV for different durations at 37°C. Results indicated increasing bacterial colonies with extended UV exposure, with potential factors such as cross-contamination and uneven sample distribution. Notably, a 60-minute UV exposure at 37°C effectively reduced bacterial colonies, particularly fecal coliforms. The study aligns with prior research on UV disinfection in sewage water. This optimal 60-minute duration holds promise for improving clean water quality in aquaponic systems. Future experiments could explore UV and ultrasonic techniques' combined effects, considering temperature variations. Techniques like filter membrane, Quantitative PCR, and pour plate methods merit consideration in subsequent studies. The findings underscore the potential for synergistic benefits in aquaponic systems through combined UV and ultrasonic approaches, paving the way for enhanced environmental sustainability and pollution reduction.

Abstract Name: Comparing the Housing First Model vs the Treatment as Usual Model for Homelessness Stabilization

AbstractBackground: Homelessness is on the rise, and it does not discriminate by age, gender, culture, or any other factors. Homeless creates an increased risk for the abuse of drugs, alcohol, and other substances. Because of that, there is an increase in the rates of death, disease, and comorbidities. Orem’s Self-Care Deficit Theory states nurses should help ensure a person’s basic needs are met to improve overall functioning, wellbeing, and therefore health. The Housing First Model is an initiative aimed at combating homelessness. This model focuses on providing safe and adequate housing as a prerequisite to treating addiction and predisposing factors. In Oklahoma City, the Homeless Alliance provides daytime housing, multiple employment opportunities, education, and access to case management to homeless individuals. Unfortunately, there is inadequate research into the effectiveness of the Housing First initiative in Oklahoma City on preventing and managing substance abuse. Because of this, there is a need to surveying of homeless individuals within Oklahoma City to determine if those needs are being met. Aim: The aim of this study is to assess the correlation between the homeless population and substance abuse by examining the Housing First model compared to the treatment as usual model. Method: This correlational study will compare the frequency of substance abuse in those participants who received housing through the Housing First model versus those who receive housing through other means. Conclusion: Individuals who are homeless are dying of preventable diseases and exposure to environmental elements. The provision of housing is a basic need for individuals. It is expected the provision or housing prior to life stabilization will improve long-term outcomes for those with alcohol, drug, and other substance abuse. Keywords: Homelessness, Health, Housing, Dependance, and Comorbidities

Abstract Name: HEAVY METALS: SILENT CONTAMINANTS IN THE BAY AREA

Heavy metal elements occur naturally through geogenic sources at concentrations that are typically harmless to their surrounding environment. However, a legacy of leaded paint, gasoline, and other industrial pollution has allowed the creation of pathways to concentrate these metals. Without monitoring, awareness campaigns, and proper remediation, they can expose communities to elevated concentrations via interactions with soils, dust, and even household items. Historically, discriminatory policies like redlining have disproportionately exposed minority communities to higher concentrations of heavy metals like Arsenic (As), Cadmium (Cd), Lead (Pb), and Mercury (Hg). Long-term exposure to these metals is known to be hazardous to human health, as they are identified as carcinogens and have been related to child growth and development problems. Through redlining, they have been shown to pollute neighborhoods near industrialized areas disproportionately. While minority neighborhoods are often exposed, they are also typically under-equipped to understand, measure, and remediate the heavy metal contamination that stems from historic environmental injustice. This project aims to prioritize community needs, where project direction was provided by community members in East Palo Alto (EPA), and the greater San Francisco Bay Area. To further understand the complexity of this contamination, soil samples from two parks were screened for heavy metals using a portable X-ray fluorescence (PXRF) spectrometer. Additionally, interactive maps were created to visualize the exposure, inequity, and health effects of heavy metal contaminants in the area. Lastly, suites of contaminated soil standards were also developed to support the “Soil Screening, Health, Outreach, and Partnership” (soilSHOP) program nationwide, to ensure accuracy between these important environmental justice outreach projects.

Abstract Name: Residential design for Open Angle Glaucoma Occupant

The project's purpose is to design a functional and intuitive single-family house that caters to the needs of someone with open angular glaucoma. This condition causes blurry vision that differs in severity and can worsen over time. Through in-person interviews and prior case studies, it is noted that there are six essential factors to consider when designing for those with open-angle glaucoma: task lighting, spatial layout, furniture considerations, material considerations, and organization. The most utilized characteristic in this space is contrast. The color palette is amber, charcoal, and cream with a mix of dark and light brown wood accents that provide high contrast. Contrast is taken into consideration with both the hues used and the light reflectance values of the paint colors, which vary significantly so they are easily defined. Each room is defined by primarily using one of the colors, providing intuitive wayfinding between each area. The furniture is also highly contrasted with surrounding environments to ensure safety. Task lighting provides focal illumination to work areas rather than illuminating the entire room. Spatial layout is critical to maintaining a hazard-free and intuitive path throughout space. Designing wide walking paths while reducing the number of physical obstructions (i.e. structural components like walls or physical items like furniture) and implementing wayfinding features ensure occupants maneuver through the space safely. Some materials provide extra safety by being non-slip or low-glare surfaces. The abundance of cabinetry, pantry space, and closets with built-in

shelving make organization simple throughout the home. A design with these six characteristics prioritized provides a safe and functional environment for those with open-angle glaucoma.

Abstract Name: Brown Weasel Woman: An Exhibit on the Shattering of Norms

A specific figure from American history who exemplifies the ability of individuals to persevere and challenge the societal restraints placed upon them is Brown Weasel Woman. In order to bring stories like hers to the American public, my research involved the creation of a public history exhibit in which multiple items will be used in cohesion with the location to immerse viewers. The exhibit objects tell a piece of Brown Weasel Woman's story and include both artifacts and artworks. The descriptions behind each item incorporate both primary and secondary sources to explain their spot in Brown Weasel's progression. For example, one artifact is a war robe. Commonly, the Blackfoot tribe created robes with hand drawn images which portrayed their stories. While we do not have a replica of Brown Weasel's robe, another Blackfoot war robe is presented to give viewers a visual of what her robe would have looked like. This robe demonstrates the first time Brown Weasel portrayed her warrior self to her tribe. To save her family from a stampede of cows, she acted quickly, and threw her robe over the cow's leader blinding it. This strayed the cows away thus saving her family and creating food for her tribe as the cows fell off a cliff. Through this action Brown Weasel demolishes the norms of males being the protectors as she keeps not only her family safe but also her tribe. However, this was the start for her. She was later named Running Eagle due to her constant shattering of norms that have left an impact even now. Thus, through this exhibit of Brown Weasel's story, the American public is able to feel empowered while learning about the life of an Indigenous American woman, as this exhibit highlights aspects of the American past that are often silenced.

Abstract Name: Automating the analysis of language samples obtained from the Frog Story series: Step 1.

The purpose of this project was to create systematic, reliable rubrics for using the Frog Story series in language sample analysis for the diagnosis and treatment of children with developmental language disorders (DLD).Language sample analysis is a critical part of the assessment process by speech language pathologists

(SLPs) for determining whether a child has a developmental language disorder. This is accomplished by analyzing a child's use of vocabulary, sentence structures, and grammatical markers (i.e., past tense) and comparing it to their typically developing peers. Once diagnosed, language sampling is used as part of progress monitoring efforts to ensure the child is making reasonable progress toward their language goals in one (or all) of these areas.Elicitation of language from a child is often achieved by asking them to tell a story. One popular way that SLPs have obtained samples is to ask them to retell one of four popular wordless picture books from the Frog Story series by Mercer Mayer. This series involves the antics of a frog and his boy as they encounter different adventures. There is no rubric or "analysis key" associated with the stories leaving the SLP to decide how to use the information obtained from the story independently. This makes it hard to obtain reliable results over multiple time points for use in progress monitoring.In this project, a team analyzed all four Frog stories for their inclusion of specific story elements (i.e., character, setting, episode), vocabulary and sentence structures; and separate rubrics were created. The methodology for identifying the language parameters of interest, reliability in coding, and uses for the rubrics will be described. The rubrics will be automated using a web application so clinicians can upload their child's story and have them instantly scored, making their use in analysis more reliable and consistent.

Abstract Name: Gender Difference in Spatiotemporal Gait Parameters and Gait Symmetry During Treadmill Walking

Gender has been an important determinant in gait analysis as males and females walk differently. Previous studies reported females had higher cadences and shorter stride lengths even when normalized by leg length. Some studies showed gender differences in hip and knee joint kinematics during walking (Hurd et al., 2004) and running (Ferber et al., 2003). As of recent times treadmill usage has been increased in gait rehabilitation for individuals with gait impairments as well as for healthy populations, however, it is not known if this difference exists in spatiotemporal gait parameters among healthy young adults while walking on the treadmill. PURPOSE: The purpose of this study was to investigate gender differences during treadmill walking at the preferred walking speed in spatiotemporal gait parameters including step length, step time, step width, and toe clearance. METHODS: Healthy young adults aged 18 to 35 years old (18 males / 22 females) participated and performed a walking trial on the treadmill at their preferred speed. VICON human motion capture system was used to collect kinematic data and we calculated step length, step time, step width, and toe clearance in addition to the symmetry index and gait asymmetry as a measure of gait pattern. Independent samples t-test was performed using IBM SPSS Statistics (Version 29.0) at a significance level of 0.05. RESULTS: There were no significant differences between males and females in spatiotemporal gait parameters including normalized step length, normalized step time, normalized step width, toe clearance, symmetry index, and gait asymmetry during treadmill walking, except for step length before normalized by leg length. CONCLUSION: Once normalized there was no significance for gender differences in any categories including step length. Furthermore, normalized spatiotemporal parameters are strongly recommended to avoid and minimize gender effects resulting from physical and biological differences when conducting research with a treadmill.

Abstract Name: Maternal aye-aye (Daubentonia madagascariensis) anxiety peripartum

Mothers are anxious peripartum. Our previous pilot study of three hours per day for three days peripartum demonstrated that a mother aye-aye (Daubentonia madagascariensis) displayed anxiety behaviors such as repetitive, non-purposeful movements (stereotypies) (unpub). In this study, a mother aye-aye's anxiety behavior peripartum was assessed 24 hours before, the day of, and 24 hours after birthing an infant. It was hypothesized that anxiety behaviors would change over the three days. With IACUC approval, Pelco IMM12027-1S cameras were placed in a Duke Lemur Center (DLC) aye-aye mother's enclosure and nest to record her activity the three days peripartum. The resulting videos were watched and continuous focal animal sampling was used to note the time, duration, and type of repetitive behavior such as scratching or grooming. Data were analyzed using a Kruskal-Wallis Test and Chi-squared test. Results showed that the day before birth, the mother repeatedly constructed and deconstructed nests significantly more than the other two days (n=162x), while on the birth day, the mother auto-scratched and examined her genitalia significantly more (n=37x, n=27x, respectively). The day after birth, the mother was hyper-alert significantly more times (n=19x). Therefore, the hypothesis was supported as the mother exhibited signs of behavioral anxiety, and her behaviors changed over the three-day period. Limitations included the small sample size (n=1). This study is the first to examine maternal anxiety in aye-ayes over three complete days peripartum. The results yield insight into maternal behaviors exhibited by the rare and difficult-to-see aye-ayes.Funding generously provided by NC State's Provost's Professional Experience Program.

Abstract Name: Data-Driven AI Modeling of Emerging FETs: XGBoost Deep Learning Approach

This paper tackles the urgent need for advanced modeling techniques for newly developed emerging Field-Effect Transistors (FETs). We aimed to leverage XGBoost for fitting the current-voltage (I-V) characteristics of Carbon Nanotube FETs (CNTFETs), thereby addressing the gap in precise modeling for this novel transistor type through an experimental study. Our methodology encompassed a comprehensive review of FET modeling literature, careful dataset identification, and preprocessing to accommodate CNTFETs' unique characteristics. We applied the XGBoost algorithm, fine-tuning hyperparameters to optimize prediction accuracy. A quantile transformation on the output data (Ids) was employed to normalize the distribution effectively, dealing with small values efficiently. XGBoost, renowned for its effectiveness in the computer vision field, also excels in predicting tabular data for regression problems. We expect the results to demonstrate superior performance, evidenced by low Root Mean Square Errors (RMSEs) and a high R^2 score, even with a constrained dataset. With 90% of the data allocated for training and 10% for validation, we anticipate an R^2 score exceeding 99.8% for the trained data, underscoring the model's precision in predicting

I-V characteristics. This research not only propels CNTFET modeling forward but also proves the XGBoost algorithm's efficacy. The significance of our findings lies in offering an efficient and reliable method for predicting I-V characteristics, paving the way for further advancements in the field of emerging transistor types.

Abstract Name: Machine Learning in Autism Spectrum Disorder Detection and Classification

Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition with a wide spectrum of symptoms that affect an individual's social communication and behavior. Early detection of ASD is crucial for timely intervention and improved outcomes. This study explores the potential of machine learning algorithms for detecting ASD through the analysis of clinical data. A diverse dataset incorporating demographic information, medical history, and behavioral assessments along with comprehensive genetic profiling of individuals with and without ASD forms the basis of this research. Various machine learning algorithms, including Support Vector Machines, Random Forests, and Neural Networks, are employed to decipher intricate patterns within the dataset indicative of ASD. To enhance the models' performance, feature selection and engineering techniques are applied, ensuring that the algorithms effectively capture relevant information for accurate detection. The study evaluates the models based on sensitivity, specificity, and overall accuracy to assess their efficacy in ASD detection. The research investigates the robustness and generalizability of the models across diverse demographic factors and clinical presentations. Ethical considerations and the interpretability of machine learning outcomes are emphasized to underscore transparency and accountability in the decision-making process. The study yielded promising results, achieving an impressive accuracy rate of 89.5% using the Random Forest algorithm. This level of accuracy represents a significant advancement in the field and underscores the potential of machine learning as a powerful tool for enhancing the diagnostic capabilities of ASD detection models. By providing evidence of the models' accuracy and generalizability, the study lays the foundation for the development of scalable and data-driven tools that can assist clinicians in the early and precise identification of ASD, thereby facilitating timely interventions and improving long-term outcomes for individuals affected by this complex disorder.

Abstract Name: Enhancing Bridge Inspections with Drone Technology and Computer Vision

This research project centers on addressing the significant challenges inherent in traditional bridge inspection techniques, such as labor intensiveness, time consumption, high costs, and the often-required temporary closure of bridges. These closures lead to traffic congestion and pose considerable inconveniences to the local populace. With these issues in mind, the primary question driving this research is: How can the integration of advanced computer vision techniques and drone technology transform and enhance bridge inspection processes, making them more efficient, accurate, and cost-effective, all while minimizing disruptions? Safety and proper maintenance are of utmost importance in transportation infrastructure, particularly in bridges. Yet, existing inspection methodologies have left much room for improvement. In response, our methodology introduces a novel approach, employing drones coupled with machine learning algorithms. The drones, equipped with high-resolution cameras, capture detailed aerial data, which is then processed to produce intricate 3D virtual models of the bridges. These models facilitate a comprehensive inspection and generate critical data for subsequent numerical and structural analyses, thus aiding in informed decision-making processes concerning maintenance and repairs. Preliminary findings indicate that this automated bridge inspection framework considerably elevates the accuracy of inspections, providing infrastructure managers with a more in-depth insight into a bridge's condition. This streamlines the entire inspection process and augments the durability, safety, and reliability of these crucial infrastructure assets. By leveraging emerging technologies, transportation authorities can overcome the challenges of traditional inspection methods. Ultimately, this research embodies a pioneering exploration into technological avenues that could redefine the landscape of bridge inspections, emphasizing the vital role of innovation in addressing infrastructural challenges while simultaneously reducing costs and disruptions.

Abstract Name: Technological Advancements in Domestic Oil and Gas Production: Implications for Labor Markets and Sustainable Policy Shifts

In 2023, the United States hit a new record for the amount of oil and gas produced domestically. This occurred despite the fact that production rig counts are at near historic lows and are well below long-term averages. In this work, I discuss how technological advancement has impacted labor markets in states endowed with oil and gas resources. To do so, I make use of highly granular Job-to-Job flows data and a shift-share instrumental variables design. I find that the number of jobs supported by a shock to oil or gas production is decreasing over time, and that the elasticity of labor demand with respect to commodity price movements has also decreased. My work has implications for policymakers as they seek to transition to more sustainable technologies. Given the declining need for labor per unit of oil or gas production, policies like the 'energy communities' provision in the Inflation Reduction Act may have a larger benefit than originally envisioned.

Abstract Name: Modulating the Epigenome of Cells Derived From Arboleda-Tham Syndrome Patients using Small Molecule Inhibitors

Histone modifying proteins play an essential role in facilitating cellular processes such as transcription, DNA replication, and cellular fate through altering post-translational modifications found on chromatin. While lysine acetyltransferase (KAT) and histone deacetylase (HDAC) enzymes regulate gene expression by adding or removing acetyl groups from histones, their dysfunction has devastating consequences on gene regulation. Specifically, nonsense mutations in the gene coding KAT6A have been linked to a pediatric neurodevelopmental disorder observed in more than 350 people worldwide known as Arboleda-Tham syndrome (ARTHS). Understanding the function of KAT6A and what downstream abnormalities result from this nonsense mutation on a transcriptomic and proteomic level are at the forefront of research toward treating individuals with ARTHS. Recent technological development of small molecule inhibitors of KAT6A offers a novel approach in phenocopying the broken acetylation pathway observed in ARTHS patients and providing insight into KAT6A's role in controlling cell cycle progression and neurological development. A survey of the histone residues acetylated by KAT6A according to literature gave rise to a quantitative analysis of western blots, revealing a decrease in acetylation at histone 3 lysine 18 and 23 with the introduction of KAT6A inhibitors. Conversely, the inhibition of HDACs increased acetylation at those marks, indicating a potential route for therapeutic treatment to counteract the changes in acetylation caused by KAT6A dysfunction. Applying this treatment protocol to an immortalized Schwann cell line, we observed a decrease in the same acetylation marks in fibroblasts and demonstrated a change in two new histone 4 marks. This establishes a new method for phenocopying ARTHS, but RNA sequencing data will be required to establish which genes are differentially expressed due to acetylation changes. Better models of how KAT6A functions present an exciting opportunity to establish a standard methodology in developing a treatment for ARTHS and other similar rare genetic diseases.

Abstract Name: The Antimicrobial Efficacy of Wasabia japonica on Sushi

Japanese sushi has become incredibly popular in the United States. Sushi is traditionally made with vinegar rice, seaweed wraps, vegetables, raw fish, and occasionally cooked seafood. Eating sushi is risky, especially if precautions are not taken. The CDC estimates that 48 million people get sick, 128,000 are hospitalized, and 3,000 die each year in the U.S. from foodborne illnesses. Raw seafood can contain various pathogens such as Vibrio parahaemolyticus, non-agglutinable vibrios, and Staphylococcus. Wasabi (Wasabia japonica, Japanese horseradish) is an edible plant that contains a variety of phytochemicals. In Japan, wasabi is traditionally consumed as a condiment with sushi. Wasabi has shown to have antimicrobial activity, which contributes to

the safety of eating raw fish. This study aimed to explore the antimicrobial properties of wasabi compared to a chemical alcohol disinfection product for food. Sushi was left at room temperature for 24 hours and sampled for microbial growth observation. After 12 hours of incubation on TSA plates, sushi with no wasabi and no alcohol showed significant microbial growth. Sushi treated only with wasabi had 1 beige bacterial colony, sushi treated only with alcohol had no colonies, and sushi treated with wasabi and alcohol combined had 1 transparent raised colony. Our findings showed that wasabi is effective in reducing microbial growth. Further studies could evaluate the most effective way of adding wasabi to foods as a safe alternative to using food service chemicals to prevent foodborne illnesses.

Abstract Name: Anthropogenic Contaminants Alter Microbial Diversity in Aquatic Ecosystems of the Delaware Watershed.

Water quality analysis of surface waters in Philadelphia County reveals that storm events induce significant alterations in pollutant concentrations, including polycyclic aromatic hydrocarbons (PAHs), antibiotics, and heavy metals. These changes have potential repercussions for both aquatic microorganism diversity and human health. Despite the known impact on chemical pollutants, there exists a notable gap in understanding the responses of microbial communities in these environments to such disturbances. This study seeks to address this knowledge gap by conducting comprehensive culturing and genomic analysis of microorganisms isolated from surface water samples at two distinct time points: under typical conditions and three days post a storm event.Utilizing colorimetric water quality assays, the research aims to assess common pollutant levels and observe variations in the relative concentrations of different chemicals, particularly in the Schuylkill River following storm events. Microbial diversity is investigated through Gram staining and culture analysis of isolated colonies from Philadelphia County waterways. Genomic DNA extraction, followed by PCR amplification of the 16s rRNA gene, is performed in preparation for genomic sequencing. The subsequent analysis of genomic sequencing data, facilitated by bioinformatics software, aims to identify microorganisms and classify taxa.Preliminary results indicate a discernible influence of storm events on the microbial diversity within the Delaware River Watershed. However, to further comprehend the intricacies of this impact, additional analyses are imperative. Future work involves a more in-depth examination of pollutant levels and metagenomic data to elucidate specific correlations between pollutants, potential pathogens, and their collective influence on microbial diversity. This multifaceted investigation not only contributes to our understanding of the complex interactions within aquatic ecosystems but also underscores the importance of integrating chemical and microbial assessments for comprehensive water quality evaluations.

Abstract Name: Biodiversity and Phylogenetics Study of Mushrooms from Southeast Nigeria using DNA Barcoding Methods

Over the past two decades, DNA barcoding has gained popularity in the field of molecular biology as a tool for solving the issues faced by traditional taxonomical methods. Here, we explored the use of thistool to identify and classify various mushroom species found in the diverse ecology of southeast Nigeria (Enugu and Ebonyi states). Fungi are ubiquitous in both natural and human-made environments. They play important roles in the health of plants, animals, and humans, and in broad ecosystem functions. Thus, having an efficient identification system could significantly enhance our ability to make the most use of them for both nutritional and therapeutic values as well as monitor the spatial and temporal patterns of fungal distributions and migrations. By using DNA barcoding of nuclear ribosomal internal transcribed spacer (ITS) of the rRNA gene, with fungal specific ITS primers (ITS 1 AND 4), ITS barcodes were generated for 71 representative mushroom samples. The generated barcodes sequences were analyzed using the DNA subway online platform. Sixty-four out of the 71 samples were identified to the species level with Lentinus squarrosulus and Neonothopanus hygrophanus as the most abundant species. Four major groups of mushrooms were identified: Clade A - genus Leiotrametes complex; Clade B - genus Lentinus complex; Clade C – genus Neonothopanus; and Clad D – genus Choanephora. Overall, all the students acquired the skillsets and mastered the basic techniques in molecular biology research

Abstract Name: Optimization of Ion Confinement in Surface-Electrode Traps for High-Coherence Quantum Information Processing

Trapped-ion quantum information processing devices rely on optimized ion confinement to enable high-coherence operations. Surface-electrode ion traps are commonly used to confine ion qubits in space, using a combination of radio frequency (RF) and static (DC) electric potentials. A key aspect of optimal ion control is in determining appropriate electrode potentials for stable ion confinement. Here, we present multi-physics and numerical simulation techniques expanding upon Allcock et. al. to characterize surface-electrode Paul traps. Through this, we generate corresponding optimized basis potential sets, paving the way for in-situ experiments. We also compare the efficacy of these methods in performing characterization tasks.

Abstract Name: Spirituality, Materialism, Isolation, and Virginia Woolf

At first glance, it might seem like materialism and spirituality are mutually exclusive in Virginia Woolf's To the Lighthouse. To be sure, within the novel, the human mind longs for spiritual moments, like Mrs. Ramsey's experience of the lighthouse, even as material conditions inhibit or limit them. Woolf conceives of spirituality dialectically, as the experience of perfection that cannot be found in the physical world. The experience of the tension between the spiritual and the material creates strife within the novel's characters. The very nature of experience is the push and pull of spirituality and materialism as opposed forces. As a result of this, Woolf's characters mourn death, believing that the spiritual is unattainable in the face of tragic materiality. This fear of death drives the characters more deeply into themselves rather than towards one another. However, even in the face of this dialectical tension, Woolf suggests a more nuanced view of the human experience. Though Woolf's world is full of people talking past one another, a natural world that is alien, and individuals who are tormented by tragedy, Woolf demonstrates that this existential loneliness is the precondition for individuality and its creativity. Out of isolation come the vast spaces within the human self, leading to dazzling human variety and artistic creation. The potential for tragedy in life therefore also becomes the precondition for art, which aims to heal the alienation from which it arises. Woolf does not paint an idealized picture of reality but depicts a generative dialectic in which the truth of human experience shines out in all its terrible beauty despite the vicissitudes of tragedy.

Abstract Name: Teacher and Administrator Perceptions of Restorative Practices in Schools

Most schools use exclusionary discipline, which is a disciplinary practice that removes students who misbehave from the learning environment through suspensions or expulsions. This form of discipline is associated with adverse outcomes including academic disengagement, lack of support, and increased interaction with the criminal justice system. Black, disabled, and Queer students are disproportionately involved in this form of discipline. Some schools and teachers have begun shifting to using non-exclusionary strategies as a way to make discipline more effective and equitable. These restorative practices focus on proactively building trusting relationships within the classroom and, potentially, school-wide and repairing any interpersonal harm done while maintaining students' connections to their school environments. Despite the increased use, its value remains misunderstood by school personnel, parents, and communities. The current research study seeks to understand how teachers and administrators implement restorative practices and non-exclusionary discipline in school environments and their motivations for doing so. Existing research assesses educators' attitudes following district-wide training and implementation of non-exclusionary discipline and restorative practices. The current research differs in that it compares the experience of teachers and administrators who have chosen to implement these practices on their own. Semi-structured interviews were conducted with 12 teachers and administrators who currently use restorative practices and advocate for their use by others. Preliminary findings indicate that teachers and administrators use restorative practices because they are motivated to create a more equitable school environment and positive long-term outcomes for their students. Beneficial practices include restorative conversations and circles, specifically those that

focus on prevention of interpersonal conflict and disruption in the classroom. The lack of school-wide buy-in, consistency of implementation, and lack of time are obstacles that teachers and administrators face. The participants advocated for expanded use of these practices, increased training, and community-wide education.

Abstract Name: Solving Real-World Challenges: A Mentor-Student Model for Evaluating and Improving Law Enforcement Training

Recent events involving negative interactions between law enforcement officers (LEOs) and individuals with autism have made national news, particularly use of force incidents captured on body-worn cameras. This has led to calls for better training for LEOs during encounters with autistic individuals. Training programs have been developed and are thought to be effective in reducing the likelihood of use of force incidents, but these programs are not standardized, and many do not involve outcomes measures. Our project sought to identify the optimal training program and deliver this program locally. This involved several stages, including searching for existing training programs and entering key variables into a database, identifying gaps and weaknesses, identifying the optimal program, getting trained by an expert, and getting buy-in from local LE agencies. Over the course of 10 months, a three-person team (mentor and two undergraduates) achieved these goals and delivered seven trainings with approximately 50 participants in Yavapai County, Arizona. Accomplishing this required considerable assistance from the undergraduate researchers. The two students who are the subject of this talk started in a unique position – they were involved from the inception of the project to the point of delivering these trainings. Both have been invaluable to the project and have contributed meaningfully to our success while learning they can contribute to positive change locally and in society. By utilizing a collaborative mentor-student partnership model, both contributed based on their strengths and interests, and this method has paid off. One was instrumental in creating a database of existing trainings and the other helped develop a novel problem-based learning exercise, which was then incorporated into our protocol. Throughout the process, their ideas and contributions have made our training better and helped address a real-world problem. The impact on students and transferability of the model will also be discussed.

Abstract Name: Intracellular Network Modeling to Predict Cardiac Fibrosis: Fibroblast Activation Protein

Cardiac fibroblasts are an essential part of the structural integrity of the heart. These cells regulate the extracellular matrix scaffolding which is critical to the heart's ability to function mechanically, chemically,

and electrically. Through focusing on the different ways these cardiac fibroblasts react to certain stimuli, it can be predicted on how to treat the heart when these stimuli disrupt its integrity in various disease conditions. It has been found that the heart has a network of proteins and other small molecules that interact to create a cascade of signaling pathways. The goal of our research is to map out newly discovered pathways related to fibroblast activation protein and show how they interact with the already existing pathways using a computer program called Netflux. Our computational simulations aim to determine how different levels of each small molecule affect the outputs of the pathway. Through this computational research, different levels of each molecule can be entered and determining the outcome of effects of different stimuli can be done electronically instead of needing to be done on physical cells. This virtual therapy screen can greatly accelerate the discovery of novel compounds for improving extracellular matrix structure contributing to heart disease.

Abstract Name: Modeling Multiple Ion Transport in an Electrochemical Cell

Electrochemical cells are commonly seen across energy storage and environmental remediation devices, yet the understanding of ion transport for multi-ion electrolytes in these cells is limited. The challenge in predicting ion transport for multi-ion electrolytes arises because several processes–diffusion, electromigration, and electrochemical surface reactions–occur simultaneously. Moreover, the existing literature ignores the impact of double layers on electrochemical reactions because it requires stitching together multiple regions. Therefore, the objective of this study is to predict ion transport for multi-ion electrolytes while accounting for all these transport processes simultaneously as well as the influence of electrical double layers. To this end, our model uses a Poisson-Nernst-Planck framework with coupled double layers and a bulk electrolyte. We derive equations for concentration and potential profiles where surface reactions occur in the double layers and act as boundary conditions. We solve these equations using a Python ODE solver. Our study is able to predict concentration and potential profiles for 4 and 5 ions with a supporting electrolyte, and discover physical insights into the behavior of ions within the electrochemical cell. We are currently expanding our work to include Butler-Volmer kinetics and obtain current-voltage relationships. Overall, modeling electrochemical cells with this physics-based framework enables us to make more efficient cells by helping experimentalists optimize mass transport in their systems and predict reaction constants.

Abstract Name: Understanding Emerging Adult Latina Women's Perceptions of Mental Health

With high rates of anxiety among Latina women between 18 and 25 years of age, this study aims to understand the complex interplay of culture, gender, age, and family on perceptions of mental health among Latina women. Guiding this study is the question of how emerging adult Latina women understand mental health issues (i.e., anxiety) and protective factors in their lives. For this study, an interpretive phenomenological analysis (IPA) of 18 interviews with Latina students attending a Hispanic-Serving Institution in Southern California was conducted. Findings indicate four recurring themes, including the experience of stress from breaking away from traditional gender roles of serving men while attempting to stay attached and committed to Latinx family culture. Participants also describe incongruent perspectives of mental health between their own views and their families, yet they express that family remains their primary support system. A sense of identity threat also surfaced, with some participants stating they are not "Latina enough." Lastly, participants describe their exposure to social media as being associated with more positive attitudes toward treatment while simultaneously describing experiences of upward social comparison and anxiety when using social media. These findings can help inform culturally aware practices for therapists working with emerging adult Latinas.

Abstract Name: Assessing the Correlation and Differences between Melatonin and Cortisol levels in College Freshmen throughout the Academic Year to help Determine if they are Reliable Stress Markers

Background: Cortisol is a circadian hormone whose values increase in the morning, while melatonin is a circadian hormone whose values increase at night. Stress has been shown to disrupt both circadian responses, and college students have various stressors that can cause dysregulation in cortisol and melatonin levels. Relationships between melatonin and cortisol may help to predict stress in college students, although limited research has been done to assess the potential correlations. Purpose: The purpose of this study was to assess whether melatonin is a reliable marker of cortisol in college freshmen at various timepoints throughout the academic year. Methods: Demographic data on incoming college first-year students at Norwich University (n=40) were collected via a self-report survey in September 2023. Saliva samples are being collected six times during the 2023-24 academic year. Salivary cortisol and melatonin were quantified in the September and October samples using Enzyme-Linked Immunosorbent Assays (ELISAs). Absorbencies were converted to concentrations using R. Pearson correlation were used to assess relationships between cortisol and melatonin at each timepoint, and t-tests were used to assess differences in each hormone between September and October and between genders. Statistics were run using SPSS version 28. Results: Analyzing the data revealed that there were no notable correlations observed in cortisol and melatonin levels between September and October. Furthermore, there were no significant differences between genders and no significant diffrences in melatonin between the timepoints, although cortisol was higher in October than September (p=0.056). Conclusion: While current data suggest that melatonin and cortisol are not correlated, the small sample size might be a limitation, and we will continue to recruit participants to increase power.

Abstract Name: Immigration Detention: Its Impacts on the Health of Immigrants

Immigration detention is the process of detaining migrants and refugees for criminal, ad hoc, and administrative procedures. While immigration detention is an international problem, the United States has the most extensive immigration detention system in the world, with 211 operational facilities that can house 50,000 immigrants at any time. As of July 2023, the US detained roughly 352,882 immigrants, and worsening this issue is the fact that 90.8 percent of immigrants detained will find themselves in privately run centers that prioritize financial gain over human rights. These detention facilities have been subject to various complaints by human rights organizations and scholars that note sexual assault, denied medical care, unsanitary conditions, excessive use of force, beatings, abusive solitary confinement, and lack of legal representation. These abuses violate internationally accepted human rights in treaties signed and ratified by the US government. More importantly, these abuses have devastating effects on immigrant health. Previous research has mainly focused solely on physical or mental health, and very few take into account the privatization of these detention facilities. However, this study aims to unify these perspectives to provide an overall picture of the effects immigration detention has on immigrant health. Furthermore, this study also discusses how the trauma from experiences in these facilities affects health in the long run, as some immigrants may be hesitant to seek medical care because of their status. The research methods used in this report include interviews and the collection of complaints from organizations discussed above who have investigated the conditions of these facilities. In all, this study sheds light on disastrous immigration policies fueled by the financial motivations of private corporations, how these policies affect immigrant health, and offer cost-effective alternatives free from privatization and that respect human rights.

Abstract Name: Cowden Syndrome and why it matters

Multiple non-cancerous tumor-like growths termed hamartomas and an elevated chance of acquiring specific cancers are two features of the genetic illness Cowden syndrome. Hamartomas are developed in almost all people with Cowden syndrome. These growths can appear everywhere in the body, although they are most frequently found on the skin and mucous membranes (such the lining of the mouth and nose). A higher chance of getting many malignancies, including those of the breast, the thyroid gland in the lower neck, and the endometrium of the uterus, is linked to Cowden syndrome. Kidney cancer, colorectal cancer, and melanoma, an aggressive form of skin cancer, are among the other cancers that have been linked to individuals with Cowden syndrome. persons with Cowden syndrome typically start developing these tumors in their thirties or forties, far earlier than persons in the general population. Contrary to the general population, those with Cowden syndrome have a higher lifetime risk of developing several cancers. In addition, Cowden syndrome frequently involves other endometrial, thyroid, and breast conditions. Other indications and symptoms may include Macrocephaly, an enlargement of the head, and Lhermitte-Duclos disease, a rare, benign brain tumor, are possible additional indications and symptoms. A tiny proportion of those affected have intellectual disability, developmental delay, or autistic spectrum condition, which can impair communication and social interaction.

Abstract Name: Understanding Non-Profit Brand Awareness: The Importance of Establishing a Strong Brand Identity

Non-profit organizations often face the hurdle of establishing a strong brand identity with limited resources. The present study aimed to identify the public's perception and brand awareness of a local non-profit organization (NPO). A total of 13 subscales relevant to the topic were employed: brand awareness, brand associations, familiarity, likeability, inclusion, usefulness, efficiency, affect, dynamism, reliability, brand commitment, sincerity, and excitement. All items selected were based on a thorough literature review. The NPO distributed the completed survey to the community, and 111 valid responses were collected from October to November 2023. A one-way between-groups ANOVA was performed to analyze subscale scores based on how participants learned about the NPO. The responses were split into four groups: (1) social media/advertising, (2) word of mouth/recommendations, (3) special and/or community events, and (4) two or more of the above categories. The independent variable was how the public knew of the NPO, and the dependent variables were the survey's subscales. The results showed a significant difference in brand association, $F(3,86) = 2.976$, $p = 0.036$, $\eta 2 = .094$, and likeability, $F(3,86) = 2.825$, $p = 0.043$, $\eta 2 = .09$, across the four groups based on how participants learned about the NPO. Post-hoc results revealed that respondents who learned about the NPO through two or more sources scored significantly higher than those who learned about the NPO through special and/or community events on both brand association (Mdiff = 0.61, d = 0.71) and likeability (Mdiff = 0.58, d = 0.67). These findings support the idea that NPOs should increase their branding efforts at special and community events and focus on their likeability as a goal for these types of events. Using such surveys for NPOs could support the organization's programming, funding, and future goals.

Abstract Name: Machine Learning for Diagnosis of Traumatic Brain injury and Developing tools for Educating the General Public

Identifying brain injuries in the preliminary stages through machine learning is important to avoid more complex situations in the brain. Long-term effects of brain injury can be associated with an elevated

incidence of Alzheimer's disease and chronic traumatic encephalopathy. Machine learning is important and useful in avoiding the late realization of fatal brain injuries. The increased diagnostic accuracy of MRI (magnetic resonance imaging) technique reduces patient exposure to radiation by reduction of required scans. The goal of this research is to use machine learning techniques to detect traumatic brain injuries from MRI datasets using classification and clustering approaches. The preliminary stages involve importing the labelled dataset using python programming language and visualizing the topographical images. The next step is to convert the image data into numerical data. Then we will build a machine learning model for classifying the images either as normal or abnormal (indicates brain traumatic injury). The final step is to evaluate the accuracy of the model and calculate model's accuracy. We will present the results obtained so far.

Abstract Name: Bio-Inspired Thermal Vascular Self-Responsive Composites for Civil Infrastructure

The ever-increasing global demand for energy-efficient and sustainable building designs has led to the exploration of innovative approaches inspired by nature. This study introduces a novel concept of bio-inspired vascularized adaptive building architecture for thermoregulation, drawing inspiration from the circulatory systems of plants and animals. This groundbreaking approach aims to optimize indoor thermal comfort while reducing energy consumption in buildings. To engineer vascular networks in cementitious composites, a sacrificial polymeric filament is utilized that dissolves upon exposure to concrete pore solution which creates an engineered channel within the matrix. In order to evaluate the effective creation of vascular networks, we conducted 3D X-ray micro-computed tomography (micro-CT) of the composites. Using this technique, we characterized vascular channel topology and micro-cracking. The results revealed the successful creation of architected channels in cementitious composites with no cracks and no dimensional instability. The proposed architecture integrates a network of fluid-carrying channels within the building envelope, emulating the vascular system found in nature. Within these channels, phase change materials (PCMs) are strategically placed to store and release thermal energy as they undergo phase transitions. The system's adaptability is viewed through real-time monitoring of temperature of the samples using infrared thermography (IR) that underwent cyclic thermal conditions. During PCM phase change, an autonomous gradual heat release was observed, increasing the temperature around the vasculature. The results acknowledged the ability of PCM fluid to enter/leave vascular channels as well as its ability to remain inside the channels. The integration of bio-inspired vascularized systems with PCMs for thermoregulation represents a promising paradigm in sustainable building design. This research not only contributes to a more sustainable built environment but also opens avenues for further exploration and practical implementation of nature-inspired solutions in architectural design and sustainable construction practices.

Abstract Name: Stress Coping Strategies for High School Students at Summit High School

Project Purpose: The purpose of this project was to educate Summit High School students on stress and provide them with stress-coping strategies to overall improve their resilience.Background: Our intervention targeted high school students in Flagstaff to teach them about the effects of long-term stress and introduce them to various stress-coping strategies. 75% of American high schoolers and 50% of middle schoolers described themselves as "often or always feeling stressed" by schoolwork. Additionally, 45% of high school students admit to being stressed nearly every day while at school. As an alternative high school, Summit High School students may face adversity more often than other students which impacts their daily stressors, further increasing the importance of stress management skills.Methods: We worked with Summit High School's second period, 11th grade English class over the course of 4 days for approximately one hour each day. We plan to implement a range of activities that include a health education lesson, arts and crafts, physical activity, and mindfulness practices. Conclusions: Nearly 78% of students increased their knowledge on stress after the health education lesson. The class's overall perceived stress remained the same from the beginning and end of the intervention at a moderate level according to the Perceived Stress Scale. It is important to note that class sizes and participants consistently changed throughout the intervention questioning the validity of results. This intervention demonstrates the need for continued work with Summit High School students to build on stress management skills in order to build resiliency and support health equity.

Abstract Name: Engineering a Recombinant Hemoglobin-Based Oxygen Carrier Made From Earthworm Erythrocruorin

ChatGPTThis study explores the potential of utilizing earthworm-derived erythrocruorin (Ec), an extracellular protein, as a novel oxygen carrier, distinct from the red blood cell (RBC)-based system. Unlike RBCs, which have a limited shelf life of 42 days when refrigerated, Ec remains functional at 40ºC for up to 6 months, presenting an intriguing alternative for oxygen transport. The objective is to engineer Chinese Hamster Ovary (CHO) cells to express LtEc, creating a hemoglobin-based oxygen carrier suitable for mass production and extended storage without refrigeration.Various molecular biology techniques, including PCR, Restriction Digest, Gibson Assembly, Golden Gate Assembly, plasmid cloning, and sequencing, were employed to develop LtEc-expressing CHO cells. Currently, hemoglobin is extracted from earthworms for replication in the lab, but this method is unsustainable due to the finite number of earthworms. The aim is to produce only the protein responsible for oxygen transport and express it in CHO cells at any desired scale.Results indicate successful expression of LtEc plasmids, both with and without secretion tags. Secretion-tagged plasmids form disulfide bonds and glycosylation, with the Ec protein located outside the cell membrane. In contrast, non-secretion-tagged plasmids protect the Ec protein within the cell membrane but lack disulfide bonds and glycans. Ongoing research is focused on determining the optimal approach between these two options for an effective hemoglobin-based oxygen carrier.The significance of this research lies in the potential to address the limitations of current oxygen carriers, leading to improved efficiency, mass producibility, and prolonged storage without refrigeration. Successful outcomes could pave the way for future clinical trials, ultimately seeking FDA approval for the developed oxygen carrier.

Abstract Name: The Role of Nuclear Localization on MxA Super Restrictors Against Orthomyxoviruses

Evolutionary arms races occur when two genes place positive selective pressure on one another to evolve fitness advantages over each other. These evolutionary arms races can be identified in the context of viruses and their corresponding hosts. We are interested in the evolutionary arms race between MxA, an interferon-induced antiviral restriction protein, and its target in orthomyxoviruses, the nucleoprotein. Despite the overall amino acid sequence of MxA being conserved, several sites are under positive selection; in particular, the MxA L4 Loop includes five rapidly evolving residues important for the restriction of orthomyxoviruses including H5N1 and H1N1 influenzas and Thogotovirus (THOV). Combinatorial mutagenesis of the five rapidly evolving residues of loop L4 allowed for the creation of MxA super-restrictors which restrict H5N1 minigenome significantly better than wild-type MxA. However, H5N1 super-restrictors did not provide increased restriction of other orthomyxoviruses like THOV and H1N1. Based on data from previous experiments using wild-type MxA and nuclear localized wild-type MxA, we predicted that adding a nuclear localization signal (NLS) to the H5N1 super-restrictors would achieve super-restrictor levels against THOV and H1N1. We tested this hypothesis in 3 minigenome assays (H5N1, H1N1, and THOV) with five H5N1 super-restrictors with and without NLS. With the addition of NLS, these H5N1 super-restrictors were able to achieve super-restrictor levels against THOV and H1N1. These findings provide the basis for future experiments testing for co-localization and binding affinity of NLS-tagged H5N1 super-restrictors and their targets.

Abstract Name: Design, Analysis, and System Identification of Novel Lift-Cruise e-VTOL Aircraft

Current electric vertical-takeoff-landing (e-VTOL) solutions are limited in endurance and range due to their reliance purely on vertical lift motors. This presentation discusses the development, design, manufacturing, and testing of a novel eVTOL tandem-wing Unmanned Aerial Vehicle (UAV) tech demonstrator for long-endurance flight. The UAV is of a vertically staggered tandem wing configuration, incorporating two motors for horizontal flight, as well as 8 motors to enable vertical takeoff, hover, and vertical landings. With an architecture that combines the mobility and versatility of a traditional multicopter vehicle along with the high

ranges typical of fixed-wing aircraft, the developed vehicle has a designed flight time of 1 hour. Design methodologies, software-in-the-loop (SIL) and hardware-in-the-loop (HIL) simulations, flight testing results, and system identification and handling qualities will be discussed. Derived equations of motion for rotorcraft-wingborne flight dynamics will be presented. This architecture holds significant promise in enabling longer-range flight, coupled with the versatility of a vertical take-off capability. Potential applications include long-range medical evacuation services, search and rescue, and infrastructure inspection.

Abstract Name: PCL HA bioabsorbable scaffold and 3D printed interlocking nail delivery system for Long bone defect

O, Oti, H. Alizereej, S. Nikfarjam, M. KhandakerThe primary objective of this study was to create a tibial interlocking nail system that is suitable for a rabbit model that has a critical-sized segmental long bone defect. Our goal was to engineer both scaffold and interlocking nail systems using biocompatible and biodegradable materials, particularly PCL embedded with hydroxyapatite (PCL-HA). Our research focused on three key objectives: 1. To produce a scaffold with suitable porosity and which are bioabsorbable enough for Stem Cell addition and growth. 2. To produce an interlocked nail system for a rabbit tibia large bone defect model using phase separation casting methods. 3. To create a delivery jig for the interlocked nail system using stereolithography (SLA) 3D bio resin printing and evaluate the efficiency of this jig in securing the scaffold. 4. To conduct a mechanical characterization of PCL-HA. The bioabsorbable PCL-HA scaffold was intentionally designed to be porous, promoting faster degradation and facilitating early weight-bearing capabilities. Our prototype targeting jig demonstrated the ability to deliver nails and securely fix screws and bone scaffolds in a rabbit tibia model, marking a significant advancement in addressing critical-sized segmental long bone defects.

Abstract Name: Evaluation of 3D-PCL-PEGDA scaffold for cartilage repair with Stem Cells

The exploration of biologics like bone marrow stem cells (BMSC) for cartilage repair has progressed rapidly, aiming to boost native biology. This is a primary focus in current clinical research. However, the absence of a supportive scaffold that could house both cellular and growth factor elements, while also permitting early weight-bearing, has proven to be a limitation. This investigation successfully created a multilayered three-dimensional (3D) scaffold using polycaprolactone and Poly(ethylene glycol) diacrylate (PEGDA) hydrogel, which was then tested in vitro for its effectiveness in repairing rabbit knee cartilage. This innovative 3D PCL-

PEGDA scaffold architecture demonstrated its capacity to safeguard any potential hydrogel-based chondrogenic material, including PEGDA. We noted the unique degradation properties of our composite scaffold in cell culture media, and witnessed its increased rate of degradation (% of dry weight change) after a fortnight of immersion in each media. This confirms its superior biodegradation profile in vitro, which hypothetically suggests optimal in vivo performance, subject to further testing. We also recorded a drop in cell viability on day 7 of culture, followed by a steady rise until day 21. Ultimately, our nanofiber coating on the PCL-PEGDA scaffold significantly enhanced BMSC attachment on the scaffold surface. This ongoing research aims to identify a dependable solution for long bone defects.

Abstract Name: Antibody Production in TLR4 Knockout and Wild-Type Mice

Toll-like receptors (TLRs) are a class of membrane-bound receptors that play a key role in linking the innate and adaptive arms of immunity. Toll-like receptor 4 (TLR4) detects lipopolysaccharide (LPS) from Gram-negative bacteria, upon recognition an immediate response is initiated that leads to the activation of immune cells and the release of pro-inflammatory chemokines and cytokines. To investigate if TLR4 is necessary to generate a robust adaptive immune response, TLR4-/- mice and wild-type mice were used to compare magnitudes of antibody production in response to intramuscular administration of the model antigen ovalbumin (Ova). 10μg of Ova was administered on Day 1 to initate immune responses to the Ova antigen, a similar injection was administered on Day 14 to boost the antigen-specific adaptive immune response. Mice were bled on days 1, 14, and 28 before Ova injections were administered. Amounts of Ova-specific antibodies, isotypes IgG1, IgG2c, and IgGE, were measured using an indirect enzyme-linked immunosorbent assay (ELISA). Results indicate that wild-type mice produced a significantly higher magnitude of Ova-specific IgG1 as compared to TLR4-/- in the day 28 serums. Isotypes IgG2c and IgE Ova-specific antibodies were not produced above the level of detection by ELISA in any of the samples tested. Our study provides evidence that TLR4 is required to generate a complete adaptive immune response. Understanding the contribution of TLR4 activation in antibody production and affinity maturation is necessary to be able to initiate protective immunity in all populations of people. Results of this study support the development of modified vaccine adjuvants that are maximally effective in driving the production of antibodies in immunosuppressed individuals

Abstract Name: Exploring Book Banning Conversations on Social Media

The resurgence of book banning has become a prominent topic in both traditional media and social media discourse throughout 2023. Many parents, school board members, and government officials have taken steps to limit the books offered to students in their schools. Numerous librarians, teachers, and parents have also fought against these bans. Recognizing the rapid and frequent evolution of the media landscape, it is critical that our research methodologies also adapt and incorporate newer forms of communication. This study expands our understanding by inspecting the conversations happening on social media — which has often been overlooked in the literature on banned books.By analyzing the most influential users and prevalent words/phrases used by social media participants in YouTube videos on banned books, the study can teach what online conversations consist of and how they impact the book-banning process. The study will also discover the common sentiments of the most popular words and comments. This research plays a critical role in expanding the current scholarly conversation by using social media to learn why people seek to ban books, how book banning is perceived, and the role social media plays in these conversations. It can also inform decision-makers, such as legislators or school board members, on the sentiments of book-banning online.

Abstract Name: Explaining LIGO's discovery of gravitational waves through college-level physics

Through LIGO's successful detection of a gravitational wave (GW150914) in September 2015, the space-time we live in was experimentally confirmed for its elastic qualities. ^1 Itself may expand, contract, swing and bend just like matter. This is promising as human's curiosity of the universe echoed a hundred years after a conjecture. ^2 The interest among the public and college students prompted this pedagogical study. ^3We dive in by analyzing the three stages of the coalescence of black hole, which is the main event caused the GW150914. Initially, the by using Newtonian mechanics e.g. Kepler's Third law, we described the two black holes on the initial state of adequate separation. In the second stage, we develop a rate equation of the gravitational radiation by analog the gravitational field to the electromagnetic field. In the third stage, instead of introducing Black Hole Perturbation Theory, we are using knowledge of underdamped oscillations, Schwarzschild radius and event horizon, which explained on introductory physics books, to give more sense to the most complex period, ring-down, when the merged object relaxes into its equilibrium state called a Kerr black hole. ^3By parameter estimating of the coalescence events, we may inferred the key features of the event like masses of the black holes, the distance to earth, and the total gravitational radiation emitted. With a dozen of applied problems related to data obtained by and operation of LIGO, we gave college students an remarkable example for quantitative and qualitative understanding to the gravitational wave era.

Abstract Name: Effect of Noni drink and Noni extract on hIAPP aggregation in type 2 diabetes

Type II diabetes is characterized by insulin resistance and β-cell destruction caused by human islet amyloid polypeptide within the pancreas. Natural remedies such as noni fruit (Marinda citrifolia), which is traditionally found in Asian and the Pacific islands, have been used to treat diseases such as cancer, joint pain, and diabetes. In this study, noni fruit powder and a dietary noni drink were used as an experimental agent to investigate their potential influence on pancreatic cell viability. To achieve this, various amounts of noni fruit extract were introduced to cells alone or in conjunction with hIAPP, to evaluate their impact on cell viability. Noni fruit powder was extracted using ethyl acetate and added to RIN-m cells to determine their viability using an MTT assay. The results revealed that increasing concentrations of noni yielded decreasing cell viability. The tested concentrations of noni were excessively potent to pancreatic beta cells. The cells exhibited a robust health and vitality in isolation; however, the cells viability declined once exposed to nNoni fruit extract. Future research will involve lower concentrations of noni fruit extract and determination of active compounds responsible for this potent effect on pancreatic beta cells and its impact on cell viability in type II Diabetes.

Abstract Name: Beyond Polyamines: SSAT1 Unveiled as a Novel Tau Acetyltransferase in Alzheimer's Pathogenesis

In Alzheimer's disease (AD) and tauopathies, Tau, a microtubule-stabilizing protein, undergoes post-translational modifications, like hyperphosphorylation, aggregates, and ultimately contributes to neuronal death. Polyamines are aliphatic polycations with diverse physiological functions. In disease states, there is an observable flux of polyamine concentrations. Though this short-term increase may be beneficial in states of acute stress, chronic stressors result homeostatic dysregulation, termed a polyamine stress response (PSR). This research investigates the intricate role of the polyamine stress response (PSR) and the enzyme Spermidine/spermine-N(1)-acetyltransferase (SSAT1) in Alzheimer's disease progression, with a specific focus on their impact on Tau, the major pathological hallmark of neurodegeneration. Interestingly, we have found that SSAT1, an enzyme traditionally known for its role in acetylating polyamines, also acetylates Tau. This significant finding identifies SSAT1 as a novel Tau acetyltransferase via the polyamine pathway, presenting new avenues for understanding and potentially mitigating Tau aggregation in Alzheimer's.We will be employing Tau transgenic PS19 (human MAPT P301S, 1N4R) mice, which overexpress human tau, and novel SAT1 heterozygous and homozygous knockout mice as our primary subjects. Our analysis will aim to identify a broad range of acetylation sites on Tau, utilizing novel antibodies created by our lab via Western blotting and immunohistochemistry (IHC). We plan to conduct detailed measurements of Tau tangle pathology, neurodegeneration, and inflammation, providing a comprehensive picture of the disease state.Underpinning our research is a hypothesis, supported by our preliminary data, that decreasing SSAT1 activity or genetic ablation of SSAT1 will significantly reduce Tau acetylation and subvert the Tau-PSR. This, in turn, is expected to reduce Tau pathology, potentially slowing the progression of Alzheimer's. The anticipated outcome of this study has the potential to greatly enhance our understanding of the role of SSAT1 and the PSR in Alzheimer's disease, possibly leading to the identification of novel therapeutic targets.

Abstract Name: The Relationship Between McDonalds and Ronald McDonald House Charities

Have you ever been to a McDonald's drive-thru and noticed the donation box labeled "Round Up for RMHC?" Ronald McDonald House Charities (RMHC) is a non-profit corporation that provides a "home-away-from-home" to families and children in need receiving treatment, supporting and facilitating family-centered care. Their mission statement is to create, find, and support these programs that directly improve the health and well-being of children and their families. Fortunately, technological advancements bring newer healthcare treatments; however, access to these resources is limited, and staying near those things is an added cost to families. RMHC is there to bridge the gap to lessen the burden. Many people expect the multi-billion dollar fast food chain to contribute to their name-sake charity annually; however, this could not be further from the truth. RMHC only gets 10% of its revenue, over $182 million, from McDonald's via donation boxes and round-up contributions. The Round-Up feature allows customers to round up to the nearest dollar to donate to RMHC. In recent years, McDonald's has begun implementing the Round-Up program on their app and self-order kiosk. However, critics claim McDonald's may benefit more from this relationship through promotional and publicity benefits. RMHC has stated they appreciate the awareness behind the cause and believe it reaps positive benefits, but the benefits might be disproportionate. This project aims to bring awareness to Ronald McDonald House Charities, and the audience will learn about the misunderstood relationship between McDonald's and RMHC and specifically how RMHC Baltimore functions without help from McDonald's.

Abstract Name: Athlete Motivation

Problem or Major purpose: In the world of sports, athletes are guided by the coach's decisions and behaviors. Athlete perception of the coach's interpersonal behaviors has the potential to impact the athletes sport development (Lopez de Subijana et al., 2021). The purpose of this study is to understand how the athlete's perception of the coach's behavior may impact the athlete's basic psychological needs, and how meeting those needs may impact the athlete's overall motivation for sport. Procedure: Through convenience sampling, approximately 200 collegiate athletes ranging in age from 18-25 years old, from the selected minority serving institution will be selected as participants. Researchers will select half identified as female (n=100) and the other half as male (n=100). The collegiate athletes will be participants from the following sport teams: soccer, basketball, cross country, volleyball, track and field, bowling, and golf. This will be a non-experimental, mixed methods design that will utilize a correlational survey to measure coach interpersonal behaviors, athlete basic psychological needs satisfaction, and athlete sport motivation. The majority of the questionnaire items will be close-ended provided with a Likert scale ranging from 1-7, with the exception of the demographic part of the survey. Results: The research team anticipates that athletes who perceive coach interpersonal behaviors as supportive will experience satisfaction of their basic psychological needs resulting in self-determined (intrinsic motivation). Similarly, the research team anticipates that athletes who perceive coach interpersonal behaviors as thwarting will experience dissatisfaction of basic psychological needs resulting in controlled motivation. Conclusions or implications: The research team anticipates that other variables and demographics such as age, nationality, years of sport participation, accredited competition

level, and the duration of coach-athlete relationship will be significant in the athlete's perception of coach interpersonal behaviors and basic psychological need satisfaction, overall affecting the athlete's motivation for sport.

Abstract Name: Homeownership and Mortgage Loans: How Important is a Conventional Loan?

Communities across the United States face a housing crisis that stems in part from a scarcity of conventional home mortgage loans. In 2020, the Urban Institute reported that when applying for a mortgage, Black applicants were denied 27.1% of the time, yet White applicants were denied only 13.6% of the time. These denial rates are highly correlated with homeownership rates. Today, despite policy efforts, the difference in White and Black homeownership rates is higher than in the 1960s when the government enforced discriminatory housing policy.Because lenders often cite credit score concerns and high debt-to-income ratios as rationales to deny someone's mortgage application, policy alternatives must address these barriers while improving mortgage application approval rates and reducing the mortgage denial gap by race. While various legislation has attempted to ameliorate the concerns above, progress has been muted and slow. After considering how numerous alternative policy options advance equity, improve effectiveness, and minimize implementation costs, I make following recommendations to the United States government: Enact regulations that mandate credit reporting agencies include 12 months of positive rental payment history when computing someone's credit score. Increase access to free educational resources regarding the homebuying process. Conduct further research to investigate the impact of conventional mortgage access on homeownership. Credit scores would rise and assuage the worries of lenders. Information would be more available to uninformed borrowers. The importance of conventional mortgage access would be known, and the need for change would be illuminated. By putting these policies into place, evidence suggests that conventional mortgage access would increase to create more positive outcomes for people across the United States.

Abstract Name: Artificial Intelligence tool Optellum outperforms traditional lung cancer prediction model BRODERS

Lung cancer claims more lives than any other malignancy, with 127,070 annual deaths in the United States. While improvements in lung cancer screening have led to decreased mortality in high-risk populations, it has also led to a dramatic increase in the detection of indeterminate pulmonary nodules (IPNs). Analysis of IPNs leads to morbid and costly complications derived from biopsies and invasive procedures. The development of an accurate non-invasive risk predictor such as radiomic tools would help primary clinicians through artificial

intelligence (neural networks and machine learning) to classify patients at higher risk depending on clinical characteristics, exposures (tobacco, air pollutants), and images from low dose computed tomography scans (CTs). Characteristics such as nodule texture, density, location, and volume are being developed as one such noninvasive predictor. In the present study, radiomic analysis was applied to a cohort (N = 450) of patients with nodules posing significant diagnostic challenges. Previously validated traditional radiomic tool BRODERS (Benign versus aggRessive nODule Evaluation using Radiomic Stratification) and novel AI-based Optellum analyses were performed on patient CT scans with Optellum (AUC = 0.68) performing significantly better than BRODERS (AUC = 0.52). Optellum's performance is unprecedented, being the first predictive model applied to this cohort to produce accurate predictions. These results indicate that Optellum and other related AI tools may provide the most predictive value for clinicians, especially when examining clinically puzzling cases.

Abstract Name: Exploring Medicinal Polysaccharide-K (PSK) Production from Trametes versicolor used for Biofuels

The white-rot fungus, Trametes versicolor, has been examined as a potential pre-treatment agent for biofuel processes as a means to increase biomass digestibility while improving sugar yields. Although this technology has the potential to reduce biomass-to-bioenergy costs, the overall economic viability of using lignocellulose for biofuels remains a concern. An effective method to overcome low profit margins is to create a co-product that adds value to a process. To that end, Trametes versicolor has been used as a source of a macromolecule called polysaccharide-K (PSK) that has clinically-demonstrated health benefits. Although the fungi used for bioenergy purposes should be able to produce PSK as a co-product, the strain of Trametes versicolor used for lignocellulose pretreatment (52J) is different than the strain used for PSK production (CM-101). In the present study, the CM-101 strain was grown in liquid culture before being applied to chopped miscanthus straw and allowed to grow for five weeks in a biomass pretreatment scenario typically used with strain 52J. The resulting treated material was milled and examined for lignin degradation, fermentable sugar yield, and calorie content. Meanwhile, to examine PSK production from the 52J strain, it was grown in liquid culture for approximately one week before being filtered from the media. The filtered fungal material was then milled in liquid nitrogen and proteins were extracted to detect the presence of PSK. The results from these two experiments indicate that T. versicolor strain CM-101 is as effective as strain 52J for treatment of the miscanthus straw, with comparable biofuel metrics between the two strains. Additionally, early results suggest that T. versicolor strain 52J is an effective source of PSK, although further research is required to compare yields and examine potential differences in the carbohydrate content of this medically significant macromolecule.

Abstract Name: Beyond Blueprints: A Comprehensive Exploration of the Impact of Rendering Methods on Architectural Communication

In the vast landscape of architectural mediums, the key to capturing clients' attention and ensuring a comprehensive grasp of a proposed project lies in the choice of rendering methods. This research endeavors to pinpoint the most effective communication medium through an experiment employing various rendering techniques. Four renderings of a single exterior façade will be crafted, each utilizing diverse media methodologies. To convert the renderings into quantifiable data an innovative approach involves subjecting the renderings to AI-driven algorithms, predicting where the human eye is drawn to in the images in the first 3-5 seconds superseding the influence of cognitive bias, and aiming to identify which of the images inherently captures the most attention. The research results will be examined and the significance of differences between rendering methods addressed. This research delves into the implications for architects, exploring how these findings may influence presentation strategies, considering potential impact of passing fads, taking into account the alignment of media style with architectural subject matter, and noting whether the experiment requires diverse architectural styles for optimal effectiveness. The current hypothesis regarding these results is that the images with contrast and hierarchy in the composition, such as watercolor renderings, will outperform the other methods. The overarching objective of this research project is to discern the most effective medium for capturing the client's attention when presenting architectural projects. Due to modern advancements that increase our access to an abundance of knowledge and techniques, architects and designers must make informed choices about how they present their ideas. By comparing these mediums and formats through these methods, this research will attempt to identify the most effective strategy for engaging clients and enhancing their comprehension of projects which will also aid in contributing to a clearer understanding of visual communication in the architectural field.

Abstract Name: The Association of Limited Health Literacy with Frailty and Mortality among Older Adults with Cancer- The CARE Registry

Background: Health literacy is the ability to obtain, process, and understand health information. Limited health literacy can lead to poor identification and management of comorbidities. Frailty is a state of vulnerability from age-related decline impairing one’s ability to handle stress, is common among older adults with cancer, and is a risk factor for death. Older adults have high rates of poor health literacy and frailty, but

the role of health literacy on frailty and death among older adults with cancer is understudied.Methods: We included 850 older adults ≥60y with cancer from the Cancer & Aging Resilience Evaluation (CARE) Registry completing a selfreported geriatric assessment at first visit to medical oncology. Self-reported health literacy was the exposure. Outcomes were frailty and death. We used modified Poisson regression to examine the association of limited health literacy on outcomes adjusting for age, race-ethnicity, sex, and cancer type/stage.Results: Median age at enrollment was 68; 57.5% were male; 20.1% were non-Hispanic Black. The most prevalent cancer types included colorectal (27.4%) and pancreatic (18.5%) at advanced stage (46.1% Stage IV). Those with limited health literacy were older (70 vs. 68, p: <0.001), male (62.5% vs. 55.2%, p: 0.043), non-Hispanic Black (28.4% vs. 16.2%, p: <0.001), less educated (≤HS: 62.1% vs. 28.5%, p: <0.001), and retired/disabled (86.4% vs. 71.2%, p: <0.001). In multivariable analysis, limited health literacy was associated with higher prevalence of frailty (PR: 2.63, 95% CI: 2.12-3.26) and death (PR: 1.27, 95% CI: 1.02, 1.58), compared to those with adequate health literacy.Conclusions: Older adults with cancer and limited health literacy had higher adjusted prevalence of frailty and death. Interventions to address limited health literacy should be explored as potential prevention for poor outcomes in the vulnerable and growing older adult population with cancer.

Abstract Name: Exploratory study in Attitude, Behavior, and Motivation to Cosmetic Dentistry Between Generation X and Z

The purpose of this study is to compare the effects of social media on the perceptions of cosmetic dentistry between Gen Z and Gen X. This study proposed the following research questions 1) What are the differences in the attitudes and motivations between Generation Z and Generation X regarding cosmetic dentistry and oral health? and 2) How does social media play a part in those differences? Two theoretical perspectives were employed to guide this study: Theory of Reasoned Action and Self-Determination Theory. A qualitative method study with semi-structured interviews was implemented. With IRB approval, 16 interviews were conducted consisting of 11 females and 5 males between the ages of 18 and 58. The participants were located in the Midwest and Southeast regions of the United States. Gen Z resulted in higher positive and negative attitudes than Gen X who presented more neutral attitudes. Results were consistent with Gen Z and Gen X characteristics. Overall, Gen Z was more motivated toward caring about their oral health and cosmetic dentistry compared to Gen X. Gen Z was more influenced by their strong opinions, intrinsic and extrinsic motivation, and previous knowledge of the subject of cosmetic dentistry and oral health due to their high involvement in social media. Gen X experienced a slightly higher social influence compared to Gen Z. However, when considering the values of Gen X, being that they are more concerned with their status symbols and image in the eyes of others, this finding coincides with the introjection aspect of extrinsic motivation as Gen X individuals tend to perform actions to avoid anxiety or enhance their ego. This study implicates industry practitioners in implementing dentistry cosmetics digital and social media marketing and branding strategies. This study suggests further investigation on assessing the border sample and quantitative hypothesis testing social media and generational effects.

Abstract Name: Un-Masking Hidden Phenotypes for PA14 Ivyp1 and Ivyp2 Knockout Strains by Observation of Tetracycline Sensitivity and Restoration of Resistance

Pseudomonas aeruginosa (PA) is a gram-negative bacteria that has been known for its adaptive resistance to antimicrobial agents. Inhibitors of vertebrate lysozyme protein (Ivyp1 or Ivyp2) are periplasmic proteins that have been linked to the resistome of PA, with previous findings demonstrating a tetracycline-sensitive phenotype for Ivyp1 knockout under growth conditions in parallel with the cystic fibrosis lung environment. However, the resistivity of Ivyp1 and Ivyp2 knockouts has not been tested under standard laboratory conditions. This study investigates the tetracycline sensitivity of knockout strains of PA deficient in Ivyp1/Ivyp2 proteins linked to PA's resistance. The Kirby-Bauer and MIC assays were used to determine the minimum inhibitory concentrations for the wild type, Ivyp1-, and Ivyp2- strains of PA14. Ongoing studies focus on complementing Ivyp1 inactivation loop using exogenous peptide and evaluating its sustainability using a six-amino-acid cyclic peptide. The aim is to assess the restoration TetR phenotype and establish Ivyp1's necessity and sufficiency for LT regulation.

Abstract Name: Advances in Molecular Approaches for Improving Shoot Proliferation and Organogenesis/Somatic Embryogenesis in some Fruit Species

This study aims to evaluate the shoot proliferation and organogenesis/somatic embryogenesis potential of nine fruit species. The primary objective is to contribute to the immediate regeneration of genetically modified crops after gene transformation. The emphasis on the role of phytohormones and organic supplements in these molecular breeding processes adds a unique dimension to existing literature and advances our understanding. The methodology involves assessing shoot proliferation potential in semi-solid MS media enriched with phytohormones and organic supplements. Organogenesis is conducted using leaves from in-vitro grown shoots, cultured in various types of growing media.Despite challenges faced during research, successful shoot proliferation and organogenesis were achieved in guava, peach, plum, and grapes. Shoot proliferation was most successful in semi-solid MS media with 1.0 mg/L BA and 0.1 mg/L IBA, alongside organic supplements such as 0.1 mg/L Thiamin, 0.5 mg/L Pyridoxine, 2.0 mg/L Glycine, and 100 mg/L Inositol. Preliminary observations on organogenesis were successful by using induction media with phytohormones (5.0 mg/L BA, 1.0 mg/L TDZ, and 1.0 mg/L NAA), kept in dark conditions for 21 days,

followed by media with 1.0 mg/L TDZ and organic supplements as expression media. Finally, regenerated shoots were transferred into shoot elongation media with 0.2 mg/L TDZ, 0.1 mg/L IBA, and 0.2 mg/L GA3, which was effective in forming callus and immediately regenerating adventitious shoots.The identified species hold promise for future research by contributing to understanding the vital role of phytohormones and organic supplements in these processes, addressing the current gap in knowledge, and providing practical insights for improving ex-plant regeneration and somatic embryogenesis techniques in fruit species. The findings have potential applications in genetic modification and molecular crop breeding.

Abstract Name: Consequences of Environment and Loss on Maternal Behavior, Anxiety, Boldness, and Memory in Rats

Rodent models have been used for the study of maternal behavior as various factors can be controlled or manipulated to assess their effects. Previous literature has attributed negative life experiences as a primary contributor to deficits in social function and memory. In contrast, other research has pointed to the implications of the environment and that individuals with an enriched environment have better neurological outcomes in comparison to control groups. In this transgenerational study, we identified loss and environmental enrichment as key factors in the effects of maternal behavior. We have assessed these variables through our main research question: can environmental enrichment ameliorate the negative consequences of maternal rats that have experienced loss? We predict that maternal rats suffering from loss will exhibit greater cognitive deficits in comparison to mothers not experiencing loss. In addition, we predict that rats exposed to enriched environmental conditions will have improved cognitive function despite the experience of loss compared to mothers in standard environmental conditions. Female Sprague-Dawley rats across three generations were separated into one of four groups which varied by the conditions of their environment and the keeping or losing of their pups. Several behavioral assays were utilized to measure cognitive function; Elevated Plus Maze (EPM) for anxiety-like behavior and boldness; Novel Object Preference (NOP) for non-spatial memory; and Objection Location Maze (OLM) for spatial memory. Using multiple generations of rats, this study aims to assess the epigenetic effects of these factors.

Abstract Name: Multi-Region Assessment of Fungicide Exposures in USA Wadeable Streams

Fungicides, commonly used in agricultural practices, have been detected in urban streams. These compounds pose potential risks to human and wildlife health. This study examines the prevalence and distribution of 16

fungicide compounds across wadeable streams in the United States. From 2013 to 2017, the United States Geological Survey (USGS) conducted the Regional Stream Quality Assessment (RSQA). This study analyzed 485 sample streams in five different regions of the USA, taking weekly measurements over a twelve-week period. Fungicide compounds were detected in about 93% of all measurements, with the maximum concentration in the entire study being 24 µg/L Myclobutanil found in Alisal Creek, CA. There is a statistically significant difference between fungicide concentrations in the 5 regions (p < 0.01). Upon further analysis, California had the lowest overall concentration levels, likely due to more stringent legislation. Considering the potential effects of fungicides and their byproducts on ecosystems, these results could suggest a need for better regulation of fungicide compounds, and better ways to mitigate fungicide contamination of streams across the country.

Abstract Name: Lacanian Language and Trauma in Toni Morrison's Beloved

Scholars have studied the celebration of communal bonds in the rhetoric of Toni Morrison’s Beloved, particularly in relation to trauma. However, while trauma theory is employed in these studies, few scholars place the novel in a deliberate dialogue with the field of psychoanalysis. This presentation proposes to perform a psychoanalytical analysis of trauma in the novel through the theories of such figures as Freud and Lacan. This presentation argues that Beloved challenges the phallocentric lens of psychoanalysis by deconstructing the gendered binaries inherent in the Lacanian paternal Symbolic order. The novel offers a maternal space which rejects the Symbolic order. Ultimately recognizing the psychological and historical necessity of a Symbolic order, however, the novel advocates for a Symbolic order which itself doesn’t reject the maternal. The novel demonstrates how such an order is possible through healthy relationships among people and through the construction of nurturing and supportive institutions. By employing the Laconian notion of language, this presentation aims to clarify the novel’s conclusion, emphasizing the specific ways in which language (the Symbolic order) both determines and is determined by social realities. The characters of Beloved, deprived of their parents’ African tongues, inherit a linguistic system of racist and psychologically constraining signifiers. The use of language, connected to a traumatic past, also serves as a means to escape the trauma of the past.

Abstract Name: Knowledge and Risk Perception for Type 2 Diabetes Among College Students with Family History of the Disease

Type 2 diabetes is a chronic disease characterized by the body’s inability to respond tothe insulin that is being

released or not enough insulin is released in comparison to the level of blood sugar (What Is Diabetes?, 2023b). One important unmodifiable risk factor that can lead to type 2 diabetes is a family history of the disease; a family history of type 2 diabetes has been linked to an increased knowledge and a negative risk perception of the disease (Montgomery et al., 2003). Previous literature indicates college students are likely to have knowledge regarding type 2 diabetes but are more likely to have a positive outlook on their perceived risk factors of developing the disease despite this knowledge. This study aims to examine responses from college students who have a known family history of type 2 diabetes on their outlook and perceived risk of developing the disease. This will be accomplished using a cross-sectional study design utilizing data collected from currently enrolled students at UCF using three main survey instrumentations: National Diabetes Survey, the Prediabetes Risk Test, and the Diabetes Knowledge Test-2.

Abstract Name: "Pipeline to Prostitution": Sex Culture and Taboo Conversations within the California Child Welfare System

This study employs care theory to assess the vulnerability of former foster youth in California's child welfare system, focusing on their inclination towards sex work. Utilizing qualitative interviews with eight individuals aged 25-43 from diverse ethnic backgrounds, it explores their experiences in foster care and the transition thereafter. The research reveals prevalent instability and isolation in foster homes, contributing to their vulnerability. A majority of participants engaged in sex work post-emancipation as a survival tactic due to systemic failings, including insufficient stable environments and basic needs. Care theory, advocated by Engster, Kittay, and Fineman, serves as the study's foundation, emphasizing the necessity of physical, emotional, and developmental support in caregiving. However, significant gaps in the foster care system's application of these principles are evident, especially in stable care provision and sexual health education. The study critically examines the Independent Living Programs (ILPs) and the child welfare system's approach to sexual health education. Despite federal efforts to support youth transitioning to adulthood, these programs inadequately address the unique sexual health literacy needs of foster youth, leaving them underprepared for post-emancipation life. In conclusion, the study highlights the urgent need for comprehensive reform in the child welfare system. It advocates for inclusive sexual health education, improved support systems, and policies targeting the root causes of foster youth vulnerability. By addressing these areas, the study aims to enhance the child welfare system's efficacy, facilitating a smoother transition for foster youth into adulthood and reducing their propensity to consider sex work.

Abstract Name: The Louisiana Freshwater Sponge Project: Examining Changes in Species Richness through a Comparison of two Ecological Studies

Beginning in 2019, the Louisiana Freshwater Sponge Project (LFSP) is a longitudinal study focused on describing freshwater sponge species richness in Louisiana water systems. While very understudied, freshwater sponges have been reported to be environmental health indicators. Tracking any change in species richness over time may provide a picture of the overall health of a water system as well as determine the sensitivity freshwater sponge species have on environmental changes. This LFSP ecological survey compares current freshwater sponge species richness with the defined species richness documented in the previous survey conducted in 1969, “Freshwater sponge taxonomy, ecology and distribution throughout Louisiana,” by Michael A. Poirrier. Using Google maps, and the provided descriptions in the previous survey, the LFSP has resurveyed over 81 sites from the original study. In addition to comparing previous water systems, the study has been expanded to include over 170 new sites and has analyzed over 1,300 samples. Utilizing the same sampling method from the previous survey, submerged substrate from up to six feet from shoreline was collected and examined. Freshwater sponge species are identified through spicule morphology and COX-1 sequencing and analysis. Comparison of the results collected from the two studies, indicates some consistencies and differences. Consistent with the previous study, the most prevalent species are still Trochospongilla horrida and Eunapius fragilis. The most significant difference is the overall decline in species richness across Louisiana.

Abstract Name: Bioancestría: A sound exploration of life stories and natural heritage of the townships of Medellín

Colombia occupies one of the first places in cultural and natural diversity, due to its variety of ecosystems that are home to a great wealth of fauna, flora and ethnic communities making up the country. Disseminate this richness is fundamental to conserve our territory during a global environmental crisis; however, it is important to recognize the gap between scientific argot and common language to raise awareness about the importance of protecting our territory. In this sense, Bioancestría seeks to capture through the sounds of nature and the voices of the people, the biodiversity of our territories, specifically from the five townships of Medellin, Colombia (San Antonio de Prado, Altavista, Santa Elena, San Cristóbal and San Sebastián de Palmitas). In addition, to learn about some social problems of the communities that inhabit them, especially those related to the people surrounding and the environment; this will contribute to the research and dissemination of new knowledge, understanding the implications of these problems for the environment and society. Through a microethnography, which includes documentary research, field trips, interviews, recording of the soundscape and observation of the territory; this documentary podcast, which mixes fiction and non-fiction, shows how the narratives, accompanied by bioacoustics, allow the dissemination of multidisciplinary knowledge in the Colombian context, and reach all types of audiences, also serving as a repository of scientific information. From this research, it was obtained that the city, in its rural territory, has a great natural wealth that should be protected, but the accelerated growth, pollution and human activities are affecting it, with species in danger of extinction that are fundamental for the future. Therefore, it is necessary to raise

awareness of these problems to safeguard the legacy of our ancestors and the future generations.Note: This presentation will be in spanish.

Abstract Name: Study and report on the migration of foreign people through Necoclí, Antioquia —the “other gap”— to realize the dream of going to the United States and Canada

This research/creation project studies the historical and current causes of the massive migration of foreigners through Medellín and Necoclí, located in Antioquia, Colombia, to go to the United States and Canada, and seeks to understand the human drama involved and the social, geopolitical and economic issues that determine it. In addition, it bets on the journalism of solutions, discovering people and institutions to tell the story of migration beyond the tragedy that the mass media have spread.In Necoclí there has been a migration crisis since 2000, when the Darién Gap began to become a route for migrants heading to the United States and Canada. Since then, the number of irregular migrants has been on the rise: between 2010 and 2021, 247.617; in 2022, 248.284; and until October 2023, 458.228.The research was carried out in two segments: one, the study and analysis through the consultation of documentary and testimonial sources of information of authority on the subject to know the historical and current causes of the massive migration of foreign people through this region of Antioquia. Two, the field work of the student reporters to gather testimonies and stories of migrants in transit, using the strategies of immersion and solutions journalism. From the achievements of this project we highlight: first, the knowledge about the causes, motivations, problems and opportunities that migrants who transit through Necoclí or settle in Medellín have; second, the realization of a collaborative, multi-format and multi-platform report through the use of different journalistic inquiry tools and the integration of various journalistic products and, third, the publication of this report in the convergent content laboratory Bitácora of the EAFIT University under the title Ilusiones migrantes: https://bitacora.eafit.edu.co/ilusiones-migrantes/. The presentation of this research project will be conducted in Spanish.

Abstract Name: “Does the Right to Life, Liberty, and the Pursuit of Happiness Exist for Children?”: Problems and Solutions to Discriminatory Legislation for Low-income in Child Welfare

The failure of state legislation on child welfare disproportionately harms children in low-income communities, as parents who lack adequate welfare support go through investigations and child expulsions while essentially struggling with unresolved material hardship. The study cross-analyzes the rhetoric of broad

abuse definitions with policies that fail to target causes of child abuse, which misrepresents the inability to clothe, feed, or house a child or symptoms of poverty as parts of definitions of abuse. Cross-sectional analysis of national child welfare maltreatment report data in families who lack welfare support helps demonstrate the over-representation of low-income children in the historical trends of child abuse rhetoric. Though some children rely on leaving their biological family to survive from intentional injury, the prevalent removal of children into the foster system due to the causes of poverty resulting in the over placement of low-income children into the traumatic foster system. This study examines solutions to the legislative pendulum effect: a historical lack of preventative support for low-income communities that leads to unnuanced care of low-income children in either biological homes or harmful foster homes. Solutions to the child abuse legislature, such as providing working parents with proper child care and supporting foster children in and out of the system, are the cornerstone to improve the livelihoods of abused children from low-income backgrounds. Through a meta-analysis and cross-sectional analysis, the study of child maltreatment reporting criteria is critical to tailor impactful solutions focused on increasing the quality not quantity of well-addressed child abuse cases from the overrepresentation of the child welfare system due to poverty.

Abstract Name: Investigating Parental Autonomy Support and Topic Expansion's Relationship with Children's Science Talk and Memory During Informal Science Learning Conversations After a Visit to the Aquarium

Previous studies have shown that parental autonomy support and topic expansion foster children’s motivation to learn, their memory recollection, and how they explain past experiences during everyday conversations. However, there is a gap in research studies investigating parental autonomy support and topic expansion’s relationship in predicting children's STMB talk and memory during reminiscing conversations after visiting an informal science learning environment. This study seeks to bridge this gap and aims to understand parental support and topic expansion’s correlation with children’s STMB talk and memory during at home reminiscing science conversations after visiting an Aquarium. Parent-child reminiscing conversations after visiting an aquarium were collected through audio recording devices. The sample of 13 parent-child dyads from diverse racial and ethnic backgrounds were recruited at the Aquarium of the Pacific in Long Beach, CA. Data were analyzed by transcribing conversations verbatim, the aquarium conversations were coded for autonomy support and topic expansions while the at home conversations were coded for child memory and STMB talk. Research assistants coded the transcribed conversations using a microanalytic approach with coding systems adapted from previous literature including Parental Autonomy Support, Topic Expansion, Science, Technology, Mathematics, Biology Talk, and Child Memory. The Intercoder reliability for child STMB talk

was k = .77 and child memory talk was k = .80. As for the reliability of autonomy support and topic expansion, it will be established on 20% of the transcripts. Upon conclusion of the analysis, we anticipate that parental autonomy and topic expansion at the aquarium will predict children's STMB talk and memory during reminiscing conversations after the visit. Although the analysis is ongoing, the findings have the potential to empower parents to initiate more discussions about science with their children to build STEM learning and reiterate that everyday interactions can encourage science learning in children as well.

Abstract Name: Investigating the Biological Activation Mechanism of the ROS-Activated Prodrug

Cancer poses a formidable challenge due to its intricate nature, making treatment endeavors complex. The inherent heterogeneity of cancer further complicates researchers' efforts to comprehend the metabolic pathways of therapeutic drugs. The Peng group has recently engineered a groundbreaking H2O2-activated prodrug known as FAN-NM-CH3. This prodrug transforms into a potent DNA alkylator upon interaction with H2O2. Upon activation, it hinders the replication of DNA within cells, inducing apoptosis. Examination of mass spectrometry data indicates that the prodrug undergoes a reaction with H2O2, resulting in the formation of a hydrolyzed-activated iteration of the drug. To delve deeper into the drug's mechanism of action, various ROS quenchers - Catalase, PEGCatalase, MnTBAP, GSH, and Mannitol, were employed to neutralize accumulated ROS or hinder its production, thereby reducing the drug's efficacy by limiting the availability of ROS for activation. Our current data indicates that in vivo, catalase effectively quenches H2O2, albeit with a limited extent. The introduction of this new series of quenchers promises a more comprehensive understanding of the specific ROS types present in cancer cells. Additionally, it serves as crucial evidence to delineate the activation pathway of the prodrug.

Abstract Name: Methods of Political Mobilization and Social Media Usage

In the current technologically advanced age, every click, swipe, and share can impact an individual's behavior in the real world from fashion choices to political engagement. This paper dissects the complex relationship between political mobilization and social media usage. Expanding upon the conventional understanding of social media as a positive catalyst, this paper will undercover the nuanced impact of social media usage on political mobilization which is often dismissed. Additionally, it will focus on how race can influence this relationship. Through extensive research in existing literature, evidence points out that there may be a negative relationship between political mobilization and social media usage specific to different racial demographics.I hypothesize that in comparing individuals, those having higher social media usage will be less likely to engage in political mobilization outside of a digital space than those having lower social

media usage. Controlling for race provides us results on how this relationship can vary by racial demographics. This is important to understand since identity impacts the behaviors of individuals within the digital space and outside.The results indicate that the various social media platforms have influence on political mobilization in various ways. The results support the hypothesis that those having higher social media usage will be less likely to engage in political mobilization outside of a digital space mostly for White Americans compared to other racial demographics. Further research should be done to provide analysis on the variety of social media platforms and modes of political participation. With further research, it can lead to greater understanding of political behavior amongst specific racial groups.

Abstract Name: Developing Tumor Treating Fields resistance in glioblastoma patient-derived xenolines to explore potential therapeutic mechanisms

Background: Glioblastoma (GBM) is the most common and deadly primary brain malignancy. Standard of care treatment consists of maximal safe resection, chemotherapy (temozolomide), and radiotherapy, followed by adjuvant temozolomide and Tumor Treating Fields (TTFields). Tumor recurrence is universal and potentially mediated by the growth of a robust subpopulation of cells called brain tumor-initiating cells (BTICs). BTICs can self-renew, sustain proliferative capacity, and promote tumor maintenance and therapeutic resistance. TTFields is a treatment modality that administers alternating electrical fields at a 200kHz frequency. However, little is known regarding BTICs resistance to TTFields. Therefore, we developed TTFields-resistant patient-derived BTICs (xenolines). Methods: Xenolines were cultured in serum-free conditions to maintain BTICs in vitro. Xenolines were plated two-dimensionally onto matrix (Geltrex/Laminin) coated 22mm coverslips. Coverslips were transferred to the Novocure Inovitro system ceramic dishes and baseplate 24 hours post-plating. The baseplate was connected to the fields generator and placed into an incubator set at 20% O2, 5% CO2, and 18°C to account for heating induced by the electromagnetic field. Xenolines were exposed to various rounds of TTFields treatment over some time (round 1: 2 days of continuous TTFields and round 6: 7 days of continuous TTFields). Following each round of treatment, xenolines were cultured in control conditions for a week to allow for recovery. Results: Xenolines that underwent round 6 of TTFields treatment (5 days of continuous TTFields) demonstrated a 93% cell viability with a 68.75% increase in growth compared to round 1 of TTFields treatment (3 days of continuous TTFields) with a 45.68% decrease in growth. Conclusions: Ongoing studies focus on validating and optimizing the development of TTFields resistance in GBM xenolines. We can then assess TTFields-induced resistance on a kinomic level to detect downstream signaling pathways associated with resistance mechanisms to identify potential therapeutic strategies to increase the efficacy of TTFields.

Abstract Name: Assessing the Effort of Working Memory Removal

Working memory allows individuals to briefly hold, manipulate, and access a limited amount of information at the forefront of their minds during the completion of cognitive tasks. Research conducted to expand understanding of the brain's capabilities and capacity in working memory proves useful for developing strategies for learning and behavioral health. Novel ways to approach intrusive thoughts in mental disorders such as anxiety, depression, and PTSD can be constructed from the research of working memory and removal processes. More of the brain's potential can be exercised, and childhood education can be revolutionized when its strengths and limitations are understood.The research aims to assess the amount of cognitive effort required to remove information from working memory. Both subjective and objective measurements of distinct removal operations have helped researchers understand cognitive control. Replacing an image in the mind is the simplest removal technique, whereas suppressing a specific image from working memory is the most difficult. Although fMRI, EEG, and self-report survey data can be utilized to gain a better insight into the responses to removal operations, pupillometry may prove to be a better objective index for cognitive effort. Utilizing pupil dilation measurements at different stages of the encoding, operation, and probe processes within a task is useful in learning the amount of effort required to conduct a removal operation successfully.It is expected that after encoding images into the individual's working memory and asking them to perform one of four operations (maintain, replace, suppress, clear), once individuals are probed with the manipulated image again, their response times will be indicative of the success of the operative task. Maintenance suppression or suppressing thoughts of a targeted image after encoding is hypothesized to result in the longest response times, largest pupil dilations, and thus the greatest amount of cognitive effort.

Abstract Name: Using 3D Printing Technology to Build Economical Prosthetics

The loss of a limb can be a life-changing event. Without a hand, the independence they once had to perform simple tasks like typing, picking up objects, and cooking, is significantly impacted. Oftentimes, these individuals must rely on others to help them with basic daily functions and overcome barriers. Aside from the physical repercussions, disabilities like this can damage the individual's self-image and mental health, leading to a dark road of more complex issues. However, a voice-controlled, fully customizable, 3D-printed prosthetic arm could be an effective solution with the ability to change the lives of many individuals. The aim of this research is to leverage 3D printing technology to build more economical prosthetic devices than are currently available. The improved affordability and accessibility of prosthetic limbs for amputees would consequently increase their independence and self-esteem. Prosthetic limbs can cost from several thousand to tens of thousands of dollars and with limited insurance coverage, many amputees have little to no access to

these devices. With the help of 3D printing technology, prosthetic assembly kits can be developed at an affordable cost, increasing access to prosthetics and offering a potential solution for amputees in underdeveloped countries or underserved communities. Created utilizing widely available 3D printers and materials including an Ultimaker S5 3D printer, PLA filament, Arduino electronics, servo motors, fishing line, and a variety of bolts and screws, the arm uses cost-effective materials to build a product operating on programmed commands and a 7.4-volt battery. This fully-functional $100 prosthetic can be sold for over 10 times less than the current market alternative prosthetics. With a short assembly time of 1 to 2 hours, a customized fit, and functional hand movements, this prosthetic limb demonstrates how biomechanical engineering and technological innovation can serve the needs of a wide range of people.

Abstract Name: Antiproliferative activities of native Euphorbia dentata and Euphorbia maculata (Euphorbiaceae) in T47D and MDA-MB-231 cancer cell lines

The utilization of medicinal plants has seen a notable rise over the past few years. Certain plant extracts have been found to have anti-cancer properties and some have been utilized in the development of chemotherapy treatments. This study evaluates the antiproliferative activities of Toothed Spurge, Euphorbia dentata and Spotted Spurge, Euphorbia maculata ethanol extracts on ER-positive T47D and triple negative MDA-MB-231 cancer cell lines, based on the fact that Euphorbiaceae are known medicinal plants. E. dentata is a plant species native to North and South America, while E. maculata is native to North America. Both plant species have been introduced to other continents. E. maculata is known for its medicinal properties but its antiproliferative activity has yet to be fully studied. There has been no research done on the biological properties of this species that we could find in the literature. E. dentata extract has antiproliferative activity in T47D but not in MDA-MB-231 cancer cells. A biphasic effect was observed with T47D breast carcinoma in which the E. dentata extract at low concentrations increased and at high concentrations decreased cell proliferation by 35% at 500µg/ml extract. At 500ug/ml concentration E. maculata reduced T47D and MDA-MB-231 cell viability. Although the reduction was not significant, the decreased cell viability trend implies that higher concentrations of plant extract may have antiproliferative properties. Future work will focus on fractionating E. maculata and E. dentata extracts and characterizing the antiproliferative activities and mechanisms of action of the diterpene and isoflavone fractions, which could lead to the discovery of new therapeutics for breast cancer.

Abstract Name: Profiling the Populations of Immune Cells in the Skin of Wild Type and DNMT3a Mice

The DNMT3a gene plays a role in DNA methyltransferase. If this gene mutates, it leads to clonal hematopoiesis and an increased risk for Acute Myeloid Leukemia (AML) development. AML is a cancer of the blood and bone marrow. The DNMT3a mutation can also lead to skin dermatitis, which presents as a painful rash. Most patients with AML develop dermatitis after diagnosis; however, the dermatitis may lead to DNA hypomethylation which suggests a lack of DNMT3a in the skin. This lack of DNMT3a could cause an increase in skin cancers in AML patients. To profile the immune cell population of the skin, DNMT3a mutant mice versus healthy mice were compared. The skin of the mouse was taken and treated with collagenase to prepare and separate the immune cells for study. The cells were stained using fluorescent antibodies and were analyzed using flow cytometry. The initial staining showed populations of B Cells, T Cells, gamma delta T Cells, macrophages, neutrophils, and iNKT cells. The initial analysis showed a decrease in CD45+ cells, B Cells, and T Cells in the skin of DNMT3a mice. The percentage of gamma delta T Cells was unchanged. The percentage of macrophages has increased substantially in the skin of DNMT3a mice compared to that of wild-type mice. As more trials are performed the expected results should be consistent with the initial analysis. In the future, fluorescent microscopy will be used to locate the specific skin populations in the skin of Wild Type and DNMT3a mice to better understanding of how the cells in the skin communicate with one another.

Abstract Name: Investigating the Role of the ESCRT Protein STAM-1 in Extracellular Vesicle Biogenesis

Extracellular vesicles (EVs) are lipid-bound vesicles that can transport various biological macromolecules and act in communication between cells. In Caenorhabditis elegans, EVs are shed from the primary cilia, organelles that play a role in signal transduction and transmission. They are exposed directly to the environment, making it easy to observe and analyze EV release. Two significant ciliary EV cargoes are released: one that contains the TRP polycystin channel PKD-2, and another that contains the ion channel CLHM-1. The EVs are visualized by tagging CLHM with tdTomato and PKD with green fluorescent protein (GFP). These EV subpopulations are differentially shed, as PKD-2 EVs are released from the ciliary distal tip, while CLHM-1 EVs are released from the ciliary base. I am investigating the effects of the loss of stam-1 on the shedding of CLHM-1 EVs, PKD-2 EVs, or both subpopulations, as stam-1 is a protein that assists in the ubiquitination of cargo, which then goes through vesicle sorting and viral budding by the endosomal recycling complex required for transport (ESCRT) machinery. Along with its role in EV biogenesis, it is involved in the downregulation of PKD-2. Genetic crosses with C. elegans first had to be formed to produce nematodes that are homozygous for the stam-1 mutation and the transgenes that express the EV cargoes tagged with fluorescent proteins. After the desired strain was isolated, EV images were obtained using the Andor Dragonfly microscope and analyzed using Imaris to quantify EV release. Through this, it was discovered that the loss of stam-1 does not significantly affect EV release in C. elegans. Through this research, there may be a greater understanding of the mechanisms that regulate the shedding of EV subpopulations CLHM-1 and PKD-2.

Abstract Name: Guiding Brilliance: Empowering First-Generation Scholars with a Group Advising Model for the NCUR Journey

The STEM academic advising unit at the Center for Educational Opportunity (CeO) for Diversity, Equity, and Educational Achievement at the University of Wisconsin-Madison brings together aspiring researchers and provides opportunities for the college community to discover what lies beyond the campus horizon. In particular, the CeO STEM unit strives to holistically support students during their journey through academic commitments, work/financial, and life demands. We do this by encouraging high-impact practices such as undergraduate research. During this presentation, we will share how holistic and high-touch approaches to recruitment and mentorship support first-generation, income-eligible, and/or disabled undergraduates to persist during their pursuit of undergraduate research and serve to build self-efficacy towards engaging in conferences such as NCUR. We will highlight our accountability partnerships that serve as a cornerstone to facilitate regular mentoring sessions, group workshops and community support. Additionally, mentored undergraduate CeO scholars will also share their journey of actively refining their research skills through frequent checkups, workshops with campus experts, and collaborative discussions. Utilizing this group advising model, the CeO STEM advising unit has been successful in cultivating an effective and supportive learning community for engaged undergraduate researchers that extends beyond the academic realm, transforming the entire experience into one that is enriching, enjoyable and balances life and work scheduling.

Abstract Name: Equilibrium Surface Coverage for Reversible Adsorption of Dimers on Various Finite Lattice Structures

Dissociative adsorption of diatomic molecules on metal surfaces (e.g. O2 on Pd) is a pivotal process in understanding surface chemistry and heterogeneous catalysis, fundamental in numerous industrial and environmental applications. We investigate the dynamics of dissociative adsorption and desorption on finite lattice structures, including two-dimensional (2D) square lattice with periodic boundary conditions or terminal sites. To this end, we employ a dual approach to analyze these systems: (1) an analytical approach to use combinatorial expressions for the number of accessible surface configurations for different lattice structures; and (2) a computational approach to perform kinetic Monte Carlo (KMC) simulations to validate the analytical results. One of the focuses of this study is to explain finite system-size effects on the equilibrium surface coverage for different 2D lattice structures. Similar to the 1D cases (i.e. linear lattice) in

the previous study, we confirm that for 2D cases the equilibrium surface coverage can be analytically investigated via the number of accessible configurations, which depends on the specific geometry of the lattice. We present analytic expressions for equilibrium surface coverage as a function of the size of a lattice for various lattice structures and KMC simulation results as validation. The implications of our findings are substantial for the field of surface chemistry and heterogeneous catalysis, where understanding surface interactions and adsorption dynamics is crucial for designing more efficient and selective catalytic processes.

Abstract Name: Impact of Sediment-Amendment and Plant Restoration on Microbial Soil Communities in a Southern California Salt Marsh

Salt marshes protect endangered species and preserve a diverse microbial community, but they are experiencing decreased marsh elevation due to human activities, urbanization, and sea level rise. In attempt to restore an impacted salt marsh, Spartina foliosa, a native cordgrass, and sediments were added to portions of the Seal Beach National Wildlife Refuge (SBNWR). We predict that the addition of the sediments will decrease bacterial diversity in the sediment-amended salt marshes without plant (S. foliosa) addition. We also predict that over time bacterial diversity will be restored to what is seen in the unaltered salt marsh (control). Every 6 months over a one-year period, we extracted sediment samples from 3 sites in SBNWR including an unamended control, sediment-amended marsh with no plants and amended marsh with the addition of S. foliosa to determine how sediment and plant addition affects bacterial diversity in salt marshes. Results showed no significant changes in overall community diversity across site or over the 12 months. However, when we examined specific bacterial 16S rRNA sequence diversity the two sediment-amended sites (with and without plants added) were significantly different from the unamended vegetated source sediments. This indicates that like plants and animals, amendment causes long-term detectable community shifts that do not recover after one year of transplanting Spartina. We predict that more time will be necessary to observe any potential impacts of planting.

Abstract Name: Concept Mapping: A Tool to Inform NGO’s Program Outcomes through Empirical Research

The COVID-19 pandemic has heightened the discussion of proper orphan care. The caution and concern over proper care of vulnerable children have been initiated by the NGOs in the field. For three years since 2019, one NGO in Southeast Asia initiated home care program instead of orphanage care in order to improve outcomes via familial connections. This presentation describes the faculty mentorship over a student-NGO partnership that sought to analyze the experiences of 37 children who transitioned to home care. It suggests

ways to utilize concept mapping discussion as a tool that connected the two parties – the NGO that wanted to evaluate the effectiveness of the program change, and student researchers who needed to answer a research question using the findings from an empirical study design. The interview data come from 37 children who have transitioned from orphanage care to home care and remained under the NGOs supervision/subsidies for the past three years. The respondents were 16 years of age at the time of data collection. The student researchers created a set of open-ended questions for semi-structured in-depth interviews. The interviews were conducted in respective native languages by the staff of the NGO, who translated and transcribed the content. The student researchers analyzed the transcriptions to detect patterns, and conducted Chi-square correlation tests on demographic data.This presentation aims to identify ways to make academic research more impactful and practical, particularly in interfacing with the assessment needs of community serving NGOs. Three learning objectives to consider when mentoring an NGO-student partnership include: Identifying the mission of the NGO and how they are related to theoretical framework, Utilizing concept mapping in creating research instrument, and Understanding ways to translate the findings into actionable policy ideas Mentorship over students' data analysis is on-going and will be completed by early 2024.

Abstract Name: A general method for the development of quantitative biosensors enables the measurement of free Nedd8

Nedd8 is a ubiquitin-like protein that regulates cellular signals through conjugation to other proteins. The concentration of free (i.e., unconjugated) Nedd8 relative to conjugated Nedd8 is important for normal cellular function, and perturbations of this balance caused by defects in Nedd8-related enzymes or cellular stress are implicated in various disease pathways. Despite the biological significance of Nedd8, there is currently no method which can directly quantify free Nedd8, which presents a critical barrier to developing a general method of studying Nedd8 dynamics and its associated enzyme activities. Genetically encoded biosensors are well-established tools for directly studying dynamic systems like the free and conjugated Nedd8 pools, but limitations of current biosensor design methods make them unsuited for free Nedd8 quantification. To solve this problem, we have developed a generalizable method of developing genetically encoded biosensors consisting of two reporter domains, which interact to form a functional reporter, attached to a target-binding domain (binder). Target quantification is based on competition between target binding and the interaction of the two reporter domains. To apply our design strategy to free Nedd8 quantification, we used rational design methods to engineer a free Nedd8 binder and combined it with a pair of FRET-based reporters. Our sensor is capable of quantifying free Nedd8 from nanomolar to micromolar concentrations. We also demonstrated that the affinity of the reporter domains can be adjusted to tune the sensor's dynamic range and a detectable concentration range for a target.

Abstract Name: Effect of Predator Odor on Unconditioned and Conditioned Defensive Responses in Syrian Hamsters

Biologically relevant odors, including those related to predators, will induce fear and anxiety-like behaviors, including risk assessment, avoidance and freezing in laboratory animals as well as elicit avoidance to the odorant. In addition, animals previously exposed to predator odors will show conditioned place avoidance. In contrast, animals exposed to aversive, non-biological odors, such as formaldehyde, will also show defensive behaviors, but importantly, they do not exhibit conditioned place avoidance. While there are many studies examining the effect of predator odors on defensive responding in rats and mice, there is currently a dearth of information using hamsters as test subjects. In this study, biological and non-biological odors were used to evaluate both unconditioned and conditioned defensive responses in male Syrian hamsters. Specifically, we examined whether coyote predator odors will elicit unconditioned avoidance behaviors in hamsters using a novel runway box. We compare these effects to formaldehyde, a non-biological odor. We hypothesized that while coyote odor exposure will elicit unconditioned and conditioned avoidance, animals exposed to formaldehyde will only show unconditioned avoidance. These results not only add to the existing literature regarding the neurobiological basis of innate avoidance behavior, it also be the first to examine predatory avoidance behaviors in hamsters.

Abstract Name: RT-PCR to Determine Genetic Mutations in In-Situ Melanoma

Melanoma in-situ is a non-invasive form of melanoma that could become invasive. Assessing negative margins of these melanomas is crucial to patient management and outcome. Molecular and genetic analysis has greatly improved our understanding of melanoma and its biologic behavior including novel drug development. However, less has been studied in melanoma in situ lesions. The aim of this study is to identify common mutations in melanoma in-situ samples compared to their negative margins using reverse transcriptase polymerase chain reaction (RT-PCR). 30-50 melanoma in-situ samples and their negative margins were collected from the tissue archives at the Epiphany Dermatology Dermatopathology Laboratory. DNA will be extracted from these samples and run through RT-PCR to isolate melanoma-associated regions. The negative margin DNA sequences will be subtracted from the melanoma in-situ sequences to isolate the DNA mutations found in the melanoma in-situ regions. The mutated sequences will be analyzed and compared to look for commonalities between the various melanoma in-situ samples. Common mutations will be gathered to further understand the progression of melanoma in situ particularly if there are any that can be

associated with recurrence of melanoma in situ after complete excision. These findings could have a significant impact on the treatment and prognosis of patients with melanoma in-situ. Knowing specific genetic identifiers in melanoma could allow for a deeper understanding of melanoma in-situ progression and treatment options.

Abstract Name: Psychological Safety in Higher Education: Evaluating Perceptions of Personal Engagement the Classroom

Psychological Safety or the degree of personal inclusion, contribution, and engagement one experiences in a given situation has lately become a topic of extreme interest in industrial settings (Clarke, 2020). Empirical research indicates that in the workplace, psychological safety can increase creativity (Castro et al., 2018) and engagement (Frazier et al., 2016), and reduce distress (Obrenovic et al., 2020). While research on psychological safety has increased dramatically in recent years, this concept has seldom been studied beyond the workplace. Because increasing creativity, improving engagement, and reducing distress are all critical factors for improving education, an empirical examination of psychological safety in the college classroom warrants systematic investigation. The present study has been examining student perceptions of psychological safety in various courses at Virginia Tech through an innovative 36-question survey. At this point, 134 students have provided answers to this survey, each responding with reference to a particular university course they have taken recently. This questionnaire measures psychological safety with an eight-question “Psychological Safety in Education” scale, adapted from psychological safety scales created for industrial settings. Additional questions in our survey assess variables that might impact a student’s perception of psychological safety, including the student’s academic year, the number of students in the course, the course subject, as well as other related contextual factors. While a larger sample is needed for confidence in these results, the current data indicate that psychological safety is influenced significantly by the number of students taking a course, the student’s success (i.e., grade) in the course, and the subject matter of the course. Following the evaluation of additional survey results, we will document our findings and recommendations for cultivating psychological safety for college/university applications. This study is ongoing, and with additional data we expect to reveal barriers and facilitators of psychological safety in various educational settings.

Abstract Name: Investigation of the tumor promoting characteristics of MSK1 and STK11 in canine breast

cancer

MSK1 and STK11 are key regulatory genes in the signal transduction cascade controlling cell proliferation in cancer cells. The open reading frames of the genes encoding MSK1 and STK 11 expressed in mammary cancers of domestic dogs, Canis lupus familiaris, were analyzed to find highly conserved sequences for designing an rtPCR reaction that can specifically amplify the targeted region of each of the coding sequences, as well as using gel electrophoresis to verify the results. To optimize the PCR protocol for amplifying the targeted sequences, first, rtPCR primers were created by using the genomic sequences of the MSK1 and STK11 genes in Canis lupus familiaris. The canine genome was then analyzed to identify primer pairs also conserved in Homo sapiens that were within protein coding sequence and spanned an intron-exon junction. Once the successful primers were synthesized, they were utilized in an rtPCR reaction to find the targeted sequences. The rtPCR protocol was optimized by analyzing the amount of RNA and MgSO4 added to each reaction, then changing these amounts based on the results obtained when the bands were observed through non-denaturing agarose gel electrophoresis. When the MgSO4 concentration was changed from 1 mM to 1.5, this resulted in a brighter and sharper band when analyzed. The addition of DMSO allowed the primers to be more specific in this binding. The theoretical length determined from the sequence of the MSK1 gene is between 203-230 nucleotides and for STK11 is between 230-336 nucleotides in length. The gel electrophoresis results showed this length of nucleotides for each gene sequence. This approach has produced a highly optimized rtPCR protocol that will allow specific amplification of the target sequences to then be used further for gel extraction and sequencing to verify the results.

Abstract Name: Horizontal and Vertical Spatial Symptoms of Cyanobacteria Blooms

Cyanobacteria harmful algal blooms (cHABs) develop in high nitrogen and phosphorus conditions caused primarily by agricultural runoff. They are a growing threat in freshwater lakes, as they release the liver toxin microcystin, which causes abdominal pain, nausea, and liver damage in humans and has been shown to cause death in animals. Past studies have measured toxin levels at a limited number of lake sites, which fails to adequately assess ecological and recreational risks for swimmers, boaters, and anglers throughout entire waterbodies. This study, however, aimed to address variation in microcystin concentration throughout a lake and to determine if surface blooms of phytoplankton corresponded to elevated microcystin concentrations. Twenty-six locations on Lake Menomin in Menomonie, WI were sampled for microcystin at the surface two times in July to analyze its spatiotemporal variability. Phytoplankton pigments, phycocyanin and chlorophyll, were also measured at the surface and 2-meter depth at each site to examine the development of surface blooms of cHABs. Toxin concentrations varied throughout the lake, most likely due to prevailing wind patterns and water currents. As the summer progressed, the amount of toxin increased, indicating greater health risks later in the summer. The development of surface cHABs was also observed, evidenced by the greater dominance of phycocyanin in the phytoplankton community at the surface versus depth at the later sampling date. These findings suggest that assessing total human exposure to toxins requires sampling not only at beaches where people recreate but also at deep points of lakes, as these areas show high levels of microcystin. Additionally, measuring phytoplankton pigments can be an effective and relatively cost-effective way for health officials to predict cHAB growth and public health threats.

Abstract Name: Ab initio calculations of the threshold displacement energies in lead free inorganic halide perovskites

Perovskite materials have gathered significant attention in recent years due to their exceptional properties and potential applications for solar cells. Certain environmental risks, including toxicity and ground leaching, associated with lead-based perovskites have raised concern. Our research focuses on the investigation of tin-based perovskites as a promising eco-friendly alternative. We are particularly interested in understanding the radiation resistance of these emerging tin-based perovskites, a critical aspect of their long-term viability in space photovoltaics and agriculture. In space, materials are exposed to high radiation levels, affecting their performance. Therefore, predicting the radiation damage in such materials is desirable. Most currently available models that predict radiation damage in materials depend on their constituent atoms' threshold displacement energies (TDE). The TDE is the minimum amount of kinetic energy that must be given to an ion in a solid to create a stable defect in the material's lattice. In this work, we use ab initio Molecular Dynamics (AIMD) to simulate the early radiation interaction stage and calculate the TDE in the halide inorganic perovskites $CsSnI_3$, $CsSnBr_3$, and $CsSnCl_3$ in their cubic phase. The purpose of these calculations is to provide TDE values for these materials to improve the accuracy in posterior radiation damage simulations, and to compare our results among the three different perovskites to better understand the role of the anion in the radiation damage process of these materials.

Abstract Name: Maximization of the Conductivity of Poly(lactic acid) 3D Printing Filament for 3D Printed Circuits

3D printed circuits have been attracting a lot of attention recently because they are cheap, easy, and fast to design and make, and produce less waste than other traditional methods to make circuits. PLA, or poly(lactic acid), is a conjugated polymer plastic that when infiltrated with a conductive material such as graphite or carbon black becomes a conductive filament. PLA is compatible with many if not all 3D printers, which makes it an ideal candidate for 3D printed circuits. Using SQUID microscopy, we can image the current going through the 3D printed circuit, which allows us to track and maximize the conductivity of the filament. Some ways we attempted to maximize the conductivity of the filament was to try different extruding patterns, temperatures, and areas and shapes. Electroplating the 3D printed parts was also an area of research in order to maximize the printed part's conductivity. By maximizing the conductivity of PLA, the performance of the circuits could get closer and closer to traditional circuits and they can start to be used in some applications.

Abstract Name: Bortezomib disrupts nuclear transport by increasing nuclear import and decreasing export

Bortezomib is a chemotherapy used for multiple myeloma and lymphoma that inhibits the 26S proteosome inhibitor leading to an accumulation of certain proteins. However, when bortezomib causes protein accumulation, it can also lead to mislocalization. For example, p53, a key protein for triggering apoptosis, is localized in the cytoplasm upon Bortezomib treatment, which makes p53 incapable of transcribing pro-apoptotic genes in the nucleus. Therefore, we asked if nuclear transport is disrupted by Bortezomib treatment. Nuclear import is carried out by importin-α,β binding to a cargo protein in the cytoplasm, transporting it through the Nuclear Pore complex and into the nucleus; whereas, nuclear export requires the transporter Exportin. Hela cells were treated with 2.5, 5, and 10 uM Bortezomib, and a MTT Assay was used to determine cell viability before observing nuclear transport. We then observed the effects of 2.5 and 5 uM Bortezomib localization of Importin-α,β and Exportin using immunofluorescence, because these concentrations had the largest impact on viability. Neither 2.5 or 5 uM Bortezomib had an impact on nuclear localization of Importin-α. 2.5 uM slightly increased nuclear localization of Importin-β, while 5 uM led to a doubling of Importin-β in the nucleus. The increase of importin beta, but not importin alpha in the nucleus likely means nuclear import was decreased. 2.5 uM had no impact on nuclear localization of Exportin, while 5 uM led to a reduction in nuclear localization of Exportin, indicating that nuclear export was increased. Because Bortezomib disrupted nuclear transport by increasing nuclear export but decreasing import this likely contributes to the mislocalization of p53 to the cytoplasm. This result will be used in the future to combine bortezomib with another drug or supplement that restores nuclear transport to help retain p53 in the nucleus and improve its function.

Abstract Name: An International Analysis of Bilingual Education and its Role in Achieving Universal Quality Education: Spain, Colombia, and the United States of America

As of 2022, 60% of the global population are considered multilingual. Multilingualism is defined as the act of learning two or more languages, and is attributed to cognitive benefits such as increased development of executive function skills, test performance, and empathy. Although most of the world population has this advantage, a global disparity exists in access to resources and equitable education for many students contributing to an achievement gap. According to the United Nations (UN), in 2020 only 83% of primary and secondary school teachers were formally trained and nearly 258 children did not attend school. In response to this, the UN has named one of their Sustainable Development Goals (SDG 4) to ensure inclusive and equitable quality education worldwide. This research focuses on the progress of bilingual education in three distinct countries, the United States of America, Spain, and Colombia, and the role bilingual education has in achieving the UNSDG of universal and equitable access to quality education. The three countries chosen to be analyzed for this research were decided by each country's distinctive histories and educational reforms.

Data was analyzed across the three countries after collecting data through in-person observations and interviews from teachers in the U.S., Spain, and Colombia. Data was compared to analyze lesson design and content, classroom academic resources, teacher preparations, teaching practices, and uses of bilingualism across the three countries in terms of addressing the UNSDG 4. International approaches to bilingual instruction prove there are many ways to promote bilingualism. Despite the accessible materials observed, students were still gaining a bilingual education through their teacher's well-structured quality lessons. The results from this study reveal that effective teaching strategies persist despite varied access to resources. Through continued research in the field of advancing quality education and teacher training, quality education could be achieved internationally.

Abstract Name: Australopithecus afarensis: We're weak in the talus for you

Obligate bipedal locomotion, mandatorily walking on two legs, is vastly important as it is the fundamental precursor to the human lineage; it precedes tool usage and language. Chimpanzees, our closest living ancestors, according to recent DNA analyses, are often the proxy and are the dominant subject of human bipedalism studies. However, there are additional species, such as arboreal Japanese macaques (Macaca fuscata), who habitually travel through the trees bipedally. Including arboreally facultative bipedal primates (FBP) introduces a new lens to how our talus and calcaneus mobility has adapted to environmental shifts such as the transition from arboreal habitation to terrestrial habitation. Studying ankle and heel morphology across multiple species with varying levels of bipedalism allows us the opportunity to better understand how lower limb mobility and stability differ as primates become more terrestrial. Therefore, I propose quantitative and comparative analyses of tarsal morphology in three early hominins: Australopithecus afarensis, Australopithecus africanus, and Homo habilis along with FBP (chimpanzees, M. fuscata) and obligate bipedal primates (Homo sapiens sapiens) by using a visual quantitative method known as geometric morphometrics (GM). GM is a standard in the field of comparative functional anatomy and allows researchers to identify patterns in variation of morphology. This research seeks to delineate the relative shape of important muscle attachments between these different primate lineages. We hypothesize that the morphology of the ankle joint will be more similar between early hominins and modern humans than that of FBP. This research will improve our current understanding of how paleoenvironmental changes in the past 3 million years have influenced the evolution of bipedalism of primates. We also hope this work will facilitate further inclusion of FBPs in studies of hominin functional morphology.

Abstract Name: Exploring the Effectiveness of AI-Driven Algorithmic Trading Through Sentiment Analysis

Artificial intelligence (AI) has been rapidly evolving, giving rise to AI-based algorithmic trading, which allows financial instruments to be purchased and sold programmatically[1]. AI models can scrape sources such as social media, news articles, and financial forums and decide whether the sentiment is bullish or bearish[1][2]. This information gives an extra edge for an investor or trader to buy or sell with higher conviction. This study aims to break down the structure and effectiveness of using AI to algorithmically trade based on sentiment analysis. We will be dissecting multiple sentiment analysis models to find which is the most effective and comparing the models' stock picks with the S&P 500[2]. These indicators include the public's opinion on the company/instrument, various trends on social media, and consumer feedback across online platforms. Through the results and backtesting on historical market data, we can see the effects of using sentiment analysis on real-world investing scenarios[3]. This research project shows the advancements in AI models for investing along with how mass public opinion plays a pivotal role in shaping the market. This project provides additional insight for retail and institutional investors alike by diving deeper into tools all investors can access[3]. Through a deeper understanding of market sentiments, investors can make more informed decisions. This project's goal is to increase awareness of the potentially revolutionary impact that AI-based sentiment-driven trading strategies can have on the profitability of algorithmic trading.

Abstract Name: Using FreeSurfer to Quantify Cortical Thickness and Surface Area in Young Children

FreeSurfer, developed by researchers at Harvard University, has become a key software used by multiple neuroimaging labs, including UNC's Child Imaging Research on Cognition and Life Experience Lab, for the analysis of brain data. Freesurfer can be used to acquire measurements of brain structure, such as cortical thickness and surface area. By utilizing images acquired by Magnetic Reasoning Images (MRIs), FreeSurfer identifies white and gray matter and uses a template to mark those gray and white matter boundaries. Additionally, FreeSurfer is able to assign "names" to subcortical and cortical areas. However, FreeSurfer is not always able to provide accurate white and pial matter boundaries, so multiple rounds of edits have to be done, utilizing control points, skull stripping and white matter edits. Each type of edit either works to extend, adjust or rein in boundaries. Making the boundaries as exact as possible provides the most accurate measurements of cortical thickness, making data analysis more precise. FreeSurfer is utilized in a variety of research projects to investigate associations between cortical structure and behavioral outcomes. For example, a study published just this year (Machlin et al., 2023) measured associations of deprivation and threat with alterations in brain structure in early childhood and utilized FreeSurfer to ensure that measures of cortical thickness were as close to their actual values as possible. The study found that threat was associated with widespread decreases in cortical surface area across the prefrontal cortex, and deprivation was associated with increased thickness in the occipital cortex, insula, and cingulate.

Abstract Name: Assessing the Efficacy of Perinatal Care for Black Women: A Review of the QI Tools, MADM, PCPC, and PREM-OB By Constructs

Low-quality perinatal care, a growing public health crisis associated with rising maternal mortality, disproportionately affects Black women in the U.S. Existing perinatal care protocols lack patient-centricity for Black mothers, leading to less effective care. Quality improvement (QI) tools, such as the Mothers Autonomy in Decision Making Scale (MADM), Person-Centered Maternity Care Scale (PCPC), and Patient-Reported Experience Measure of Obstetric Racism (PREM-OB), constructed with patient perspectives, aim to address this issue. Despite their potential, these tools are underutilized due to limited awareness.To aid understanding, this study aimed to conduct a comparative analysis of perinatal care QI tools to investigate how patient-centered constructs are measured. We conducted a literature review to identify papers describing the existing use of the aforementioned QI tools with a focus on Black mothers. Common themes relevant to each tool and patient experience were extracted and reviewed. Definitions for identified constructs were gathered by reviewing each tool. Finally, the tools were compared for each construct. Results show that autonomy, time, and communication are prevalent constructs assessed by QI tools. PREM-OB provides a comprehensive measurement for each construct, while PCPC offers more evaluative constructs with broader definitions. The MADM scale, despite its name, measures respect in addition to autonomy.The study suggests integrating these tools into routine QI initiatives to address persistent structural issues Black mothers face in patient-provider interactions. Additionally, further research where the QI tools are embedded in a clinical trial or test of an intervention is necessary to understand the connections between the constructs measured and patient experience.

Abstract Name: Effects of Transitioning from Morphine to Buprenorphine (Medication for Opioid Use Disorder) During Pregnancy on Maternal Care and Offspring Neurodevelopment in a Translational Rodent Model.

The number of Opioid Use Disorder (OUD) diagnoses during pregnancy has increased by a factor of four from 1999 to 2014. Pregnant women who are diagnosed with OUD are often prescribed medications for opioid use disorder such as buprenorphine (BUP). Clinical evidence suggests that BUP treatment results in better outcomes for exposed infants as compared to discontinuation of illicit opioids or the continuous use of illicit opioids during pregnancy. In the current study, we utilized a translational rodent model to investigate the effect of transitioning from morphine to BUP during pregnancy on maternal care and offspring neurodevelopment. Female rats were randomly assigned to one of five experimental groups: Vehicle (VEH), BUP continuous (BC), morphine continuous (MC), morphine to BUP (MB), or morphine to vehicle (MV). Drug administration was initiated 7 days prior to breeding. The MB group switched from morphine to BUP

on gestational day 5 (GD5) and continued BUP exposure until postnatal day 2 (PN2). The MV group switched from morphine to saline on GD5 and continued saline exposure until PN2. These groups simulate real-world scenarios in which women are either already taking BUP before conception (BC), switched to BUP once they become aware of their pregnancy (MB), or continue using an illicit opioid (MC). MV serves as a control group for MB to account for early morphine exposure during gestation. Maternal care behaviors were observed, and offspring mortality and neurodevelopment were recorded. Dams and litters were sacrificed on PN2. The BUP groups elicited deficits in maternal care behaviors, increased pup mortality, lower pup body weight, and increased pup withdrawal as compared to our control groups. These findings suggest that BUP exposure during gestation still carries a risk for dam and offspring, warranting further investigation into the underlying mechanisms that contribute to these outcomes.

Abstract Name: Observing the Potential Function of Tfap2d in the Ocular Anterior Segment

The vertebrae eye has two main components the anterior segment (AS) and the posterior segment, including the retina, with both being essential to proper vision. The AS includes the cornea, lens, iris, ciliary body, and iridocorneal angle. It functions to properly collect and project light onto the retina. Anterior Segment Dysgenesis (ASD), a potentially blinding disorder, occurs when there is an abnormality in AS formation. The gene family tfap2 is essential for the development of the vertebrae eye. The tfap2 gene family encodes the protein Transcription Factor AP-2. Expression of this protein occurs in premigratory Neural Crest and associated derivatives the Neural Crest Cells (NCC). NCCs are vital for the formation of the Periocular Mesenchyme Cells (POM cells). POM cells are necessary for the formation of numerous AS structures. In zebrafish there are 5 orthologs of tfap2, tfap2a-e. One, tfap2a, is an established marker of the zebrafish AS. It is crucial for proper AS development in mammals and the absence of tfap2a results in Branchio-Oculo-Facial syndrome. The tfap2d transcription factor, being a crucial modulator in the heart and central nervous system, was absent in the NCCs during murine eye development, but Tfap2d has not been well explored in zebrafish AS targeting mesenchymal cells. We hypothesize based on our Wholemount In-Situ Hybridization and cryosectioned data, in 4 days post fertilization zebrafish embryos, that tfap2d expression is functionally present in the AS specifically, the angle mesenchyme. To test this hypothesis our goal is to use two color Wholemount Fluorescence In-Situ Hybridization and Immunohistochemistry to compare the presence of the tfap2d mRNA and protein with established angle mesenchyme markers. Through these analyses we will determine the function of tfap2d to elevate knowledge upon already known genetic markers during zebrafish ocular development which will help establish better clinical outcomes for rare congenital ocular disorders.

Abstract Name: Modeling Encephalomyosyangiosis After an Ischemic Stroke

Ischemic strokes make up 87% of all strokes causing potential long-term disabilities for patients. The discovery of a novel treatment is imperative especially because there is no effective treatment for stroke patients. The brain's ability to recover and self-heal from an ischemic stroke is limited by discontinuous blood supply to the impacted area. Encephalomyosynangiosis (EMS) is a neurosurgical procedure that promotes angiogenesis in patients with moyamoya disease. This procedure consists of a craniotomy where the temporalis muscle that surrounds the skull is grafted onto the ischemic part of the brain. By conducting a histological assessment using immunofluorescence techniques, we hypothesize that EMS promotes angiogenesis around the infarcted area and creates an enriching environment that allows the brain to quickly recover from an ischemic stroke. We can study the effects of EMS by conducting Middle Cerebral Artery Occlusion (MCAo), a surgery that replicates an ischemic stroke environment in mice. After 60 minutes of MCAo, mice were randomized into two groups, MCAo only and MCAo + EMS treatment. EMS was performed 3-4 hours after MCAo. Mice were sacrificed at either 30 or 60 days after MCAo only or MCAo + EMS treatment. Immunostaining showed increased levels of angiogenesis and blood vessel maturity providing evidence that this procedure is an effective treatment option for acute ischemic stroke.

Abstract Name: Quantification of Cadherin Expression in Pro-Vasculogenic Human Fibroblasts

Fibroblasts are an essential cell type associated with connective tissue growth and matrix remodeling. They also play a significant role in the maintenance, regulation, and growth of blood vessels. Cadherins are important in cellular communication through cell-cell junctions; two common cadherins associated with fibroblast mechanobiology are neural cadherin (N-Cad), and vascular endothelial (VE-Cad). Recent work has suggested that cadherin signaling may regulate mechanobiological crosstalk between cell types through heterotypic cadherin interactions. Advancing our knowledge of how cadherin signaling between fibroblasts and endothelial cells in blood vessels regulates vascular structure and function will help us develop novel tissue-engineered scaffolds or treatments for cardiovascular diseases. We hypothesize that fibroblast cadherin signaling can support vascular growth and that this is related to the level of contractility exhibited by the fibroblasts. Our objective was to quantify the VE- and N-Cad expression of normal cardiac fibroblasts (NHCF), normal human dermal fibroblasts (NHDF), and normal human lung fibroblasts (NHLF), all of which have been previously shown to support blood vessel growth in 3D microtissue models. Using immunofluorescence staining, our results show microtissue models with NHCFs had significantly higher N-Cad levels than NHDFs and somewhat higher levels than NHLFs. Levels of VE-Cad were similar in all three cell lines. The Pearson’s correlation coefficient (PCC) was calculated for N-Cad:VE-Cad for each cell line; results show moderate correlation (0.3-0.5) in all lines, suggesting limited co-localization. This may mean that N-Cad and VE-Cad are expressed on neighboring cells but not forming heterotypic bonds in our studies. In future studies, we will investigate how the contractile events or matrix distortions generated by NHCF, NHDF, and NHLF regulate cadherin signaling in co-cultures with endothelial cells and how these behaviors affect vasculogenesis.

Abstract Name: The Enduring Influence of Bradbury Thompson on Graphic Design

This essay provides an in-depth analysis of the life and career of Bradbury Thompson, shedding light on his remarkable contributions to the field of design. Thompson's passion for design and dedication to his craft allowed him to rise above challenges and succeed in the industry. His work significantly impacted the design world, generating interest and captivating audiences. It examines his designs and his significant role in shaping the design field. It also explores his involvement in creating the US Postal Service stamp and exploring different languages, showcasing how he bridged communication gaps between cultures. Thompson's legacy in the design industry is highlighted, showcasing his hard work and achievements throughout his career. Despite facing numerous challenges, he persisted through dedication and hard work, communicating knowledge to audiences through his designs. This essay also emphasizes how he gained a large following in the design world, becoming an influential figure in the industry. Overall, Thompson's work became essential to the world of design and education, making him a significant contributor to the field.

Abstract Name: Should Academia Thrive for Research Citation in Policy? A Case Study on Five Universities in Illinois.

Academics and policymakers are seen as operating separately, which limits the potential impact of research on society. The influence of university research on policy documents is frequently underestimated, given that cutting-edge research is being conducted at universities. Therefore, it is crucial to unveil the role of academic research in fostering evidence-driven policymaking across various public service domains. In this study, we conducted an in-depth exploratory data analysis and statistical summarization to comprehensively understand the level of academic research present in policy documents. We chose five public universities from the state of Illinois and collected research and policy citation data for those universities from Overton between 2011 and 2022. We found that, for all universities, most of the research articles cited in the policy documents were not funded, and the average minimum policy citation lag ranged from 2 to 3.5 years. Moreover, the research articles primarily received citations from government policy documents published by the USA and the UK.

Abstract Name: Customizing a digital support intervention for mothering women with substance use disorders

Background: Evidence suggests digital technology may be leveraged to promote social connectedness and access to meaningful substance use disorder (SUD) recovery support networks. Positive social connectedness has been strongly associated with improved health outcomes among patients with chronic diseases, particularly SUD. Pregnant and early-parenting people with SUD are at an increased risk for continued SUD related to decreased peer support and an inability to balance parenting and recovery needs.Purpose: To explore meaningful themes of parenting and recovery supports for pregnant and early parenting people initiating recovery from SUD that will inform the development of a tailored digital platform.Method: Using a community-based participatory approach, pregnant and early parenting women (n=30) were recruited from a women's residential drug recovery support facility in a Southeastern state. After informed consent, participants were interviewed in person and online using a semi-structured interview guide. The interviews were digitally recorded and transcribed. Themes regarding tailored supports were identified using thematic analysis and results were integrated in the digital application.Results: The five broad themes from participant interviews were (1) guilt and shame, (2) limited access to recovery supports in rural areas, (3) lack of social support for recovery, (4) lived grief and loss experiences, and (5) parenting and recovery-related educational supports. Tailored supports included parenting resources, parenting skills, parenting education, housing supports, recovery supports, childcare resources, occupational supports, and spirituality.Conclusion: Visual examples of the digital application's customization will be demonstrated and discussed.Implications: Future research will need to examine the extent to which the use of community-guided and theory-based tailored digital technology can provide the level of parenting and recovery support needed for pregnant and early parenting people seeking recovery from SUD.

Abstract Name: Internalized Fear Response in Chinese Undergraduates: Collectivist Cultures and Academic Procrastination

Academic procrastination is a global factor that may impede academic success among undergraduate students of various ethnicities, races, and genders. However, the specific relationship between academic procrastination and collectivist cultural upbringing in Chinese undergraduate students has not yet been thoroughly researched as this group of students is often overlooked in a global context. This review specifically explores the psychosocial causes of academic procrastination in undergraduate college students of Chinese ethnicity to determine if their internalized fear response to failure may be due to a collectivist cultural upbringing, which may further examine the relationship between cultural upbringing and student success. This study analyzed various articles discussing the relationship between academic self-concept, fear of failure, and procrastination in collectivist cultures. This comprehensive literature review found Chinese undergraduate students raised in collectivist cultures or with collectivist values were more likely to create their academic self-concepts based on the opinions of other individuals, resulting in anxiety that may translate into a fear of failure. These students often employ avoidant coping mechanisms to manage their fear of failure, which is correlated with increased levels of academic procrastination. The relationship between this collectivist cultural upbringing and overall academic procrastination displayed the need for further research

to determine how academic success and mental health can be improved for Chinese undergraduate college students through the possibility of targeted counseling and mental health resources.

Abstract Name: Hemolysis of Blood Samples: Best Practice for Inpatient Lab Draws

Hemolysis of blood samples is a common problem in the inpatient hospital setting that can lead to patient harm and increased cost. The review of literature showed a gap in knowledge concerning methods and specific components or devices used in phlebotomy and their effect on hemolysis as well as a lack of knowledge of current research findings among nurses. The literature also provided current guidelines and recommendations in the research for hemolysis prevention, accuracy of laboratory values through different methods of phlebotomy, appropriate waste volumes, rates of hemolysis using different phlebotomy methods or devices, and opportunities for improvement such as incorporating other blood drawing devices. The purpose of this project is to develop a decision-making tool for nurses to supplement clinical decision making when it comes to hemolysis prevention and best practice for obtaining blood samples. The proposal consists of creating an evidence-based decision tree for nurses to use in practice that will be presented with an educational in-service for nurses on specific units in the inpatient setting. Evaluation of the project would include baseline hemolysis rates for the unit with data collection continuing for a few months after the project. Qualitative data from the nurses regarding the effectiveness of the education material and their experience using it in practice will also be collected. This project will provide nurses with the knowledge to determine best practice with their patients when it comes to phlebotomy. Keywords: Hemolysis, PIV catheter, butterfly, phlebotomy, blood draw

Abstract Name: What's in the Water? Detecting Chlamydia and Gonorrhea in Treasure Valley Wastewater

Wastewater-based epidemiology (WBE) gained prominence as a reliable method for predicting SARS-CoV-2 outbreaks and trends during the COVID-19 pandemic. We modified the technique to detect Chlamydia (C. trachomatis) and Gonorrhea (N. gonorrhoeae) in wastewater sourced from four wastewater facilities in the Treasure Valley (West, Lander, Meridian, and Nampa) using variations of two extraction methods, the AllPrep PowerViral DNA/RNA Mini Kit and paper filtration (0.22µm and 0.45µm). Both pathogens were detected in samples from both Boise, Idaho facilities (West and Lander) on three of the six days tested (N. gonorrhoeae 6/14/23, and C. trachomatis and N. gonorrhoeae 6/19/23 and 6/28/23). Neither pathogen was detected in samples from the Meridian and Nampa facilities. Pathogens were detected in 25% of all treatment facilities sampled. The 0.22µm filter paper produced positive results in 3 of 4 tests (75%), while the 0.45µm paper did not produce any positive results. Surprisingly, Nanotrap A, designed for viral detection, was more effective in detecting the bacteria than Nanotrap B, designed for bacterial detection (50% vs 33%).

Abstract Name: Mathematically modeling how trapping regimes that target specific crayfish life stages impact removal efficacy

The red swamp crayfish, Procambarus clarkii, is an invasive species introduced into several streams within the Santa Monica Mountains (SMM) in California. Crayfish predation decimates native aquatic species. The Mountains Restoration Trust (MRT) has worked to remove crayfish through regular trapping in Malibu Creek. To aid conservation efforts, former student Dev Patel developed a mathematical model of crayfish removal efficacy. His discrete model of the crayfish life cycle newly accounted for cannibalism but was not yet parameterized to stream data. We expand Patel's model to better predict the efficacy of crayfish removal efforts in the SMM. We separate crayfish based upon life stage and total length: eggs, two monthly juvenile stages, small non-reproductive adults, medium adults, and large adults. We construct and parameterize this preliminary predictive model of crayfish population levels with and without trapping. We use literature and crayfish removal data provided by MRT to fit the model to the Middle Las Virgenes portion of Malibu Creek. We numerically simulate how the crayfish population changes over time and find that the model dynamics are highly sensitive to juvenile monthly survivorship. We determine the best crayfish life stages to trap to most efficiently decrease crayfish population size; specifically, model predictions suggest that a smaller mesh size that traps juveniles in addition to adults is necessary to reduce crayfish populations to local extinction.

Abstract Name: How Working Students (Don't) Balance Work and School

As the number of college students who work while attending school continues to grow due to the rising costs of college and the defunding of higher education at the state level, the working college student makes up a significant sector of college students. Although these students have jobs and could drop out of college and just work, they are getting college degrees in order to improve their future job prospects and develop skills to help them in their future careers. Understanding the experiences of these students is crucial to finding ways to support their success. Using online surveys and semi-structured interviews we have found that many working college students feel invisible to their university institutions, which often assume their full-time students are supported in other ways, and isolated from their peers due to their competing responsibilities. Most students who work during the school year are doing so to meet their basic living needs and in an attempt to reduce their need to take on hefty student loans. Because of this, many working students have little opportunity to reduce their work hours when courses become more demanding. Oftentimes, work interferes with a student's ability to attend class, study, or complete assignments on time. While the experiences of working college students are unique to every individual, many feel that the resources available to them on campus are insufficient for their needs or inconvenient for them to access. Greater discussions around the experiences of working college students could increase the visibility of these issues and potential solutions. Government reinvestment in higher education is crucial to the university system, and working college students in particular, so that tuition is not such a burden on students and so that they can better apply themselves to their coursework and future career goals.

Abstract Name: Prevalence of Normal Weight Obesity Amongst College Students

Background: Normal weight obesity (NWO) is an individual exhibiting low body mass index (BMI) or normal BMI but has high percentage body fat. Identifying individuals with NWO is clinically relevant given the link between adiposity and hypokinetic diseases. Purpose: To determine the prevalence of normal weight obesity amongst a young, non-sedentary population. Methods: Two hundred and fifty-four apparently healthy volunteers (Age = 22.2 ± 7.2 yrs; Height = 171.5 ± 9.6 cm; Body Mass = 69.9 ± 13.4 kg) provided informed consent prior to participation. Body mass index was calculated by dividing body mass (kg) by height squared (m2). Percentage body fat was quantified via the BODPOD® G/S. Class I Obesity and Low/Normal BMI categorizations were defined by the American College of Sports Medicine. Results: Data revealed that 12.2% of the overall sample exhibited NWO, with a higher prevalence among males (17.2%) compared to females (9.8%). Conclusions: Of interest is to determine if the identified NWO individuals have elevated health risk(s) compared to individuals with similar BMI. From a practical perspective, identifying individuals with

NWO is an opportunity for clinicians to proactively educate their clients regarding the health risks associated with hypokinetic disease(s).

Abstract Name: The Pursuit for Safer Batteries

Today's Li-ion batteries are unsafe for public use due to their flammability and toxic components such as cobalt, graphite, and lithium. They are also harmful to the environment when disposed of improperly. Ion solutions with high conductivity would eradicate the problems Li-ion batteries pose while maintaining their effectiveness as a battery. In order to understand the ion solutions as battery fluid, it is important to note the relationship between the solutions' viscosity, conductivity, and pH level.

Abstract Name: Period Power: Addressing Period Poverty in Wicomico County - Pesidential Citizen Scholars

Period poverty and insufficient access to menstrual resources and education is a global issue that impacts millions of people who menstruate (United Nations, Sustainable Development Goals). Menstrual hygiene products are a basic human right and necessary to be able to live with dignity and security. A negative stigma exists surrounding menstruation, labeling menstruation as dirty, unclean, or shameful. Addressing period poverty among youth is especially vital in reducing the educational gap and breaking this stigma and discrimination surrounding menstruation. Compared to the Maryland state average of children in poverty at 12%, Wicomico County, MD has a rate that is 7% higher at 19% of children living in poverty. Additionally, 49.5% of students in Wicomico County qualify for the free and reduced lunch program, through which we assume some of these students have had inadequate access to menstrual resources and education. According to the State of the Period report (2021) commissioned by Thinx and PERIOD, 70% of students aged 13-19 say that they are self-conscious about their period due to the school atmosphere. Furthermore, 62% believe that society has made it difficult to confidently navigate their menstrual cycle, and 58% have been negatively affected by the stigma that exists. Through Period Power, we are researching the stigma surrounding menstruation and addressing it by starting conversations around the community, partnering with the Wicomico County Board of Education (WCBOE) to provide menstrual products and educational materials to

middle school students in the Wicomico County Public School System (WCPSS), specifically piloting our project in Salisbury Middle School and Wicomico Middle School, and connecting the WCBOE and WCPSS with Aetna Health Insurance, who will provide the necessary resources for our project. Through these efforts, we hope to reduce discomfort and shame that may exist when discussing menstruation as well as combat period poverty at its core.

Abstract Name: Feelings of Loneliness in the Older Adult Population

Background: Older adults are those 60-65 or above and make up around 16% of the United States population. This population can face challenging transitions such as retirement, change in living situations, new diagnoses of chronic health conditions, hospitalizations, and loss of loved ones. These changes put older adults at an increased risk for experiencing loneliness. Loneliness can be caused by emotional or physical separation and can lead to physiological or psychological distress and even mortality. Animal assisted therapy has been shown to greatly reduce feelings of loneliness in the older adult population. Aim: This research aims to show the correlation between assisted animal therapy and decreasing feelings of loneliness in older adults. Method: The anticipated population for this project is 30 participants who live in a long-term care unit in a metropolitan retirement community. Loneliness will be measured using the 20-item Revised UCLA Loneliness Scale (RUCLALS). Participants will then spend 45-minutes in animal assisted therapy and then loneliness will again be measured using the RUCLALS. Conclusion: Older adults experience life changes that make them more susceptible to experiencing loneliness. Over 30% of older adults experience loneliness. Animal assisted therapy has been shown to decrease feelings of loneliness in the older adult population by 85%. Nurses can use the evidence found to advocate for and support older adults in moments of distress. By doing this, nurses can help decrease feelings of loneliness and increase the well-being of this rapid growing population. Keywords: older adults, elderly, loneliness, mental health, animal assisted therapy

Abstract Name: Nineteenth Century Collegiate Secret Societies and Their Roles Within the Female World of Love and Ritual

This paper uses records of women’s collegiate secret societies to expand on the origins and manifestations of nineteenth century female companionship as described by historian Carrol Smith-Rosenberg in her 1975 seminal work, “The Female World of Love and Ritual: Relations between Women in Nineteenth-Century America.” By analyzing the emergence of collegiate secret societies in the nineteenth century and subsequent member correspondence, organizational documents, and society publications, this paper will argue that these collegiate societies were instrumental in the development of what Rosenberg has termed the “Female World

of Love and Ritual.” Careful and meaningful comparisons are made of primary source evidence used by Rosenberg (primarily letters), and the archival materials of female-only collegiate societies founded in the nineteenth century. This study will reveal that multiple phenomena discovered by Rosenberg’s analysis such as lifelong friendship, an exchange of passionate language with each other, taking extensive getaways together, and a system of generational mentorship were also present in the organizational context of collegiate societies. This paper will definitively show that women’s collegiate secret societies created a cultural space where the intimate female friendships of the “Female World" could thrive. At a time when women lacked political and legal rights, nineteenth century women’s collegiate societies were instrumental in creating a “Female World" in which women found both intimate friendship and a collective sense of purpose. Connections between Rosenberg’s “Female Word” and collegiate societies have been hitherto unnoticed in historical literature. As a result, this paper makes a significant contribution to understanding the dynamics of female relationships in the nineteenth century.

Abstract Name: Gene Editing Using PiggyBac Transposon to Study APOE and TOMM40 in Alzheimer's Disease

While mitochondria are central to theories of aging and a significant biomarker in Alzheimer’s disease (AD), their connection to APOE and TOMM40, the high-risk genes of AD, has not been elucidated. AD can be characterized by a drastic decline in mitochondrial health compared to the natural decline in most aging individuals. This disease leads to impairment in brain function, including memory loss, confusion, and difficulty in completing activities of daily living. APOE and TOMM40 potentially contribute the AD pathology through regulating cholesterol metabolism and membrane pores. Such changes could result in declined ATP synthesis, elevated reactive oxygen species (ROS), and dysregulated cell homeostasis. This project is designed to assess the impact of two genetic risk factors for Alzheimer's disease, APOE ε4 and TOMM40 rs2075650, on mitochondrial function and integrity. PiggyBac transposon plasmid is used to construct the homology-directed repair sequences to achieve foot-print-free editing. To ensure homozygous editing, a PiggyBac transposon plasmid carrying GFP, puromycin, and hsvTK genes is the template vector for one allele, while another contains RFP, geneticin, and hsvTK genes. Primers then join the APOE ε4 and TOMM40 SNPs into the homology arms. After amplifying this region, restriction enzymes and ligation are used for plasmid cloning. Cells edited with CRISPR cas9 permit the transfection of the transformed template vector containing the SNPs of interest. Top 10 possible off-sites are sequenced to ensure minimal off-target effects. Mitochondrial ATP synthesis and ROS are quantified using assay kits. Mitochondrial morphology will be evaluated using fluorescent microscopy. Off-site evaluation will confirm the fidelity of the gene editing. Evaluating mitochondrial health through ATP synthesis, ROS generation, and morphology will provide quantifiable biomarkers for AD progression. The overall project will provide insight into therapeutic interventions mitigating AD genetic risk factors through the regulation of mitochondrial function.

Abstract Name: Late Antique Irish Hymnology: A Study of Saint Brigit of Kildare Through Brigit Bé Bithmaith

The arrival of Christianity to Ireland in 400s CE began a process of Christianization unique to the island itself. Celtic Polytheism, a faith that involved the worship of deities through nature, moved from the dominant religion to influencing Irish Christianity. The version of Christianity that emerged was Celtic Christianity, a Roman Christianity with a monastic system and mysticism of Celtic culture and Polytheism. A number of figures traversed this unique landscape in their Christianization efforts, including Saint Brigit of Kildare. As abbess at Kildare in the late 400s and early 500s, she played a significant role in reaching the local community through agrarian miracles and Celtic mysticism. After her death, a number of hymns and writing pieces such as Brigit Bé Bithmaith, “The Hymn in Praise of Saint Brigid of Brogan-Cloen”, Cogitosus: Life of Saint Brigit, and Bethu Brigte were composed by different authors. Each emphasized different themes to Christianize in different manners. Using a historical methodology focused on religion and theology, one can learn more about the image of Saint Brigit that was based on her life and the historical events in Late Antique Medieval Ireland. This crossover of late antique medieval history, religious studies, and theology allows for a unique niche of research on a saint that has been predominantly studied for her relationship to the Virgin Mary and Celtic Polytheism. Looking closer at Brigit Bé Bithmaith, one can learn more about Saint Brigit’s portrayed identity of goodness and humility, learn about the author of the piece of Saint Ultan, and understand more about the Celtic Christian and broader Irish culture and its value of intercession.

Abstract Name: "The Babel Problem: Brexit, Nonprofit Cross Cultural Communication, and Underserved Refugee Women in the UK"

In today's increasingly transnational world, Migration and refugeehood continue to be leading topics of international political discourse. Existing scholarship often lacks an intentional focus on migrant women and girls’ engagement with the state, and where private third sector refugee organizations fall in the geography of resettlement and rebuilding. This project investigates the ways that societal internalizations of Brexit impact refugee third sector practitioners and their interactions with the migrant women they serve. Through a thematic analysis of interviews with UK-based refugee third sector workers, as well as firsthand experience working for a women’s refugee organization in London, this research examines the institutional pressures that shape London-based third sector organizations’ work with women, and the ways that the state is able to extend itself into the private advocacy sector. This project engages literature of border internalization, translation violence, migrant vulnerability, and nonprofit gap filling. It finds that women’s refugee nonprofit spaces in the UK are now often reverberations of post-Brexit political imagination, and identifies a need for more informed advocacy.

Abstract Name: An investigation of incubation behavior in the American Kestrel (Falco sparverius)

Incubating birds face an evolutionary tradeoff between survival and maintaining the thermal requirements their eggs need for normal embryonic development. Thus, incubation schedules are adaptations that reduce the effort needed to maintain the tradeoff. We investigated incubation behavior as it relates to temperature in nesting American Kestrels (Falco sparverius) in west-central Pennsylvania. Our objectives were to measure variability in frequency of egg rotation, feather adjustment and preening related to time of day and ambient temperature. We predicted that females altering their incubation behavior would increase overnight when ambient temperatures are lower due to the need for continuous incubation and more attention to maintaining critical egg temperatures. We monitored nesting activity of breeding kestrels in a nest box system (n=50) in June-July 2023. Clutch size ranged from two to five (mean= 4.18). We used camera systems in 2 kestrel nest boxes during late stages of incubation (day 10-20 of 30-day nestling period). On average females rotated eggs 18.7 times during overnight incubation bouts and 11.7 times during daytime bouts (t=-0.527, df=1.42, P=0.668). Females adjusted their feathers on average 23.7 times during the night and 6.7 times during the day (t=-1.25, df=1.19, P=0.404). Lastly, females preened on average of 25.3 times during the night and 4 times during the day (t=-11.3, df=2, P=0.008). Ambient temperature varied by 20° F between overnight and daytime. Our results are important for understanding how life history behaviors may influence reproductive success of kestrels. Kestrels are experiencing population declines in our region, which may be related to climate change. Understanding whether kestrels can alter incubation behaviors in response to changing environmental conditions is important for maintaining populations and directing future conservation.

Abstract Name: Energy Harvesting from Suspension Systems to Enhance the Battery Performance of Electric Utility Vehicles

In response to the growing demand for sustainable transportation solutions, this research project explores the innovative concept of harnessing energy from suspension systems to enhance the performance of electric utility vehicles (EUVs). The research background highlights the pressing need to optimize energy efficiency and extend the driving range of EUVs as a crucial step in reducing greenhouse gas emissions and promoting

electric mobility. The primary goal and objectives are to design, implement, and evaluate a regenerative suspension system that can capture and store energy generated during vehicle motion. The research methodology combines mechanical and electrical engineering principles to develop and test the system. Preliminary results indicate that energy harvesting from suspensions has the potential to significantly enhance the energy efficiency and battery performance of EUVs, potentially extending their range and reducing the frequency of recharging. This study not only addresses an urgent need in the field of electric vehicles but also contributes to the broader effort to create more sustainable and environmentally friendly transportation solutions. In conclusion, the findings of this research project hold promise in advancing the capabilities of electric utility vehicles and pave the way for more energy-efficient and eco-friendly transportation systems.

Abstract Name: Ionic Liquids: Determining the Polarizability and Chemical Hardness of Ionic Liquids

Ionic liquids are common solvents that exhibit low volatility, high thermal stability, and numerous solubility characteristics. Ionic liquids research is becoming more prominent in numerous domains due to their customizable properties through the selection of cations and corresponding anions. Imidazolium-based ionic liquids exhibit characteristics including non-toxicity, biodegradability, solubility in water, and cost-effectiveness. Using Wolfram Mathematica and GaussView, we constructed a database encompassing over 100 optimized monomers and dimers. Monomers refer to the structures of ionic liquids characterized by the presence of a singular cation and a singular anion. These monomers were optimized through Gaussian using Density Functional Theory with B3LYP functional and 6-31+G(d) basis set. The monomer structure was then used to build dimers, where a dimer refers to sets of 2 cations and anions each. The database containing more than 100 optimized monomers and dimers was constructed through the extraction of SMILES codes for imidazolium cations and anions from a pre-existing compilation of all SMILES codes for imidazolium cations and anions. We performed calculations on the database to determine the polarizability and chemical hardness properties of imidazolium ionic liquids. Polarizability refers to the tendency of a molecule to acquire an electric dipole moment. Chemical hardness describes the resistance of a molecule when exposed to changes in electron density and relates to the energy required to add or remove electrons from the molecule. Understanding the concept of chemical hardness is important, as this can be used to predict the behaviors associated with ionic liquids. These properties comprise a high-quality quantum mechanical set of descriptors that could empower machine learning algorithms to predict the chemical properties of ionic liquids.

Abstract Name: Development of a Stochastic Differential Equation Model for Traffic Flow Optimization

This paper proposes a new set of stochastic differential equations for modeling and optimizing traffic flow in multi-lane highways as one way of dealing with extensive traffic congestion challenge. To that effect, we develop a model based on stochastic car-following dynamics with variable K representing drivers' sensitivity parameter. Uncertainty is incorporated into the reaction accelerations of vehicles through these values due to human drivers being unpredictable. This is further strengthened by our addition of a lane-changing function based on probabilistic assessments of adjacent lane conditions that captures the decision-making process involved in driver manoeuvres. A function embodies the relationship between vehicle density and velocity consistent with accepted traffic flow principles. This model involves a lot of non-linear and stochastic elements that are navigated using numerical approaches involving Runge-Kutta techniques, as well as agent based modelling. Such techniques are effective for modeling dynamic traffic behavior helping finding appropriate flows and developing practical traffic control decision-making solutions. This framework therefore does the current congestion abatement efforts, and provides a basis to subsequent empirical studies. This study becomes a reference for other studies aimed at improving the traffic flows and may change our approaches towards eliminating traffic problems.

Abstract Name: The Experiences of Latinx faculty, staff, and students at a Predominately White Institution aspiring to become a Hispanic-Serving Institution

Over recent years, higher education has experienced an increase in underrepresented racial populations, translating into an urge for institutions' diversity, equity, and inclusion efforts (Gasman & Samayoa, 2019). In an increasingly diverse nation, predominantly white institutions seeking to become Hispanic Serving Institutions must acknowledge the challenges associated with this designation. The experiences of Latinx faculty, staff, and students are interconnected, which impacts their success, access, and retention within higher education. Thus, fostering an inclusive and supportive environment for these populations is critical for their future success. As predominantly white institutions develop better resources for Latinx populations, institutions can create a more diverse, equitable, and inclusive environment. This literature review presents an analysis of existing literature surrounding Latinx faculty, staff, and students. The literature review also aims to explore these populations' interconnected experiences and how predominately white institutions can aim to support these populations better. In addition, gaps in previous research on Latinx staff success and their impact will be examined. Thus, the guiding questions are: What does existing literature tell us about the experiences of Latinx populations in higher education spaces? What do predominantly white institutions need to consider as they aspire to become Hispanic-serving institutions? What are the experiences of Latinx faculty, staff, and students at predominantly white institutions? How can institutional policies and practices be designed to promote diversity, equity, and inclusion for Latinx faculty, staff, and students? This literature review seeks to contribute to the ongoing efforts to create a more diverse, equitable, and inclusive higher education environment for Latinx faculty, staff, and students. For this review, I searched for literature to present the obstacles Latinx populations face within institutions, along with current resources and support that positively impact Latinx populations.

Abstract Name: Using AI-Predicted Therapeutics in Precision Medicine: A Path Forward for GNB1-Related Disorders

GNB1-related disorder is a rare autosomal-dominant disease with less than 100 known cases. Almost all reported cases involve a heterozygous, de novo pathogenic variant in the gene GNB1, which encodes for G-protein β1 subunit (Gβ1).Similar to most rare disorders, GNB1-related disorders do not have an FDA-approved treatment. Therefore, our research goal is to identify potential therapeutics for GNB1-related disorders by exploring the mechanism of the Gβ1 I80T variant and identifying FDA-approved treatment options.The methodology consists of two components: a literature review and an AI-based drug repurposing search.Through a literature review conducted on the I80T variant, the missense mutation was found near a critical binding region with the GIRK channel subunit, GIRK2. Typically, during G protein-coupled receptor activation, the Gβ1 subunit dimerizes with the G-protein γ subunit to form the effector that activates the GIRK channel to regulate neuronal firing. However, in vitro experimental methods have demonstrated the I80T variant causes reduced G-protein βγ-dimer binding to the GIRK channel, resulting in loss of GIRK activation, leading to reduced hyperpolarization and decreased inhibition of CNS neurons. Utilizing the NCATS Biomedical Translator AI tool, potential therapeutic approaches, such as GIRK activators, have been identified that may compensate for the loss of GIRK activation caused by the I80T variant. Many therapeutics target an alcohol-binding pocket within the GIRK channel which has been reported to be an alternative method of GIRK activation.As part of the research consultation service offered by the Hugh Kaul Precision Medicine Institute for rare disease families, the next steps involve refining the selection of FDA-approved compounds identified by AI with emphasis on those well-tolerated in pediatric patients. A formal report on our findings will be submitted to the patient's treating physician, who then can facilitate clinical decision-making on treatment application.

Abstract Name: The Perceptions and Awareness of Trauma-Informed Education in Religiously Affiliated Schools

This research project addressed a gap in the literature of equity-based, trauma-informed education by examining the awareness and perceptions of this educational movement from educators in religiously affiliated schools. Past research has shown that trauma and toxic stress can negatively impact almost every aspect of a child's school experience, but that trauma-informed education and trauma-sensitive approaches can mitigate the impacts of trauma. The research on trauma-informed education is usually centered in general education and public PreK-12 settings, so this project contributes by specifically investigating educators' awareness, perceptions, and insights about trauma-informed approaches within the context of religious-affiliated schools. We aimed to add this additional layer of educators' voices and experiences to better understand if and how trauma-informed approaches are being interpreted and integrated into religious-affiliated schools. This study was mixed methods in design, utilizing an explanatory sequential design with

two distinct, yet interconnected phases, undertaking a survey phase and interview phase to provide both breadth and depth to findings. The first phase was a Qualtrics survey distributed to and through administrators at two religious schools to their corresponding faculty. The survey yielded 14 responses to 80% completion or more, six of which were completed to 100%. At the survey closure, educators had the opportunity to provide identifying information to be contacted for interviewing. Phase two of the study consisted of interviews of consenting participants to provide in-depth details regarding their perceptions of trauma-informed education and its role in their practices and schools. Of the 14, one participant consented to be interviewed to share insights to better understand the religious school context in relation to trauma-informed care. Implications of the findings will guide future research design to further explore this topic in religiously affiliated schools, and inform education policy and trauma-informed education professional development within the religious-school arena.

Abstract Name: Shifting from Zero Tolerance Policies to Address Substance Use among Black High School Students: Disrupting the School-to-Prison Pipeline Using a Whole-Child Approach

Black high school students are significantly more likely to be incarcerated as adults than their White counterparts, presenting the question of how current policies in public schools may increase the racial disparities of the school-to-prison pipeline. In order to understand how to mitigate future incarceration of Black high school students, this comprehensive literature review investigates how zero-tolerance policies and whole-child policies may impact substance use and racially disproportionate suspension rates in high schools in the United States. Unlike whole-child policies, zero-tolerance policies fail to address reasons for maladaptive behavior, often weaken student-teacher relationships, and neglect academic success. Zero-tolerance policies often inadvertently increase substance use and academic disengagement rather than ameliorate these issues. Zero-tolerance approaches increase suspension rates while whole-child approaches decrease the incidence of suspension, indicating that the inclusion of whole-child policies and decreased use of zero-tolerance policies may reduce youth incarceration rates. Black students who use substances are also more likely to be suspended than their non-Black counterparts and those who have been suspended have a higher likelihood of being incarcerated, signifying that a reduction in suspension rates in high schools may decrease racial disparities among incarcerated young adults. Thus, the use of whole-child policies may mitigate the incidence of substance use and racially disproportionate suspension practices among Black students, reducing incarceration through the school-to-prison pipeline.

Abstract Name: Interval Exercise Stimulates a Greater Transcriptional Response than Continuous Exercise within Aging Skeletal Muscle

Exercise is one of the most effective strategies for preserving skeletal muscle health and function with advancing age. However, the molecular mechanisms behind these benefits are less established, and thus to what extent various modes of exercise can be utilized to target impairments in aging muscle is not fully understood. The purpose of this study was to identify the transcriptional response of older adult skeletal muscle to acute high-intensity interval (HIIE) or moderate-intensity continuous (MIC) cycling. Eight older adults (5M, 3F; 67±2yr; BMI: 26±2kg･m-2) completed two exercise trials separated by ~1 week. One trial consisted of HIIE (ten, 1-min intervals, 85-95% heart rate max, 1-min rest between intervals) and the other consisted of MIC cycling (30-min, 65-70% VO2peak). Muscle biopsies (vastus lateralis) were obtained before and 4h post exercise. Whole transcriptome next-generation sequencing was performed on cDNA synthesized from skeletal muscle RNA. Sequencing data were analyzed using HTSeq and differential gene expression from pre-exercise was identified using an adjusted P value of ≤0.10. A total of 55 genes were responsive to both HIIE and MIC. Regarding the unique response to each exercise mode, 264 genes were only responsive to HIIE whereas 149 genes were only responsive to MIC. Interestingly, TNFRSF12A, a gene that has been linked to muscle growth, was upregulated by HIIE but not by MIC. These data highlight that despite less total work, acute HIIE stimulates a greater transcriptional response within the skeletal muscle of older adults as compared to MIC, at least in the immediate hours following exercise. While future work is necessary to determine how these transcriptional responses correlate with specific skeletal muscle adaptations, HIIE may provide a stimulus to promote muscle growth/delay muscle loss in older adults.

Abstract Name: C. elegans axonal anchoring complex plays a role in transporting cellular waste for degradation

Autophagy is the process in which cellular components are degraded and recycled. The ternary complex, composed of the microtubule-associated proteins (MAPs) UNC-33, UNC-44, and UNC-119 contributes to the development and stability of axons by anchoring microtubule bundles to the cortex, and facilitating transport along the axonal cytoskeleton. Defects in the ternary complex proteins have been linked to various neurodevelopmental and neurodegenerative diseases. In our laboratory, we recently began investigating the autophagy process in C. elegans mutant lacking the components of the ternary complex: UNC-33, UNC-44, UNC-119 and those lacking motor proteins UNC-104, and UNC-116. We hypothesize that the lack of these functional proteins will result in defects in autophagy due to microtubule instability or defects in autophagosome transport. To test this hypothesis, we monitored the location of autophagosomes and autolysosomes in C. elegans AIY neurons using fluorescent markers and confocal microscopy. Results from confocal microscopy show a significant increase in autolysosomes present in neurites of ternary complex mutants unc-33 and unc-119. This accumulation of autolysosomes in neurites mimics the one found in the motor protein mutants unc-104 and unc-116. Conversely, autophagosome count in the soma was significantly decreased in unc-33, unc-44, and unc-116 mutants. These results suggest that the ternary complex proteins together with axonal motor proteins may contribute with transporting autophagosomes to the soma for waste degradation. Microtubule sliding, a phenomenon seen in MAP mutants, may lead to mislocalization of

autolysosomes in the neurite and has a negative impact in the process of autophagy. Taken together, these findings support the role of the ternary complex proteins in autophagy in C. elegans neurons.

Abstract Name: Asian and Latino Second-Generation Students and their Sense of Belonging

My research will focus on the experiences of second-generation Asian and Latino students residing in New York and how they understand their sense of belonging in their families. I define a sense of belonging as how students' perspectives on love, marriage, family obligations, heritage, and morals match or don't match with their parents. While there has been an ample amount of research done on the sense of belonging of second-generation students with their families, there has not been a strong comparison among Asian and Latino children. This research will allow us to better comprehend the relationship dynamics between each generation and the obstacles and experiences second-generation Asian and Latino students encounter with their immigrant parents. I will explore the similarities and differences among these two groups concerning their experiences with their extended/immediate family. I will use semi-structured interviews with demographic questions about the participants and their families and 15 questions regarding their personal experiences. In addition, I will use snowball sampling to recruit 20 participants: 10 Asian second-generation students and 10 Latino second-generation students. Interviews will be manually coded for themes, similarities, and differences among participants' responses. I propose that individuals whose parents are closely tied to their heritage and culture and individuals who are the oldest children will feel closer to their parents' perspective and have a stronger sense of belonging at home. However, individuals whose parents are more strayed from their culture and individuals who are the youngest children will feel a lower sense of belonging at home and a stronger belonging with friends and in other social settings. In addition, I believe that Asian and Latino students will produce similar levels in their sense of belonging in their families, and there will be fewer differences in their answers.

Abstract Name: Microwave Assisted Synthesis of Strontium Fluoride Nanoparticles.

Metal-containing fluoride materials have been around for many years. Particularly, calcium fluoride (CaF2) is abundant in nature and serves as one of the primary sources of fluoride for the world. CaF2 has been found to have many useful thermal and optical properties used in chemical industry. These properties have been found to be especially useful in the nanomaterial field. CaF2 nanoparticles exhibit many favorable optical

properties. Our preparation methods use microwave radiation to assist the synthesis of the nanoparticles under controlled reaction conditions including the temperature and radiation power. Strontium has very similar properties to calcium and strontium fluoride (SrF2) has the same cubic structure found in calcium. Since it has the same outer electron count as calcium, it has also been synthesized in a variety of ways. Our goal is to optimize the synthetic process of SrF2 nanoparticles using the CEM Discover 300W microwave to be able to control the size and the yield. Size is also controlled with differing concentrations of starting reagents. The X-ray powder diffraction pattern confirmed the cubic crystal structure of the nanoparticles. Dynamic light scattering (DLS) studies of the SrF2 nanoparticles confirmed the particle size ranging from 120 nm to 260 nm. The nanoparticle size was measured using scanning electron microscopy and found to be 85 nm.

Abstract Name: Engineering “designer” biomolecules in planta for enhanced biomass processibility

Plant cell wall biomass represents the most abundant renewable carbon sources on the earth. However, efficient conversion of lignocellulosic plant biomass to biofuels and biobased chemicals is plagued by high production costs associated with biomass pretreatment and enzymatic hydrolysis. In-planta expression of lignocellulose degrading enzymes presents a promising strategy for reducing production costs. This approach harnesses biomass feedstocks to simultaneously act as enzyme suppliers and substrates for biofuel production. However, many in- planta-expressed enzymes targeted for secretion were mainly retained inside the cytoplasm membrane instead of being secreted into the apoplast/cell wall, which failed to exert the expected role in reconstructing the cell wall matrix. This project leveraged an innovative in planta enzyme engineering strategy, which involved optimizing the expressed enzyme by adding two unique posttranslational modification modules: hydroxyproline (Hyp)-O-glycosylated peptide (HypGP) and glycosylphosphatidylinositol (GPI) anchor. This will not only create the enzyme with improved stability but also facilitates the deposition of the enzyme macromolecules into cell wall matrix and modify the cell wall structure. The well- studied E1 endoglucanase from thermophilic bacterial strain Acidothermus cellulolyticus was expressed in both model plant tobacco and dedicated bioenergy crop switchgrass with the HypGP glycomodule composed of 30 tandem repeats of “Ser-Pro” peptide and a C-terminal GPI anchor. The engineered HypGP module and GPI anchor facilitated the accumulation of E1 in the apoplast/cell wall of plants, which increased the biomass saccharification efficiency by 3.5-fold without affecting plant growth.

Abstract Name: Titrimetric Fresh Water Analysis: Monitoring Salinity and Total Water Hardness in Locations along the Kinnickinnic River

The salinity and total water hardness of three sites on the Kinnickinnic River near Alverno College in Milwaukee, WI in parternship with Milwaukee RiverKeeper were monitored weekly for salinity and total water hardness. The locations were Zablocki Park, Wilson Park, and Jackson Park. Samples were collected and analyzed weekly for four weeks during the month of June in 2023. The water at all three sites were determined to be very hard (219-478ppm) and salinity levels (150-566ppm) to be considered fresh throughout the four collection dates. River water is expected to be soft and fresh. Samples were analyzed by titration with standardized titrants of silver nitrate for salinity and EDTA for total water hardness. Four replicates were collected for each sample, with percent errors being less than 5%.

Abstract Name: “Determining Oxytocin’s Role in Social Motivation of Mice"

Oxytocin is a neuropeptide that is associated with social behaviors such as pair bonding, social exploration, and social recognition. Oxytocin has been found to influence some psychiatric disorders such as schizophrenia and autism. It also has been suggested that oxytocin may play a role in shifting motivation towards other social stimuli. However, our preliminary data in the lab indicates, have suggested that oxytocin, which typically increases social behaviors like sniffing, actually decreases motivation to seek out social stimuli. Dopamine is a neurotransmitter that is linked to motivation and natural rewards. There is also evidence to suggest that oxytocin acts on dopaminergic pathways. Because of this potential interaction, we examined the effects of both oxytocin and dopamine on social motivation. Male and female C57BL/ 6J mice (n=30) were dosed intranasally with saline, oxytocin, or dopamine (6M per nostril). All mice were subjected to each drug condition with washout periods in between each round. The mice then performed a series of behavioral assays including a weighted doors task, ladder task, FDSI, EPM, and siCPP. These tasks measure behavior such as anxiety, sniffing, and social motivation. The social motivation tasks, weighted door and ladder task, increase in effort needed per trial to reach a social stimulus. Noldus Ethovision XT and lab members will code the behavioral assays. We expect our findings to show dopamine has a significant difference on social motivation, while oxytocin and saline do not. The findings of this project can lead to further investigations of the neurochemical pathways in social motivation.

Abstract Name: Novel Tasks to Measure Social Motivation in Mice

While behavioral measures for general social exploration in mice are established, few measurements exist for social motivation. We have created novel behavioral tasks to measure social motivation by requiring mice to perform a task that requires increasing effort to access a social stimulus. The first task, the weighted doors task (adapted from Borland et al., 2017), requires mice to push open a one-way door to access a social stimulus. The task starts with no weight and increases per trial. The second task, the ladder task, requires mice to climb a ladder to access a platform containing a social stimulus. The height of the platform and angle of the ladder is successively increased with each trial. All social stimuli used in our tasks were matched subjects. To validate the novel social motivation behavioral tasks, we measured behavioral outcomes across multiple measurements of social motivation, correlated outcomes across these measures, and compared these social motivation measurements with classic social behavior tasks. Additionally, we compared behavioral outcomes across sex and three mouse strains (C57, DBA, and BTBR). We found statistically significant positive correlations within social motivation tasks ($r = 0.58$, $n = 31$, $p < 0.001$). Social motivation measures were not correlated with sociability as measured by the three-chamber task (ladder task: $r = -0.11$, $p > 0.05$; weighted doors: $r = -0.29$, $p > 0.05$). A mixed methods ANOVA indicated that sex was not a significant variable in social motivation variability as measured by the ladder task or weighted doors task, but that strain had a significant effect on social motivation in both tasks (ladder task: $F(2, 45 = 19.02$, $p < 0.001$; weighted doors: $F(2, 41) = 13.08$, $p < 0.001$). These novel measurements of social motivation allow for the investigation of unique neurochemical and pathway contributions to social motivation.

Abstract Name: Substrates Methylated by PRMT7 and The Effects of Cellular Stress on PRMT7 Expression

Our research focuses on understanding the role of protein arginine methyltransferase 7 (PRMT7) in mediating breast cancer aggressiveness. PRMT7 is a monomethyl transferase that plays a key role in various intracellular processes. Overexpression of PRMT7 has been associated with epithelial-to-mesenchymal (EMT) transition in breast cancer cells and increased metastatic aggressiveness, both in vivo and in vitro. Multiple pathways by which PRMT7 induces EMT have been proposed. However, there has yet to be a defined mechanism of action. Our investigations include the following: (i) Assessing PRMT7 expression levels and cellular localization upon cellular stressors, including alterations of pH and temperature in cancerous and non-cancerous breast epithelial cells by qRT-PCR, Western blotting, and immunocytochemistry. (ii) Identifying a proteome-wide profile of substrates methylated by PRMT7 by mass spectrometry. (iii) Determining the expressional regulation of oncology-associated proteins upon PRMT7 over-expression using antibody arrays. Results from these investigations will reveal how PRMT7 promotes cancer metastasis and identify downstream mediators of metastasis that could be therapeutic targets.

Understanding the function of PRMT7 is thus crucial in preventing metastasis, which is the cause of over 90% of tumor-associated deaths.

Abstract Name: Phylogenetic Analysis of West Nile Virus Isolates from Oklahoma

West Nile Virus (WNV) is a virus that is spread through the bite of an infected mosquito and can cause West Nile fever or, in severe cases, West Nile neuroinvasive disease. In Oklahoma, a total of 852 human WNV infections and 1,364 equine WNV infections have been reported between 2002 and 2022. The virus has undergone adaptive evolution, allowing it to be endemic across the continental U.S. The most well-known amino acid substitutions that have emerged in WNV are the E-V159A in the envelope protein of the WN02 genotype, and NS4A-A85T and NS5-K314R in the SW03 genotype. The goals of this study were to report whole genome sequences of WNV from OK, perform a phylogenetic analysis of isolates, and characterize variants. Mosquitoes were collected using Fommer gravid traps, carbon-dioxide-baited Biogents, and CDC light traps. RNA that is positive for WNV by RT-qPCR TaqMan assay was used to synthesize cDNA to amplify WNV genomes via a multiplex targeted amplicon PCR. We analyzed 99 WNV genomes, including 21 sequenced from mosquitoes collected in Oklahoma between 2019 and 2023 as part of this study. Phylogenetic clustering revealed that WNV variants circulating in central Oklahoma form 5 clusters with isolates from Louisiana and New York. We detected 54 nonsynonymous consensus mutations with 92% on nonstructural genes, predominantly in NS3, NS4B, and NS5. Amino acid substitutions C139S, R204C, and S172G appeared in over half of the 21 isolates from this study. Here we report preliminary information on the genomic structure of WNV and the lineages circulating in Oklahoma. Further investigation is needed to determine how the amino acid substitutions contribute to the transmission and prevalence of WNV in Oklahoma.

Abstract Name: A Brief Mindfulness Intervention and its Effect on Stress Response and Recovery: Rumination as a Moderator.

It’s inevitable that every human will encounter stressors in their life. Therefore, research on this topic is generalizable and carries a heavy weight. While facing one stressor may not have a significant impact, it’s the degree of the stressors and the response to them that can dictate if it leads to serious consequences. Mindfulness has been shown to be effective in stress recovery specifically from negative affect. Additionally, some people have higher tendencies to ruminate, and high trait rumination has been linked to prolonged

negative affect and stress responses. The current study examines mindfulness intervention as a technique for stress recovery while also seeing how an individual's rumination level affects stress recovery. Participants were asked to fill out a questionnaire at the baseline of the study measuring trait rumination. Participants completed the Trier Social Stress Task where they were given two minutes to form a 5-minute speech about why they should be a candidate for their ideal job. Following, they presented their speech to a panel of judges acting harshly. For the recovery period, they were assigned to the mindfulness condition or the control condition. For the mindfulness condition, participants were instructed to listen to a five-minute audio of a guided meditation. For the control condition, participants were instructed to rest for five minutes. Stress recovery was measured through participants' negative affect and blood pressure, which was measured throughout the study. Participants in the mindfulness condition showed better stress recovery specifically for negative affect than those in the control. Participants rating high on trait rumination showed worse stress recovery specifically for negative affect than those in the control. The findings imply that mindfulness serves as a useful tool to lessen negative affect and emotional stress while experiencing stressors, and that rumination can have a negative impact on these experiences.

Abstract Name: The role of lin-41 in the neuronal maturation and synaptic connectivity of C. elegans

Developmental disorders are largely associated with mutations in the molecular pathways involving the maturation of the brain during development. Considering the importance of these pathways, maturation of the post-mitotic nervous system is understudied, especially the intrinsic heterochronic and molecular targets controlling such events. The model organism, C. elegans, is ideal for studying such questions due to their fast and stereotyped post-embryonic development, invariant cell lineage, transparency, and well-understood compact nervous system. The regulatory pathway involving the evolutionarily-conserved let-7 microRNA and its downstream target, the RNA-binding protein lin-41, are of particular interest because they are implicated in the temporal progression of mitotic cell types in C. elegans. We aim to understand the role of lin-41 and let-7 in post-embryonic, post-mitotic neuronal maturation, specifically focusing on its role in synaptic connectivity. Using transgenic fluorescent reporters, expression patterns of lin-41 and let-7 across post-embryonic development were observationally characterized and quantified in the AIB interneuron, which plays a crucial role in forward/backward locomotion. To examine the functional role of lin-41, we examined the locomotory behavior of transgenic worms, in which the activity of lin-41 was manipulated in the AIB interneuron, using the worm tracker. We found that the downregulation of lin-41 was important in the maturation of the AIB interneuron resulting in juvenile behavior when manipulated. Next, we are investigating whether the potential downstream target cdh-5 is being regulated by this pathway. Cdh-5 is a cadherin protein that is important for inhibiting and promoting the formation of synapses between neurons. Preliminary data suggests lin-41 is playing a downstream regulatory role based on expression quantification and imaging. Additionally, we have identified the synaptic formation of the AVA and AIB neurons that may be regulated by cdh-5. Understanding these mechanisms will allow us to better understand neurodevelopmental processes and potentially identify novel therapeutics for neurodevelopmental disorders.

Abstract Name: Loyalty to The Mountains

This paper delves into the contributions of three extraordinary mountaineers—David Brower, Paul Petzoldt, and Bob Bates—and their profound impact on American outdoor recreation. In the historical narrative, skiers from the 10th Mountain Division of World War II gain more attention, overshadowing the less-explored realm of climbers' contributions. Brower, a stalwart conservationist, zealously advocated for land preservation as the Executive Director of the Sierra Club; Petzoldt, a mountain of a man with a personality to match, imparted essential climbing skills, and created the National Outdoor Leadership School (NOLS); and Bates, a scholar, and high mountain expert, played a pivotal role in advancing mountaineering equipment.Contrary to the prevailing emphasis on skiers, this paper argues that the climbers within the 10th, armed with a unique combination of mountaineering expertise and military training, wielded a significant influence on the landscape of outdoor recreation in the United States after World War II. Historically, the legacy of these climbers has been overshadowed, with scholars primarily focusing on the exploits of skiers. By analyzing their individual pursuits and collective impact, this paper seeks to rectify this oversight and shed light on the instrumental role climbers played in shaping the nation's recreational landscape.As climbers, Brower, Petzoldt, and Bates navigated terrains both vertical and strategic, skills honed during their service. Beyond the military context, their post-war endeavors paved the way for an outdoor revolution. By standing on the high peaks, these climbers left an enduring legacy that surpasses military history, because their loyalty was not to the military, but to the mountains.

Abstract Name: Understanding the Relationship Between Environmental Exposures and the Risk of Pediatric Obesity using Unsupervised Machine Learning

Obesity is caused by the accumulation of adipocytes in the body. In the US, the prevalence of pediatric obesity has grown rapidly in recent years, with about 19.7% of children and adolescents aged 2-19 affected in 2020. Exposures in prenatal and early life are implicated in development and outcomes of several diseases. The role of how temporal patterns of exposures affect health are not well understood. Characterizing differential and additive effects of continuous low-level and intense sporadic multi-agent exposures require advanced big data and artificial intelligence methods. The objective of this research was to determine the role of transitions from prenatal to postnatal exposure profiles in pediatric obesity risk.To generate exposure profiles from the ISGlobal Exposome data challenge 2021, we will utilize existing methods with the Exposure Health Informatics Ecosystem to generate events that are semantically coherent and available with spatiotemporal attributes. Next, we will use longitudinal unsupervised K-means clustering (kShape) with shape respecting distances on these exposure trajectories. The clustering performance will be evaluated using the Silhouette score and the Calinski-Harabasz score. We will evaluate prenatal and postnatal exposure trajectories associated with the onset of pediatric obesity. Principal component analysis will then be used to

understand contributions of specific exposures and combinations of exposures in relationship to Chemical Entities of Biological Interest. Potential limitations are in the quality of the trajectories which could be addressed by other methods such as shapelet transformations.

Abstract Name: The Binding of Isaac Through a Trans Artist's Lens

I am an artist who tells stories through the medium of oil paint. I make art to give myself representation as a trans person and to show others like me that their existence is beautiful. I work with oil paint because I'm inspired by the art of the late renaissance and baroque periods and I'm drawn to the rich history behind them, especially when they reference mythology or religion. My latest series references the Binding of Isaac and personally identifying with Isaac in the Bible. I see the parallels between Isaac and people like me who have been killed or attempted to be killed in the name of loving God. This is what inspired me to reimagine the Binding of Isaac in a modern setting in which Isaac is a trans man and Abraham doesn't take his coming out well. This leads to Isaac's complicated feelings about father figures, his own fatherhood, and masculinity later in his life. When I start creating artworks I begin by drawing them digitally on a drawing app called Procreate. Then I mix a palette using the primary colors against a medium gray background on my palette in order to achieve tone accuracy. I tend to mix a palette suitable to the mood of the painting while keeping color theory in mind. Then, I apply layers of paint at a time with walnut oil mixed to hasten the drying time and to thin the paint while keeping it a silky texture. I know a piece is done when the entire canvas has been touched by paint and I'm satisfied with the transitions of hues and tones.

Abstract Name: Andrew Jackson: Choke with Rage

Andrew Jackson, America's seventh president, is an American icon. He is the founder of the Democratic party and hero of the battle of New Orleans. He also is famous for his less than favorable seminole campaign and the Indian Removal Act. Regardless, the man is on the $20 bill and needs to be understood better. Currently, there's an overwhelming amount of speculation on masculinity in America. Toxic masculinity, ideal masculinity, male violence, and male loneliness are just some of the topics being discussed in the cultural zeitgeist of 2023. Jackson fits in many historic and modern interpretations on masculinity, toxic or otherwise. This project explores the application of some of these themes with Andrew Jackson and answers questions about what an American man was in the early republic of this country and what an American man is today. This project includes insight on Jackson's three duels with Waightstill Avery, Charles Dickinson, and John Sevier as well as several other duels in this time period. Duels were the highest form of expression of masculinity, especially when that masculinity is being threatened.It's no secret that a vast majority of contemporary mass shooters are male, most violent gang members are young men, and that most violence in society seems to be propelled by men. I hope this project will answer questions about male violence in today's society and that the echoes of our past can assist us with understanding ourselves in today's world just a little bit better, warts and all.

Abstract Name: Cancer Studies: Enhanced Activation of ROS-Responsive Prodrugs via Prooxidant ROS Generation

Xiaohua Peng's lab has reported a potent Phenylboronic acid nitrogen mustard containing reactive oxygen species (ROS) activated prodrug, FAN-NM-CH_3. This drug selectively targets cell lines with higher endogenous hydrogen peroxide (H2O2) levels. Due to heterogeneity of cancers and development of resilience against single agent therapies though, these traditional treatments are generally ineffective at producing desired outcomes. Combination therapies have shown greater efficacy in animal models, yet most fail due to

adverse effects. A deeper exploration of combinatorial agents with enhanced efficacy of anti-cancer agents and lower risk of negative effects is essential. Prooxidants have long been investigated for their anti-cancer properties on an individual basis, however various researchers have claimed that these can selectively deliver H_2O_2 to sites of cancer. Integration of insights from these studies, alongside combination of prooxidants with the FAN-NM-CH_3 prodrug has exhibited enhanced toxicity towards TNBC, MCF-7 and U-87 MG cancer cell lines, while sparing MCF10A normal cells. A notable reduction in viability of cancer cells as opposed to with FAN-NM-CH_3 treatment alone has been achieved by the synergistic therapy. This discovery establishes a promising strategy that allows for lower drug dosage while maintaining selectivity and efficacy, paving the way for improved cancer treatment methods and further research.

Abstract Name: Signaling Safety: The Role of Black Instructors in STEM for White Female Students

Prior research has concluded that Black women and men scientists act as highly effective identity safety cues (i.e., aspects in a setting that signal to minoritized members that their identities are valued and welcomed) among Black female students, attracting Black women students to Science, Technology, Engineering, and Math (STEM) settings. Like Black women students, white female students have been historically excluded from STEM and anticipate gender-based discrimination within STEM environments. Moreover, similar to Black scientists of all genders, white women are stereotyped as incompetent in STEM settings. Despite previous research, there has yet to explore whether Black scientists serve as effective identity safety cues among white women students. The present study utilized an online experiment and we investigated whether a Black instructor in STEM would serve as an efficacious identity safety cue for white women students. White women students were recruited via Prolific (N= 374) and viewed a webpage for a fictitious STEM school. Participants were told to imagine they were a student at the school and were next randomly assigned to learn about a White woman, White man, Black woman, and Black man professor working in the school. Participants next reported their identity safety by answering questions that measured their anticipated belonging, trust, and interest in STEM as a student in the professor's courses. Relative to the other conditions, the Black woman professor produced the highest levels of identity safety.

Abstract Name: Engineering High Zip-Lignin Conjugates in Sorghum Cell Walls

Sugar alcohols synthesized from digested agricultural biomass provide a viable energy alternative and a means for decreased dependency on fossil fuels. Commercial agriculture produces abundant plant biomass,

making this a renewable source of fuel that could minimize the disastrous anthropogenic effects on the planet. Industrial anerobic digesters have shown promise in breaking down agricultural biomass and converting it into bioenergy precursor metabolites. However, robust plant walls that contain chemically stable lignin act as a current roadblock for maximizing the available energy yield, in these industrial systems. Anerobic digester systems require extremely high temperatures and pressurized environments to break down tightly bonded chemical structures within plant walls. Our experimental approach targets chemically strong ether bonds within the cell wall lignin backbone via point mutations in key Sorghum bicolor lignin biosynthesis genes, generated by CRISPR-Cas9, namely p-Coumaroyl-CoA: monolignol transferase (PMT), feruloyl-CoA: monolignol transferase (FMT), and cinnamoyl-CoA reductase (CCR). These mutations have allowed us to engineer the cell wall to incorporate monolignol conjugates into the lignin backbone via relatively weak ester bonds.We predict that overexpression of FMT, coupled with knocking out PMT and CCR will reduce the abundance of lignin-bound monolignol p-coumarates and increase the abundance of monolignol ferulates. We confirmed the presence of the point mutations in our target genes by DNA sequencing. We are quantifying the effects of these Cas9-mediated point mutations by RT-PCR, qPCR, RNA-sequencing, and chemical analyses of lignin composition by derivatization followed by reductive cleavage (DFRC), base hydrolysis, and mild acidolysis. We hypothesize that these modifications to lignin structure will increase cell wall digestibility, reduce the cost of anaerobic digestion, and increase the energy yield. Preliminary results from our chemical analyses of these modified plants suggest that they may have effects on lignin composition early in development that are less evident in later growth stages.

Abstract Name: ‘Life’s So Fun!’: Positive Representation, Celebration, and Queer Joy as Resistance in LGBTQ+ Popular Music Artists

While the LGBTQ+ community has faced immense amounts of violence and oppression throughout history, music has been an important piece of hope and joy to celebrate queerness in the face of oppression. As popular music has a history of breaking gender norms and bringing queerness into the mainstream, it serves as a space where queer people can express themselves safely with limited consequences. Research continuously shows positive representation of queer people in the media has led to further acceptance by the general public, and literature increasingly examines marginalized communities’ use of joy in media as active resistance to oppression. While literature exists on the impacts of positive queer narration in pop culture and joy as resistance in other marginalized communities, there is a large gap in the literature on queer joy, especially related to popular music, media, and pop culture. Drawing on the theoretical frameworks of queer theory and Muñoz’s queer utopia, this thesis seeks to fill the gap on queer joy as resistance through modern LGBTQ+ popular music artists’ performances and careers. This thesis creates case studies using qualitative content analysis to examine six current LGBTQ+ popular music artists’ expressions of queer joy in their work as resistance to anti-LGBTQ+ rhetoric, creating larger acceptance of the queer community. By analyzing various media channels such as on-stage performances, music videos, interviews, and more, I expect to find queerness used as a celebratory device, switching up the rhetoric of being queer or trans as doomed to a difficult life. This thesis seeks to highlight the concept of queer joy as empowerment, queer celebration in pop culture media as resisting harmful anti-LGBTQ+ rhetoric, and radical queer performance in successful LGBTQ+ popular music artists as working to increase society’s acceptance of the queer community.

Abstract Name: Isolating the CDR-H3 region from domestic ferret antibodies

The domestic ferret (Mustela putorius furo) pathophysiological response to influenza infection is similar to the human response, which makes the ferret an ideal model to study influenza and other respiratory infections. However, currently the ferret genome is incomplete and there is a lack of ferret-specific reagents, which limit the immunological assays and analyses available for such studies. To better assess the ferret immunoglobulin (antibody) response to influenza, we developed tools to analyze plasma antibodies. We purified immunoglobulin G (IgG) from ferret plasma and sequenced the proteins using mass spectrometry. Our lab optimized this protocol, which involved first optimizing an old method of crude antibody isolation, ammonium sulfate precipitation, followed by affinity chromatography using Protein A. Purified IgG was confirmed with SDS-PAGE and the antibody protein was digested with a panel of proteases in order to determine the best way to generate CDR-H3 peptides. The third complementarity-determining region of the variable heavy chain (CDR-H3) is the region of the antibody protein that is responsible for recognizing antigen (pathogens, like viruses and bacteria). This work advances the ferret immunological information available by uncovering the repertoire of CDR-H3 sequences expressed in ferret plasma during the response to influenza. Furthermore, it allows for synthesis of ferret monoclonal antibodies, which could be used as tools to determine the binding patterns of ferret antibodies to components of the influenza virus or vaccine, which would inform future vaccine design.

Abstract Name: Energy Efficiency Study of Pool Covers: Reducing Energy Loss of Heated Pools

Our College presented us with an applied question about the efficiency that the pool covers have on heat loss in the pools. Our college has an Olympic-sized pool and a warming pool. Each pool is connected to two different boilers, in a circulating heating system. Our College uses opaque covers that greatly reduce the rate of evaporation and solar radiation compared to transparent and bubble covers. Our task was to figure out if covering each pool for a few hours between activities would reduce the work the boilers have to do to keep the pools heated at a certain temperature in a sufficient amount as to justify the labor of such covering. The work presented here studies the conditions that would affect each pool's heating, including natural heating loss due to outside temperature, evaporation, and solar radiation. The work presents a study of the BTU (British Thermal Unit) loss of both pools as a function of various of those variables and the desired temperature. Our study suggests that the pool cover is convenient at all times with the big pool, due to evaporation loss on such a big surface. The findings of the smaller pool differ. Due to less area and an

increase of solar radiation due to shallower waters, the smaller pool does not benefit greatly from a pool cover in temperatures 5 degrees below or higher than the desired temperature. The methodology presented here could easily be used to study pools in other scenarios, such as at residential areas.

Abstract Name: Aptamer Selection for an Anti-Superoxide Dismutase 1 (SOD1) Aptamer for Tracking SOD1 Migration and Aggregation in Neurodegenerative Diseases

While it is known that superoxide dismutase 1 (SOD1) is associated with neurodegenerative diseases, there is much to learn about the mechanism of toxicity and migration of this protein in the human body. Mutant forms of SOD1 protein are implicated in the gain of toxicity in neuron cells in neurodegenerative conditions such as Amyotrophic Lateral Sclerosis (ALS). Even though there are about 5,000 new ALS diagnoses each year in the United States, the mechanism behind the formation of mutant SOD1 is still an ongoing area of research. This research aims to create a molecular tool, specifically an aptamer, to visualize the migration of SOD1 proteins in neuron cells. Aptamers bind their targets with high binding affinity and specificity and are composed of oligonucleotides. To study the migration of SOD1, the anti-SOD1 aptamer will be fluorescently labeled so that it will be visualized in live-cell imaging techniques. This work will employ the Systematic Evolution of Ligands by Exponential Enrichment (SELEX) technique to find an aptamer against SOD1. The conditions of each round of selection, such as pH at 7.4 and 37℃ temperate, were kept constant as those mimicked the conditions of the human body. Iterative rounds of SELEX will be conducted to enrich the oligonucleotide pool and ultimately isolate aptamers from the original N71 RNA pool. This research is currently in its fifth round of SELEX out of potentially 5 to 20 SELEX rounds. The enriched RNA pool is currently being sequenced using Next Generation Sequencing. This will determine if the research can move to further developing the aptamer sequence. The further success and development of this study will allow real-time visualization of SOD1 protein and give medical and biomedical researchers a better understanding of the association of SOD1 enzyme in ALS, Alzheimer’s, Parkinson’s, or other neurodegenerative diseases.

Abstract Name: Artificial Intelligence in Deception: Unraveling the Role of AI and Large Language Models in Online Financial Scams and Countermeasures

This study investigates the sophisticated role of Artificial Intelligence and Large Language Models in perpetrating online financial scams, such as phishing, identity theft, and investment fraud. The research focuses on the mechanics and effectiveness of AI in these scams, and how AI-driven solutions can be

employed to detect and prevent such fraudulent activities. This research aims to contribute to the fields of AI ethics, cybersecurity, financial technology, and consumer protection, where there is a growing need to understand the role of AI in both enabling and combating financial scams.The research methodology is twofold. Qualitatively, it involves conducting interviews with a diverse group of participants, including cybersecurity experts, financial fraud investigators, victims of online financial scams, and AI developers. These interviews are designed to shed light on the operational mechanisms of AI in financial scams, the psychological impact on victims, and the challenges in effectively combating these scams. Quantitatively, the study will analyze data from financial institutions, cybersecurity firms, and online platforms to identify patterns and characteristics unique to AI-generated scams. This involves statistical analysis to evaluate the current AI-based detection and prevention tools.The study is expected to yield an in-depth understanding of how AI and LLMs are used in online financial scams and provide a critical assessment of the existing AI-based detection and prevention methods. It aims to offer practical recommendations for improving these tools and developing guidelines to help consumers and financial institutions recognize and protect against AI-generated scams. The results will be discussed in the context of enhancing financial security and consumer protection, contributing to the broader dialogue on ethical AI use and the challenges it poses in the financial sector. This research is significant as it addresses the urgent need to understand and mitigate the risks of advanced AI technologies in online financial security.

Abstract Name: The Role of Parent-Child Conversations in Child Emotion Learning During Informal Science Learning

Previous literature suggests that parent-child conversations and informal learning environments play a role in developing children’s science thinking, however, less is known about the relationship between these conversations and children’s emotion learning in an informal science learning context. This study examined how parent-child conversations support child emotional learning in an informal science learning environment. It was hypothesized that parents who used more emotion talk in the aquarium would have children who used more emotion talk. We hypothesized that there would be a higher prevalence of negative emotion talk compared to positive talk for both child and parent.The sample from the previous study included 50 children and parents and the children had to be 3 to 8 years old. Parent-child conversations were recorded and then transcribed verbatim. Audio recordings were coded for emotion and examined for emotion valence; methods adapted from Lagattuta & Wellman (2002). The “Contextualizer” tool in the Linguistic Inquiry and Word Count program was used to find the emotion terms in the transcripts while providing context to the utterances. A second trained coder checked for accuracy in 100% of the transcripts.Results supported the first hypothesis that parent emotion talk was positively correlated with emotion talk at the aquarium when controlling for child age; $p = 0.008$. However, our second hypothesis was not supported. Instead, we found positive emotion was more prevalent among children and parents than negative emotion. This inconsistency between the current study and previous studies may be due to the differences in parents’ socialization goals. Overall, these findings may help educators and parents create stronger learning environments for their students and children as the influence of conversations is explored in the context of informal science learning. Future research could focus on the quality of parent-child conversations to understand how they talk and improve child learning practices.

Abstract Name: Regulation of Murine Arthritis Symptoms by Type I Interferon Receptors

Sterile inflammation associated with autoimmune murine arthritis serves as a model to investigate pathways of mechanical hypersensitivity (tactile allodynia) and nociplasticity. In the murine K/BxN serum transfer model of arthritis, interferon beta is used as a therapeutic agent temporarily ameliorated allodynia. We hypothesized that type 1 interferon receptors (IFNAR1) influence pain-like behavior in this model. To test this theory we used the K/BxN serum transfer model with C57BL/6 wild type (WT), and type I interferon receptor knockout (Ifnar -/-) mice of both sexes. Ifnar1-/- mice were compared to WT mice for clinical inflammation in ankle swelling using a caliper and mechanical allodynia in withdrawal thresholds by the von Frey method over a 28 day time course. The female Ifnar1-/- mice had more ankle swelling than WT males and females and male Ifnar1-/- mice [F(3,29); p<0.0001 two-way ANOVA]. The withdrawal thresholds were similar within strain. Both the Ifnar1-/- male and females had a minimal change in withdrawal threshold from baseline and were significantly different than the WT mice over the time course [F(3,67.18), p<0.0001 two-way ANOVA]. These results indicate that type 1 interferon receptors play a critical role in the onset of inflammation induced allodynia and regulate the level of paw swelling differently in male and female mice. Sex differences in some but not all inflammation related symptoms in the Ifnar1-/- mice may relate to sex differences in the response to therapeutic agents that target the type I interferon pathway currently in clinical use.

Abstract Name: The Effects of Beneficial and Pathogenic Marine Bacteria on the Sea Anemone Exaiptasia diaphana

In mitigating the effects of climate change, probiotics have become a promising solution for enhancing coral resilience. Corals and the sea anemone Exaiptasia diaphana (a laboratory model for corals) establish symbiotic relationships with dinoflagellate algae, but under environmental stress, the host expels their algal endosymbionts and “bleaches.” Although past research has explored the general effects of bacterial strains on host health, this study sought to further illuminate coral-bacterial relationships by examining the survival of E. diaphana simultaneously exposed to known beneficial and pathogenic bacteria (Ruegeria mobilis and Vibrio alginolyticus, respectively) at ambient and elevated temperatures. Considering the heat resilience of V. alginolyticus, it was hypothesized that this bacterial strain would outcompete R. mobilis under normal and heat stress conditions. In three independent experiments, bacterial cultures were prepared to a density of 8×107 cells/mL in sterile seawater. Anemones were inoculated with (1) both strains simultaneously, either (2) R. mobilis only or (3) V. alginolyticus only, or (4) no bacteria. All anemones were incubated at either 27.0˚C (ambient temperature) or 32.0˚C (elevated temperature). Metrics to quantify host health included survival and algal abundance (to detect bleaching); in healthy anemones, both metrics should be relatively high. According to the data, simultaneously inoculated anemones under heat stress had increased mortality relative

to uninoculated anemones at the same temperature. This suggests that temperature alters the effects of V. alginolyticus and R. mobilis on host health, and simultaneous inoculation may be an additional stressor that synergizes with temperature. Furthermore, R. mobilis may not be a promising probiotic to administer to wild coral populations already exposed to V. alginolyticus and/or heat stress. Together, these results elucidate compatible/non-compatible cnidarian-bacterial and bacterial-bacterial relationships, thus progressing the development of conservation techniques that will help us preserve our coral reefs.

Abstract Name: Enhancing Restaurant Service: Implementing Autonomous Robots to Improve Customer Experience at Bowls of Steel in Malaysia

This research determines whether the integration of a social autonomous robot into the restaurant business can enhance customer experience. The overarching idea involves utilizing robots to elucidate menu items, thereby allowing restaurants to run even with a shortage of human staff. Motivated by my experience working at Bowls of Steel, a Malaysian restaurant that closed down after experiencing a detrimental loss of staff, the impetus for this study stems from the challenge of staffing and the subsequent consequences. Although labor shortage, especially in the food industry, has always been an issue, the recent pandemic saw almost 450,000 new job openings in the industry as compared to 2019. Other factors, such as an aging population, childcare costs, and an inability to pay workers, have led to this shortage as well. 62% of operators say they can't staff up to meet demand, and 80% say they have a hard time filling open positions, leading to an uptick in restaurants that are forced to shut their doors. The novelty of employing robot staff, proficient in menu elucidation, potentially could sustain the restaurant's operations. The NAO robot was programmed based on previous experience and corroborating research, leading to a prototyped autonomous robot that could replace front-of-house staff in this global labor shortage. It was demonstrated to a group of peers and members of the public to gather feedback, and should consequently be used in a controlled restaurant setting to test its effectiveness before being deployed to the general public. As the programming currently in this specific NAO robot satisfies the guidelines for BOS, more programming will have to be done in order to work in other environments. Although robots have been used in Malaysia to transport food, this is the first instance of a robot socially interacting with customers.

Abstract Name: Cobalt-Catalyzed Carbene Insertion: An Eco-Efficient Route to Construct C-O Bond

The synthesis of Carbon-Oxygen (C-O) bonds is of paramount importance to the development of many

pharmaceuticals, agrochemicals, and natural products. Catalysis by transition metals facilitates the straightforward and efficient insertion of carbenes into O-H bonds, offering a reliable and atom-economic route to the creation of C-O bonds. Although significant progress has been made in this field, previous research has primarily revolved around the utilization of noble metal catalysts, such as rhodium and ruthenium complexes. These noble metal catalysts, while effective, often come with substantially higher costs and produce environmentally harmful byproducts. The exploration of base metal catalysts, especially cobalt, remains notably underrepresented in the existing literature. In this study, we present a highly efficient carbene insertion reaction into O-H bonds catalyzed by a well-defined cobalt complex, employing diazo compounds as carbene precursors.Our research showcases the remarkable versatility of cobalt as a catalyst for this transformative reaction. Alcohols, phenols, and carboxylic acids all undergo smooth and efficient reactions catalyzed by cobalt, with good to excellent product yields. This finding can be extended to the late-state diversifications of natural products and bioactive molecules, underscoring the immense potential for practical synthetic applications using inexpensive cobalt catalysts to catalyze carbene insertion reactions.Cobalt's role as a base metal catalyst opens up new avenues for cost-effective and sustainable synthesis in various chemical industries. Furthermore, the development of efficient and selective transformations of O-H bonds using cobalt catalysis has the potential to significantly impact the field of organic synthesis, enabling the streamlined production of valuable compounds.

Abstract Name: Habitecture & Bioreceptivity: Combining Ecology, Engineering, and Art for Enhancing Biodiversity

Bioreceptivity is the ability of a material to be colonized by living organisms and is a new term in ecology to discuss the beneficial applications of building materials for ecological uses. Bioreceptivity is both nature-inspired and nature-integrated where colonization by the microbiome and organisms plays a role in the architectural design of an object or space. Land space is limited due to increased urbanization and the challenge of human dominated landscapes reducing regional biodiversity. To adapt to these challenges, designers are seeking new technologies to identify, describe, and create prime locations to enhance biodiversity. The application of ecology, engineering, and arts towards improving biodiversity could address key climate challenges by reducing urban heat islands, protecting pollination services, and improving food security. However, the combination of these disciplines has not yet been analyzed and discussed for educational or design potential. Hence, expanding on the applications of Bioreceptivity theory for artistic and engineering uses is imperative towards ecological design builds. Habitecture and Bioreceptive design can allow us to create urban spaces that appeal to both natural organisms and humans in the built environment. I explore the use of fabrication techniques such as 3D printing and Laser Cutting for habitat development that can be integrated into the urban environment. I illustrate how pollinator reefs can be created to protect wild pollinator populations through a combination of laser cutting and 3D printing. Additionally, I show how artistic sculptures can serve as habitats, such as bat houses or oyster housing sites, that serve to both enhance city aesthetic and biodiversity. Lastly, I discuss the applications of habitecture education through the creation of Habitat Fabrication Labs (3D HAB-Lab) as student organizations at the university level. Key words: Bioreceptivity, Habitecture, Design, Fabrication, Ecology

Abstract Name: Uncovering the Unknown Functions of Saccharomyces Cerevisiae Gene ECM13

In saccharomyces cerevisiae nearly 10% of genes are still classified with unknown functions. Ecm13 is a non-essential gene with an unknown function. However, it is induced by treatment with 8-methoxypsoralen and UVA irradiation. Using the database Genemania, we identified a genetic interaction with Ecm13 and Rad27. Rad27 is an endonuclease required for Okazaki fragment processing and evolvement in long-patch base-excision repair and large loop repair. Therefore, we hypothesized that Ecm13 functions with Rad27 to execute cell cycle specific processes. To test this, we used ecm13Δ strains under conditions that are known to challenge the cell cycle. Our positive control was dun1Δ, a cell-cycle checkpoint serine/threonine protein kinase. We found when treating cells with 100j/m2 ultraviolet radiation, relative value averages in all experiments show cells deleted for ECM13, ecm13Δ, did not mimic our positive control strain, dun1Δ. We determined that the growth of ecm13Δ appears to have an increased fitness under these conditions. Since there are multiple repair mechanisms and cell cycle checkpoints, it is possible that ultraviolet radiation is not appropriate to test ECM13's functioning in the cell cycle. Further experiments will be required to rule out its potential cell cycle functioning. Understanding uncharacterized genes, such as ECM13, will provide a wealth of knowledge to the field.

Abstract Name: "Clearing the Air: Hospital-Reported Airborne Illnesses and Dumpsite Dangers"

Dump sites, a breeding ground for endotoxins and bioaerosols, have become increasingly concentrated over the last decade due to the rise in human population, the mass production of goods, and waste resulting from that. Long term exposure of just small bioaerosols and air pollution from these dump sites have shown an increased risk of diagnosis of asthma, skin irritation, and long term cough. Past studies that focused on connecting dump sites in proximity to residential communities found a direct correlation between air quality and reported illnesses. Therefore, this study aimed to examine if these correlations are relevant in local communities within a ten mile radius from dump sites in Gwinnett and Cobb County. The methodology of this experiment included examining and correlating reported airborne illnesses in those communities and the level of air pollutants. To contrast, cities outside of the 10 mile radius were explored to see if there were decreased illnesses reported with the increased proximity from the dump site respectively. As a result, a positive correlation was found between reported airborne illnesses, air quality, and residential proximity to dump sites. Further analyses would be needed to accumulate more data to continue this agenda. Key words: environment, air quality, pollutants, dump sites, toxins, bio-aerosols, inhalants, asthma, respiratory

Abstract Name: Rooted in Place: A Classroom Reimagined

This presentation will showcase the structure and impact of a novel ideation of a classroom on eco-humanities taught in a garden. The Judy Genshaft Honors College garden is our classroom. Eager students warmed by the Florida form tactile connections with the plants interlaced in their fingers. They unearth how agriculture, ecology, and human flourishing entwine. We sought a need for community-building in the aftermath of the COVID-19 pandemic. In August 2021, we reimagined the garden as a classroom, where students could learn from the soil rather than the whiteboard, and hence Rooted in Place was born. Rooted in Place was founded on the philosophy that building a sense of place also builds community, drawing on constructivist learning theory and active learning to promote dialogue between students to assimilate new knowledge, while challenging preconceived ideas. We wanted our fellow students to absorb how ecology impacts agriculture, mitigates food deserts, and promotes food sovereignty. In the process, they dig into their own cultural roots and explore individual identities and values as an exercise in narrative empathy. Here, we highlight our course modules and discuss their impact on ecological stewardship and community education: (1) Eco-Community, (2) People, Culture, and Food, (3) Sustainability and the Future, and (4) Reconnecting with our Roots. The students moved forward with a heightened understanding of sustainability, stewardship, community, and culture. It is our prerogative to present this pedagogical model as an opportunity for other schools and universities to establish a culture of learning and stewardship as we have.Key Words: Ecological Stewardship, Community Education, Food Education, Narrative Empathy, Ecology.

Abstract Name: The Invisible Box: How Heteronormativity and Intersectionality Shape Public Sexual Identity

The main purpose of my research is to show how the compounded interactions between heteronormativity and intersectionality shape public perceptions and expressions of sexuality. From my research into these concepts, involving many articles from peer-reviewed scholarly journals and research reports, my main findings reveal the consistent reinforcement of heterosexuality in normative gender roles, perpetuating power imbalances and oppressive societal attitudes. The non-disclosure of non-heteronormative identities emerges as a response to perceived stigma, impacting personal and professional lives, with intersecting identities influencing the decision of how and whether to explore and express one’s authentic self. My research methodology includes a meticulous analysis of studies exploring queer disclosure decision-making, familial influences, and workplace dynamics. The theoretical framework for all of my sources includes queer theory, sociological perspectives, and gender studies. My conclusion clearly states that the widespread effects of heteronormativity ultimately shape how society views queerness and how negative views of queerness

influence individuals' expression or masking of sexual identity. My key findings underscore that perpetuating oppressive social, legal, and political strictures reinforces consequences for queerness, leading to harmful masking being perceived as preferential. Individuals with intersecting identities, including racial, cultural, or gendered dimensions, face compounded difficulties in living authentically. Despite improvements in the public perceptions of non-heteronormative identities, the rise of Christian nationalism and anti-LGBTQ+ legislation, the political weaponizing of queerness/straightness on party platforms, and pervasive hate crimes demonstrate the continued danger of expressing authentic identities, forcing individuals to remain closeted for their own safety. By phasing out heteronormativity and embracing intersectionality, we can create a more compassionate and inclusive society where stigma dissolves, authenticity is established as the norm, and conformity is no longer rewarded.

Abstract Name: Antimicrobial Hydrogel

Metal organic framework has been a topic of interest for while within the scientific community. Zeolitic imidazolate framework (ZIF-8) has raised many interests with its application as a potential drug carrier. With a similar application, this research focuses on creating a hydrogel with zinc nitrate hexahydrate-derived nanoparticles, namely ZIF-8. Since ZIF-8 has the ability to encapsulate and release zinc, it holds potential as an application on human skin in the form of wound dressing. This study intends to use a water-based production process instead of the conventional methanol method, which can cause health concerns due to its toxicity level. The objective of this project is to enhance the hydrogel's safety profile while preserving its effectiveness. The effects of commercially manufactured ZIF-8 and ZIF-8 nanoparticles made from water synthesis will be extensively compared against the Gram-positive (Bacillus subtilis) and Gram-negative (Escherichia coli) bacteria under the incubation period of 16 hours through multiple of comprehensive tests. The objective of this comparison analysis is to identify any differences in antimicrobial activity and to assess the antibacterial capabilities of the hydrogel, hence illuminating the possible benefits of the water-based synthesis strategy concerning its safety and effectiveness. This finding will open opportunities for creating hydrogel formulations that are safer and more effective particularly to use on human skin. The growing need for antimicrobial materials makes it critical to comprehend the subtleties of nanoparticle manufacturing, particularly when it comes to skin-contact applications. The results of this study could lead to improvements in the creation and manufacturing of hydrogels with specific characteristics, benefiting the consumer and biological healthcare markets.

Abstract Name: Socio-Ecological Factors Associated with an Opioid Use Disorder: Results From a National Survey

OUD (Opioid Use Disorders) is associated with overdose, psychological stress, comorbid chronic pain, and mental illness. The recent opioid epidemic has dramatically reshaped policies regarding substance use and rehabilitation with over 100,000 deaths being attributed to opioid overdose during 2021. Data for this analysis were derived from survey responses from the 2019-2020 National Survey on Drug Use and Health (NSDUH) data set. NSDUH data. Descriptive Analysis of Socio-Ecological Factors Associated with an OUD are sponsored by Substance Abuse and Mental Health Services Administration (SAMHSA) to collect data on drug use, mental health, and overall health among noninstitutionalized populations aged 12 years and older. Persons are systematically recruited across the United States using multistage area probability, weighting, and oversampling of minoritized groups to enhance generalizability. The final sample included 176 individuals meeting the criteria for a current OUD based on the inclusion/exclusion criteria. Overall, the majority of participants met the criteria for a severe OUD N=137 (77.8%), followed by a mild OUD N=27 (15.3%), and a moderate use disorder N=12 (6.8%). Factors including feeling anxiety and a history of substance use treatment were associated with having a severe OUD compared to a mild OUD. Individuals reporting anxiety were more likely to report a current OUD compared to individuals without anxiety (β=1.44; P.<0.001). Participants indicating lifetime substance use treatment were less likely to report an OUD compared to participants with a mild OUD (β=0.25; P=0.014). Factors including reporting anxiety and having previously received substance use treatment were statistically associated with having a current OUD. Interestingly, individual sociodemographic factors were not statistically associated with an OUD in our sample. Potentially suggesting targeting mental health and substance use treatment outcomes may serve as a critical step in reducing the burden of OUD among those meeting the criteria for a severe OUD.

Abstract Name: Elucidating Monomeric and Self-Associated Conformations of TREM1 during Disease Pathology and their Relation to TREM2-mediated Microglial Activation through In Silico Methods

Alzheimer's disease (AD) is a devastating and complex disease, with no singular genetic cause identified. Potential therapeutics fail to fully mitigate disease progression, let alone cure the disease. Several genetic risk factors have been associated with the development of AD, including mutations on a family of transmembrane microglial proteins called triggering receptor expressed on myeloid cells (TREM). The role of TREM2 in AD pathogenesis is highly studied, but there is little work regarding TREM1's potential therapeutic impact. Previous studies identified that TREM1's proinflammatory immunological function induces microglial phagocytosis of Aβ plaques, one of the hallmarks of AD, yet the mechanisms underlying TREM1 function in AD are unknown.Understanding how both TREM1 and TREM2 conversely act in the presence of AD-based ligands may help clarify how they can be targeted for AD therapeutics. The application of molecular dynamics (MD) simulations allows for atomistic-level insights on the short-term behavior of protein-ligand interactions. Herein, we describe the use of the MD engine, GROMACS, to provide mechanistic insights on TREM1 and TREM2 behavior and structure due to the presence of AD-risk variants and AD-associated ligands. Comparisons of TREM1 and TREM2 simulations over the span of 1 microsecond, combined with alignment analyses of their amino acid sequences, revealed key differences in TREM1 and TREM2 behavior. Simulations of the homodimeric form of TREM1 provided insight into the function of TREM1's monomeric and homodimeric forms, and how these structures impact ligand binding capabilities. Ultimately, uncovering

these mechanisms will help elucidate how binding causes conformational changes and downstream signaling events that impact microglial function during disease pathology.

Abstract Name: Social Responsiveness Measures of School-Aged Children During Facilitated Conversation

This study aimed to compare social responsiveness skills in school-age children diagnosed with Autism Spectrum Disorder (ASD), other children identified with social communication deficits not related to ASD, and their typically developing peers. Participants included 12 male students between the ages of 10-15 years. Skills were elicited during conversational language sampling tasks that included three standardized prompts followed by intentional socially based bidding and responses from the examiner. Social bidding and responses frequently included the use of mental state verbs, stating preferences, and/or emotional vocabulary. Through video analysis and transcript review, both quantitative and qualitative data were collected and analyzed to determine differentiating patterns of performance. More specifically, for every social bid produced by the examiner, the study measured whether or not the participant provided a response. Quantitative data reflects percent response to social bids. In addition, during observation of the recorded conversation and transcript, the quality of each social response was rated on a scale of 0-3 that reflected the appropriateness and specificity of the response by context. During analysis, challenges to consistent rating were examined, resulting in further refinement of the rubric for more practical clinical use. Preliminary data analysis indicates minimal group differences in quantity of responses, predictably due to children this age with social deficits learning to respond to communication partners through direct intervention targets. Much greater variation has been noted in the quality of social responsiveness and more detailed analysis is being completed to determine if there are group differences. Challenges to eliciting verbal social skills during authentic assessment and finding measurement tools for this purpose will be shared. The importance of assessing social responsiveness to determine intervention priorities for social communication will also be discussed.

Abstract Name: Concurrent Use of Nicotine and Fluoxetine: Effects on Aggression and Cortisol Levels

Nicotine dependence is notably higher in individuals diagnosed with mood disorders. Nicotine has been

shown to alleviate symptoms associated with mood disorders, therefore some individuals will take up smoking tobacco in order to self-medicate. On the other hand, there is some evidence to suggest that nicotine use might precipitate mood disorders, with studies showing that smokers have a higher risk of developing depressive symptoms than nonsmokers. 80% of adult smokers started during adolescence, and adolescents who smoke every day have a 70% occurrence of psychiatric disorders, and greater rates of comorbidity in adulthood. Because of the large overlap between nicotine use and dependence and mood disorders, it is essential to understand the interactions between nicotine and commonly prescribed antidepressants, such as fluoxetine (trade name Prozac), and their effects on those who intake both. Betta splendens, commonly known as betta fish, are aggressive creatures which allows them to be ideal candidates for behavioral studies. In several studies, Betta splendens were given fluoxetine in their aquarium's water. These fish proved to be less aggressive than those left untreated. This shows that the Betta splendens have the same serotonin receptors as humans and can be used as a model for mental illness treatment. In this project, betta fish were administered nicotine and fluoxetine and then their behavioral aggression was measured. Each fish underwent an untreated test, and randomly a fluoxetine only, nicotine only, or fluoxetine and nicotine test. A mirror was placed in each aquarium to quantify aggression levels by recording and quantifying frontal displays (erecting the operculae, fins, and tail while facing an opponent), broadside displays (swimming with the side of the body facing opponent accompanied by erection of fins and tail), and average distance from the mirror.

Abstract Name: Swap-Worthy? The Geopolitical Determinants of China's Bilateral Swap Agreements

China's Bilateral Currency Swap Agreements (BSAs) were fueled by its RMB internationalization agenda. Apart from trade and investment promotion, these swaps have also been valued by recipients as backstop liquidity facilities. I theorize that given the benefits to its partners, China weighs economic (RMB internationalization) and political benefits (rewarding its allies) to itself when selecting swap recipients. I hypothesize that geopolitical alliance from a supplier's perspective is an overlooked determinant of BSAs. More importantly, I point out that signing a swap is only the beginning. Scarce attention has been given to factors determining the status (cancellation, renewal and expansion) of these signed swaps. I hypothesize that signed swaps remain contingent on bilateral relations with China. I compare the ideal point distance (in UNGA votes) between countries and China and BRI summit participation (2017 and 2019) as proxies for alliance, both in the extensive and intensive margins to test these hypotheses. This study, if the results confirm our hypothesis, portrays how smaller economies are both rewarded by following China's economic leadership and yet also constrained by China's financial statecraft.

Abstract Name: Effect of a 10-Week Employee Wellness Program on Exercise Barriers and Physical Activity

Introduction: University employees' physical activity (PA) levels vary depending on their individual job, but many are sedentary in nature. American College of Sport Medicine (ACSM) guidelines recommends 500-1000 MET-min-wk-1of PA. However, university employees may face numerous barriers to meeting these guidelines due to job requirements and a reduced self-efficacy. Purpose: The aim of this study was to determine if participation in a 10-week physical activity (PA) program has an impact on participant PA level and barriers self-efficacy (BSE). Method: Participants (N=15) were a convenience sample recruited via an e-mail sent to employees at a regional university. Participants completed the International Physical Activity Questionnaire (IPAQ) and the Barriers Self-Efficacy Scale (BARSE) at baseline. The IPAQ is a self-reported questionnaire used to estimate weekly volume of exercise spent in walking PA, moderate PA, vigorous PA, and moderate-to-vigorous PA (MVPA). The BARSE is a 13-item questionnaire scored as an average of 0%-100% confidence to overcome specific barriers to exercise. Participants were then matched with a student trainer to complete individualized exercise programming a minimum of once per week. Data were collected again at the end of 10 weeks. A paired samples t-test was used to determine if changes occurred to PA or BSE. Results: Weekly total PA (MET-min-wk-1) significantly increased from pre- (M=1705.2 ± 2416.23) to post-assessment (M=3030.87 ± 1920.28; p=.05). No other PA variables significantly changed (p>.05). Barriers did not change significantly (p>.05) from pre (M=65.94%±14.65%) to post-test (M=63.07% ±4.79%). Conclusion: While PA almost doubled, BSE was not impacted by programming. More strategies may need to be utilized to impact BSE, but an individualized program may be sufficient to modify PA. Future research should examine PA habits following completion of trainer lead programming to determine if PA habits are sustained autonomously.

Abstract Name: Vito Pilosi IV Deception Tactics: The Successful Use of Maskirovka for the Soviet Union during WWII

Deception tactics were a widely used strategy during World War II for every country involved in the turmoil. Deception tactics, also known as Maskirovka within the Soviet Union, is the misleading of the enemy in a strategic manner to benefit the army. Deception tactics were used by Axis and Allied Powers on multiple fronts during the war. Fifteen hundred attacks were carried out using deception tactics, and up to five hundred tons of bombs were dropped on dummy airfields. Many scholarly sources discuss deception tactics, but not one looks at how the fight along the Eastern front helped the Allies along the Western front. How did the use of deception tactics during World War II help the Soviet Union win decisive battles along the Eastern front? Primary sources such as Russian photos and diaries from the time explain how successful the deception tactics were. Combining background research on Maskirovka with primary sources demonstrates that the battles won were vital in the Soviet war effort. German troops fought a two-front war. The use of Soviet deception tactics helped the Soviet Union by keeping the Germans occupied on the Eastern front to alleviate pressure on the Western front.

Abstract Name: Solar Flare Gamma Ray Spectroscopy

The Gamma-RAy Spectrometer and Pointer (GRASP) is a simple and robust instrument design aiming to do spectroscopy and, in high count situations, locate X- and gamma-ray bright sources at the Sun. It includes four high-energy resolution scintillation detectors along with a front-facing aperture. In this poster, we discuss the importance of such an instrument and its reliability. To prove the concept for GRASP, we created a simple engineering design model using Bismuth-Germanate (BGO) Scintillator detectors and a variety of radioactive sources. Using the data from these tests, we then performed a series of Geant4 Monte-Carlo simulations to compare with our lab measurements. Our goal with GRASP is to piggyback on a future high-altitude balloon experiment, supplement the imaging of solar flare bright features, and validate the concept for a possible future instrument to be sent to space.

Abstract Name: Template-coating pair derived macroscale carbon foams for CO2 sequestration

The continuous rise in carbon dioxide emissions highlights the dire need for additional research in the Carbon Sequestration and Storage (CSS) field. Porous carbons (PCs), a promising class of materials for CO2 sequestration, are lightweight and possess extraordinarily high surface areas. Furthermore, their scalable synthesis and remarkable thermomechanical stability make them suitable for demanding environments. Additionally, their hierarchical porosity helps optimize capacity and kinetics. While PCs have shown great potential, the fabrication of CO2-selective PCs derived from cost-efficient and sustainable starting materials and at industrially relevant quantities has remained a challenge. Using a template-coating pair design, this work demonstrates that PCs can be fabricated using a divinylbenzene-based Polymerized High Internal Phase Emulsion (Poly(HIPE)) as a template and polybenzoxazines, thermally stable, sustainably-derived polymers, as a coating. The carbons synthesized through this method exhibit excellent thermal and mechanical stability, having reached unprecedented atomic efficiency of 98.7%. Scanning Electron Microscopy (SEM) images confirmed the successful fabrication of this material, which can be enhanced for selectivity through the functionalization of nitrogen-rich molecules, enabling carbon capture at ambient conditions.

Abstract Name: Antibiofilm and Antimicrobial Properties of Schinus terebinthifolia Fruit Extract

In the past few decades, the misuse and overuse of antimicrobials has led to an increase in the number of antimicrobial resistant infections, which according to the World Health Organization, has become a major worldwide concern and a threat to public health. The need to develop new therapeutic alternatives to address the ineffectiveness of conventional antimicrobial treatments is crucial. The rising field of phytotherapy offers an efficient approach to addressing this global health crisis. In this study, we investigate the Schinus terebinthifolia plant fruit extract as a potential low-cost alternative to antibiotics. This highly available plant is widely used in gastronomy and known in folk medicine for its wound healing and health-promoting properties. In this study, we evaluate the plant's fruit extract antimicrobial and antibiofilm properties against 22 different strains of bacteria and fungi using the broth microdilution, biofilm, and spot assays in microtiter plates. The results show that the fruit extract has a significant antibacterial effect on several gram-positive and gram-negative pathogenic bacteria including Staphylococcus aureus, Enterococcus faecalis, Pseudomonas aeruginosa, Acinetobacter baumannii, Bacillus subtilis, Bacillus cereus, Escherichia coli, and Staphylococcus epidermidis. In addition, the plant extract displays varying degrees of antibiofilm properties at different concentrations against bacteria and fungi. These findings suggest that the S. terebinthifolia fruit extract has the potential to be used as a novel antimicrobial alternative in the treatment of infectious diseases. Future studies will focus on further characterization of the fruit extract.

Abstract Name: Utilizing a Convolutional Neural Network to Classify the Pathological Patterns of Pneumonia

Pneumonia is a respiratory infection that causes over a million hospitalizations and 50,000 deaths every year, making it the fourth most common cause of mortality overall. Artificial intelligence has provided us with the ability to transition from traditional diagnostic tools to a more machine-driven version through the analysis of patient chest X-ray scans, which can significantly improve diagnoses of pneumonia in terms of cost, time, and accuracy. In the current work, a preliminary model utilizing the convolutional neural network algorithm to analyze chest X-ray images from Kaggle (an open-source database) has been developed for predicting pneumonia presence. Having performed with an accuracy in the high 90s, the model was adapted to differentiate between pneumonia types as well. The diagnostic process for this disease when it comes to analyzing chest X-ray scans includes classification in terms of acquisition setting, severity, and pathological pattern. Previous research studies of this type have primarily focused on attempting to to determine the cause of the pneumonia, which includes a bacterial, viral, or fungal source. However, these different causes can manifest as different radiological patterns, limiting the ability of physicians to make this diagnosis regarding cause directly from chest X-rays. This work focuses instead on improving machine-driven diagnostics based

on the pathological patterns of pneumonia in chest X-ray scans, specifically lobar, interstitial, and bronchopneumonia. After categorizing the previous Kaggle data further into these types, the model performed with a moderately high accuracy of about 78.65%. While differentiating between different pneumonia cases in this manner might not always correlate to a certain type of cause for the disease, this characterization can give doctors a much more comprehensive understanding of what they are dealing with. Furthermore, these categorizations can inform doctors of overall pneumonia severity and progression in patients, thereby influencing and improving treatment plans.

Abstract Name: The Equine Industry's Opinion on Bacteriophages as an Antibiotic Alternative

In the last decade, antimicrobial resistance (AMR) has become a large topic of concern across both human and animal medicine. With a dwindling list of effective antibiotics, and a growing list of resistant infections and deaths, the need for alternatives is reaching its peak. When discussing antibiotic alternatives, considering both their efficacy and their acceptance into medical practice is important, especially in veterinary medicine. Physicians and owners must accept the alternatives for them to be a practical and effective replacement to antibiotics. In the equine industry, antibiotics have a complicated history, as many owners opt to treat horses on their own, in a practice known as farm medicine. Practices such as these may perpetuate AMR and be a major obstacle to implementing antibiotic alternatives. To assess perceptions of AMR and antibiotic alternatives (phage therapy), a survey of individuals within the equine industry, including veterinarians and non-veterinarians, was conducted. While this study demonstrated that on-farm antibiotic practices are prevalent in the equine industry, many members of the industry demonstrated a desire for antibiotic alternatives—responding favorably to the use of bacteriophages as a potential alternate therapy. Participants had positive opinions regarding phage therapy, but highlighted the necessity of future research and education. These findings indicate that the equine industry could be ready for, and serve as a leader in, the advancement of veterinary medicine by embracing antibiotic alternatives.

Abstract Name: Examining Working Memory as a Predictor of Public Speaking Distress

Public speaking anxiety (PSA), a social anxiety subtype, can inhibit speech performance. Severity of social anxiety has previously been negatively associated with working memory (WM) performance. Conversely,

stronger WM capacity may lead to lower levels of speech distress for individuals with PSA. Our research explores whether WM performance predicts changes in speech distress over time in individuals with PSA. We hypothesize that Operation Span (Ospan) WM performance will predict changes in Subjective Units of Distress Scale (SUDS) ratings, with higher Ospan scores associated with lower SUDS scores. Participants (n=25) completed a speaking related behavioral challenge where they performed three speeches while they rated their distress using SUDS. A repeated measures GLM analysis showed that WM scores did not predict maximum SUDS scores across speech trials. However, three trends were observed: 1) a general downward trend of SUDS scores across trials, 2) higher WM scores were associated with lower initial SUDS scores and a smaller change in scores across trials, 3) lower WM scores were associated with higher initial SUDS scores and a larger change in scores. Considering the small sample size of the study, results may be insignificant due to inadequate power. Further research may benefit from a larger sample size to explore the trends present that align with previous literature.

Abstract Name: Evaluating the Moderating Effects of Chronic Alcohol Use on PTSD Symptoms and Working Memory Capacity

Comorbid Post Traumatic Stress Disorder (PTSD) and Alcohol Use Disorder (AUD) is common among Veterans. Previous literature states that PTSD symptoms and chronic alcohol consumption are separately correlated with working memory (WM) deficits, and suggests that novel computerized WM training is effective in PTSD symptom reduction. Considering that AUD and PTSD may impact WM and its malleability with training, we hypothesize that alcohol use will moderate the relationship between the change in PTSD symptom scores and WM over time in Veterans with clinical PTSD. Participants completed the Clinician Administered PTSD Scale for DSM-5 (CAPS-V) (n=43) and Reading Span (RSpan) WM task (n=36) prior to and following eight weeks of computerized WM training. The Timeline Followback was used to assess the maximum number of alcoholic drinks consumed in one day within the past thirty days (AlcMax) to gauge drinking severity as a continuous variable. Using SPSS 28.0.0, we conducted repeated measures GLMs for pre- and post- CAPS-V and RSpan, with and without AlcMax as a covariate. Pairwise comparison analyses wer conducted, with High or Low Drinking groups defined by DSM-V criteria for high alcohol consumption (males: >4 drinks, females: >3 drinks) to categorize AlcMax values. There were significant main effects for PTSD symptoms (F=51.420, p<.001), and RSpan (F=11.417, p=.002) over time. The main effect of WM capacity scores over time was moderated by drinking severity (F=5.146, p=.030), while PTSD symptom change was not. High alcohol consumption was associated with a greater change in WM capacity scores over time (F=21.804, p=.003) than low alcohol consumption (F=4.014, p=.056). The data suggests that chronic alcohol consumption moderates the effect of training on WM capacity change over time. Future research can explore the impacts of chronic alcohol use by including individuals with severe AUD to expand upon drink-wise categorization and analyses.

Abstract Name: Sustainable Data Collection and Analysis for Nonprofit Applications

Data plays a pivotal role in the operations of every nonprofit- yet the lack of resources and data-focused experience in grassroots organizations often leaves vital data uncollected or underutilized. Proper usage of data can strengthen grant writing, better inform business decisions, and allow organizations to tell the stories of the communities they serve. Through an analysis of current nonprofit data practices and a secondary data analysis for The Food Pantries for the Capital District, this presentation provides nonprofits with the groundwork for sustainable data collection and analysis. Surveys show that the biggest challenges among small nonprofits are collecting appropriate data and having the skills, software, and personnel to analyze it (EveryAction and NonprofitHub 2016). This guide discusses specific nonprofit applications for descriptive statistics, hypothesis tests, and regression- as well as the data that must be collected to do so. With the addition of a practice template, organizations can be equipped to answer questions such as: “How has our clientele changed over the past X years?” and “How do varying clientele characteristics predict service levels?” in an easily replicable manner.

Abstract Name: Identity Formation of Orphaned and Destitute Children Transitioning from Non-Kinship Care to Family-Based Care

With the rising mental health issues among minors, several studies have shown that children who are separated from their families show clear signs of distress symptoms or even post-traumatic stress disorder. This study worked with an NGO in Southeast Asia that provides shelter, education, and care for orphaned and destitute children. The NGO was hoping to find recommendations in order to create better policies for the program. This study helped with creating in-depth analytical questions for the research instrumentation. This study aims to see: How does transitioning to kinship care after undergoing their program affect the identity formation of vulnerable children? Each respondent was monitored by the NGO. In order to answer this research question, this study analyzed 37 respondents in the form of in-depth interview transcriptions. This study uses chi-square crosstabulation using, to find correlations between the variables included in the data set. Our preliminary interview findings show that many of these children had a traumatic familial history, but overall plan to continue their education, have a positive outlook on life and have set plans for their future careers. One limitation of this study is the language barrier between the data analyzers and the interviewers. This means that some of the language used in the transcriptions could have been lost in translation. Another limitation this study had is that the respondents knew their interviewers personally, so they could have been giving ‘correct’ answers rather than ‘honest’ answers. For further studies, this study proposes continuing the data collection in a longitudinal study design.

Abstract Name: Exploring Social Learning Strategies on YouTube through Sing-along Videos, Active Participation, Social Interactions, and Problem-solving Skills

Bandura's Social Learning theory says children can learn skills and behaviors through modeling. Free media platforms like YouTube have increased children's access to video content and created new ways to learn skills and behaviors via social learning. One type of content children watch is sing-along songs. Songs can enhance learners' listening and speaking skills. Using the modeling theory, do songs encourage children to learn other skills and behaviors, and if so, how? Prior research is conflicting on how effective sing-along songs are in teaching children's skills. For example, because songs do not encourage conversational turns, they may not be as effective for language acquisition. On the other hand, sing-along skills may encourage social interaction and active participation. This study examined the prevalence of three skills among sing-along videos: active participation, social interactions, and problem-solving skills. We hypothesized that sing-along videos encourage active participation and social interactions but not problem-solving skills. An online survey was distributed to parents across the U.S. (N=232, Mage = 4.43 years) asking them to provide the three most recent YouTube videos their children watched. We preliminarily coded 60 videos in ranges of 5-15 minutes. Out of the 60 videos, 52% were sing-alongs, and of these sing-along videos, 12% were active, 69% had social interaction, and 54% had problem-solving. Although somewhat contradictory to our hypotheses, these findings suggest that sing-along videos are recommended for parents who want to encourage social interaction and problem-solving skills with their children. This study is important because it helps parents make informed decisions about the content their children are watching, ensuring it aligns with their educational goals, promotes social skills, teaches them problem-solving skills, and contributes positively to their children's development.

Abstract Name: Early Studies on the Effectiveness of Industrial Hemp as a Phytoremediator of Polluted Waters

Nitrogen and phosphorus are essential nutrients for plant life, however, too much is detrimental. Fresh water lakes and waterways in Florida are declining as the result of nutrient pollution. Excess nutrients from fertilizer, animal feed, phosphate mine events and human waste have been identified as major contributors to this decline. Industrial hemp (Cannabis sativa) is a well-known soil remediator, shown to remove pollutants such as heavy metals and radioactive chemicals from polluted soil. This project tests the effectiveness of industrial hemp in removing excess nitrogen and phosphorus from polluted water. The goal is to grow plants that will survive in impaired water long enough to pull out some of the excess nutrients. The hypothesis is that the excess nitrogen and phosphorus in the impaired lake or pond will provide nutrients needed for the

plants to survive. The growing strategy used here conditions seedlings to seek water directly and three generations of plants have demonstrated the ability to survive with roots submerged in water for over three months. Established EPA methods were used for segmented flow analysis of Total Kjeldahl Nitrogen (TKN), and Total Kjeldahl Phosphorus (TKP) in the water. Preliminary data show that over a period of 36 days and 12 samplings, five plant setups removed a total of 49.4% of the phosphorus provided and 53.0% of the nitrogen provided. Net contributions by the plants alone accounted for 62% of the TKN removed and 73% of the TKP removed. Additional trials are pending and nitrate/nitrite studies are underway. We also have a subsequent group of four cloned plants grown from cuttings of plants raised in water, which are collectively taking up 1757 mL on average every three days and growing rapidly. We predict that the nutrient uptake by these clones will be higher than the preliminary data reported here.

Abstract Name: Welcoming First Year Students into an Undergraduate Research Community through Peer Mentorship and a Course-Based Approach

Many students enter their universities concerned about their lack of research experience, intimidated by older and well-credentialed faculty, and overwhelmed by the lack of clarity about how to get started in undergraduate research, especially at large R1 universities. To enhance and accelerate their entrance into the research community, approximately 200 students a year participate in Accelerated Research, a "Special Opportunity" granted through UNC-CH Admissions and administered through the Office for Undergraduate Research (OUR). The program provides first year students with increased outreach from the OUR, a peer mentor, and access to one of two one-credit courses (“Modes of Inquiry” or "Research Beyond Academia") that both provide them with explicit instructions and assignments for finding and/or creating research opportunities. Each of these classes also provides ~10 guest speakers who are researchers within academia (“Modes of Inquiry”) or researchers who are in industry, the non-profit sector, or governmental organizations (“Research Beyond Academia”). Participants in these courses took surveys to self-report how the courses affected their confidence levels and feelings of inclusion at the university. This presentation will share data from these surveys as well as qualitative reports about students’ reactions to Accelerated Research at the end of their first semester, their first year of the program, and during the spring semester of their final year at the university. Survey and qualitative data both show increased confidence in getting started in undergraduation and increased motivation to work in research-related fields.

Abstract Name: Exploring Media for Leveraging the Voices of Families of Students with Disabilities in Teacher Preparation and Research

Family-school partnerships are a high leverage practice impacting student outcomes across academic, social, and behavioral goals (CEEDAR, 2017). In special education, literature on family engagement indicates the critical nature of parent-to-parent support for advocating effectively with schools on behalf of their children (Rossetti & Burke, 2018). This presentation describes the implementation of a common social technology, podcasts, as a pathway to leveraging family voices for the purpose of connection and strategic advocacy for students with disabilities and their families. To do this, we will first synthesize research on family experiences with special education, illuminating barriers and pathways to meaningful engagement. Second, we will present preliminary findings of a study asking, How can online media, such as podcasts, promote knowledge and sharing amongst families of students with disabilities and pre-service educators? By sharing quotes and vignettes from an ongoing analysis of podcasts featuring parent voices, we will exemplify emerging themes such as the importance of early intervention, acquiring assistive technology, and the impact individual teachers can have on students with disabilities and their families. Finally, we will share early stages of a website generated from this project to educate, support, and connect families of students with disabilities. Organized into themes (e.g., advocacy) and categories (e.g., assistive technology), this site will feature parent/family voices that we wish to share at the 2024 NCUR conference. Attendees will leave our presentation with an understanding of the importance of supporting parents and families of students with disabilities, especially those who may be struggling or feeling alone, and the knowledge sharing potential of online access to a community of family voices. In closing, by contributing to a network of families willing to share their stories, needed changes to policy and practice can be better articulated and shared with policymakers, researchers, and other service providers.

Abstract Name: Density Map Estimation for Automated Cell Image Analysis

There are many images in the medical field that require computational processing to speed the process of analyzing images. In the past, scientists have manually counted cells in images which is time-consuming and leads to a risk for mistakes. Cell images are complex in their nature; they typically have a great number of cells which makes manual counting difficult and cells are oriented in a crowded manner, making automated cell detection difficult. Therefore, efforts in automated analysis have been proposed, but there are still problems with detecting cell variation in size, shape, cell crowding, and background noise in images. Recent advancements to count cells have used Convolutional Neural Networks (CNN) models. CNN models are deep learning models in image analysis that use convolutional layers to learn image features for object detection. CNN models such as Fast-RCNN, and Faster-RCNN have been used in general object detection methods, however, in cell detection there are errors in getting accurate cell numbers due to cell crowding. Further research has incorporated the use of density map estimation with CNN models to help with errors in cell crowding. Density map estimation uses the learned image features from CNN models to generate heatmaps of the image, displaying the distribution of cells in images. These density maps can improve the detection of cells by focusing on separating the counts of crowded cell areas. This research aims to create a density map to count cells in a unique dataset of limited microscopic cellular images. This dataset will be used to train and test a density map for generating heatmaps of images. The overall objective of this research is to improve the accuracy of automated cellular image analysis practices to alleviate the workload of biomedical professionals.

Abstract Name: Death and Demilitarization: The Effect of Demilitarizing Law Enforcement Agencies on Police Violence

Does demilitarizing law enforcement agencies (LEAs) decrease police violence? Over the past two decades, police killings have increased consistently, with over 1800 deaths occurring in 2021 alone. In continuing the research of Macdonald, Kaminski, & Smith (2009), and Delehanty, Mewherter, Welch, & Wilks (2017), we theorize that demilitarization, in the form of introducing less-than-lethal weapons usage polic ies and the forced recall of military supplies originally from the US Department of Defense 1033 program, leads to a decrease in police killings. Data was collected from two open-source databases (Fatal Encounters & Puppycides) along with data on use-of-force incidents from Macdonal et al. (2009). Additionally, we received data from Lowande (2021) on recalled 1033 supplies from different LEAs. We ran linear regression models to examine the relationship between recalled 1033 supplies and police killings. We also performed a time series analysis of when different LEAs implemented less-than-lethal force policies and how that affected the number of people killed by police.

Abstract Name: Identifying live solid tumor specimen preanalytical factors to reduce lab test variability

Cancer is a leading cause of death worldwide and research plays a vital role in developing better treatments. For this to happen, preserving tumors specimens until they reach the laboratory is a vital part of cancer research. Preanalytical factors of handling tissue are critical aspects that occur prior to collecting specimen and involves the process of obtaining the specimen. These factors can affect results and accounts for 32 to 75 percent of laboratory errors. The laboratory has no direct control on this process. Handling tissue specimens involves specimen collection, storage, media, storing, ischemia time (hot and cold), packaging, and transportation. The specimen spends most of the time in the transportation part of the preanalytical factors. There is a transport protocol for fixed tissue transport, organ transport, and liquid biopsy transport; however, there is not a set protocol with specific step guidelines for live tumor tissue transport. Our study’s goal is to produce a protocol for preanalytical factors of live tissue collection and handling to preserve the RNA quality and expression before specimen acquisition by the laboratory. To assess the RNA expression and tissue duality, we performed 5 different assays: RNA Sequencing Assay, KI-67 (Kiel 67) Assay, Hematoxylin and Eosin (H&E) Staining Assay, Caspase-3 Activity Assay, and Live/Dead Cell count. KI-67, H&E, caspase-3 staining intensity using ANOVA showed that there is not a significant difference between the two groups. The Cell Titer-Glo (CTG) assay was performed to assess cell viability with a t-test statistical analysis.

The cell viability in the sample before transport was not different from that in sample after transport. These samples are vital for testing new therapies leading into better understanding of the cancer development, progression, and resistance to treatment. To make all this happen, following a strict and proper live tumor tissue transport protocol is crucial.

Abstract Name: Subwavelength Near-field Control with Metasurfaces

This research shows a possible path to creating arbitrary near-field electromagnetic distributions using metasurfaces with 100% transmission efficiency. It has been previously shown that this is theoretically possible using metasurfaces of different local admittances (N. Estakhri et al., 2017 IEEE APS & USNC/URSI, pp. 1723-1724). Our research consists of figuring out a method to generate metasurfaces that produce the prescribed near field (through the implementation of such admittances over different segments of the surface). For this purpose, we first construct a platform in the electromagnetic modeling software COMSOL Multiphysics. Then we used the genetic algorithm optimization tool in MATLAB to generate a series of metasurface segments that are as close as possible to the desired calculated admittances. The final surface consists of an FR4 sheet covered in sections by a thin sheet of copper, in the same fashion as PCB printing is done today. Possible applications of near-field control are sensing, boosting nonlinear effects, and particle trapping, as high-power concentrations can be artificially created in the near field.

Abstract Name: Housing Design for Stargardt Disease

Design a single-family house for an adult with Stargardt Disease. Stargardt Disease is a rare genetic eye disease that happens when fatty material builds up on the macula. The small part of the retina is needed for sharp, central vision. Vision loss usually starts in childhood - but some people with Stargardt Disease don't begin to lose their vision until they're adults. This disease has no treatments. The symptom is a slow loss of central vision in both eyes. Gray, black, or hazy spots in the center of vision, Sensitivity to light, and need more time for eyes to adjust between light and dark places. According to the research findings through literature review and case studies, things to consider when designing for the visually impaired are lighting, floor selections, furniture placement, floor plan layouts, materials, colors, and textures. When doing lights for the visually impaired, dimmable and phone-controlled lights are high on the list. Users control their phones without searching the walls by connecting them to the lights. Using different flooring materials or colors on walls creates transition spots in the home for better wayfinding. Going from carpet to tile or changing colors

in other rooms lets users with visual impairment know which room they are entering. Shape using different shades of colors or textures in a room helps them understand what they are touching. Not having a coffee table in the middle of the living room but in the corner helps keep people from tripping accommodate to the furniture placement. Floor plan layouts are straightforward, so they don't get confused and turned around. Using a darker color on the bottom cabinet with a lighter countertop enables them to differentiate between the color tones. Housing design for the visually impaired allows designers to accommodate someone's wants by speaking to their needs.

Abstract Name: Sex Differences and the Effects of Stress on the Development of Pain Behaviors in a Rat Model of Temporomandibular Joint Disorder

Research has shown that women are four times more likely to suffer from temporomandibular joint disorder (TMD) than men. This can be attributed to the elevated levels of psychological stress experienced by women during this stage of life. Although the link between stress and orofacial pain in women has been established, further research is required to comprehend the mechanisms behind this fully. This investigation aims to employ a clinically relevant rat model of TMD pain using the unilateral anterior crossbite (UAC) method. We hypothesized that females would develop greater TMD and/or widespread pain behaviors compared to males. To test this hypothesis, we attached a dental prosthesis to the front teeth, creating a crossbite. We then measured four distinct pain behaviors every week for four weeks. We detected mechanical allodynia (response to a non-noxious stimulus) at the temporomandibular joint (TMJ), periorbital region, and the hindpaw. Also, we tested thermal hyperalgesia (enhanced response to a noxious stimulus) at the hindpaw. We added a stressor (forced swim test; FST) in a different set of rats as a comparison. We report the onset of TMD pain behaviors at the TMJ at three weeks following prosthesis attachment. Before the attachment, we did not observe pain behaviors in the rat hindpaw or the periorbital region. However, following exposure to the stressor and application of mechanical allodynia and thermal hyperalgesia, we observed increased pain sensitivity in the hindpaw, suggesting the presence of referred pain. Our results also indicate that females develop more significant TMD pain behaviors outside of the primary pain area and that stress may lead to comorbid widespread pain, affecting regions of the body inferior to the TMJ. This research was funded by NIH NIDCR AREA grant DE025970.

Abstract Name: Reducing Fatalities on the Road: Georgia’s Hands-Free Law and Other Possible Solutions

It is important to know the conditions that make driving deadly. Georgia instituted the Hands-Free law in July 2018 that requires drivers to not touch their cell phone while driving. Did the number of fatal accidents or the number of fatalities in those accidents change after the law? Websites tally fatalities, but do not study how these fatalities are associated with road conditions and structures before and after the law. The purpose of this study is to address this need and to research factors that could decrease fatalities in Georgia and the nation.Data from 10,166 fatal accidents from 2015 to 2021 in Georgia from the Fatality Analysis Reporting System's website were divided into groups before and after the Hands-Free Law. Whether the relationships changed before and after the Law were considered between these two sets of variables: Weekday, Road Type (Interstates, Metropolitan, Lower Density Roads), Collision Direction, and Weather Conditions versus the Number of Fatal Accidents and the Number of Fatalities in those accidents. In addition, 39,508 fatal accidents nationally in 2021 were also considered for the relationships between these factors and fatalities. Chi-Square Tests, Analysis of Variance, and nonparametric methods were performed.Georgia findings for 2015 to 2021 included that there were significantly more fatal accidents per day after the Hands-Free Law was implemented. However, the number of fatalities within a fatal accident was not significantly changed. After the Law, fatal accidents on interstates increased. Some of the national findings for 2021 included (1) most fatal accidents and the most fatalities occur on Friday, Saturday, and Sunday, and (2) head-on collisions on interstates are the deadliest. As a result, drivers should increase caution when driving (1) on Friday, Saturday, and Sunday, and (2) reduce speeds on roads that do not have medians.

Abstract Name: Can parenting feeding practices influence fruit and vegetable consumption among Latino Children?

Background: According to the Centers for Disease Control and Prevention, during the years 2017-2022 Latino children in the US experienced the highest obesity prevalence (26.2%) when compared to other racial/ethnic groups. Parenting styles can influence the eating habits of children. Learned behaviors on how and what to eat to sustain the body during childhood become habits that remain throughout an individual's life. Unhealthy dietary intake resulting from parenting feeding practices can contribute to the obesity epidemic among children. Purpose: To examine the relationship between parenting feeding practices and the consumption of fruits and vegetables among Latino children. Methods: Cross-sectional baseline data from the Eat, Play, Go! Obesity prevention study was used. The sample consisted of 95 Latino children ages 10-13 years old and their mother's residing in Long Beach, California. Parent and child survey data were collected to assess parenting feeding practices, child consumption of food and beverages, and socio-demographics. Chi-square tests were conducted to assess the relationship between parent feeding practices and children's fruit and vegetable consumption. Results: Findings revealed children's whose parents' provided fruits and vegetables as a snack reported eating significantly higher levels of fruit compared to those who were not provided fruit. However, there were no differences in vegetable consumption based on differences in parent feeding practices. Conclusion: Parent feeding practices can influence fruit consumption but do not have much effect on vegetable consumption. Based on the results of this study, we can conclude that there needs to be more focus on feeding practices regarding vegetable consumption. Children are more comfortable and open to eating fruits than vegetables.

Abstract Name: Kakau and Mathematics: A Multicultural Perspective on Traditional Hawaiian Tattoos

Kākau (traditional Hawaiian tattoos) use geometrical shapes such as equilateral embeddings of triangles to share and preserve genealogy. It was a rite of passage for Kānaka Maoli (Native Hawaiian) from pre-Western contact until a missionary-led prohibition. In the 1970s, it was revived as a symbolic way for Kānaka Maoli to reconnect to their culture. The symmetry within kākau triangles symbolizes the ideology to live harmoniously with oneself and the world through balance. This project aims to apply mathematical concepts underlying a traditional kākau, including an analysis of symmetry, regularity, induction, and sums, in order to investigate the inherent mathematical principles in indigenous practices.Starting with the smallest triangular structure and then gradually increasing the number of levels, brute force counting methods were employed to find the total number of triangles. Each vertex was coordinate labeled in the overall structure with the number of triangles. Visuals were created to illuminate the pattern of the various sized/oriented triangles. Patterns were determined in the total count for each sized triangle. From this validated data, summations were identified that determined the total number of uniquely sized/oriented triangles per level. A generalized formula was found through the sum of these individual sums, then was tested for fidelity and used for further predictions.Future work includes analyzing 3D tetrahedral embeddings, which are the equivalent regular equilateral shape in a higher dimension. This project highlights how mathematics and indigenous culture can enrich each other and provide agency to indigenous students in mathematics education.

Abstract Name: IIRIRA and Undocumented Immigrants Pathway to Citizenship

This research paper examines how the Illegal Immigration Reform and Immigrant Responsibility Act (IIRIRA) affects immigrant’s decisions to pursue citizenship. The IIRIRA, enacted in 1996, introduced the three and ten-year bars under Section 212, which pose significant challenges to undocumented immigrants seeking legal status. This paper specifically explores the perspectives of undocumented immigrants regarding the impact of the three and ten-year bars on their path towards citizenship.To investigate this process, interviews with undocumented Latino individuals were conducted to gain insight into their experience navigating their legal immigration process. These interviews captured the narratives of undocumented immigrants, providing insights into the complexities and hardships they face in their pursuit of legal status and citizenship, including the onerous three- and ten-year bars put in place by the IIRIRA. Findings suggest that the IIRIRA's bars complicate the process of obtaining legal status for undocumented immigrants, create obstacles that lead to prolonged separation from family members, and produce economic hardships, and emotional strain. These findings emphasize the need to reform the three- and ten-year bars to keep families unified and reduce hardships for them. Furthermore, by reforming these bars, undocumented immigrants can

be offered the opportunity to naturalize, enabling them to emerge from the shadows and fully integrate into society.

Abstract Name: An Investigation into Factors that Lead to the Most Expensive Transfers in Women's Soccer

What player factors and qualities lead to the most expensive transfers in professional women's soccer today? Eyes are on women's soccer in a way that they have never been before. As viewership increases, the money surrounding the sport continues to increase as well. The highest paid transfer fee in women's soccer history occurred in 2022 when Kiera Walsh transferred to Barcelona for €470,000. What differentiated Kiera Walsh from the thousands of other professional women's soccer players, and what lead to her transfer fee setting the record high? Previous research examined factors that influence the transfer price for men's professional soccer players, but this research has not been pursued at the same degree for women's soccer. This research includes a regression analysis that investigates the effects of matches played, goals, assists, years playing professionally, inches over 5ft, and English nationality on the transfer price. Preliminary results indicate that these variables have a positive relationship with the transfer fee. Goals, assists, and matches played in the two previous years have the biggest impact on the transfer price because the best players play in more matches and goals and assists are quantitative statistics to measure impacts. With more money getting involved in women's soccer, new questions surrounding the transfer process and pricing are bound to arise. This model will assist in predicting the transfer price of a player based on the given variables, so if a player wants to transfer, they will have the power to predict their own price tag.

Abstract Name: The Prominence of Book Bans

Books have always been seen as cornerstones of knowledge and ideas. Throughout history however, people have decided for whatever reason to get rid of specific books. In some cases the books reveal knowledge better deemed dangerous. In other cases the books reveal harsh truths that would rather be silenced. The restriction of knowledge is not a thing unique to less democratic countries as it happens frequently in the United states. According to the Office For Intellectual Freedom, 3923 total titles were challenged between January 1st and August 31st across the United States. This was a 20% increase from the same reporting period in 2022 and is the highest number of book challenges since the American Library Association started compiling data over twenty years ago. The ALA notes that the "majority of challenges were to books written by or about a person of color or a member of the LGBTQIA+ community." The purpose of my research would be to preserve some of the most banned books across the United States. I would do this by first looking state by state to find the most commonly banned materials. I would split it into two categories:

materials challenged from being in public schools and materials challenged from being in public libraries. I would purchase these books and preserve them forever in crystals. Preserving the books, and presenting them in a gallery this way prevents them from being lost to time and to censorship. Showing off challenged/banned books also keeps the conversation of censorship at the forefront of conversation. Choosing the most banned materials will help bring the issue to the brains of more people as it could be from a state in which they are from or know someone.

Abstract Name: The Economic Effect of Food and Music Festivals on the Local Economy

Western North Carolina is home to some of the most beautiful views and festivals within the entire state. It contains parts of the Blue Ridge Parkway, the Tuskegee River, and quaint towns. Specifically, Highlands, North Carolina is surrounded by protected national forests that limit land development and has not been impacted by other growing retirement and vacation communities. Highlands is home to two major festivals that participants travel far and wide to. These are the Bear Shadow Music Festival in April and Highlands Food and Wine in November. These two festivals are known to bring in a large influx of tourists, making a significant impact on the local and surrounding counties. This annual boom can be measured by jobs, revenue, and even attendance. The objective of this study is to investigate the economic impact on output and employment attributable to the major festivals on the western North Carolina economy. There has been an increasing need for festival organizers to better understand their attendee profiles and spending patterns to assist in planning, marketing, and managing different types of festival events to ensure their success. This study will analyze the services provided by local businesses to the events, and dollars generated by event attendees visiting the region. Several quantitative methods will be used to collect visitor and administrative/financial data. The data collected from these two festivals will lead statical analysis to conclusions of the proposed objectives, in addition to the role of Highlands Festival Inc. The IMPLAN software and database will be used to estimate the overall economic impact of spending at the festivals. Overall, these study results will provide the regional business and residential community and state and local policymakers with a clear understanding of the Highlands Festivals' influence on the local community.

Abstract Name: Food Deserts: A Look into Food Accessibility in Southern California

Every single day individuals and families are either growing or purchasing food to feedthemselves or others close to them. Unfortunately just based off of where they live, the food theyare consuming could be categorized as either healthy or unhealthy for human consumption. Thisreasoning is controlled by institutions

and local political leaders that control how their countiesare mapped geographically based on social structure, norms, culture, and even economics. Forthe most case, cities are structured and divided into socioeconomic groups and institutions tendto fluctuate their resources to better support what group they are in. There are many factors thatgo into place how someone may get accessed to food; utilizing their own space (i.e. garden),transportation (i.e. car, bus), outside support (family, food bank), and by walking. The level ofthese factors do changed based on environmental concerns in certain zip codes people live. Inthis case, if healthier options are located in a higher socioeconomic area where publictransportation does not exist, an individual that may be affected heavier under transportationcould not have access to those healthier options. This research will outline and address theseconcerns using data collected from locals in Southern California, the 2020 US Census, andvarious descriptive data from outside research. It will address that there are institutional policiesin place that limits people to what they have easy access to. It will end by showing you data fromvarious instruments that supports this hypothesis.

Abstract Name: Evidence to Support the Use of Parent-Child Joint Reports to Assess Dietary Intake of Elementary School Children: Data Extraction for a Scoping Review

One in five US children is classified as obese, with this rate rising annually. Obesity prevention and treatment efforts include dietary changes hence the accurate assessment of children's dietary intake is important. A 24-hour dietary recall data is commonly used to assess intake but is particularly difficult among children due to developmental and cognitive immaturity levels. National Surveys such the US-National Health and Nutrition Examination Survey (NHANES) continue to use the 24-hour recall but, have specific age cut-offs for the use of a proxy for children aged between 6-11. Previous literature showed inconsistent use of age cut points for child roles in joint recalls from NHANES 2003-2014. Considering these discrepancies, a scoping review is vital for identifying literature deficiencies, ultimately providing insights to guide children's dietary assessment methodologies. There was a total of 5,868 records; 3,652 were excluded during the first round of screening based on title and abstract. Of the 2,216 full-text articles which were assessed, 1,415 were excluded, 306 were unclear without information to be excluded, 210 were from national studies databases, and 285 were included. Included articles were published in English between 1975 to 2020 with 225 classified as cross-sectional , 36 cohorts, 15 randomized clinical trials, and 9 case control studies. Information was extracted from full-texts of included studies on the rationale for the use of joint reporting as well as references supporting its use. Cited references were identified and reviewed to determine if a validation study (i.e., doubly labeled water or direct observation) was utilized. The ongoing research study so far has revealed lack of consistency on the reporting in the literature on dietary assessments in children. Overall 64% of analyzed articles lack references to validate the use of joint reporting. In those with an associated article, direct observation as a validation method was most commonly cited.

Abstract Name: Better Together :Environmental Research and Effective Communication

This creative work explores a year long research collaboration at Jacksonville University. Together, Marine Science, Chemistry, and Communication students are taking an interdisciplinary approach to a research project: Innovative Practices in Environment Research and Communication. Graduate and undergraduates explore the environmental challenges surrounding the waterways of Northeast Florida. This video project integrates scientific research with communication strategies, utilizing video production and strategic social media initiatives to effectively communicate findings and raise public awareness.Qualitative interviews with graduate student researchers serve as the foundation for the video stories, skillfully crafted by undergraduate student journalists. The collection of video narratives showcases the research journey, features in-depth interviews, on-location b-roll and the research process, and strategic social media content. By featuring on-camera interviews and leveraging the creative insight of an advanced undergraduate communication course, this collaborative project showcases interdisciplinary efforts addressing environmental challenges and fostering informed and engaged communities.The goal of these videos is to elevate public understanding of the environmental issues and inspire viewers to adopt small yet impactful changes to enhance the quality of Northeast Florida's waterways.

Abstract Name: Examining the Impact of DEI Policies on Gender Equality in Non-profit Organizations in Southern California

This study explores how DEI policies promote gender equality among non-profit organizations. To achieve this, the project will analyze a collection of current diversity, equity, and inclusion (DEI) policies for non-profit organizations in Southern California. The central research question is, "How do DEI policies in non-profit organizations address gender equality, and what is their impact on gender representation in the workplace?"Previous research has found that DEI policies are essential for creating an inclusive and equitable workplace; however, there is a lack of research looking into the specific impact of DEI policies on gender equality in non-profit organizations. This study attempts to bridge this gap by analyzing the effectiveness of DEI policies in promoting gender equality in non-profit organizations in Southern California. The research methodology for this project involves analyzing current DEI policies of non-profit organizations in Southern California. The data will be coded and categorized to capture all relevant information. It is expected that the findings of this research will provide insights into how structural and organizational barriers influence gender equality in non-profit organizations. Furthermore, the project will provide recommendations on how non-profit organizations can address these issues and promote gender equality in the workplace.The findings will be discussed in the context of non-profit management and communication studies, offering insights for practitioners working in these fields. The ultimate goal of this project is to gain insight into how non-profits can promote gender equality at work and reduce structural and organizational barriers in the

workplace. The conclusions and recommendations of this project will be discussed within the context of non-profit organizations in Southern California. They will lay the foundation for further research and policy discussions on gender equality.

Abstract Name: SLE-associated risk alleles, TASL and SLC15A4, show strong genetic synergism among lupus male subjects

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that predominately affects women, with a female-to-male ratio of approximately 10:1. However, men that develop lupus often present with more severe disease. Slc15a4, Tlr7, and TASL(CXorf21) genes all contain single nucleotide polymorphisms (SNPs) demonstrating genetic association with SLE. The proteins encoded by CXorf21 and Slc15a4 are binding partners on the surface of the lysosome, which control lysosomal pH and regulate IFN production via the TLR7 signaling pathway, a critical driver of the disease. We predict a pleiotropic interaction between these SNPs may contribute to disease risk and/or worsen disease often observed in male SLE subjects. Methods: We genotyped 63 male SLE subjects (34 African American (AA), and 29 Hispanic American (HA)) and 80 unaffected (33 AA, and 47 HA) male subjects from the OMRF Lupus Family Registry and Repository. A case-control association study was conducted on 5 SNPs TLR7(rs3853839), SLC15A4 rs1059312) (rs1385374) (rs10847697), and CXorf21(rs887369) following a qPCR TaqMan-based allelic discrimination assay. Additionally, we identified clinical phenotypes associated with these genetic interactions. Results: All SLE-affected subjects, regardless of race/ethnicity, were more likely to have both Cxorf21 (rs887369) and SLC15A4 (rs1053912) risk alleles than the control group (AA: P=0.0238; HA: P=.0037). We also found that AA were more likely to have both the CXorf21 and Tlr7 SNPs than any other group and it was associated with anti-dsDNA (P=.0486) and anti-chromatin (P=0.0007) Conclusions: Collectively, these data suggest, that SLE-affect men with both CXorf21 and Slc15a4 alleles have increased relative risk of lupus, interferon production, serositis. Add to this, in AA men, CXorf21 and Tlr7 are associated with elevated autoantibodies, thus the combinations of these alleles may contribute to worsening disease in male lupus patients.

Abstract Name: Intersectional Effects of Pell Grant Eligibility, Race/Ethnicity, and Gender on Academic

Performance.

Evidence shows various factors, including socioeconomic status, gender, race, and ethnicity, can impact academic performance. However, research is needed to examine how these factors intersect and affect academic performance. This study utilizes an intersectional approach to investigate how socioeconomic status, race/ethnicity, and gender intersect to influence students' academic performance. Participants (22.4 ± 4.5 years; 70% women, 28% men, 2% LGBTQI; 42% Latinx|e, 15% white, 37% Asian, 2% black, 4% Indigenous, PI, and mixed race) were N=412 students from a public, urban university who completed an online survey between the spring of 2022 and the spring of 2023. Descriptives, bivariates, and multivariate linear regression were run to examine differences in GPA (academic performance measure). Next, a linear regression model was used to predict GPA using a multiplicative indicator (Pell Grant*Race/Ethnicity*Gender) to investigate the intersectional effect of Pell Grant eligibility, race/ethnicity, and gender after controlling for students' age and perceived financial situation and parents' education. In bivariate analyses, we found significant differences in GPA by race/ethnicity ($F=6.95$, $p=0.0001$), perceived financial situation ($F=5.13$, $p=0.0063$), and no significant effect of gender or Pell Grant eligibility. However, an intersectional effect was evident from the multivariate linear regression model. Compared to white males, with no economic disadvantage (Pell Grant recipients), Latinx|e males who received a Pell Grant had significantly lower GPAs ($\beta= -0.66$, $p=0.045$). The intersectionality framework posits the need to examine the multiplicative effect of various socially disadvantaged positions and identities to identify more effective interventions to improve academic outcomes and reduce inequities in education. Results from our study support these claims and highlight the need for such analysis to identify specific groups needing additional services when entering college. Our results suggest that targeted services to Latinex|e male students who are Pell Grant recipients may reduce inequities in higher education.

Abstract Name: "Missing Education: A Critical Analysis of the Systems influencing Public Education"

Philosopher and psychologist John Dewey accurately identified the pivotal role education fulfills in maintaining a democracy. Yet, as many have noticed, our schools do not appear to be preparing children to be responsible members of our society. Why do our schools fail us and our communities? This research examines the elements of public education systems that hold schools back from preparing students for college and career success. Such elements include Common Core, teacher training, teacher expectations, and distribution of resources. Using insights from John Dewey, Maria Montessori, and Jean Piaget, I argue for the de-standardization of individual schools as a means of allowing greater exploration in education with the goal of meeting the needs of diverse communities. If we want the next generations to be responsible members of our society, we have an obligation to prepare them for that role.

Abstract Name: Effects of Green Projects on the Rate of Suburban Gentrification in the BIPOC Community

Marginalized community members a part of the BIPOC community struggle in inner urban and suburban settings. From a lack of political to socioeconomic representation, BIPOC members are overshadowed by new projects proposed by politicians who advocate for the priceless benefits of sustainable ecodesign. The question is at what cost do these projects overshadow the voices of the surrounding community. There are five key categories to respond to the question using a combination of case studies, political studies, and scoping literature reviews. Already historically marginalized community members are being pushed from their inner city homes to the outskirts in suburban towns where they have to reestablish their roots. Using a combination of input from community members, responsible politicians, and these green projects, urban communities can balance the onset of modernization and culture that makes a community so strongly knit. The intersectionality between green urbanization and the marginalized has gone long unaddressed. The potential of green projects to help the community and the environment exist as long as marginalized members are included in the conversation and decision making process. The goal three fold: to achieve social sustainability when maintaining or improving the wellbeing of people and future generations; to achieve economic sustainability by practices that support economic growth without negatively impacting social or environmental aspects through deception; to access environmental sustainability or “green” status by ensuring that the environment is looked after by reducing waste and increasing biodiversity for the long run. Reversal of the damage is impossible yet community members deserve their earned space. Acknowledgement and accountability are important to reestablish trust within the BIPOC community and to save mother nature.

Abstract Name: Mathematical Modeling of Immune Response to SARS-CoV-2

In response to the profound impact the COVID-19 pandemic has had on society, the mathematics and broader scientific community has focused considerable research efforts to understand the spread of the virus. Despite a tremendous volume of research in this area, how the human immune system responds to SARS-CoV-2 has not been yet fully understood due to limited analysis of the experimental or clinical information to date. Mathematical models that account for the interaction between SARS-CoV-2 and the human immune system will improve the scientific community's ability to analyze the vast amount of data available. We develop a mathematical model for the immune response to SARS-CoV-2 to investigate the role of various molecular pathways in successful viral clearance and the key mechanisms responsible for disease severity exhibited by some patients. Specifically, our in-host model explicitly represents the interactions between the virus, innate immune cells, and selected cytokines. These interactions are formulated in a system of coupled ordinary and delayed differential equations. We conduct parameter estimation based on experimental data from literature and investigate model behaviors via computational simulations. Using this model, we use sensitivity analysis to determine the implications of variation of parameters. Our model demonstrates key aspects of the immune response to SARS-CoV-2, specifically its sensitive pathways, which might be responsible for disease severity exhibited by COVID-19 patients. This could be used to identify several therapeutic targets that would provide

hypotheses to be tested clinically, thus, serving as a foundation for the development of evidence-based therapeutic strategies.

Abstract Name: African Lion (Panthera leo) Affectionate Behaviors in the Ngorongoro Crater and Serengeti National Park, Tanzania

We were interested in affectionate behaviors displayed by the African lion (Panthera leo) in the Ngorongoro Crater and Serengeti National Park, Tanzania. We hypothesized that there will be a difference in frequency of affectionate behaviors in African lions living in the Ngorongoro Crater and Serengeti National Park. Based on this hypothesis, we predicated that lions living in Serengeti National Park will display more affectionate behaviors due to the lack of food-related stress. Data was collected over the course of five days (May 24th to May 29th, 2022) by driving through the parks and observing lion prides for a 30-minute observation period.Behaviors observed included rubbing, licking, head-butting, head-resting, and nestling. In total, 11 lions in Ngorongoro Crater and 15 lions in Serengeti National Park were observed. A Chi-square Goodness of Fit test was performed, and the data suggests that there was a significant difference in the frequency of affectionate behaviors in African lions in Ngorongoro Crater and Serengeti National Park ($x2 = 4.67$, $p = 0.03$). These results suggest that prey scarcity influences affectionate behaviors displayed by lions. Overall, this research contributes to the general knowledge pertaining to African lions and their social behaviors.

Abstract Name: Oxpecker (Buphagus spp.) Abundance and Host Species Preference in the Serengeti Ecosystem

We were interested in host species preference among the red-billed oxpecker (Buphagus erythrorynchus) and the yellow-billed oxpecker (Buphagus africanus), as well as their overall prevalence in Ngorongoro Crater and Serengeti National Park, Tanzania. We hypothesized that there would be a difference in the host preference in relation to the presence of a mane in Ngorongoro Crater and Serengeti National Park. We compared our data results to results published by Koenig (1997). We also hypothesized that there would be a difference in the number of oxpeckers between the Ngorongoro Crater and Serengeti National Park. Based on these hypotheses, we predicted that oxpeckers would prefer ungulates with manes as hosts, and that oxpeckers will be more abundant in the Ngorongoro Crater due to drought in the Serengeti that caused a decrease in tick abundance. Data was collected over the course of five days (May 24th to May 29th, 2022) by

driving through the parks and observing oxpecker host species within a 50-meter radius of the jeep. The number of hosts were tallied, as well as the number of oxpeckers present. Data analysis was conducted using a Chi-square Goodness of Fit test. The data suggests that there was a statistically significant difference in oxpecker host preference regarding the presence of manes (x2 = 21.014, p = >0.001, df = 2743). Additionally, there was a statistically significant difference in oxpecker abundance between the Ngorongoro Crater and Serengeti National Park (x2 = 7.05, p = 0.007, df = 46). Overall, this research contributes to the general knowledge regarding the behavior of red-billed and yellow-billed oxpeckers, as well as individual host preferences in Ngorongoro Crater and Serengeti National Park.

Abstract Name: Herb Lubalin: A Typographer for the Ages

Herb Lubalin was a graphic designer in the 1960s that could be inspirational or controversial because of his work. This paper strives to show the dichotomy with how a designer who shows great work could be considered controversial during his time, but great with a modern view. There is a brief biography of his life talking about how he got to where he was before he became a well renowned designer. Diving into Lubalin's life and overall portfolio is to show how people now speak about his legacy to this day. This paper goes deeper into the context of his work during his golden years of his work, and how the public viewed it during the time, which was not pleasant for the most part. The only reason he wasn't viewed with a nice light was because he considered himself a liberal in a predominately conservative society. He also kept company with a man who was later arrested for his "outrageous" liberal ideas such as posting a mixed-race couple in a magazine in the 1960s. However, with time, society has changed with the years as well as political opinions. While going over obituaries and reflections that today's designers made today can show how much of an influential legacy that he has left behind despite his skewed relationship with society before. With all this information, it's easy to surmise that the difference in generations can change a person's reputation over time. This is supported by the fact that the few designs Lubalin made were considered taboo in the 1960s are now celebrated today and boost the designer into a better light than he had before.

Abstract Name: Mirror, Mirror, on the Big Screen

Film is one of the most common art mediums people observe on a regular basis, and often times, themes in popular films reflect a population's cultural and political developments. This project aims to analyze how films reflect themes of North Americanization in Colombian culture in the last five years. Previous scholars address how films portray cultural changes and, further, how films often imitate contemporary political developments. Additionally, many researchers use film as a medium to study changes in social trends and common behavior patterns to show the influence of the film industry on a population. For this project, content analysis and thematic coding are the primary methods for data analysis, and I will be reviewing the films while paying attention to scenes exemplifying North Americanization in Colombia. The specific terms to define North Americanization come from a collection of articles discussing the North Americanization of Latin America, and the juxtaposition of the terms to the data from content analysis allows for an informed conclusion regarding the reflection of political themes in film in Colombia. The analysis would likely show how North Americanization has affected the culture in Colombia deeply enough for films to reflect the change. The analysis of films also allows for insight into the larger scheme of cultural change, as the arts are often a reflection of life when it comes to the portrayal of political themes and culture.

Abstract Name: Afro-Fashion: The Legacy of Black Culture, Creativity, and Clothing

For centuries, Black culture has influenced the fashion industry. Yet, the individuals and trends set by the culture have been overlooked, downplayed, or even discredited. In this study, we developed a vehicle of research that will explore and discuss black culture and experiences that influence the fashion community. Beyond the apparent intersections of fashion and culture, this research will also examine psychological variables that have shaped the relationship between the Black community and fashion. To begin, we gathered information about the history of mainstream fashion and the tools required to advance the industry. We then explored the relationship between enslaved Africans, indigo, silk, and cotton. From there, we started investigating which creative fashion trends and influences related to Black culture. After collecting that data, we concentrated our research on Black people who had a significant impact, paved the way, or were underappreciated in the fashion industry. Concentrating on those individuals, we examine their lives in fashion and psychological elements that shaped their cognitive processes and behaviors. Lastly, we conducted personal interviews with 10 participants, asking them questions such as: Briefly state what was your inspiration behind your outfit. Do you believe black culture influences fashion..if so, how? Name some of your favorite fashion designers, stylists, or brands (if acceptable). In one word, describe black culture. We asked the interviewees if they were familiar with any of the designers or influencers listed on our

questionnaire. After conducting these interviews, we found that many participants believe Black culture influences the fashion industry and can expand upon their reasoning. Participants can also name their favorite European fashion brands but failed to recognize many of our questionnaire's Black designers or influencers. This study was critical because it shared, enhanced, and acknowledged the impact of Black experiences and culture on the fashion industry.

Abstract Name: The Effects of Stigma Against HIV and Tuberculosis on Patient Mental Health and Healthcare-Seeking Behavior in Dharamshala

HIV and tuberculosis are highly impactful diseases in India, causing severe morbidity, mortality, and suffering for millions. The stigmatization of these diseases unnecessarily exacerbates suffering for those afflicted and their families, compounding to the existing physical and emotional burden of diagnosis. Individual interviews with healthcare workers were conducted at Delek Hospital and the Tibetan Children's Village in order to identify the existence and effects of stigma in the Tibetan refugee population in Dharamshala. Respondents reported an extremely high burden of tuberculosis in the community, complicated by the refugee status and unique infrastructural challenges of the population. The burden of HIV in the community is remarkably low, although it may be underreported. All healthcare workers noted the tangible influence of stigma, yet many believed that stigma has decreased as the disease has become normalized. Respondents reported highly detrimental consequences to patient mental health as a result of both disease diagnosis and stigmatization, ranging from elevated anxiety and depression to isolation and suicide. Finally, stigmatization of both tuberculosis and HIV are connected with four major behavioral consequences in patients: delayed healthcare visits, resistance to disclosing their diagnosis, traveling to far-away hospitals, and refusal to follow treatment regimens. Stigmatization, and its consequences to patient mental health and disruption of healthcare-seeking behaviors, serves as a dangerous barrier to effective public health interventions and disease elimination in Dharamshala.

Abstract Name: Development of Coffee Toothpaste to Inhibit Growth of Cavity-Promoting S. mutans

Dental caries is a major public health issue that affects all humans. A previous study by Antonio et. al reported a 4-log reduction of Streptococcus mutans (S. mutans), one of the primary bacteria involved in dental caries, after treatment with a Coffea canephora (C. canephora) extract (Barma et. al, 2021). This study indicated that the plaque-fighting benefits of C. canephora are only available in black coffee, without the

added cream and sugar that many coffee lovers enjoy. Coffee drinking and the use of toothpaste are morning rituals for many people. To help consumers reap the potential dental benefits of coffee in an alternative manner, would it be possible to include a C. canephora extract in toothpaste? In order to answer this overarching question, we must first ask, does C. canephora have bactericidal effects when interacting with S. mutans biofilm? One concentration of brewed green and three concentrations of light roast, as well as ten concentrations of instant coffee were used to find trends in coffee concentration and S. mutans colony count. As the concentration of light roast coffee increased, the colony-forming units of S. mutans decreased. The Minimal Bactericidal Concentration of instant coffee with S. mutans was 255 g/L. The Minimum Inhibitory Concentration (MIC) of instant coffee was also found in the 55 g/L concentration. Specifically, S. mutans was inhibited when the 55 g/L concentration was diluted to contain 5% instant coffee and 95% saline solution. The next steps include replication in triplicate to create a standard curve of coffee concentration and colony-forming units. After confirmation of these results, experiments will be repeated on model tooth substrates to find the optimal concentration to put into toothpaste.

Abstract Name: The Future of Artificial Intelligence in Medicine

Artificial intelligence (AI), the simulation of human intellect and problem-solving by machines, is a rapidly developing field with an ever-increasing number of applications in a large number of domains that affect the human experience. AI's share in the global healthcare market size is expected to grow 37.5% between 2023 and 2030. This increased incorporation of AI into healthcare is expected to cut costs by $150-$200 billion yearly. These reasons have caused AI to come to the forefront of conversation in healthcare. The potential utility of AI has been highly touted but there are also increasing concerns about its limitations, negative side effects, and unethical applications. This panel will confine its focus to the current and potential future use of AI in the medical field. AI has already made significant contributions in the fields of drug design, genomic analysis, big data epidemiological analysis, electronic record keeping, and differential diagnosis using medical images. AI can assist physicians in diagnosing patients as exemplified by the use of "ProFound AI," an FDA-approved software, that analyzes mammography images and gives a second opinion on breast cancer cases. The application of conventional neural networks in developing deep learning algorithms is particularly advanced in the field of radiology and has resulted in highly-accurate detection rates, that have the potential to transform telemedicine. Through focusing specifically on the use of AI in medicine, a topic that has been in discussion by the National Institute of Health since 1975, we hope to address the challenges and limitations of AI in general.

Abstract Name: Manipulation of chromatin structure to modulate cardiac pathology

Cardiac pathogenesis comprises complex phenotypic changes underpinned by alteration of gene expression. These transcriptional changes have been extensively studied, but how chromatin structural remodeling facilitates transcriptional responses remains unknown. A versatile player in genomic structural organization is the chromatin protein CTCF. Cardiomyocyte-specific depletion of CTCF promotes significant changes in chromatin topology, resulting in heart failure. To study whether restoring CTCF levels can reverse the KO phenotype through the re-establishment of both the pathological chromatin structure and transcriptional profiles, we designed a viral vector to specifically express CTCF in cardiomyocytes. Western blot from CTCF KO animals showed increased CTCF levels two weeks after viral injection with a sustained peak in expression to five weeks. Echocardiography experiments demonstrate that reintroduction of CTCF into failing CTCF-depleted mouse hearts rescues the pathological phenotype of the animals. This improvement is characterized by sustained progress in ejection fraction and left ventricular chamber size. Heart weight to body weight ratio confirms the reversion of cardiac hypertrophy five weeks after injection. RNA-seq experiments performed at week five after AAV9 injection detected numerous differentially expressed genes with opposite transcriptional behavior depending on CTCF levels. To also test the hypothesis that rescue of CTCF levels ameliorates cardiac disease through genomic reorganization, we examined chromatin architecture by performing Hi-C. Principal component analysis demonstrates that CTCF restoring remodels chromatin architecture to resemble healthy myocyte chromatin. Taken together, our experiments demonstrate that modulation of CTCF levels is a novel and realistic approach to regulate cardiac phenotype and, consequently, ameliorate heart failure.

Abstract Name: Exploring Pi and Infinite Series: A Journey Through the Mathematical Canon

The number pi has been expressed in different ways. Various publications from 2022 and 2023 have proposed some new expressions that have been echoed in a problem published in the most recent issue of The College Mathematics Journal, by the Mathematical Association of America. The work presented here introduces a novel development of one of these expressions, involving an infinite sum of discrete probabilities curiously resulting in the reciprocal of pi. Our development extends the methodology introduced by the pioneering works of D.H.Lehmer and Narendra Bhandari to bridge the gap between discrete and continuous mathematics. Our proof is anchored in the well known generating function of the central binomial coefficients, which, upon elegant manipulation, is discovered to hide the classic Wallis' integral. Wallis' integral, a seminal result in calculus and series analysis, is used in our proof to cement the relationship between the discrete series and the classical mathematical constant pi. The work presented here also discusses previous literature. In doing so, we converse with Pascal and Wallis. We also discuss the timeless beauty and interconnectedness of mathematical concepts spanning centuries as we comment on concepts that we

encountered in the path to our solution, such as the Wallis product, Euler's infinite product for the sine function, the gamma function and double factorials. These concepts emerged from our work in the proof, although they were eventually found to be not necessary. In our presentation we will ask you to join us in this conversation and learn about our discoveries around the iconic mathematical constant pi.

Abstract Name: Impacts of Exposure from Per- and Polyfluoroalkyl Substances on the Infant Gut Microbiota

Per- and polyfluoroalkyl substances (PFAS) are a group of chemicals widely used in consumer products which lead to adverse health effects in humans. Exposure occurs through dust, drinking water, and food. PFAS degrade slowly and therefore can cause long-term contamination of both humans and the environment. Health effects of PFAS include developmental delays in children, reduced immunity, and interference with hormones. PFAS levels in human milk have been positively associated with decreased diversity in the gut microbiome of 1 month old infants. To study the impact of PFAS contamination in Michigan, 79 mother-infant dyads provided samples of one to four month old infant stool and answered questionnaires. Questionnaire responses were analyzed to estimate PFAS exposure. DNA was extracted from stool samples, and sequencing of the v4 region of the 16S ribosomal RNA gene was performed to characterize the bacterial alpha and beta diversity. Regression was performed to determine associations between PFAS exposure and infant gut microbiota characteristics. Of 39 infants fed at least some formula mixed with water, 44% drank formula prepared with bottled water and 38% drank formula prepared with city water. Of the 59 infants at least partially breastfed, 52 mothers drank at least some tap water in the 3 months preceding stool collection. 69% of these mothers report public water supply as their primary source of tap water. 29% report a private well. Approximately 39% of participants live in counties with ≥ 9 groundwater/drinking water testing sites that detected PFAS levels greater than the standard. Since gut microbiota membership is established early in life, knowing which exposures alter the composition of this microbiota is crucial to ensure optimal child development. The results of this project will further our understanding of the impact of PFAS on the gut microbiota during this crucial developmental time point.

Abstract Name: The Effects of Social Media on the Teenage Demographic

There is no question that social media is on the rise, but it may be too much for young brains to handle. This video was done as a Digital Artifact that demonstrates these possibilities. Teenagers are one of, if not the largest, demographic of users on social media. Up to 95% of youth ages 13-17 report using a social media platform, with more than a third saying they use social media 'almost constantly' (U.S. Department of Health and Human Services, 2023). The brain finishes developing in the mid-to-late 20's, so their overuse and oversaturation of content may be detrimental to their mental well being. Additionally, between the ages of 10 and 19, teenagers undergo a sensitive period of brain development, including the appearance of mental health challenges. So, if a child is exposed to constant social media during this period, it can easily trigger mental health issues. It has been found that children who spend more than 3 hours a day on social media face double the risk of mental health problems (U.S. Department of Health and Human Services, 2023). With mental health issues being on the rise, it is important that teenagers are exposed to the definition of 'mental health'. This has been proven to not be well known in teenagers through a study done by researchers Michelle O'Reilly, Nisha Dorga, and Paul Reilly in 2016. They gathered a number of children and asked them a number of questions, one being their definition of mental health. It was surprisingly found that a majority of the participating children were unable to clearly define 'mental health' correctly. Because social media is one of the main sources of communication for teenagers, it can be argued that it is one of the main reasons for mental health issues within their demographic.

Abstract Name: Assessing the emotionality of Black and Brown Students regarding Intelligence Testing and the effect on perceived Self Efficacy

Students' perceptions of giftedness and intelligence differ immensely across the nation. When assessing intelligence and giftedness, Black and Brown students are most negatively affected by the cultural biases in the testing process. Twenty-four Black and Brown children between the ages of 8 and 18, with an average age of 11, were interviewed at the James T. Anderson Boys and Girls Club. They were asked about their perceptions of what it means to be smart and their cultural definitions of giftedness. Qualitative coding of the interviews was conducted, and frequencies were obtained for the following ideas: perceptions of what makes people smart, cultural definitions of giftedness, and children's perceptions of parental preferences for what they should learn. Children believed that they could become smarter with effort. Themes about the acquisition of intelligence were as follows: learning, paying attention, being smart, using knowledge, life

skills, and racial or ethnic identity and ancestry. Of the children sampled, there was an even representation of those placed in on-level and gifted programs. The majority of students felt neutral about their academic placement; those who did not were more likely to feel positive than negative. The findings indicated that children believe paying attention and being smart was the most important part of intelligence, whereas their parents mostly wished for them to develop academic and life skills. There is a congruency between the children's beliefs and perceptions of their parents' beliefs. Ancestry and ethnic identity may be essential elements in shaping minority children's perception of intelligence.

Abstract Name: Service Utilization among Chronically Unhoused Individuals in Northwestern Wisconsin

Service Utilization among Chronically Unhoused Individuals in Northwestern WisconsinThe purpose of this research project is to examine the type, frequency, and cost of social service utilization among chronically unhoused adults in one semi-rural Wisconsin community. A number of researchers in the United States and Canada have examined this topic, but the majority of research has occurred in urban rather than rural or semi-rural areas.Two modes of data collection will be used in this study: the Timeline Follow-Back Method (TLFB) and a review of service utilization records. The Timeline Follow-Back Method relies on respondents to retrospectively self-report how many nights they have spent in a homeless shelter, inpatient medical or mental health facility, or jail during a 365 day period. In addition, respondents are asked to recall how many times they met with a social service provider, medical provider, or public defender in the past 365 days. Respondents are also asked to sign releases of information for local medical and social service facilities in order to allow the research team to capture any additional information about service utilization that the respondent may not have been able to recall during the TLFB interview.A total of 20 individuals are slated to participate in the study from December 2023 to February 2024. These individuals were referred to the research team by the primary agency serving unhoused individuals in the focal community. The information gathered via the TLFB interviews and review of records will be analyzed to determine the average yearly per respondent cost as well as the aggregate costs for the group.

Abstract Name: Integrating Classical Music Into the Elementary Classroom

Elementary music should expose children to a wide range of musical experiences. Some of those, such as pop music, are easy to incorporate into lessons due to their fun nature but many educators struggle when considering how to effectively teach music from the classical canon. Most students think it is "boring," and

the overwhelmed music teacher might just give in to their whims. However, teachers who think this way are robbing their students of the enrichment these masterworks provide. Still, educators must be strategic about how they implement them in the classroom. Sitting still for an hour while listening to a Brahms symphony might just reinforce students' negative perceptions about this music. By utilizing movement, mutual orientation, and musical instruments, teachers can get students to engage and relate to classical music in a whole new way, transforming their future and revitalizing the genre for a new generation of listeners to enjoy.

Abstract Name: Computational studies of uranium terpyridine derivatives for potential nuclear waste applications

Nuclear power promises the future of energy production in the world. While it is an environmentally friendly replacement for fossil fuels, nuclear energy production presents the problem of creating long-lasting nuclear by-products. These nuclear waste products contain radioactive uranium which can serve as a significant environmental threat. To this end, nuclear waste treatment is an active area of research with many challenges such as the removal of radioactive uranium metal from nuclear waste. Designing selective uranium metal binding agents (chelating agents) can be a potential solution to this problem. Our research is focused on computational studies of uranium chelating agents based on terpyridine ligand derivatives. In this work, we present the molecular structures, electronic and substituent effects, and reaction free energies of uranium terpyridine complexes to aid in designing highly selective nuclear waste treatment agents. Geometry optimization and thermodynamic properties of the uranium compounds in the gas and solvent phase were calculated using Gaussian 16 software at the density functional level (DFT) of theory using the PBE0 method. Average uranium-nitrogen bond distances in terpyridine derivatives increase with increasing the electron-withdrawing nature of the substituent groups (with a maximum bond variation of 0.0162). An opposite trend was observed for the average uranium-oxygen bond distance in water molecules bound to uranium. The free energy variation in the uranium ligand coordination reaction does not follow the variation of electron-withdrawing trend. The free energies varied by roughly 1050 KJ/mol, with the lowest value, 682.63 KJ/mol coming from the nitro substituent group and the largest from the brominated complex at 1732.83 KJ/mol. The solvent phase calculations followed the same trends.

Abstract Name: A Novel Artificial Pancreas System for People With T1D

Approximately 1.6 million Americans are suffering from type 1 diabetics (T1D), and despite the proven

clinical benefits, many T1D patients hesitate to use artificial pancreas (AP) systems due to the burden of carrying an on-body insulin pump. Addressing this issue there is a pressing need for insulin delivery systems with reduced “form-factors” and other “user-centric” features to increase the greater adoption of such devices in the T1D community. To this end, we propose an innovative concept of a magnetorheological (MR) peristaltic micropump designed to offer a compact, lightweight, portable, wirelessly controllable, durable, and low-power insulin delivery system. This study employs physics-based 3D simulations conducted using COMSOL Multiphysics software, integrating the Magneto-Fluid Solid (FSI) Interaction model to evaluate the performance of the proposed MR-μPump. Our computational findings indicate that the MR-micropump can transfer up to 1.99 μL of fluid in a single pumping cycle, achieving this flow rate within 0.41 seconds with a magnetic field strength of 0.15 T. This system can be integrated into a wearable patch, including the flow chamber, flow sensors, drug reservoir, and electromagnets. Beyond insulin delivery for T1D patients, the versatility of this micropump extends to a wide range of applications, including transporting blood in artificial organs, organ-on-chip applications, and enhancing micro-cooling devices. This research presents a promising approach for addressing the reluctance of T1D patients to adopt AP systems by providing a user-centric, miniature, and highly efficient insulin delivery solution. Moreover, the versatile use of MR-micropump in different areas highlights its importance in improving both medical technology and micro-fluidic systems.Keywords: Type 1 diabetes (T1D), Artificial pancreas (AP) systems, Magnetorheological (MR) peristaltic micropump, Insulin delivery, Wearable patch, Microfluidic systems

Abstract Name: Polymer Flow Atomization with a Counter Flow Nozzle

Polymers’ tendency to stay in their molecular chains makes flow atomization difficult. As there becomes a need for more advanced materials and processes, there will be a greater demand for polymer sprays in the medical, aeronautical, and automotive industries to name a few. A process called effervescent atomization has been shown to be effective in breaking up the flows of fluids by introducing a gas flow through implementation of a counter flow nozzle[1]. The purpose of this experiment is to determine the effectiveness of effervescent atomization in atomizing aqueous polymer solutions by analyzing the size of the atomized droplets. A trial case of pure water has been taken as a baseline.The intention is to collect six water/Polyethylene Oxide (PEO) solutions using molecular weights ranging from 100E3 Kg/Kmol to 4000E3 Kg/Kmol. These six solutions will be mixed at a PEO concentration of 0.15% by weight. The liquid for every solution will have a fixed flow rate of 60 mL/min. Calculations have been made to determine the gas flow rate of five air-liquid ratios by mass (ALR) with a range of 0.2 to 1. Air is the gas that will be used in the nozzle. A camera, along with the image processing software ImageJ, will be used to determine the Sauter mean diameter (SMD) and the SMD values will be plotted against the ALR values. Each PEO’s molecular weight will be a different data series. An analysis will then be made for the plot and values. This analysis will include a comparison to previous studies by Geckler[2], Broniarz-Press[3], and Hermosín-Reyes[4]. Discussion will also include the applicability of the nozzle in real life applications, considering the experimentally determined upper limit of molecular weight which can still be atomized.

Abstract Name: Kinetics of H2 Reduction of CO/CO2 to Methanol on Commercially Available Cu-ZnO Catalyst

Methanol is a commodity chemical of great industrial significance, with over 100 million metric tons produced per year, primarily by the hydrogenation of CO over Al2O3 supported Cu-ZnO catalysts. Despite its importance and its history of over 50 years of use, the reaction is poorly understood, with the active phase(s)/site(s), mechanism, and relative role of each metal remaining unclear. Further, though hydrogenation of CO2 to methanol is also thermodynamically allowed, it is strongly kinetically limited with current catalysts. As captured CO2 becomes increasingly available as a feedstock for chemical processes, greater understanding of traditional methanol synthesis is vital to development of new catalysts that will permit economically viable conversion with CO2 as the feed, since high operating temperatures reduce the already equilibrium-limited conversion. Using a custom-built reactor system, we have examined the effect of feed and process conditions on methanol formation with a commercial Cu-ZnO/Al2O3 methanol catalyst. The rate orders of CO and H2 have also been computed from reaction data, with implications for the rate-determining step of the reaction. Addition of small amounts of CO2 to the feed significantly reduce conversion, suggesting competitive adsorption between CO and CO2; temperature programmed desorption (TPD) of spent catalysts support this premise. Finally, temperature programmed oxidation (TPO) of spent catalysts have also indicated catalyst fouling has occurred during reaction and that the foulanst are hydrocarbon and elemental carbon. These results lay the groundwork for gaining a deeper understanding of traditional methanol catalysts and pave the way for the development of a new generation of catalysts that will permit selective conversion of CO2.

Abstract Name: Bumper Stickers: America's SoapBox on Wheels

Today bumper stickers are a driver's way of communicating and sharing ideas on the road. However, when these stickers were first used in the 1920s it was for practical uses such as advertising. Surprisingly there is a strong correlation between cultural events and the design of bumper stickers you see throughout the years. Bumper stickers, and other ephemera, became a key part of political campaigns starting around the 60s. While the value and goals of these political stickers have changed over time, the design within them has not changed drastically due to their effectiveness. Bumper stickers have also been seen at the forefront of many protests. Many of these protests surround civil and human rights and were often made by those who were protesting rather than a manufacturer. Like many things in life, these movements had those who opposed them. However, the interesting thing in the case of bumper stickers is that: those who opposed them often made stickers similar to the ones who they opposed. For example, the Black Lives Matter (BLM) and All Lives Matter (ALM) bumper stickers look the same besides the swapping of “black” with “all”. One of the main reasons for doing this is the effectiveness of the design that is being ripped off. Another type of bumper sticker that has become popular in the last 10 years is stickers surrounding irony. Gen-Z has brought irony,

post-irony, and meta-irony into the mainstream, and now the road. Most of these stickers showcase “bad design” and satirical nonsense, which in itself is ironic. Whether they advocate for causes, express political views, or are simply nonsensical, bumper stickers allow our vehicles to be public forums, showcasing our beliefs to all on the road.

Abstract Name: Urban Heat and Cool Island Effects on Aerosol Microbiome Assemblages

Aeroecology is an emerging field that aims to understand the ecological function of the aerosphere. While the term was coined in 2008, its roots can be traced back to World War II when radar technology was recognized for ecological research. Aeroecology has gained attention due to its potential in studying pollution, disease, crop damage, and pest control. The atmospheric environment consists of biotic and abiotic components that influence aerosol microbiome composition. However, more research is needed to characterize bioaerosols and understand their dynamics in the face of climate change. Our study examines the impact of urbanization, particularly heat and cool island effects, on airborne microorganisms. We hypothesized that aerosol microbial richness, diversity, and evenness would vary with the time and location of heat and cool island effects. In La Verne, we observed changes in microbial richness in relation to the time and location of heat and cool island effects, but microbial diversity and evenness remained unaffected by these independent factors. Notably, the south campus of the University of La Verne exhibited the highest aerosol microbial richness, whereas Las Flores Park displayed significant changes in aerosol microbial richness between the (morning) urban cool island effect and (afternoon) urban heat island effect. Our findings emphasize the need for further research on aerosol microbiome dynamics in urban environments to better understand their impacts on human health and the environment, contributing to sustainable urban planning.

Abstract Name: Exploring the Unique Reactivity of Unsaturated Isocyanides

Isocyanoalkenes are functionalized isocyanides that facilitate the efficient synthesis of pyridines, imidazoles, and peptide nucleic acids. They have the potential to act as precursors for numerous bioactive compounds, including the antibiotics Isocyanoindole B371 and Xanthocillin X derived from Penicillium notatum. The purpose of our research is to explore the largely unknown chemistry of a specific isocyanide-based functional group— the bromoisocyanoalkene. Due to its reactivity being relatively underdeveloped, we want to discover how the compound acts in a chemical environment to learn more about its reaction mechanisms and how its unique chemistry and structure can be useful in the pharmaceutical world.To begin, the lab-made vinyl formamide, formed by a cross-coupling reaction between vinyl iodide and formamide, served as a precursor for generating two bromoisocyanoalkenes, each featuring distinct alkyl and aryl substituents. One substrate was cyclic, while the other had an OBOM group at the ortho position of its phenyl ring. Upon treating the bromoisocyanides with NaSH, we found out that the compound was converted to thiazole. The reaction pathway presumably underwent a sequence of elimination, addition, deprotonation, cyclization, and protonation reactions. The OBOM bromoisocyanoalkene produced 5-substituted thiazole, and the cyclic substrate generated cyclic thiazole.Our ongoing efforts are currently directed towards further developing the NaSH addition to bromoisocyanoalkenes into a universal pathway to thiazole synthesis by experimenting with several more substrates that offer diverse electronic and steric properties. We aim to ultimately manufacture a seamless method to produce the highest yield of various thiazole products, the next being the thiazole alkaloid, Peganumal A.

Abstract Name: Telling a Story of Freedom: The Preservation and Interpretation of New Philadelphia as a Site of Public History

New Philadelphia was founded in 1836 in Pike County, Illinois, by “Free” Frank McWorter. It was the first town in the United States to be platted and legally registered by an African American. Frank McWorter, born enslaved, was in a unique position to be able to buy his own and his family’s freedom through decades of hard work. His legacy lives on at New Philadelphia, and though the town has long since vanished, it is honored today as the newest unit of the National Park Service with the designation of National Historic Site. The townsite is also honored as part of the NPS Underground Railroad Network to Freedom, as a National Historic Landmark, and the townsite and Frank McWorter’s gravesite are on the National Register of Historic Places. This history’s significance has been recognized and remembered, but how it has been remembered, and how it will be remembered in future generations, is a matter of debate. Various interpretations over the years have taken opposing positions on how the site should be cared for and how the story should be told, causing conflict among stakeholders. Common narratives tend to exaggerate certain aspects or events and favor one extreme or the other, fixating either on beauty and harmony or adversity and strife. On both ends of the spectrum, historical evidence is misinterpreted and misused—or ignored entirely. This paper analyzes what secondary source authors, McWorter descendants, and community members have said and uses primary sources, textbooks, and other scholarship to argue that the sensationalized story being told is not the factual and well-rounded history that should be represented at this site in its future as a National Historic Site.

Abstract Name: Preliminary Comparisons of Water Quality Between Waterways Within the Walnut Creek Watershed

Aging water infrastructures impact urban stream water quality. We currently study two waterways, one in the Centennial campus at NC State University (CC), which has lost much riparian coverage due to stormwater runoff and buildings surrounding it. The second waterway is at the Raleigh Wetland Center (RWW), approximately 5 miles from CC, and has poor water quality due to aging water infrastructure, erosion, and flooding. The differences between the sites were mainly due to the differences in the non-point sources of pollution. Our initial water quality parameter data (pH, conductivity, dissolved oxygen, and nutrients) has shown fluctuations in the parameter values in RWW while more steady changes in the CC creek. The objectives of this study are to develop reference indices for freshwater quality parameters using the measurements mentioned above from CC and use the reference indices to compare data of the same parameters from RWW waterways before and after the replacement of the sewer pipes. We will use existing water quality data from RWW before and after pipe replacement and continue to monitor both waterways. The result of this study will be vital to understanding the effectiveness of replacing aging sewer pipes to enhance the water quality in urban waterways. Furthermore, study findings are expected to highlight the importance of maintaining and repairing the water infrastructures in the watersheds and have important implications for policy and budget allocation of municipalities in the fast-changing world.

Abstract Name: Identification of Phenolic compounds in Bryophyllum Pinnatum leaf using different organic solvents

Bryophyllum Pinnatum (Lam.), is a perennial native plant from Madagascar and belong to the family Crassulaceae. The leaves are widely used in traditional medicine due to their biological activities for the treatment of several diseases, including inflammation, hypertension, kidney stones, gastrointestinal disorder, and other oxidative processes. The medicinal and pharmacological properties of Bryophyllum Pinnatum are attributed to the presence of secondary phenolic compounds. This study aimed to elucidate the phenolic composition of Bryophyllum pinnatum leaf extract using different organic solvent. Preparation of the leaf extracts involved methanol and ethanol as solvents. The methanol and ethanol leaf extracts were analyzed for total phenolic content using the Folin method and total protein concentration using the BCA method. Additionally, the antioxidant capacity of the extracts was quantitatively assessed using the Oxiselect antioxidant assay. Subsequently, high performance liquid chromatography (HPLC) analysis was done to

identify major phenolic constituents within the extracts. The study results showed higher total phenolic content, and total antioxidant capacity in the ethanol-based BP extract compared to methanol-based extract. Ethanol-based BP extract had elevated total protein concentration (2610.14±5.68 μg/mL) than methanol BP extract (2464.16 ±2.94 μg/mL). These results indicate that the choice of extraction solvents affects the extraction efficiency of phenolic compounds in BP leaf. HPLC analysis identified three flavonoid compounds- kaempferol, quercetin, myricetin in both methanol and ethanol extracts. The study findings demonstrated the importance of solvent selection in optimizing the phenolic profile in BP leaf for potential therapeutic application. In addition, the identification of these flavonoids compounds contributes to understanding the phenolic composition of BP and potentially correlating with its medicinal properties.

Abstract Name: Gender Earnings Inequality: Technology vs. Total Workforce

Big and famous topics, although old, need to receive attention to be re-researched carefully because under the impact of the COVID-19 pandemic, everything has become unprecedented and unpredictable. One of the topics is the gender wage gap, with a particular focus on technology and science workers because of the importance in the field's development. Using data from Basic Monthly CPS and utilizing the Blinder-Oaxaca Model, the aim is to connect relevant components (education, gender, industry, and incomes) to provide up-to-date knowledge of the research problem.

Abstract Name: A Tail of Two Fishes: Exploring Population Structure in Two Fish Species Across the Galápagos Islands

The Galápagos Islands, a UNESCO World Heritage Site and a biodiversity hotspot with high levels of endemism, is home to over 440 species of fishes. Marine conditions across the Archipelago are greatly influenced by ocean currents in the region. The Pacific Equatorial Undercurrent, South Equatorial Current, and the Humboldt Current deliver waters rich in nutrients across the three major regions within the Galápagos (northern, western, and central). These conditions create a dynamic environment close to the equator, enabling diverse species to thrive in distinct parts of the Galápagos. Despite the rich biodiversity in the region and diverse oceanographic conditions, there has been limited research examining the genetic connectivity of marine populations across the Galápagos Islands. The objective of this study is to examine population

structure in two fish species located across the three regions of the Galápagos: the southern white tail major (Stegastes beebei) and the blacktip cardinalfish (Apogon atradorsatus). These species differ in reproductive strategies and the length of their dispersive larval stage, offering a unique opportunity to study the interplay between ecological conditions, reproductive strategies, and population dynamics. Here we use restriction-site Associated DNA sequencing on 55 individuals from each species across the three major regions. We analyzed both neutral and potentially selective loci to provide valuable insight into how species adapt to their environment, which have important implications for conservation and fisheries management in the Galápagos.

Abstract Name: Triangulating Neural Correlates of Consciousness

For decades, neuroscientists have been trying to find a plausible explanation for how our subjective experience could emerge from processes in the brain. Early work by Christof Koch and Francis Crick on the neural basis of consciousness argued that consciousness can be approached empirically by identifying the neural correlates of consciousness (NCCs). Past experiments attempted to identify the NCCs using common manipulations like backward masking to interfere with conscious perception. Although the use of this method suggests many different candidate NCCs, in theory using any one manipulation alone to identify the neural processes that define consciousness is limited. It becomes difficult to determine which candidate NCCs are specific to the manipulation, and which are general properties of consciousness. The primary aim of this project is to identify more generalizable NCCs, by using a different and more innovative approach: the "triangulation" method. Using electro-encephalography (EEG) to record brain data, this approach compares the results of three different manipulations of visual perception: backward masking, dichoptic color fusion, and inattentional blindness. By triangulating across the three manipulations, we assess the overlap in putative correlates in response to the very same visual stimuli and in the same human subjects. In particular, this specific project will focus on the representational stability of neural responses to sensory stimuli as a candidate correlate to classify data from individual trials as "seen" or "unseen." The data will provide us with a unique assessment of the overlap among NCCs and allow us to identify NCCs that triangulate across all manipulations of visual perception. Using data-driven machine-learning analyses, the triangulation approach may lead us one step closer to identifying the genuine neural correlates of conscious visual experience.

Abstract Name: Comparative Analysis of Lipid Nanoparticle and Liposomal Formulations of Light-Activated Drugs for Photodynamic Therapy Applications

Photodynamic therapy (PDT) is an advancing clinical treatment for cancer therapy that employs the use of light and photosensitive molecules called photosensitizers. PDT operates by illuminating these photosensitizers with specific wavelengths of light which leads to the production of toxic reactive molecular species in target cancerous cells to eliminate them. Visudyne, the only clinically approved nanomedicine for PDT, consists of a liposomal nanocarrier loaded with the photosensitizer BPD. Since its approval, the use of Visudyne and its subsequent liposomal BPD formulations have been extensively explored for PDT applications such as macular degeneration, pancreatic cancer therapy, and imaging, and its creation has solidified it as a prominent PDT modality. Solid lipid nanoparticles (LNPs) are novel lipid based nanocarriers with prominence in nucleic acid delivery systems, such as the mRNA based COVID-19 vaccine. The LNP nanocarrier is a novel platform that has not been deeply explored for PDT. In this study, we compare this novel LNP nanocarrier with the well-established liposome, both loaded with a lipid conjugate of BPD (BPD-PC), to investigate its optical, photochemical, and phototherapeutic properties for PDT. We conducted experiments using in vitro and in vivo models of pancreatic cancer. From our results, we revealed that the LNP formulation displayed greater hydroxyl radical generation when activated with 690 nm light and higher stability observed when carrying BPD-PC, resulting in less leakage compared to the liposome. We also revealed no significant differences in phototoxicity, tumor selectivity, or tumor penetration. Most importantly, we found that LNPs were significantly more efficient at inducing immunogenic cell death when activated with 690 nm light than liposomes. These results highlight LNPs as a promising alternative platform for PDT. LNPs hold considerably more potential than liposomes for immunotherapy applications, especially in diseases like pancreatic cancer where innovative approaches are needed to sensitize the tumors to immunotherapy.

Abstract Name: Atmospheric Balloon Measurement Control Module

Weather balloons are a key part of atmospheric research and have a rich history in collecting crucial data. In the past, obtaining such data was limited and expensive due to technological limitations. However, the arrival of modern electronics optimized this field, enabling more sophisticated controllers, sensors, and increased memory on compact boards at a lower cost. These technological changes led the way for a groundbreaking project. The design of a board that can obtain atmospheric data at a reduced cost. This project focuses on the planning, redesign, and construction of an atmospheric balloon module built with modern-day equipment like updated pressure and temperature sensors, a stepper driver, and a new automotive networking development board (PIC). The main objective is to collect important data such as pressure, temperature, humidity, and residues, from the Earth's atmosphere. The balloon will ascend to altitude, providing an overview and collecting valuable data that is not easily accessible. The balloon will be monitored through the GPS unit so that it may be retrieved easily once the flight is over. To transfer and read the data, an SD card system will be incorporated into the main board. This data collection system is low-cost and will allow easy access to the information obtained while also making it user-friendly. With the construction of these new and updated

modules, we hope to pick up imperative information that will help us learn more about climatic conditions, climate change, greenhouse effect, and atmospheric composition.

Abstract Name: Communal Canons: The Importance of Digital Fanfiction

The shift from printed fanfiction to digital fanfiction in the last two decades has resulted in an “explosion” of access, the use of which is “largely removed” from the study of researchers (Hill and Pecoskie). Unlike the widespread acknowledgment and engagement of popular media such as novels and movies, the act of reading and writing fanfiction remains relatively under the radar. Infrequently discussed yet widely accessible, the databases and engagement on fanfiction sites continue to grow. Archive of Our Own (AO3) boasts a community of over 5 million users and 10 million works. Another larger platform, Wattpad, claims to have over 90 million users globally. But what is it that makes the act of fanfiction reading and writing so popular? At the very essence of the genre, is there a dominant craving that pushes people towards these communities, or is current research incapable of offering potential reasonings?Currently, a plethora of research stands to suggest and introduce various potential explorations for the appeal of fanfiction writing. Each is widely varied, though one predominant suggestion is that fanfiction stands to be a reclamation of identity, especially for marginalized groups. These works allow marginalized persons to “push back against and offer alternatives to stereotypical and normative discourses” (Black et al). Sapuridis and Alberto, on the other hand, propose that fanfiction–more specifically, self-insert fanfictions–function as a means through which “any reader who encounters it” may superimpose themselves on the narrative and live vicariously through it. However, these studies lack consideration of the thoughts of the readers and writers of the fanfictions. My presentation seeks to fill this gap. It relies and reflects on a set of anonymous, voluntary survey responses offered up by fanfiction readers and writers to shed light on the largely unheard voices of fanfiction readers and writers.

Abstract Name: Articulatory and Acoustic Effects in Verbal Responses to an Online Quizzing Task

Speech is thought to be a pre-planned action that can be held in a buffer during a conversation. Emerging work suggests the contents of this buffer can affect lip and tongue positioning, long before speech sounds are audibly produced. The objective of this study is to expand on how speech planning is influenced by conversational cues using a verbal quizzing paradigm. Our approach involved a replication and adaptation of the approach used by Bogles et al (2015), who asked quiz questions in Dutch, in an in-person laboratory experiment. This study uses a similar design in English, using American pop culture. We formulated a set of 50 questions. Each question had both an early and late version; where early cues were in the middle of the question and late cues were at the very end. This study was designed to be fully online, utilizing novel

webcam lip-tracking software. This enables the data collected to be immediately uploaded and allows participation from anywhere. The software measures the lip-movements to determine when speech planning begins in reference to when vocal responses occur. In concurrence with prior work, we expect there to be shorter verbal reaction times with the early cued questions. This expectation is supported by the acoustic data, which suggests that participant's audible responses began sooner when questions used the early cues. The analysis of articulatory data is ongoing.

Abstract Name: The Chaotic Mind of David Carson: One of the Worlds most successful yet controversial designers

Graphic designers tend to struggle with the aspect of stepping too far outside of the box. With a field that is so diverse and endless, infinitely growing and expanding; How could this ever be an issue? Because of the creative freedom that graphic design may encompass, rules have been constructed in order to limit designers to create and put forward work that clearly tells a story in an admirable way. These rules were seemingly created in hopes of avoiding designs that may confuse the public or send them the wrong message that they may not be able to correctly comprehend. Although unaware of his claimed rule-breaking, David Carson took an approach to graphic design that required no rules. He dove into open minded exploring and forever changed the world of creating. He painstakingly expanded the minds of critics, viewers, and readers of his artistic productions, permanently opening the doors of possibility to future designers. While Carson faced many difficulties throughout his career, he continued to bring expression and meaning back into type design and format, whether it be in advertisements or his own publications. David Carson was misunderstood by most and appreciated by many. He has not only proven to be a monster of an influence in the design community, but has also forever pasted his name into the history of graphic design.

Abstract Name: The Effects of Treatment with Baytril® (Enrofloxacin) on qPCR Detectable Levels of Mesomycoplasma ovipneumoniae

Mesomycoplasma ovipneumoniae (previously Mycoplasma ovipneumoniae) is a respiratory pathogen that infects domestic sheep (Ovis aries), domestic goats (Capra hircus) and Bighorn Sheep (Ovis canadensis). This bacterium can cause acute to chronic pneumonia in domestic sheep, while Bighorn sheep often develop fatal pneumonia when exposed to this pathogen. To study M. ovipneumoniae infection in a sheep model, a specific-pathogen-free (SPF) herd of domestic sheep was established in 2020 and has been routinely screened to confirm SPF status. To test the efficacy of the antibiotic Baytril® (enrofloxacin) in treating M. ovipnuemoniae infection, ten SPF sheep were randomly selected and separated equally into a treatment group and a control group that did not receive treatment. All ten sheep were infected with M. ovipneumoniae via inoculation of the nasal and oral cavities and the conjunctival sacs and were observed for four weeks. The treatment group then received Baytril® for five days subcutaneously and via nasal wash while the control group remained untreated. All sheep were observed for four weeks after treatment and then euthanized. Weekly nasal swabs were obtained from all sheep and post mortem swabs of the paranasal sinuses, trachea and bronchi were collected immediately after euthanasia. An Eppendorf epMotion 5075 robot was utilized to perform DNA extractions on the weekly nasal swabs. Subsequent qPCR of the nasal swabs showed that M. ovipneumoniae was below a detectable level one week after Baytril® administration in all treated lambs. However, 1/5 and 3/5 lambs in the Baytril® group tested positive for M. ovipneumoniae at 2 and 3 weeks post treatment. The untreated control lambs consistently exhibited detectable levels of M. ovipneumoniae. Reemergence of infection after antibiotic treatment could be attributed to presence of M. ovipneumoniae in other respiratory tract areas. Future steps include performing qPCR on the various post mortem swabs.

Abstract Name: Synthesis & Characterization of Biofriendly Pressure Sensitive Adhesives

Pressure-sensitive adhesives (PSAs) are prevalent in daily life, ranging from everyday items like sticky notes to more critical applications in the medical field, such as bandages. However, the use of nonrenewable petroleum in adhesives contributes to environmental sustainability challenges. To address this issue and promote a more sustainable future, we investigate the potential of bio-friendly, bioderived materials such as polyethylene glycol (PEG), cyclodextrin (CD) which is a sugar derivative, and lipoic acid (LA) derived from garlic, for use in PSAs. Our research focuses on creating adhesive materials with properties comparable to petroleum-based counterparts by leveraging these bio-friendly materials to form slide-ring structures known as polyrotaxanes (PR). Polyrotaxanes, featuring rings along the main polymer strand, exhibit remarkable stress dissipation and fracture resistance due to the pulley effect. The utilization of polyrotaxanes as adhesives is not a novel concept, particularly within the realm of epoxy glues. However, using biofriendly materials to synthesize polyrotaxanes for adhesives marks a noteworthy innovation within this field. We take a 3-step approach – lipoated CD synthesis, sample fabrication, and calculation of work of debonding. In the sample fabrication step, systematic variation of adhesive formulations lets us optimize the crosslinker (LCD) percentage for adhesion in ambient air and underwater. Our ongoing testing methodologies are probe-tack testing, T-peel test, response to seawater and & biomes, and underwater load-bearing assessments over varying ratios of LA:LAPR, ranging from 1:1 to 199:1. These tests mimic the parameters the adhesive encounters during its life cycle and its projected biocompatible degradation. In conclusion, our developed adhesive composition, particularly the LA:LCD formulation, holds promise as a bio-friendly and biodegradable alternative to conventional petroleum-based adhesives and will contribute to the advancement of sustainable adhesive technologies.

Abstract Name: Viability and Efficacy of Savings Groups in Shantytowns

Savings groups are used globally in both rural and urban areas in order to promote community-based savings and lending to those who lack access to formal financial institutions. Shantytowns are a unique urban area due to their peripheral urban locations and specific socioeconomic characteristics. It is known that savings groups are used in shantytowns but there is little discussion of the viability and efficacy of savings groups in shantytowns. This paper used a synthesis of literature on savings groups and studies on shantytowns to analyze key drivers of savings group formation that relate to shantytowns. Antecedents of savings group formation and success include physical proximity, social capital, and a desire for social security. These align with shantytown socioeconomic characteristics such as physical crowding, longevity of stay, and poor living conditions. This study suggests that savings groups are likely to flourish in shantytowns due to the pattern of drivers. Effective savings groups in shantytowns can lead to numerous benefits that not only include improved social bonding and economic growth from their functioning as a savings and lending mechanism but also greater political influence that can drive greater social change.

Abstract Name: Gone Phishing: A Comprehensive Study of Phishing Prevention Tactics at the University of Wisconsin-La Crosse

Higher education institutions (HEI) have become the latest target for phishing scams due to their decentralized nature, complacent attitude toward data security, and possession of hundreds, if not thousands, of individuals' personal information. One of the most widely accepted methods of protecting valuable personal data is creating a culture of cyber security throughout the institution via information security awareness education and reporting system. This project seeks to identify the extent of the University of Wisconsin's data security policies to promote digital safety and identify ways the university can improve this policy to better protect student information. I argue that UWL is not taking appropriate measures to create a culture of cybersecurity by implementing an ineffective security awareness policy that wholly leaves out one of the university's largest stakeholders: students. I will conduct a textual analysis of UWL information security policy, UW System network security policy, and messages from the school regarding phishing scams to understand how policy language and rhetoric shapes information security awareness practices at the university. I will also conduct interviews with IT faculty leaders at UWL and UW Madison to understand how current security awareness policies for the entire UW system are successful at protecting students and creating a culture of cyber security. Finally, I will consult research in the field to recommend specific changes UWL could make to their security awareness policies to ensure students are receiving the necessary tools to protect themselves. The most important weapon HEIs have against potential data breaches that would cost the

university hundreds of thousands of dollars is a confident, properly educated school population aware of the importance of online safety.

Abstract Name: The Evaluation of Equine Diets for Determination of Nutrient Deficiencies and Surpluses

Having a balanced diet is an important part of equine welfare. Unbalanced diets have been attributed to cause poor performance, behavioral issues, poor hoof and coat quality as well as failure to maintain condition. More serious issues such as colic, ulcers or laminitis can also be attributed to an incorrectly balanced diet. The aim of this study was to evaluate the diets of 32 horses using the 2007 NRC guidelines including ratios for the micronutrients. The study horses included ? geldings and ? mares with ages from 6 to 29 years. All horses were fed ad libitum first cutting grass hay. All horses received at least one supplemental source of calories, with most receiving 2 sources of supplemental calories. The amount of energy (megacalories) and nutrients each horse required per day was calculated using their current bodyweight in kilograms regardless of their Body Condition Score (BCS). We determined that 32 horses (100%) had an unbalanced diet with the most common deficiencies being in Copper (90.6%) and Zinc (96.9%). Thirty-two horses (100%) had a surplus of iron which we established as the primary cause of Copper and Zinc deficiency. Sodium deficiency was found in 15 horses (46.9%) while Chloride deficiency was found in 5 horses (15.6%). Sodium and Chloride deficiencies could be correlated with the amount of required daily megacalories a horse received from their hay, with Chloride deficiency linked with hay intake under 30% and Sodium deficiency being linked with hay intake over 50%. These trends show that the average horse likely has an unbalanced diet which could be negatively affecting performance, behavior and overall health. Additionally, hay cutting and variety can play a large role in the nutritional value of hay, which could impact horse health as hay or pasture is the majority of most horses' diets.

Abstract Name: Estimating the Price and Income Elasticities of Domestic Passenger Travel Demand for Atlanta Airport

As we all know, understanding consumers' responsiveness to price and income changes are very important concept in microeconomics. Practitioners such as operating managers of airports also need to have information on price and income elasticity estimates to perform effective revenue management. This study examined the domestic air travel market demand for Atlanta Hartsfield–Jackson Airport (AHJA) and estimated own price and income elasticities using data from the Bureau of Transportation Statistics and

Atlanta Fed. We used the Stock-Watson dynamic ordinary least square (DOLS) procedure (Stock and Watson, 1993) which improves on OLS by coping with small samples and dynamic sources of bias. As we expected, the airfare has a negative and significant impact on revenue passenger miles. Since the absolute value of the coefficient is less than 1, it indicates that own price elasticity of demand for air travel is inelastic. In other words, air travelers are less responsive to a price change. For instance, a 10% increase inairfare, reduces the revenue passenger mile by only 4.2%. Moreover, there is a significant and positive relationship between income and revenue passenger miles. The income coefficient is greater than one and hence indicates an elastic income elasticity of demand. A 10% increase in real income brings about a 22.8 % increase in revenue passenger miles.

Abstract Name: Investigating the Zebrafish-Specific Gene wu:fj16a03 as a Tool to Visualize and Manipulate Meningeal Development

The meninges are a multi-layered membranous tissue between the skull and brain, and have been implicated as a regulator of bone and brain development. However, the specific mechanisms controlling interactions between these tissues remain unclear. The zebrafish model proves useful as a unique model for this, developing outside of the mother and allowing for in depth live imaging throughout the developmental processes, but little is known currently about meningeal development in this species. Therefore, we sought to identify meninges-specific genes that could be used to aid the visualization of zebrafish meningeal development. By performing single cell RNA-sequencing of the zebrafish skull and its associated tissues, the Farmer lab identified high expression of a previously uncharacterized zebrafish specific gene known as wu:fj16a03 in meninges. In order to test whether wu:fj16a03 labels meninges in vivo, we successfully created a knock-in line using CRISPR/Cas9 to insert a nlsEOS fluorescent protein downstream of the endogenous wu:fj16a03 promoter. Preliminary imaging suggests that wu:fj16a03 expression in the meninges emerges between early larval development and adulthood. To enable manipulation of wu:fj16a03 expressing cells, we are now generating a wu:fj16a03:Gal4 zebrafish line to enable use of the extensively utilized Gal4:UAS system for future functional tests. Additionally, we are currently focusing on understanding the precise temporal and spatial expression of wu:fj16a03 during development. These experiments lay an important foundation for the Farmer lab to use zebrafish as a model to understand intra-tissue signaling critical for proper skull development.

Abstract Name: Breaking or Bluffing: Artificial Intelligence Impact on Bay Area Businesses

Artificial intelligence (AI), a rapidly developing field, has been a topic of discourse and debate in the past decades. Throughout its development, businesses find opportunity to use AI and its generated content, in numerous areas such as marketing, product development, management, and overall strategy. The paper will review AI development within the United States, and policies introduced by the US, California State, and local governments. Additionally, the paper will discuss particularly about AI usage within the healthcare industry in the Bay Area. Subsequently, there will be three types of statistical examinations on the data: hypothesis testing, analyzing the associations to understand AI impact, and data visualizations of revenue, number of employees, and stock market valuation upon significant usage of AI. The study also reviews the current literature and perspectives on AI development, and analyzes the business policies and strategies of healthcare companies using interviews. The study concludes with some implications and recommendations for policy makers, business practitioners, and academic researchers.

Abstract Name: Conservation of Key Residues Involved in Proton Pumping Pathways in Respiratory Complex I

Respiratory Complex I is the first enzyme in the aerobic electron transport chain. It actively pumps 4 H+ across the membrane by coupling their transfer to thermodynamically energy-releasing redox reactions. In Thermus thermophilus, the membrane domain that transports protons across the membrane consists of three homologous antiporter channels and the E-channel. Each channel transports one proton across the membrane. Previous studies have revealed that there are several key residues involved in proton pumping via the Grotthus mechanism in the antiporter and E-channels of Complex I . Many of these residues are highly conserved across species. However, the conservation of nearby residues within a 6 to 8-angstrom radius is not known, so it was investigated using Basic Local Alignment Search Tool (BLAST), multiple sequence alignment (MSA), and WebLogos. Individual key residues are often highly conserved, but the surrounding residues range from moderately conserved to having low conservation. Oftentimes, there is no uniform residue characteristic, with nearby residues being hydrophobic and nonpolar, reflecting the characteristic of the interior of membrane proteins. Additionally, sequence comparison of the antiporter channels showed a similarity of less than 30% with each other. However, key residues occur in the same generalized location of the channel, indicating structure is more conserved than sequence. Using the program CoeViz, covariance studies of the key residues were conducted and revealed that residues significantly covary with hydrophobic residues. However, there is no clear pattern to the covarying residues. As a future direction, the covariance matrix will be utilized for further analysis to uncover any underlying patterns. This work is supported by NSF-REU MCB 1852496.

Abstract Name: A Comparative Intertextual Analysis of Generational Haunting in Diasporic Korean and Armenian Communities

Despite the prominence of analysis on markers of generational trauma within studies of the “comfort women” and the Armenian Genocide, these markers have yet to be studied in comparison. Generational haunting in Korean and Armenian communities are marked by historic instances of state-sanctioned mass sexual violence, which was weaponized by both the Japanese Imperial Army and the Ottoman Empire. The aim of this study is to conduct an intertextual analysis of generational trauma, haunting, and the figure of the ghost in two diasporic narratives, Comfort Women by Nora Okja Keller and Orhan’s Inheritance by Aline Ohanesian, and to place these narratives within the greater historical context of the gendered violence against the “comfort women” and Armenian women during the Genocide. Los Angeles will be my site of research due to the large Korean and Armenian American diasporic communities, which together have a history of coalition work towards memorialization and commemoration. This study addresses three things: 1) the role of diaspora in addressing gendered violence and trauma within literature; 2) the significance of different markers of generational trauma and haunting; and 3) my commitment to taking a victim-centered approach and centering survivors’ agency in my study of these texts. The ghost and generational haunting reflect how silencing, denial, and erasure–which has impacted communities targeted by Japanese military sexual slavery as well as the Armenian community in relation to the genocide–have led to subsequent generations being haunted by the ghosts of those who never got to tell their stories or whose stories were denied/suppressed by denialists and revisionists. Central to this study of generational trauma and haunting is the importance of survivors’ agency; the ghost manifests in the lives of diasporic agents due to the silencing of victims’ stories and voices.

Abstract Name: Bridging Horizons: Mentor-Student Collaboration Igniting Photocatalytic Innovations for Real-World Challenges

In the field of renewable energy, semiconductor-driven photocatalysis emerges as a pioneering force, offering extensive applications in both energy and environmental domains.Understanding the effects of different crystalline structures on photocatalytic efficiency becomes imperative as it not only influences the overall performance but also provides crucial insights for tailoring and optimizing these materials for enhanced real-world applications. This research, conducted by an instructor alongside community college students, Investigating the distinctive impacts of crystalline structures is essential for unlocking the full potential of photocatalysts and advancing the development of efficient and sustainable solutions.Tungsten trioxide (WO3), an n-type semiconductor, emerges as a promising candidate due to its stability, environmental friendliness, biocompatibility, and tunable bandgap. This study delves into the synthesis of monoclinic WO3 nano cubes and rods showcasing enhanced photocatalytic activity following calcination.Expanding the horizons of this exploration, the study investigates efficient photocatalysts for environmental remediation under LED visible light. Employing a hydrothermal method, two distinct structures of WO3 photocatalysts – Rod and Cubic – undergo thorough characterization using SEM, Powder XRD, and EPR techniques. The photocatalytic efficiency of these structures, particularly the WO3-500 cubic calcined temperature, emerges as a standout performer, achieving approximately 90% degradation of rhodamine B in just 50 minutes.Noteworthy is the consistent high-performance exhibited by both WO3 Rod and WO3 Cubic

structures across varying LED intensities. EPR measurements shed the influence of calcination temperature on oxygen vacancy concentrations, while powder XRD analysis confirms the high purity and crystallinity of the WO3 samples. The study's findings underscore the pivotal role of mentor-student partnerships in transcending academic boundaries, facilitating the development of cutting-edge solutions for real-world challenges in renewable energy and environmental remediation.

Abstract Name: More than a Monolith: How the Model Minority Myth Impacts Asian/Asian-American Students' Experiences

By understanding students' social context, we can better understand and support their mathematics learning. For example, Black and Latine students' sense of belonging is related to STEM persistence (Barbieri & Miller-Cotto, 2021). However, little research has addressed math experiences of Asian/Asian-American (A/AA) students. Anecdotal accounts indicate that Asian students experience the "model minority" myth when their mathematics competence is evaluated against the stereotype of a perfect student or the "model minority" than actual performance (Blackburn, 2019). To our knowledge, there is little to no empirical research on how the "model minority" myth (MMM) impacts students' perception of mathematical experiences. In this study, we explore Asian/Asian-Americans' prior experiences with the "model minority" myth in mathematics, including understanding whether A/AAs endorse the ideas of the myth. Also, we examine how priming the "model minority" stereotype affects A/AAs math performance. Undergraduate A/AA students (N = 50) will be randomly assigned to read about the MMM or read a control paragraph before a series of simple algebra problems. Then, they will answer questions about their experiences with math, thoughts about and experiences with the MMM, and social dominance orientation. Data collection will begin in Dec 2023. We hypothesize that priming the "model minority" stereotype will cause heightened pressure among A/AA students leading to decreased performance. We will explore patterns among different ethnic and cultural subgroups. Additionally, we will qualitatively examine themes in A/AA students' written responses about their experiences with the MMM. This research will make a novel contribution to the literature on student experiences in math by increasing the understanding of diverse perspectives in undergraduate education. In addition, it will further elucidate both the role of social identity in learning and also how shifts and emerges in identity might affect development.

Abstract Name: 3D Printed Aircraft for Extended Flight Duration: An Undergraduate Research Project

This undergraduate research outlines the project design undertaken by a team of three undergraduate engineering students from Community Cuesta College, San Luis Obispo, participating in the 2024 3D Printed Aircraft Competition at California State University, Los Angeles. The primary objective of this project is to design, construct, and test a 3D-printable aircraft with the ultimate goal of achieving the longest possible flight duration. The document provides insights into the background research, highlighting the existing knowledge base in the field. It further outlines the specific objectives of the project, including the design, construction, and testing phases. Additionally, the document addresses the project's management approach, detailing how the team plans to coordinate efforts to meet the competition's requirements. This research aims to contribute to the field of aerospace engineering by pushing the boundaries of 3D-printed aircraft capabilities. The outcomes of this project will be essential not only for the competition but also for advancing the understanding and application of 3D printing in aircraft design.

Abstract Name: Motivations for being informal carers of people living with dementia: An updated systematic review

Informal caregivers offer vital continuous, unpaid care to improve the quality of life of people with dementia and ease the demand for care services. The dyadic process of caregiving has multifaceted impacts warranting efforts to reduce caregiver burden and improve well-being, understanding motivations for adopting a caregiving role can predict experiences, perceptions, and impacts on caregivers. A systematic review conducted by Greenwood and Smith found motivators for informal caregivers. Substantial evidence documents variations in cultural perception and social values influencing caregiver experiences and motivations. The purpose of this systematic review was to update the searches by Greenwood and Smith to describe and compare the motivations of caregiving between demographics, ethnicities, and cultures. Six electronic databases were searched from August 2018 to August 2023. Titles and abstracts screened using Machine Learning approaches (ASReview). A subset of full texts was screened in duplicate. Included studies were appraised using the Mixed Methods Appraisal Tool (MMAT). Extracted data were grouped into themes. Initial database searches identified 1,530 articles and the following deduplication and screening 12 shortlisted studies were included. These were added to the existing 26 studies from Greenwood and Smith. Cultural explanations for motivations for caregiving include familism, ethnic identity, cultural values and beliefs, obligation, and sense of fulfilment. Cultural perception and social values influence caregivers' experiences and perceptions thus affecting the family's engagement/acceptance of formal care/support. Further research is warranted to inform advances in psychosocial support interventions for ethnically diverse caregivers to achieve personalised care and reduce the burden on family caregivers.

Abstract Name: The Role of SCN5A in Sick Sinus Syndrome and other Cardiovascular Diseases: A Bioinformatic Study

Background: Sick sinus syndrome (SSS), also referred to as sinus node dysfunction, is a heart disorder that occurs when the natural pacemaker in the heart fails. The condition is found in approximately 1 in every 600 individuals, often affecting both male and female populations. SSS primarily manifests in older adults but can occur at any age, stemming from a combination of genetic and environmental factors. In many cases, the cause of the condition remains unknown, but genetic changes may play a role, leading to abnormal heartbeats and other symptoms associated with SSS. Identifying these genetic factors could enhance monitoring, diagnosis, and treatment strategies for individuals at risk for this condition, particularly neonates and young infants.Objective: To explore the genetic basis of SSS, we conducted a literature-based review of epidemiological studies to identify potential genes and genetic variants associated with this condition and their occurrence in the population. This survey revealed multiple genes associated with SSS including SCN5A, HCN4, and GNB2.Methods: Bioinformatic resources, such as ClinVar and Human Gene Mutation Database (HGMD), provided information on reported mutations in these genes and their clinical significance.Results: Particularly, several mutations were reported in the SCN5A gene, such as residue changes F1250L, associated with drug-induced long QT syndrome (LQTS); P1298L, associated with SSS; and R1629Q, associated with changes in voltage-gated sodium channel activity, thereby prolonging inactivation recovery and resulting in Brugada syndrome (BrS). These bioinformatic studies identified multiple mutations in the SCN5A gene that contribute to various cardiomyopathies, with particular significance in infants.Conclusion: Building upon these findings, a comprehensive variant analysis has been conducted to understand the impact of these variants and their contribution to the pathophysiology of SSS. Future studies will explore the functional impact through modeling specific mutations in SCN5A using in vitro cardiomyocyte cultures.

Abstract Name: Judging a Book by its Cover: A Case Study Analysis on the Rich Publishing History of Daisy Jones & the Six

While the text within a book may remain the same over the course of several years, decades, or centuries, the material contents of the book — i.e., the bibliographic code — is very likely to undergo several changes. These changes are featured primarily on the different covers of a book, whether it's the cover art, title font, or awards received, alongside other attributes.My research chronicles five different editions of Daisy Jones & the Six, a book written by Taylor Jenkins Reid and first published in March of 2019. As I dissect the bibliographic changes this book has undergone through these past five years, I emphasize the importance of each change within the overall world of book publishing and readership. I also analyze the impact of the book's 2023 television adaptation, and how it has contributed to an increase in the circulation of the book. The past year has been monumental in the book's readership, and this has been further reinforced by the bibliographic contents of the novel. While the well-known adage goes, "Don't judge a book by its cover" — it

is in fact these features that are accentuated within the publishing world to better increase a book's visibility and credibility.

Abstract Name: Social Healthcare in a Nursing Home Setting

Nursing homes can be defined as end of life healthcare facilities generally for the elderly in which care is provided to those that are usually sick, have some health disorder or are incapable of taking care of themselves. These facilities are primarily occupied by medical professionals such as doctors and nurses that make sure that residents are able to carry out the rest of their life in a reasonable manner. A central component of these facilities and sometimes not present enough are leisure activities. Leisure activities may be delineated as any sort of activity that an individual takes part in voluntarily such as playing games, meeting family or even something as simple as engaging in social interaction with others around you. It has been observed that increased participation in these activities have led to an overall positive impact on the health of these individuals. Variables such as mortality rate, duration of time post-admission, self-report measures and even brain scans corroborate the positive impact of such activities on the individual. A statistical analysis with correlation coefficient values at the forefront will be conducted in order to demonstrate the type of relationship and strength of relationship between the leisure activities and the health variables (variables that describe the overall well-being of an individual). An increased attention to this area of health may lead to a better end of life experience for nursing home residents in the future.

Abstract Name: Educational Reform to Correct Racial Disparities

One key asset individuals in our ever-changing society should have is a strong educational background. However, access to high-quality education is inequitable across persons and places. Educational disparities are prevalent in the state of Alabama, which ranked 39th in reading and 40th in math among fourth-grade students (according to the 2022 National Assessment of Education Programs). Among eighth graders, educational achievement is even worse: Alabama eighth graders ranked 52nd in math and 49th in reading. Unfortunately, the majority of students affected by such disparities are Black and Latino students, who are more likely to attend resource-poor schools and be subject to increased surveillance and disciplinary practices. Disrupting this apparent school-to-prison pipeline means focusing on the qualitative improvement of education for these students, changing their destination from impoverished communities to flourishing careers. The project will present preliminary data from a collaboration between UAB’s JEDI (Justice, Equity, Diversity, & Inclusion) Legal Lab and Growing Kings, a local non-profit organization providing school-based mentoring to struggling students from grades 4th - 12th. Growing Kings supports student success by

providing developmentally-specific instruction and peer mentorship within elementary, middle, and high schools. Using a tight budget for nearly 10 years, Growing Kings has a wealth of hard copy student assessment tracking program participants. The Legal Lab provides data entry support needed for Growing Kings to document program outcomes. The findings of this project have led to the demand for constitutional reform and governmental action. Section 256 of the Alabama State Constitution permits the application of the morally wrong doctrine “separate but equal.” Therefore, it is the best interest of minority students that an amendment to the constitution is approved by the state legislature and is ratified, so that this abominable provision is corrected. With this, public education can institutionalize the fundamental right to quality education for all.

Abstract Name: Casa Amanecer: Inclusive Universal Residential Design for the Visually Impaired, merging traditional methods and advancing technology.

This project presents an approach to residential design tailored for an individual living with his family with severe visual impairments with very little to no vision. The research findings indicate that wayfinding, color placement, and innovative voice-activated technological strategies can enhance quality of life of people with visual impairment.Speaking with a specialist who has worked in a vision service organization shared several best practices and methods of wayfinding, and color placement. Several conversations with the client help relate desired use and implementation of technological advances. Several Case Studies assisted reinforced the choice and hue of warm color tones.For safe and effective wayfinding, wood casing is considered along walls in hallways, and various floor materials of different colors and textures are applied to help users distinguish different space. Color theory is implemented by choice of paint color using warm yellow tones to help maximize ease in visual potential. Contrasting colors like kitchen countertops and cabinets are strategically applied to denote changes. Various floor materials of different colors and textures help distinguish different space uses.Integrating technology, including smart applications and appliances, is a crucial component of the design strategy. Universal design principles ensure these technologies are accessible and user-friendly for individuals with varying degrees of visual impairment, making these spaces all-ability friendly. Smart home systems, equipped with voice-activated controls and sensory feedback, empower residents to manage their living spaces independently.This residential design approach solves various concerns visually impaired individuals face using traditional wayfinding principles, color theory, and universal design technologies to create a subtle, seamless blending of physical and digital elements all family members can enjoy.

Abstract Name: Improving Social and Behavioral Skills in Children with Autism Through Arts and Crafts

Autism spectrum disorder (ASD) is a disorder that affects some structures of the brain and its functions. ASD is a broad disorder that varies from child to child and impacts every child differently. Children with autism are often characterized by having difficulties in communication, social skills, and behavior that can affect their home and school life.This service-learning project aims to help children with Autism improve their behavior and social skills through arts and crafts. The participants were children who were on divergent spectrum levels and had behavioral issues from Autism Hope of El Paso organization (ages ranging from 3-13). The program consists of arts and crafts sessions every week for one month to help improve the behavior of children on the spectrum through the implementation of collaborative projects. Materials used were paint, paintbrushes, clay, markers, colored pencils, wooden crafts, and printouts for the children to use during the arts and crafts sessions. Data was collected through a modified version of the validated Child-Behavior Questionnaire which was provided to the parents at the beginning of our sessions and at the end. A dependent t-test was used to evaluate changes from pre- to post-sessions. The T-test revealed that there was a statistical improvement in the children's social and behavioral skills between the pre-and post-program [t (7) = 5000, p = 0.020]. As a reflection, our service-learning project has given us the opportunity to understand children with Autism and to help them improve their social and behavioral skills through arts and crafts.

Abstract Name: Analyzing the Interplay of COVID-19, Employment Rates, and Politics: A County-Level Study in California

This research delves into the relationship between the COVID-19 pandemic and employment rates by county in California, with a focus on testing rate, positivity rate, unemployment rate, claim rate, and death rate. The rapid spread of COVID-19 led to widespread business closures, resulting in a rapid escalation of unemployment rates. As COVID-19 positivity rates escalated, different counties responded differently, in closure policies and enforcement of local and state mandates. Consequently, this study examines the relationship between COVID-19 positivity rates, the deaths that came from the disease, and their influence on employment and unemployment rates. Further, I investigate the ramifications of political affiliation by leadership and voters on employment and COVID-19 positivity rates and mortality rates. This study hopes to shed light on several factors in each county that led to differences in the effects of the COVID-19 pandemic. This study combines data from local, state, and federal sources to best identify causal effects. Using quantitative research, this research intends to understand more thoroughly what worked well, and what did not with hopes to make future policy decisions more effective in helping residents in California and elsewhere.

Abstract Name: Loneliness Predicting Artificial Intelligence Attitude and Job Satisfaction

Tang et al. (2023) suggest that feelings of loneliness have a positive correlation with the use of artificial intelligence (AI) in a workplace setting. If AI continues to be used in workplaces, it will continue causing negative effects in those working with it. There is a lack of literature on how AI use and perception may relate to loneliness in individuals who do not work directly with AI in their day-to-day lives, a gap that the current study aims to fill. However, the loneliness paired with disclosure of the participants were in most cases tested in correlation to the Minnesota Multiphasic Personality Inventory (Archer,1979) (Franzoi & Davis, 1985). Many studies only discuss theories and background literature, but do not perform actual statistical investigations. For that reason, I will be performing a multiple regression where loneliness will be the predictor of job satisfaction and AI attitude. The data will be collected from participants across the United States using a panel service. The current study uses the Loneliness-Deprivation Scale (de Jong-Gierveld, 1987), the Basic Psychological Need Satisfaction at Work Scale (Eriksson & Boman, 2018) and the

General Attitudes Towards Robots Scale adapted for AI (Koverola, M. et al., 2022). The first hypothesis is that loneliness will have a moderate negative correlation with a job satisfaction subscale, explaining relations they have with coworkers. The second hypothesis is loneliness and AI attitude will have a high positive correlation. The third hypothesis is job satisfaction is positively correlated with AI attitude. The findings of this study can be useful to those trying to reduce feelings of loneliness. The results can also be useful to employers worried about their employee's well-being as AI becomes more integrated in our society. The findings will be incredibly useful for research involving AI moving forward in terms of workplace implementation.

Abstract Name: Constructing Supramolecular Chelate for Sequestration of Heavy Metal Toxins

Heavy metals, such as mercury, cadmium, and lead, are consider potent toxin, because they can crosslink cysteines in proteins hindering protein activity, ultimately leading to apoptosis. Due to the lipophilicity of heavy metal toxin, they tend to accumulate in lipid-rich organs, such as brain and liver, which are hard to reach by hydrophilic antidotes. In this project, we are developing molecular cages decorated with heavy metal binding groups, with the aims to 1. capture heavy metals toxins and 2. isolate them from physiological proteins by trapping them in the hydrophobic cavity of the cage. Current achievement includes synthesis and optimization of a molecular cage formed by mine condensation. Future effort will be to reduce the imine to amine groups, which allows for subsequent installation of metal-binding groups, such as dithiocarbamate (DTC).

Abstract Name: Comprehensive Phishing Detection: A Machine Learning Approach

Phishing attacks pose a growing cybersecurity threat, demanding effective detection mechanisms. This study explores the utilization of machine learning and natural language processing techniques to enhance the detection of phishing emails. The research objectives include analyzing linguistic patterns, evaluating model performance, and exploring the applicability of AI models. The investigation drew upon a comprehensive literature review. It utilized a labeled dataset to develop and evaluate an algorithm capable of classifying unseen data as spam or non-spam. Pre-processing techniques included tokenization, stopword removal, logistic regression, and other classification algorithms. Evaluation metrics such as accuracy, precision, and confusion matrices were used to assess model performance. The research demonstrates the effectiveness of

machine learning models in accurately identifying and classifying phishing emails. The logistic regression model achieved a high accuracy score of 98.3% and 98% precision, supported by the logistic regression classification report. The analysis highlights the significance of linguistic patterns in distinguishing phishing emails from legitimate ones. Furthermore, an AI model, ChatGPT, is incorporated to generate and identify phishing emails, using prompt engineering to improve questions for the best results. Those results were tested on the created model to see how well it could categorize them as spam, and the results confirmed the model's competence in distinguishing between genuine and simulated phishing efforts. This investigation showcases the crucial role of machine learning and natural language processing in enhancing phishing detection and emphasizes their potential to strengthen cybersecurity defenses. In the future, the scope of the research will broaden by testing and training the model on a more diverse dataset to improve its adaptability in detecting phishing attempts. In addition, ChatGPT's ability to generate more personalized and targeted phishing emails will be tested. Assessing risks tailored to individual users for a more comprehensive assessment of cybersecurity solutions.

Abstract Name: Modulus-Weighted Failure Analysis of an Auxetic Hip Implant Under Eccentric Loading

This paper presents a numerical investigation of an auxetic hip implant under eccentric loading. The long-term stability of hip implants is influenced by various factors, and the loads acting across the hip joint are crucial. Hip implants are designed to replace the natural hip joint and restore functionality and mobility. The loads on the hip joint can be affected by factors such as body weight, activity level, and the biomechanics of an individual. Surgeons and orthopedic professionals consider these factors when selecting and implanting hip prostheses to optimize long-term outcomes and minimize the risk of failure. Additionally, ongoing research and advancements in materials and design continue to improve hip implant longevity and overall patient satisfaction. In this study, the femoral implant with circular cross sections subjected to an axial load and uniaxial bending moment is modeled using an iterative modulus-weighted scheme in MATLAB to examine the mechanical behaviors at the bone-implant interface. The auxetic materials with a negative Poisson’s Ratio on the retracting side of the femoral implant are utilized herein to help address the problems associated with the resultant bending effect and prevent aseptic loosening. The maximum loads (axial load and bending moment) acting on the implant are of great interest, and they can cause implant stability problems, which can lead to implant failure. Results reveal that the member carrying capacity of the auxetic hip implant is approximately 32% higher than that of the conventional hip implant. Thus, it can be concluded that auxetic implants greatly increase the strength of the bone-implant interface and decrease the risk of failure.

Abstract Name: Chemogenetic activation of midbrain astrocytes during cocaine condition placed preference

Substance use disorders (SUDs), which affects approximately 15% of the US population, are often characterized by a strong urge to consume drugs. One of the challenges with treating SUDs is the high incidence of relapse, which can be precipitated by exposure to drug-paired cues. As such, there is a critical need to identify the neural systems involved with establishing the association between drugs and drug-paired cues. Preclinical studies commonly use the condition place preference (CPP) assay, which is a rodent task that assesses the strength of the association between drugs and contextual cues. Previous work has demonstrated that ventral tegmental area (VTA) dopamine neurons are critically involved in mediating cocaine CPP. Increasing evidence highlights that drugs of abuse can alter astrocytes and how they interact with neurons. However, it is unclear though if astrocytes in the VTA are regulating the development of cocaine CPP. To address this, we will use chemogenetics to selectively activate Gq signaling in VTA astrocytes in animals trained to undergo cocaine CPP. This research will pave the way to understanding if astrocytes in the VTA can be targeted to break the association between drugs and drug-paired cues.

Abstract Name: The Effects of Patriarchy on Crime

Patriarchal ideologies exude outside the hands of a male body, and into the coffins of female victims. In the United States, men commit acts of crime that disproportionately affect women. A patriarchal society when involved with crime, provides women the counteractive benefit of comfort and pronoia. In this research, I expand on the established definition of femicide with specific acknowledgement of the fourth wave of feminism using data from the department of justice. These data are specific to both the gender and the relationship between the victim and the perpetrator(s). I study domestic violence incident report convictions, femicides, and rape with reference to laws that are meant to maximize the bodily autonomy of women. This project sheds light on the patriarchal ways of thinking, and shows that these ideologies pose a significant threat to women in modern day American society.

Abstract Name: The Impact of Exposure to Equity, Diversity, and Inclusion Education

This review examines the impact of implementation of Equity, Diversity, and Inclusion (EDI) content within higher education to recognize the structural inequities that exist in the larger society. EDI is a powerful strategy to acknowledge self-awareness and identify strong biases that are currently present in our culture, specifically within education and employment. This research focuses on the effect of Equity, Diversity, and Inclusion on students both in and beyond the classroom. Previous research has shown that EDI has been ineffective due to the adoption of information deficit model approaches which work to solely educate the audience through a yearly training course. In contrast, utilizing alternative methods such as those that employ interactive discussions, mandated programs, and projects allow students to acquire a new perspective. To measure whether EDI is truly effective, the use of pre- and post-surveys would provide researchers with evidence of how successful current programs are. Social work departments in higher education often set the tone for EDI courses, and at the University of Wisconsin-Eau Claire, EDI is prominent on campus, more specifically within the social work major. To improve this, we can use these methods which will give us a better understanding of why EDI is not more known campus wide. With an in-depth understanding of its positive impact on students, we can also expect that there will be an association between EDI and future places of employment. Using these expected findings, we can ensure that incorporating EDI curriculum goes beyond the social work department and into other majors. The future of this study creates potential for a positive change on educational environments such as the University of Wisconsin-Eau Claire.

Abstract Name: Measurement of Behavioral Characteristics in Free-Moving Ants

Personality is a major area of research in psychological science because it allows us to understand behavioral diversity among people as well as the consistency of those differences across situations. To claim that non-human animals possess personality requires that behavioral characteristics are consistent over time, similar to what is observed in humans. The purpose of this study was to examine behavioral characteristics in an invertebrate animal model, harvester ants, to see if their behaviors meet the criteria to be characterized as personality. We conducted two 5-minute tests separate by approximately 45 minutes in which ants were placed in containers and their behavior was recorded. We measured the expression of several different behaviors in each test: locomotor activity, open field behavior, and self-grooming in both tests. We assessed the distribution of these behaviors across our sample and found that only locomotor activity was distributed in a way that approximated a bell curve, which is characteristic of personality traits in humans; self-grooming behavior showed a left-skewed distribution and open-field behavior showed a right-skewed distribution. We also examined the consistency of behaviors by correlating individual ants' measurements in test 1 vs. test 2. We found that none of the correlations were significant (p's > 0.13), suggesting that there was little consistency observed in the expression of individuals' behaviors. These findings fail to support the theory that these behaviors can be used to describe personality characteristics in ants. Future research can examine other behaviors, such as necrophoresis and aggression, to see if they provide support for the expression of personality within individual ants.

Abstract Name: Rosa Bonheur Symbolism of Equine Portraiture

This research project delves into 19th-century French artist Rosa Bonheur’s profound fascination with horses and seeks to uncover the symbolic messages embedded in her equine masterpieces. The driving question revolves around understanding how Bonheur's portrayal of horses reflected her personal identity and the message of the value of these animals. The significance of this research lies in unveiling the nuances of Bonheur's unconventional career, challenged gender norms, and contributing to the broader discourse on the intersection of art, identity, and societal values in the 19th century. As an influential female artist, Bonheur's unique perspective on horses provides valuable insights into gender dynamics, artistic expression, and societal shifts during the 19th century. This paper will explore just some of her many equine related artworks and attempt to understand the symbolism Rosa Bonheur depicts and the impact horses on both art and society during the 19th century.

Abstract Name: Heavy Metals in Honeybees Along an Urban to Rural Gradient in the Philadelphia Region

Honeybees provide critical ecosystem services, such as pollination to a variety of economically important crops. There has been increasing concern about honeybee health due to incidences of ‘colony collapse disorder’ and declining honeybee populations. Since honeybees pollinate a variety of flowering plants near their hive, honeybee health may also be indicative of the health of the plants they pollinate and the soil those plants grow in. The goal of my research was to evaluate heavy metal content in honeybees along an urban to rural gradient in the Philadelphia region. Honeybees were collected at nine sites along this gradient, from Center City, Philadelphia to Chester Springs, PA. Three samples (consisting of 10 bees each) from each site were microwave digested and analyzed for heavy metals and several other elements (Mg, Cr, Mn, Fe, Cu, Zn, As, Cd, and Pb) by inductively coupled plasma mass spectrometry (ICP-MS). The land use for each site was analyzed with a 1.5km radius, which is the honeybee foraging radius. The foraging habitat from bees collected along the urban to rural gradient ranged from 1.68 to 84.50% impervious surface. I found that Pb, As, and Fe content in the honeybees increased with increasing impervious surface (p < 0.05), while Mn content decreased (p < 0.05). My results indicate that honeybees living in urban environments have higher Pb, As, and Fe content, indicating higher exposure to those heavy metals in urban environments. There were statistically significant differences between sites for Cu and for Mg (ANOVA p < 0.05), but I did not find a relationship between land use or impervious surface and Cu or Mg, suggesting other factors not investigated in this study may influence honeybee heavy metal content.

Abstract Name: Wages, Work, and Worry: Effects and Circumstances of College Students' Part Time Jobs

As college tuition increases and minimum wage makes little effort to catch up, the relationship between students and employment shifts as well. In order to evaluate the current state of student employment, a variety of sources were reviewed in order to establish the effect employment has on both academic achievement and student health, the societal and workplace-related circumstances around employment and its effects, and the steps that can be taken to mitigate negative effects. This paper argues that employment in certain fields, such as food service and retail, has negative effects– first, on student wellbeing, and second, on academic performance– due to the intensity of the job and the conditions of the workplace. Additionally, this paper advocates for a three-pronged approach to solving this problem: firstly, with financial changes that reduce the monetary burden on the student; secondly, with institutional changes that reduce the stress and pressure on the student; thirdly, with personal changes that the student must encourage in themselves in order to better balance the remaining challenges they may face.

Abstract Name: Her Constant Beauty Doth Inform: Translating the Medieval into Modern, Edward Burne-Jones and The Legend of Briar Rose

In 1859, Sir Edward Burne-Jones, an Exeter College dropout and amateur illustrator, traveled to Italy for the first time. A seminal moment at the beginning of his career, Burne-Jones experienced a cultural center of the Middle Ages with the fresh eyes of a talented and curious young man. In this paper, I plan to show how Edward Burne-Jones' 1859 tour of Italy's medieval creative centers was instrumental in his neo-traditional and multi-disciplined career as a leader in the early English decorative arts movement by examining the conceptualization, design, and installation of his 1890 Legend of Briar Rose paintings.Based on the Grimms Brothers 1812 version of The Little Brier-Rose, the paintings also take some inspiration from Alfred Lord Tennyson's contemporary narrative poem "The Day Dream," from which the title of this paper comes. Painted on large horizontal canvases, hedges of rosebushes visually connect the paintings, one of many symbols the painter used to communicate the fairy tale to viewers in the know. The composition of the paintings was my first clue to Burne-Jones' Italian influence. To create works that complemented a relatively small home saloon, the painter abandoned the techniques that allowed works to stand out in a cavernous academic salon gallery. By combining the perspectival tools of the 15th-century Siena School with contemporary literary and decorative themes, Burne-Jones was not necessarily discovering a dead visual language but translating it for a modern audience. Burne-Jones explored The Briar Rose through several mediums, linking his understanding of medieval craftsmanship with the contemporary tendency to superimpose material and message. By examining the pieces and the interior spaces that Burne-Jones viewed in Italy with a critical eye toward materiality, symbolism, and compositional tools, I intend to work backward through Burne-Jones' career to correlate The Briar Rose series with the foundations of medieval art.

Abstract Name: Data Analysis and Monitoring Crew: A UWRF-Led, Public-Private Student Training Program Putting Freshwater Collaborative Support Into Action

The Data Analysis and Monitoring Crew (DAM Crew) is a student training program that implements a 10-year monitoring plan developed for the Kinnickinnic River (the Kinni) in and around River Falls, Wisconsin. The monitoring plan is a response to the expected removal of 2 small dams in River Falls in the coming 3-5 years. The city of River Falls is working with the environmental consulting firm Interfluve and the non-profit Kinni Corridor Collaborative to raise funds for dam removal and subsequent river corridor restoration. The monitoring plan provides a pre-removal baseline of the river's ecological health while allowing river stakeholders and managers to understand changes in the river over time. With support from the Freshwater Collaborative of Wisconsin (FCW), UWRF developed a professional training program for students to use this unique community setting as a living laboratory.The Kinnickinnic River is designated an Outstanding Resource Water and a Class 1 Trout stream by the Wisconsin DNR, with trout densities in certain stream reaches greater than 5000 trout per mile. Dams threaten the self-sustaining trout fisheries below the City of River Falls by changing temperature, flow regimes, and altering habitats. The DAM Crew collects water quality, stream morphology, and habitat data. They receive training from river restoration professionals in industry. They also collect the formal data for the Kinni Monitoring Plan and provide a valuable service to their community as it implements river management.

Abstract Name: Improving the Efficacy of Glioblastoma Multiforme Detection and Treatment Using Migratory Interneurons

Glioblastoma Multiforme (GBM) accounts for nearly half of all known malignant brain tumors and is prone to impacting and invading surrounding brain tissue. By concentrating on the role of neocortical interneurons in GBM development, enhanced detection and treatment of the tumor could be attained. Using mice cell lines and brains, a form of human Glioblastoma was introduced to observe the efficacy of injected migratory interneurons in targeting and locating the tumor location. Glioblastoma cells are known to express the protein stromal cell derived-factor-1 (SDF-1), the main target point for the interneurons. Migratory interneurons were

then injected, with these interneurons expressing cytokine receptor-4 (CXCR4), a cytokine with the ability to target the Glioblastoma SDF-1 proteins. To conduct this project, cell culture techniques were performed to derive the growth of neural stem cells. Subsequently, histological techniques were used to accurately localize and detect the interneurons and the tumor. Mice brains were sectioned into slices that allowed for the injected tumors to be located within the margins of each section. Immunostaining allowed for the visualization of the interneurons and the tumor using a primary antibody to bind to the CXCR4 cytokine and the SDF-1 protein, with a complementary secondary antibody as a visual marker (primarily RFP, GFP, and DAPI). The use of immunofluorescence microscopy allowed for the identification of the interneurons and the tumor in each section. The results of these experiments display the promising ability of interneurons to accurately locate and track down the GBM tumor at various injection sites. These results are potentially groundbreaking, as accurately detecting the GBM tumor in the early stages of embryonic development could limit its extraneural metastatic potency. Significant therapeutic implications are also associated with these results, but further experimentation on developing a novel GBM cell-based therapy with the use of migratory interneurons must be conducted.

Abstract Name: Beyond Clicks: The Art of Continuous Authentication via Mouse Dynamics

In the ever-evolving landscape of cybersecurity, the quest for robust and unobtrusive user authentication methods has become paramount to maintain system security. Traditional static or one-time authentication techniques possess an inherent vulnerability as they only guarantee that the user is genuine at the time of their initial login. In light of this, continuous authentication aims to overcome this vulnerability by continually authenticating a user throughout their entire session. In this approach, once a user gains access to a system, they are validated using behavior-based metrics to ensure the system is being accessed by a genuine user throught their entire session. This is achieved through the use of machine learning which constructs a model of the user's behavior that is then continually evaluated throughout their use of the system. Out of several approaches of continuous authentication, this study focuses on mouse dynamics as it is thought to be the most unintrusive and accessible approach as it uses how a user interacts with a mouse to validate their identity. The central research question that this study will tackle is whether UI context will impact how a user would use a mouse and if a machine learning model can identify those differences or the underlying pattern of behavior that the user exhibits. To this end, this study will collect mouse data from users interacting with two different UI contexts. This data collected will be used to develop and evaluate several machine learning models. Based on the results of model testing, the efficacy and viability of continuous authentication using mouse dynamics in both similar and differing UI contexts will be determined.

Abstract Name: Free Docking of Cross-Reactive Lupus Antibody to Epstein–Barr Virus Nuclear Antigen 1 (EBNA-1) and Double Stranded DNA

Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by anti-double stranded DNA (anti-dsDNA) antibodies. While the origin of anti-dsDNA antibodies is unknown, it may be due to molecular mimicry of dsDNA by Epstein–Barr virus nuclear antigen 1 (EBNA-1), the major nuclear protein in Epstein-Barr Virus. A monoclonal antibody to EBNA-1 (designated 3D4), generated in our laboratory, cross-reacts with dsDNA. Epitope mapping revealed that 3D4 recognizes a 160 amino acid fragment, LS9459-619, in the carboxyl region of EBNA-1. Understanding similarities between interaction sites of 3D4 with LS9459-619 and dsDNA may indicate origins of anti-dsDNA antibodies. Recent x-ray crystallography of the 3D4-LS9459-619 complex revealed contact residues, which were confirmed by mutational analysis of Complementarity-Determining Regions (CDRs) of the heavy and light chains of 3D4. However, further modeling via docking, can test reproducibility of the 3D4-LS9459-619 crystallized structure (3D4-LS9459-619-cs) and assess the power of computational modeling for predicting 3D4-dsDNA interactions. HDOCK, a Fast-Fourier-Transform docking web-server, was used for free docking of 3D4-LS9459-619 and 3D4-dsDNA. 3D4-LS9459-619 docked models (3D4-LS9459-619-dms) and 3D4-dsDNA docked models (3D4-dsDNA-dms) were ranked by lowest energy and analyzed for orientation and intermolecular interactions via PyMol and LigPlot+. 3D4-LS9459-619-dm rank 4 has significant overlap with the 3D4-LS9459-619-cs, supporting validity of docking for binding site prediction. Comparison of the top ten 3D4-dsDNA-dms with mutational analysis reveals 3D4-dsDNA-dm rank 6 most likely represents putative interactions of 3D4 CDRs with dsDNA. Future studies using HDOCK will test if other dsDNA sequences demonstrate similar putative interactions with 3D4. Furthermore, x-ray crystallography of 3D4 and dsDNA will validate the putative interactions observed in HDOCK 3D4-dsDNA-dms.

Abstract Name: Exploring the Activity of MECP2, Its Interactors, and DNA Damage Proteins In Rett Syndrome Models

Rett syndrome is a rare intellectual and developmental disorder that causes severe physical and cognitive impairment due to mutations in the X-linked DNA-binding protein methyl-CpG-binding protein 2 (MECP2). Though the specific pathogenic mechanism of MECP2 activity is unclear, its loss impacts neuronal development – our lab observed that mutant neurons with loss of MECP2 function have less branching and increased p53, senescence, and DNA damage. The OpenCell database lists an MECP2 interactome connecting it to proteins like PARP1, NUCKS1, CHRAC1, SNX1, etc., many of which are involved in chromatin modification and DNA damage responses. This sparked the question of whether these proteins closely localize to MECP2 in neurons and if loss of MECP2 function impacts their activity. Indeed, confocal microscopy showed significant PARP1-MECP2 and NUCKS1-MECP2 colocalization. An in vivo enzyme-linked immunosorbent assay detected lower PARP1 activity in mutant than control neurons. We hypothesize that manipulating PARP1 activity will affect DNA repair in neurons and produce a Rett-like phenotype. This will be investigated by adding PARP1 inhibitors to control neurons and noting the effect on dendritic branching and senescence, along with observing if NAD+ supplementation, which boosts the DNA repair function of PARP1, reverses this effect. Overall, assessing protein interactions of MECP2 and its role in

PARP1-mediated DNA repair will help characterize what proteins may be involved in contributing to the Rett phenotype.

Abstract Name: Analyzing the Validity and Content of Damodaran's Modified Discounted Cash Flows Model

Aswath Damodaran is a professor at NYU Stern School of Business who created a custom discounted-cash-flows valuation model using Microsoft Excel. This valuation model allows for customization through the inputting of an individual investor's custom estimates and additional growth levers, such as research and development. This analysis of the validity of the model will assess the model's ability to produce reasonable and useful estimates of the value of a firm's equity. In doing so, we hope to show that this model can be used by individual investors as an aide to make better-informed investment decisions. Firstly, we obtained the model through Damodaran's blog. We then obtained financial data from the Bloomberg Terminal to input into the spreadsheet. Finally, we analyzed how the spreadsheet calculated the value of equity by exploring and explaining the inputs and calculations. Furthermore, we showed how an investor could find the data required for inputs and how those inputs were used to find the value of equity. Overall, the spreadsheet allowed for greater accuracy over standard models due to the addition of growth levers not found in standard models. However, due to the model requiring estimates that may vary from investor to investor, the model's accuracy is reliant on variable investor estimates.

Abstract Name: Bartonella Prevalence within People Experiencing Homelessness

Bartonella is a genus of vector-transmitted, fastidious bacteria, responsible for various diseases, including trench fever, Oroya fever, Carrion's disease, endocarditis, peliosis hepatis and cat-scratch disease. Despite a noticeable increase in Bartonella cases worldwide, there is limited research on its prevalence, including among persons experiencing homelessness (PEH). Due to environmental/housing conditions and other risk factors, a substantial number of Bartonella infections may be observed among PEHs in urban areas. Our objective was to review the prevalence of Bartonella in PEH and evaluate the importance of Bartonellosis in

this population. A scoping review of PubMed, CINAHL, Scopus, and Embase databases was conducted using the following search terms, ("Homeless Population" OR "Homeless Persons" OR "Homeless*") AND ("Bartonella" OR "Bartonella quintana"). The search returned 382 articles for title/abstract review and 177 articles for full-text review. Article exclusion criteria was: a. published in a language other than Portuguese, Spanish, or English, b. tests Bartonella prevalence in samples other than human blood, c. articles were case studies/reports, review articles, animal studies, or conference abstracts. Data was extracted from 16 studies included in the review. In each step of the process, articles were screened/abstracted by two researchers independently, and a third researcher resolved any conflicts. Covidence software was used to manage this review. Bartonella prevalence differed depending on the geographical region, population characteristics, and test/test cut-off used. Prevalence ranges were: B. henselae IgG 0.2%-54%, B. quintana IgG 0%-57%, B. quintana IgM 2.3%-7.1%, B. elizabethae 12.5%-52.1%, B. grahamii IgG 2.1%, and B. spp 29.2%-62.5%. Through this novel scoping review, we can conclude that Bartonella is a disease of concern for the increasing population of PEH.

Abstract Name: Is Cosplay a Labor of Love or Dollars? Part 1: Love is Winning

This research is about cosplay, a process of bringing a fictional character to life via costuming and acting. More specifically, cosplay has been described as an act of transformation and self-expression in the production of a chosen identity through performances within a certain time and space. In cosplay, a chosen identity may fluctuate as the participant moves from one temporary identity to another based on their changing interests and passions.Prior research has found that cosplay participants often form groups with others from the same fandom. As individual cosplayers move fluidly between characters, they also move between groups in a more ephemeral form of communal organization recognized as “neo-tribalism.” Neo-tribes are based on shared experiences and shifting cultural patterns rather than traditional demographics.Because much cosplay is enacted during pop-culture fan conventions (e.g., San Diego Comic-Con), it has personal, communal, and commercial relevance. Thus, we are interested in exploring the meaning of cosplay from the perspectives of various stakeholders. The study presented here is the first part of a planned three-part research project to examine the meanings of cosplay from the perspectives of participants, fan convention organizers, and convention venue management.During our interviews with avid cosplayers, key questions included, “What is your motivation for cosplay?” and “What makes cosplay authentic for you?” Early findings reveal the importance of personal values, “resonating with the character you portray,” and the joy of tribal communion for both motivation and authenticity. A related theme that emerged was freedom of expression, i.e., “exercising choice in what is revealed versus what is reserved.” Finally, as one participant succinctly stated, “Cosplay is the highest form of fandom.”This research will continue with quantitative surveys of participants and interviews with fan convention organizers.

Abstract Name: Participatory Design, Educational Equity, & Undergraduate Research Mentoring

Within technical communication, researchers have often used participatory design methods attentive to issues of equity (Shalamova, 2020; Watkins & Lindsley, 2020; Sonka, McArdle, Potts, 2021). As the field of technical and professional communication grapples with ongoing conversations around social justice (Walton, Moore, & Jones, 2019; Constaza-Chock, 2020), there is a need to further develop mentoring practices and pedagogies that work towards greater educational equity in our classrooms, labs, and academic support services. To this end, this presentation asks: how can we use participatory design methods to mentor undergraduate researchers on equity-focused educational research projects?This presentation reflects on two participatory design studies with undergraduate research partners and offers strategies for inclusive and empowering mentoring. The first study used participatory design to imagine, design, and implement a new writing and design lab attentive to the localized needs of diverse community stakeholders. This multi-year study provided experiential learning opportunities for students in technical writing, business communication, human factors psychology, and user experience writing. The second study focused on cultivating a greater sense of belonging for women and underrepresented students in introductory engineering courses. In this two-year study, student research collaborators used participatory design methods to investigate and analyze women engineering students' experiences in the classroom and pilot a small-scale educational intervention. Ultimately, this presentation offers insights for students working on educational equity research projects and mentors seeking to further their inclusive mentoring practices.

Abstract Name: Understanding Local Efforts to Change Attitudes and Behaviors Regarding Plastic Pollution and Waste Management in West Bali, Indonesia: A Case Study on Plastic Free Bali

Plastic pollution is a pressing global issue that affects every corner of the world. While the existence of plastic in Earth’s environments alone is dangerous, its tendency to degrade into microplastics causes even further damage to human, plant, and animal life. When it comes to changing the way we consume and dispose of single-use plastic materials, action oriented community-based organizations are often the leaders of anti-plastic movements. This transdisciplinary qualitative case study explores how one such community-led initiative, Plastic Free Bali, an organization under Yayasan Biosfir Indonesia, is working to combat plastic pollution in West Bali, Indonesia. Dedicated to changing local attitudes and behaviors regarding single-use plastic consumption and waste disposal, the organization’s approach involves a combination of education, vocational training, and the government-funded building of waste management infrastructure on the village level. Data collection took place over the course of a three-month internship at the organization from September to November 2023 and consisted of structured and semi-structured interviews, door-to-door surveys in local neighborhoods, archival research, and participant observation. Three major themes emerged from the research, including that empowering women through educating them to be community leaders lies at the heart of Plastic Free Bali’s approach. Secondly, the research found that there is a need for combining local infrastructure development and education at the household level. Finally, the findings highlighted that tourism can be a major factor in driving community action against plastic pollution.

Abstract Name: Feasibility and Effects of a New Treadmill Perturbation Protocol in Younger and Older Adults

Slips and trips are the leading cause of anxiety and injury in older adults. Research indicates a relationship between neuromuscular adaptations to mitigate fall risk through reactive balance training. Comparative analysis outcomes between younger and older populations completing perturbation balance training need further research. This information is vital for comprehending degenerative brain mechanisms and biomechanical adjustments, contributing to our knowledge of strategies to address fall risks in older adults. PURPOSE: To examine the feasibility of a new treadmill perturbation protocol in younger and older adults as well as neuromuscular adaptation differences in younger and older adults associated with trip-specific training. METHODS: St. Olaf College students (N=20; aged 20 ± 2) and community-dwelling older adults (N=20; aged 64.9 ± 6.8) were recruited to participate in eight perturbation treadmill sessions, each incorporating various stability challenges (trunk stability, step stability, and continuous simulations) while being distracted with conversation adding the element of dual tasking. Additionally, pre and post-testing including functional assessments. RESULTS: The perturbation intervention was feasible in these populations as both showed adaptability to repeated perturbations. While both improved, older populations show a significant improvement in functional assessments sit to stand and timed up and go. Overall, there was a decrease in reaction time to slips and trips in both populations. DISCUSSION: This treadmill perturbation intervention protocol was feasible in both populations. Older adults did not show deficits in stability after perturbations but showed prolonged and long-term adaptability. Perturbation intervention protocol should be considered for decreased fall risk.

Abstract Name: Reinforced Concrete Corrosion Probabilistic Service Life Model Utilizing Zeolite

In 2021, the American Society of Civil Engineers (ASCE) reported that 7.5% of all bridges in the U.S. were structurally deficient, and the cost of retrofitting and rehabilitation of these bridges was around $125 billion. The primary reason for the structural deficiencies in these bridges is chloride-induced corrosion. This project aims to develop a robust service life model for reinforced concrete structures which includes the corrosion initiation and propagation times.This research is particularly urgent as new reinforced concrete bridges utilize emerging and durable materials that current corrosion service life models do not adequately account for. To bridge this gap, various binary- and ternary-based high-performance concrete (HPC) mixtures using zeolite as the primary SCM were investigated. Additionally, other parameters such as cover depth, rebar size, and rebar type were explored to observe their influence on the service life. Nondestructive electrical resistivity testing was performed on each concrete mixture and the data was then utilized in the numerical models to compute the service life.Baseline service life was determined using deterministic models, Fick's second law of diffusion for computation of the initiation time, and the existing Vidal model for the propagation time. The same data was then compared to probabilistic model results from two service life modeling software, Life365 and Korozeeneck. Life365 allows for more geographical variability in results. However, it is mostly limited to corrosion initiation times. Korozeeneck, on the other hand, demonstrated more comprehensive results by computing reliable corrosion propagation times. In general, binary and ternary-based concrete mixtures blended with zeolite showed significant improvement in service life over the ordinary Portland cement concrete mixture. In summary, this study is a step towards enhancing probabilistic service life models by including sustainable and durable materials.

Abstract Name: Enzymology of Intestinal Short Chain Fatty Acid Metabolism

Integral roles for colonic microbiota in human physiology, metabolism, and health are well established. Colonic microbiomes in Western populations are generally dominated by species belonging to two bacterial phyla, Firmicutes and Bacteroidetes. Bacteroidetes includes well-recognized commensal and mutualistic species that serve to break down complex polysaccharides in the gut and generate products such as carbohydrates, propionate, and acetate that can serve as nutrients for the host and other microbial community members. In turn, Firmicutes utilize available resources (carbohydrates, acetate, etc.) to produce metabolites including an array of short chain fatty acids (SCFA), primarily acetate, propionate and butyrate, through fermentation. Numerous studies have revealed how these SCFA mediate important community level metabolic interactions within the gut, as well as provide critical signaling and metabolic outcomes for the host. One enzymatic pathway for SCFA production involves two distinct enzymes: 1) an SCFA kinase and 2) an acyltransferase. Together, these enzymes reversibly interconvert fatty acids with their acyl-CoA derivatives. The genome sequences of various gut microflora species, including Bacteroides thetaiotaomicron (BT), Phocaeicola vulgatus (PV), and Roseburia intestinalis (RI) encode enzymes exhibiting amino acid substitutions predicted to generate novel substrate preferences compared to previously characterized SCFA kinases. Heterologous expression of histidine-tagged variants of the BT, PV, and RI enzymes in E. coli has allowed characterization of biochemical properties regarding these variants. Results from these experiments provide insights regarding potential physiological roles for these enzymes in branched-chain fatty acid and medium chain fatty acid metabolism, as well as SCFA metabolism, that may influence community dynamics within the gut.

Abstract Name: Bioremediation of Crude Oil using Native Fungi

Oil spills have devastating consequences for the environment, impacting both the affected areas and the methods employed to rectify them. With our heavy reliance on oil for various purposes globally, activities like oil extraction, drilling, and refining are widespread, inadvertently leading to environmental contamination. This issue is particularly pronounced in states heavily reliant on oil, such as Oklahoma. To address this pressing concern, numerous techniques—ranging from chemical, physical, to thermal processes—are employed to remediate oil spills. However, these methods often come with high costs and environmental risks. Consequently, there's a growing emphasis on identifying more eco-friendly and cost-effective approaches for cleaning oil-contaminated regions.Bioremediation stands out as a natural means of breaking down environmental pollutants by harnessing the capabilities of living organisms. We have set out to discover an indigenous fungus from Oklahoma that thrives in its natural habitat and climate, capitalizing on its enzymatic prowess to degrade hydrocarbons and remediate oil-contaminated areas.Our recent findings involve the isolation of several novel fungi types (phylogenetic analysis is ongoing) from an Oklahoma drill site. These fungi, when introduced to a medium containing 1% crude oil as the sole carbon source, demonstrated the capacity to degrade the oil. Our ongoing research involves subjecting these candidate fungi to an aqueous medium with 1% crude oil for varying durations—1, 7, 14, and 21 days—to assess the extent and pace of oil degradation. This evaluation utilizes flame ionization detector-gas chromatography (FID-GC) to identify the oil components degraded by our fungi. Additionally, an Ultraviolet-visible (UV-Vis) spectrophotometer will measure the total concentration of dissolved hydrocarbons. These analytical tools will aid in identifying an indigenous Oklahoma fungus capable of efficiently degrading oil. The envisioned outcome is to utilize this fungus as an affordable, efficient, and natural solution to combat oil spills across Oklahoma.

Abstract Name: UV reflectance and fluorescence in flying squirrels for mate choice

Ultraviolet reflectance and fluorescence (UV R&F) are newly discovered phenomena in mammals and highly novel for flying squirrels. No current explanation is known for the adaptive purpose of UV R&F other than speculations for their use in several areas: predator evasion or mimicry tactics, interspecific or intraspecific communication, adapting to the surrounding terrain or nighttime environment, and mating

purposes. Previous studies have suggested that flying squirrels can perceive UV light so they may use it for mate choice as other species like Melopsittacus undulatus (budgerigar parrot) and jumping spiders do. No known studies have previously been performed on mate choice in flying squirrels specifically, and the reasons behind flying squirrel UV R&F could be applied to other UV R&F species as well. To evaluate, two experiments will focus on mate choice and will work to answer whether UV R&F is important in flying squirrels, if these features are used in mate choice, and which feature is more useful in mate choice: UV reflectance or UV fluorescence. During the first experiment, flying squirrels will be exposed to same-sex or opposite-sex animals under different control lighting conditions. Experimental UV and neutral density filters light conditions will be used in the second experiment to alter the R&F perceived by subject squirrels. Over a duration of about an hour, the amount of time the subject spends in front of a box will be recorded for all lighting conditions and compared between lighting conditions to determine if flying squirrels respond differently when UV R&F information is available for decision making. Data collection will be completed and analyzed by February 2024.

Abstract Name: Integrating VDC with Drones, AI, and Automation to Operate and Maintain Structures: Martian Colony Application

AbstractThe global construction engineering industry is rapidly developing technology to construct more sustainable, analytical, and serviceable human habitats. This includes but is not limited to the use of drone hardware, integrated sensors, artificial intelligence for big data management, and virtual design and construction software. These provide a significantly enhanced ability to collect, analyze, and convey information about structures. Simultaneously, capabilities for construction in interplanetary space are recieving increasing attention from both governmental and private enterprise organizations. This report examines the potential utilization of modern construction technology to optimize the operation and maintenance of remotely constructed human habitats on Mars. Relevant details on the Martian environment, descriptions of active missions, a background of operation and maintenance practices in space, and a review of literature regarding the most recent construction industry technology is included. Case studies are presented where key proof-of-concept is established for the future remote monitoring of structures. Finally, a system schematic is provided to display how existing technology could be most effectively integrated to remotely maintain extraterrestrial structures. Index TermsMars, Martian Construction, Martian Structures, Martian Colonization, VDC, BIM, IoT, Drones, Operation and Maintenance, Remote Construction, Construction Technology

Abstract Name: An Experimental Study of Flow Dynamics in a Model CDC Biofilm Reactor Using Particle Image Velocimetry

When bacteria group together on a sub aquatic surface, they create what is known as biofilms. Biofilms are commonly used in the world today and are responsible for treating our water, improving plant growth, and much more. Biofilms are grown using biofilm reactors, which consist of a beaker with multiple coupons and a baffle to stir and create flow within the reactor. Controlling the environment within the reactor is crucial to ensure that biofilms grow properly. There are many laboratory reactors that can be used to grow biofilms under different conditions. Some of these conditions include the temperature, the composition of the microbes, and the carbon source, for example. Another way to control the environment is to manage the fluid flow with the biofilm reactor. Although it is known that flow inside of a biofilm reactor affects the growth of biofilms, it is not yet fully understood. To that end, this study aims to characterize the flow dynamics within a model biofilm reactor by quantifying the velocity fields and shear stress employing particle image velocimetry. To facilitate PIV measurements, a specially machined CDC biofilm reactor was created that will allow light to pass through the reactor without distortions so that the particles can be properly illuminated and traced. These PIV results will provide valuable insight into the physics and effects of flow dynamics in biofilm reactors, providing guidelines for new engineering designs.

Abstract Name: Holy Roman Progressivism, the Legacy of Maria Theresa

The Habsburgs of the 17th and 18th century recognized a need to evolve in order to survive as a ruling family, and adapted their methods to avoid destruction and to stabilize power. Enlightened Absolutism was the use of progressive, publicly beneficial ideals and social understandings for the purpose of enhancing the position of the absolutist monarch. While the scope of this project covers four generations of Habsburg monarchs, it shows how this practice of enlightened absolutism was mastered by Maria Theresa, who used her careful understanding to grow imperial power, and ultimately culminated into a truly progressive emperor in Joseph II. My research involved an assortment of well-preserved documents that needed to be translated into English, such as The Family Pact of 1703 and Pragmatic Sanction of 1713. Many private writings, particularly Maria Theresa and Joseph II, were used to gain a better understanding of their minds, along with imperial law and declarations at the time of their reign. Particular secondary sources I would like to credit are The War of Spanish Succession by James Falkner, Joseph II: Volume 1, In the Shadow of Maria Theresa, 1741-1780 by Derek Beales, and Maria Theresa by Edward Crankshaw. The sources prove that Joseph II was a more radically neoteric ruler than his Maria Theresa, but also that she was more effective than he managed to be due to her patient use of the tools at her disposal. This project concludes on the relevance of these tactics on the modern world and the influence they had during the Enlightenment era.

Abstract Name: Water Quality: The Basis for Marine Health

Estuaries are the first line of defense for water flowing into the ocean, catching inputs from upstream. The system allows for natural filtration but is only able to handle a certain amount of materials. Like any system, there is an equilibrium that can be irreversible if tipped too far in any one direction. Nutrient loads are just one example of equilibrium within marine ecosystems and when tipped too far can lead to eutrophication and hypoxic conditions which are unsuitable for life. Humans are the main source of increased nutrients and other chemicals through increased urbanization along coastal areas. Changes in the barrier along the estuary waterways, or changes in land use, can impact the level of nutrients entering the water. A way to monitor nutrient loadings and evaluate the health of the aquatic ecosystem is through tracking water quality. Water quality refers to the physical, chemical, and biological characteristics of water, and together can communicate the health of the water depending on known parameters for a particular ecosystem. Evaluated nutrients include nitrogen and phosphorus which are present in elevated levels notably from fertilizer runoff from agricultural operations. Chlorophyll A is representative of plant growth and can be useful in tracking levels of algal growth which at high levels can be detrimental to the ecosystem. Environmental factors such as pH and salinity are monitored as fluctuations can exceed the ranges suitable for organisms to survive. Dissolved oxygen monitoring is key in tracking hypoxic zones often as a result of eutrophication and leaves the area uninhabitable. Together, these parameters serve to communicate the health of aquatic ecosystems and track the impacts humans have on the estuaries.

Abstract Name: Cross-cultural Synthesis: Soviet Romanticism and Azeri Tradition in the Music of Fikret Amirov

“I adore the West. But I am a proud son of the East.” These were the words of the twenty-six-year-old composer Fikret Amirov when defending his contribution to the Easternization of music in Soviet-occupied Azerbaijan. In the wake of increased political pressures, unstable global landscapes, and reemerging national identities, the young Amirov endeavored in 1948 to stimulate the then nascent East-West synthesis movement, balancing stringent Soviet pedagogy with colloquial Azeri tradition. As a promising and eager ethnomusicologist, Amirov conducted several ethnographic campaigns in the distant corners of both Azerbaijan and the Middle East, employing his discoveries to bring Western attention to Eastern ideas. As a result, he created a series of enduring national masterpieces, including the famous Piano Concerto on Arabian Themes (1957) (in collaboration with Elmira Nazirova). This paper focuses in on three factors that allowed Amirov the opportunity to redefine the compositional traditions of Azerbaijan: Soviet political pressure, Western indoctrination, and the birth of new composed genres. By examining the writings of Aida Huseynova, John Morgan O’Connell, and Boris Schwarz on the cultural, political, and academic traditions of Azerbaijan and the ethnomusicological efforts of Amirov himself, I will concentrate on the afore-mentioned concerto, identifying how it simultaneously reaffirms and redefines traditional Western classical aesthetics. Through analysis of the concerto form, the socio-political implications of folk culture in high art, and the reception of symphonic mugham among soviet historians and musicologists, I will demonstrate the

significance of Amirov's musical ethnography in the construction and legacy of the postmodern Azerbaijani national identity.

Abstract Name: What Makes or Breaks Fieldwork?: Exploring Factors Which Affect Student Experience and Pedagogical Effectiveness

Fieldwork activities within natural sciences offer numerous student benefits, including solidifying higher-order thinking, transferable skills, and analytical reasoning. Despite the evident benefits of fieldwork which supplement classroom learning, many students have reservations or choose not to participate. An interview and questionnaire were administered to undergraduate students taking the Spring 2023 geological field techniques class at California State University Fullerton. Questions analyzed how perceptions of self-efficacy, identity as a geologist, and sense of belonging changed throughout the class, as well as how comfort and preparedness affected the students' experience. Over 50% of post-course participants mentioned class topics as problematic, stating they would like more guidance on the subjects and assignments. Survey data showed improvement in all geological field techniques and methods, yet some factors related to sense of belonging declined from 94% in pre-course to 75% in post-course. Students expressed concern about knowledge on assignments, what to bring, and the conditions of working outside. Notably, lacking outdoor experience had no adverse effect on students' fieldwork experience; the majority had confidence in instructor preparedness. Students' self-efficacy and identity as a geologist generally positively changed by the end of the course. While students felt confident in the instructors and improved geological techniques, the lack of preparation for working outdoors and feeling lost on assignments negatively impacted their experience. Future renditions of this course and other classes across multiple disciplines can benefit from focusing pre-field class time on preparing for field assignments, situations one may encounter, and how to prepare for them.

Abstract Name: Prevalence and Indicators of Gym Intimidation in Female College Students

The purpose of this study was to determine indicators of and measure gym intimidation in female college students. A survey was emailed to female college students at a large, public university in the southeastern US (n=357). Class standing, academic college, major, gym frequency, gym equipment used, and sports

participation were assessed. Gym intimidation was measured using the Social Exercise and Anxiety Measure (SEAM) subscales: social exercise self-efficacy (SES: 5-items, 0-100 scale, assesses confidence in the ability to exercise in various environments), gym avoidance (GA: 4 items, 0-7 scale, assesses gym avoidant behavior), and exercise importance (EI: 3 items, 0-7 scale, assesses priority of exercise). Respondents were 50% confident in exercising at a crowded gym compared to 95% confident at a private gym. The GA item with the strongest score was “I think people are judging me”. Pearson’s correlations, t-tests, and ANOVAs were used to identify significant relationships. Pearson’s correlations revealed a relationship (p<0.01) between frequency of gym attendance and all SEAM questions. Self-predicted success is correlated with exercise importance and ability to use a gym. Significant differences (p<0.01) were found for all SEAM scores between exercise science majors and non-exercise science majors; between those who use strength equipment and those who do not. SES and GA scores were lower in freshmen than other class standings. Gym intimidation is prevalent in the female college students and is a barrier to participation in exercise. Most concerns focused on perceived judgment as opposed to exercise itself. Combating intimidation from perceived judgment is critical.

Abstract Name: The Effects of -Methylamino-L-Alanine in Mesenchymal Stem Cell Differentiation and Neurogenesis

-methylamino-L-alanine (BMAA) is a biotoxin produced by cyanobacteria species found in algae blooms that bioaccumulate in food webs. Human exposure to BMAA over an extended period is thought to lead to bioaccumulation in the brain resulting in neurodegeneration and the development of amyotrophic lateral sclerosis/ parkinsonism-dementia complex (ALS/PDC); however, the specific action of BMAA in neurons is a complex mechanism that is incompletely understood. Further, no therapeutics or treatments exist to counteract toxin exposure and neurodegeneration. We have previously found that BMAA causes cell dysfunction in IMR32 human neuroblastoma cells via a mechanism at least partially dependent upon the upregulation of canonical WNT signaling. Further, we have found that BMAA is capable of modulating neuronal differentiation in this cell line, presumably through WNT-mediated mechanisms. WNT is a critical signaling pathway involved in a diverse array of physiological processes including neuronal polarization, differentiation, proliferation, and mesenchymal transition. This study investigates the potential role of BMAA in altering cell differentiation and neurodevelopmental processes in human cells. The data presented here support the hypothesis that human exposure to BMAA during development may impact neurogenesis to predispose individuals to neurodegenerative disease. Human mesenchymal stem cells or iPSC-derived neural progenitor cells were treated with sub-excitotoxic concentrations of BMAA throughout critical stages of in vitro differentiation from stem cell to neural progenitor to dopaminergic neurons and glia. Expression of differentiation markers, proliferation, cell lineage distribution, and morphological changes induced by BMAA were analyzed. Our findings characterize developmental defects driven by exposure to BMAA and indicate the possibility of developmental origins of sporadic neurodegenerative diseases.

Abstract Name: The Life of Richard Hollis Career

I'll discuss about Richard Hollis and the topics he taught students in this paper. I'll turn to Richard Hollis's "Writings About Graphic Design" to understand his perspective on graphic design. He enjoys making observations about how visuals are used, for example. I'll go into greater detail regarding his artistic influences and where he got his work's style. I'll discuss his work as a printer, magazine editor, art school professor, and multi-published author. He has lectured at numerous art schools, published books, and worked as a printer as a magazine editor. He also co-founded the West of England College of Art's School of Design. In 2019, Hollis was named an Honorary Fellow of the Royal Society of Literature.

Abstract Name: Effect of frailty on mortality of patients requiring mechanical ventilation

Background: One out of six older adults in the U.S are frail. Critically ill patients that require mechanical ventilation have a high morbidity and mortality. Limited information is available regarding how frailty impacts outcomes in mechanical ventilated patients. Our aim was to determine whether frailty affected mortality in mechanical ventilated patients. Methods: We performed an observational cohort study of critically ill patients admitted to the ICU at the University Hospital and the South Texas Veterans Health Care System in San Antonio, TX over a two-month period (November-December) in 2022. We included patients that required invasive mechanical ventilation and excluded all patients that only received high flow nasal cannula (HFNC) or non-invasive mechanical ventilation (NIV). Our variable of interest was frailty measured by the Clinical Frailty Scale (CFS) with a score of ≥ 5 compared to non-frailty patients (CFS < 5). The primary outcomes were all-cause ICU- and hospital mortality. Results: We included 74 patients that required invasive mechanical ventilation. The patients were stratified as frail (CFS ≥ 5; n=46, 62.2%) and non-frail (n=28, 37.8%). Patients tend to be male for both frail and non-frail groups. However, frail patients tend to be older (mean age 66.7 +SD 10.1) compared to non-frail patients (mean age 50.9 +SD 13.7). Among all the patients that required invasive mechanical ventilation, the ICU mortality was 35.1% and the hospital mortality was 40.5%. The ICU mortality was numerically higher among frail patients (n=20, 43.5%) vs. (n=6, 21.4%) non-frail patients (OR 2.82, 95% CI 0.96-8.26, p=0.06). Additionally, frail patients had higher hospital mortality (n=24, 52.2%) vs. (n=6, 21.4%) non frail patients (OR 4.00, 05% CI 1.37-11.69, p=0.01). Conclusion: Our results suggest frailty is associated with higher hospital mortality, but not ICU mortality. Further studies should assess whether frailty hospital survivors may have higher long-term mortality.

Abstract Name: Enhancing Veteran Transition: Assessing Community Support Impact

This study acknowledges the pivotal role of community support for veterans transitioning from active-duty service to civilian life, recognizing the potential life-altering challenges in the absence of such support. Amidst the complexity of veterans' reintegration, the research aims to comprehensively assess the scope and effectiveness of community support mechanisms. The investigation centers on understanding the crucial role of community engagement, spanning various services and initiatives. Posed by my research question, "To what extent do the scope and efficacy of community support systems contribute to facilitating a successful transition for military veterans from active-duty service to civilian life?"—the study designates community support systems as the independent variable and the successful transition of veterans as the dependent variable.Employing a survey with 86 veteran participants responding to 40 questions, the research establishes a strong correlation between veterans' transitioning experiences and their expressed need for community. The findings not only underscore the significance of community support in successful reintegration but also contribute valuable insights to inform targeted initiatives and policies enhancing the transition experience for military veterans.

Abstract Name: Proteomic Dynamics of Succinylation During Myogenic Differentiation

Myogenesis, the formation and development of muscle tissue, is the process by which myogenic precursor cells transition into multinucleated myotubes. The determinants of this process are essential in the understanding of skeletal muscle regeneration and atrophy. This study focuses on the role of succinylation, a posttranslational modification in which a succinyl group is added to an exposed lysine residue, thereby altering protein structure and function. We investigated the impact of SIRT5, a sirtuin that reduces the level of protein succinylation as a metabolic regulatory system. Primary muscle progenitor cells (MPCs) and C2C12 myoblasts were systematically cultured through proliferation and differentiation phases, and subsequent lysates were analyzed by western blotting using Anti-SIRT5 and Anti-Total-K-Succinylation antibodies. This analysis revealed a temporal upregulation of SIRT5 and an advancing decrease of succinylated proteins, corresponding with the progression of cellular differentiation. Induced hyper-succinylation via Dimethyl Succinate was observed to perturb protein function at molecular weights ~55 kDa and ~200 kDa, leading to impaired myogenic differentiation. This was evidenced through immunocytochemistry by reduced expression of the differentiation marker pan-Myosin Heavy Chain. Pathway enrichment analysis of succinylated proteins implicated vacuolar fusion, cytoskeletal integrity, cellular signaling, and ATP metabolism, among other integral processes. These results demonstrate that succinylation and SIRT5 play critical roles in myogenic

differentiation by modulating critical cellular pathways. Identifying the molecular mechanisms of succinylation enhances our understanding of myogenesis and reveals potential targets for therapeutic intervention in muscle wasting associated with age, malnutrition, disuse, injury, and disease.

Abstract Name: Subhuman: Incel Fantasies That Create Victimhood

Incels, short form for “involuntary celibates,” are men who are angry with their lack of romantic and sexual relationships and are infamous for turning their resentment towards women. Research on incels has increased due to the rise in social media platforms that allow them to connect (O’Malley, Holt, & Holt, 2020) and the increase in high-profile, violent incidents involving incels (Baele, Brace, & Coan, 2019), and due to the overall potential threat posed by them (Cottee, 2020). However, there is a lack of research on understanding why incels see themselves as outsiders beyond their lack of confidence or self-esteem. Using fantasy theme analysis, this study centers on the fantasies incels invest in that contribute to their self-proclaimed status as “Othered.” Results from the study found the following fantasies: subhuman, or stories of low self-worth, roping, the idolization of suicide, and foids, stories of women who act against incels. Within this study, it was also revealed that there exist subgroups within the incel community that maintain beliefs that contradict previous research, such as subverting the idea that all incels are celibate. These new revelations highlight the need for shifting lenses of analysis to reach a fuller comprehension of incels. Understanding the incel community and its complexities is imperative to creating preventative measures to dismantle their beliefs. Future research will focus on a fixed analysis of a single subgroup in the incel community, allowing a broader perspective of knowledge that would help inform efforts to reform current incels by deconstructing their misogynistic views as well as adding to current preventative measures.

Abstract Name: Synthesizing a thiophenol precursor for thiol-bridging mix-valent metal complexes.

Mix-valent dinucluear complexes are unique models used for the exploration of intriguing magnetic properties and used to comprehend active sites in numerous biological enzymes. Among these complexes, those bridges to sulfur are especially interesting due to the enhanced orbital overlap between sulfur and transition metals. For this research project, the goal is to synthesize an important thiophenol precursor that will be used to help prepare a diverse range of dinuclear complexes conveniently. So far, a dialdehyde phenol has been successfully synthesized through a two-step synthesis. The continuation of this project will allow for the conversion of the phenol into a thiophenol group.

Abstract Name: A Multiwavelength View of Star Formation and Feedback in Active Galaxies

Active Galactic Nuclei (AGN) are supermassive black holes at the centers of galaxies that are actively accreting matter. This process can drive powerful outflows of matter and radiation into the host galaxy, which can enhance and/or shut off star formation, in a process known as AGN feedback. I present images of these outflows in multiple electromagnetic wavebands: 22 GHz radio images taken by the Very Large Array, X-ray images from the Chandra space telescope, and visible light images from the Hubble Space Telescope. This multiwavelength view gives us a better understanding of the AGN-galaxy interaction: the radio images map the outflows themselves, visible light shows us how large the jet is relative to the galaxy and the locations of star formation, and X-ray emission maps the sites of interaction of the outflow and host galaxy gas. The radio and X-ray images were used to determine which galaxies to further analyze using spectroscopic images from the MUSE IFU instrument on the VLT, which provides spectral information for every spatial pixel in a galaxy image. I analyze a sample of both archival and newly-obtained MUSE data, resulting in maps of ionized oxygen and hydrogen gas. These images also provide velocity information, revealing distinct regions of red-shifted and blue-shifted gas emission that can indicate rotation, outflow-driven gas velocities, or turbulent motion due to shocks at interaction sites. Future work will use the MUSE data to determine the strength of the outflow, and it will also verify that it is caused by an AGN and not other radiative sources such as supernovae.

Abstract Name: Cosechando Poder Through Transformative Research Practices

This presentation aims to highlight two transformative research approaches that center on historically marginalized students as we acknowledge the cultural values, wisdom, and practices they bring to the lab and collaboratively build on those. Our research practices extend beyond traditional research bounds to honor the conocimiento (knowledge systems), value, and wisdom of students and their communities. Our research practices seek to dismantle the hidden curriculum by fostering mutual partnerships between students and faculty mentors from marginalized communities. Through this presentation, we will share the critical components of our approach, including the development of culturally and linguistically responsive research frameworks, liberatory research labs, and capacity-building initiatives. Some of the methodologies we use are participatory action research, indigenous methodologies, and community-based research. We will provide examples of how these methodologies can be implemented and share three fundamental approaches that attendees can adopt to their research groups such as active role modeling, power-sharing, and intentional de-centering of the traditional role of “researchers” in academia.

Abstract Name: The Relationships of Social Media Use, Self-Esteem and Loneliness

Humans have an inherent need for social connections, where the quality of relationships holds greater significance than quantity, as the absence of such connections can lead to loneliness and diminished self-esteem (SE). Baumeister and Leary describe this as an innate drive for meaningful social interactions. Social media (SM) plays a pivotal role in fostering and sustaining these connections, reducing the reliance on in-person interactions. Single individuals with a large social circle may find that SM has a limited impact on their sense of companionship but can contribute to more substantial relationships.In committed relationships, the use of SM can serve various purposes, potentially indicating unmet companionship needs within the relationship. The quality of connections with a partner can significantly influence SE and feelings of loneliness.It is hypothesized that: H1) Among single people with few friends, SM users will have higher SE and experience less loneliness than non-users; H2) Among single people with lots of friends, SM users will have no difference in levels of SE or loneliness than non-users; and H3) Among people who are married or in a long-term relationship, SM users will have lower SE and experience greater levels of loneliness than non-users.Data will be obtained anonymously at an online survey site from 100 people over the age of 18 years. They will complete questionnaires including basic demographics, the amount of SM usage, the UCLA 3-item Loneliness Scale (LS), and the Rosenberg Self-Esteem Scale (SE).H1 will be supported if SM users have lower LS scores and higher SE scores than non-users. H2 will be supported if users and non-users have similar LS and SE scores. H3 will be supported if SM users have higher LS scores and lower SE scores than non-users.

Abstract Name: DOOR 46

Although the United States is known for attracting the most immigrants around the world it continues to lack a system designed to aid common barriers that new residents face. Therefore, DOOR 46, a temporary housing facility for immigrants will provide a community that emphasizes gathering individuals with similar struggles while exposing them to different cultural experiences that improve their adaptation to the new country. The design focuses on traditional aspects of the most common immigrant cultures for each State while enhancing the curiosity of other cultures. This community can provide the residents with a sense of cultural familiarity by designing a space with their cultural aspects and still being surrounded by other cultures. The middle ground of balancing the familiar spaces with other cultures will allow the immigrants to ease into their new lifestyles in the States. After conducting various forms of research such as surveys and articles, it is evident that this specific project required deeper one-on-one conversations to conduct the most authentic research.

Within the research, it became evident that new residents encounter lots of barriers, such as being homesick, culture shock, and lack of knowledge. Therefore, DOOR 46, will have a small community of culturally inspired homes with a public building in the center, filled with spaces designed to improve their adaptation in the United States. The homes will consist of common elements prevalent in each group of the specific culture, such as materials, shapes, colors, textiles, and much more. Meanwhile, the main public building will have spaces that will enhance the development of the new residents, like classrooms for English and citizenship classes and a minimarket with authentic food. Altogether, DOOR 46 will provide a comfortable and inviting space for all the new immigrants to have access to all their physical and mental needs.

Abstract Name: Traditionalism in Assimilation: A Case Study of Filipino Literature

This research examines the impact of cultural traditionalism on the Filipino diaspora when assimilating into other cultures through an examination of Filipino literature, including Regie Cabico's depiction of his family's immigration to the US in "Mango Poem," and Mia Alvar's short story exploring the lives of Filipino families settled in Bahrain in "Shadow Families." With a population of approximately twelve million people spanning over two hundred countries, the Filipino diaspora is one of the largest dispersed communities in the world. While many studies have assessed how Filipino culture impacts the diaspora's assimilation into foreign cultures, what is less explored is how the stories produced from this process present assimilation. First, this paper investigates the normalcy of Filipino immigration through the research of Filipino cultural analyst Maharaj Desai and migration policy expert Kevin O'Neil, locating key aspects of Filipino culture to better understand the origins of the Filipino diaspora. Then, W.E.B. Du Bois' theory of the Double Consciousness is analyzed for its usefulness as a culturally focused framework for investigating the Filipino immigration experience. Finally, a comparative analysis of the cultural symbols, including those representing Filipino Catholicism, seen in the "Mango Poem" and "Shadow Families" is conducted through the lens of the Double Consciousness. Ultimately, this analysis suggests that Filipino adherence to traditionalism plays an important role as a coping mechanism for migrants; however, it can also place Filipinos in a position to be alienated within the culture they are immigrating into. These two examples of Filipino fiction provide representations of immigrants who hold onto certain cultural identity markers during assimilation, which continually connects them to the greater Filipino immigrant community and argue that the Filipino immigration experience is similar for most Filipino migrants.

Abstract Name: In Vitro Selection of DNA Aptamers for Kavain

Kava, Piper methysticum, is a plant characteristic for Pacific islands. Currently Kava is gaining attention in its ability to dissuade anxiety as an alternative to conventional prescription drugs. The primary active principle in Kava is kavain. Despite the observed benefits surrounding kavain, there have been recent studies linking the molecule to several adverse effects and even liver failure. Traditional methods for detecting kavain require expensive equipment and highly trained staff. Due to the possible link between kavain and liver toxicity, the development of the sensitive, but still rapid and robust analytical method for detection of kavain is needed. The objective of this project is to develop a biosensor made of single stranded DNA-aptamer that will bind to kavain with high affinity and high specificity. In our lab we are isolating DNA-aptamers through the process of an in vitro selection and amplification- SELEX (Systematic Evolution of Ligands by Exponential Enrichment). We use a commercially available ssDNA library of 36 random nucleotides flanked by two primers. A nucleic acid library that has 36 randomized positions potentially contains 436 different oligonucleotide sequences, each one with a unique associated structure. Through multiple rounds of SELEX, all members of the library which interact with a target kavain will be favored for PCR amplification and would be more likely identified as binders. Currently we have completed 10 rounds of SELEX, and the target kavain has maintained at a concentration of 100 mM. In our next steps we plan to start decreasing the concentration of kavain, and to start introducing a counter-target, Pipermethystine at 1mM. This will be followed by cloning and sequencing in order to isolate a DNA-aptamer for kavain in low nanomolar range. We expect that our study will enable development of the more advanced biosensors for detection of challenging small molecules of interest.

Abstract Name: Synthesis and Testing of a Nanobead Sunscreen from Kaempferia galanga Rhizomes, a Green Chemistry Approach

Kaempferia galanga is a member of Zingiberaceae. It has medicinal properties such as anti-inflammatory, anti-fungal, and pain-relieving effects. K. galanga rhizomes are rich in cinnamate derivatives; these are common sunscreen agents due to their ultraviolet (UV) radiation absorbing properties. This study aimed to extract ethyl-p-methoxycinnamate (EPMC), an abundant cinnamate derivative in K. galanga rhizomes, and encapsulate it within Pluronic nanobeads to form a nanobead sunscreen effective against UV radiation, specifically ultraviolet-B (UVB). Overexposure to UV radiation without protection increases the risk for skin damage and cancer. The method consists of three phases. EPMC was extracted from dehydrated K. galanga rhizomes through maceration with 70% ethanol, fractionation with n-hexane and ethyl acetate, followed by drying via a rotary evaporator. The nanobeads were synthesized with extracted EPMC using a custom Flash NanoPrecipitation (FNP) apparatus. Thin Layer Chromatography (TLC) verified the presence of EPMC in the nanobeads, and UV/Visible Spectroscopy (UV/Vis) confirmed the ability of the EPMC nanobeads to absorb UVB radiation. The effectiveness of the EPMC nanobeads was investigated using a UVB chamber and radiometer. 2x diluted unseparated EPMC nanobeads showed a 48.23% UVB absorbance rate. 2x diluted unseparated and 2x diluted aggregated EPMC nanobead samples were assessed for effectiveness in UVB absorbance throughout extended UVB exposure. After five hours, 54% and 41% efficiency respectively were reported. Ongoing is an efficacy assessment of the EMPC nanobeads on calf thymus DNA exposed to UVB. 6-4 photoproducts (6-4 PP) will be measured using Enzyme Linked Immunosorbent Assay (ELISA). The results are expected to show a significant reduction of 6-4 PP on the DNA with the protection of EPMC nanobeads compared to the control - DNA without the protection of the EPMC nanobeads. The results of this EPMC nanobead sunscreen demonstrate a potential to offer human skin cells protection against UV-induced damage.

Abstract Name: Investigation of Infant Postural Duration, Frequency, and Milestones During The First Year of Life

During the early stages of motor development, infants engage in a variety of postures, which support their ability to acquire motor skills in the future, such as walking (CDC, 2023). In this investigation, we assessed the patterns of infant postures, as well as, the average onset of milestones (e.g., sitting, crawling, cruising). Longitudinal observations (1-12 months) followed the motor behaviors of eight infants (5F, 3M). Naturalistic observations occurred via monthly home visits; in which a researcher recorded wakeful infant playtime for 20-30 minutes. Data analysis consisted of continuous coding to determine the frequency and duration of infant posture. As anticipated, results reflected an emergence of sitting skills around 4 months, with a slow increase in average, past the functional onset (FO), (M = 6.37 months). This pattern is followed by a notable decrease around 8 months, creating an inverted U-shaped curve of sitting skill expression across the first year of life. Prone postures indicated a similar expression range, reflecting an inverted U-shaped curve. The data shows that infants engage in low percentages of prone postures at 2 months, which increase around 6 months, and decline in the final 6 months. Pronation skills resulted in a later average FO (M = 9.09) due to the inclusion of crawling skills. Our analyses also revealed an increase in upright posture percentages with age, emerging around 9 months. The range of upright postures resulted in an increasing pattern until the FO (M = 12.8 months). Identifying posture frequency, duration and milestone ranges can impact the field of motor behavior by providing a deeper understanding of developmental influences within the first year of life.

Abstract Name: Understanding the Role of Gap Junction Molecule innexin-19 in Neuronal Maturation and Aging

Many molecular and functional changes occur in post-mitotic neurons throughout post-embryonic nervous system development/maturation and aging. One emerging hypothesis is that defects in neuronal maturation early in development can predispose individuals to impaired neuronal aging and neurodegeneration later in life. One of the most prominent changes, crucial for proper neuronal maturation, is the downregulation of electrical synapses/gap junctions, one of two major modes of neuron-neuron communication. Our goal for this project is to understand if and how the downregulation of electrical synapses contributes to neuronal maturation and aging, using Caenorhabditis elegans (C. elegans) as our experimental model due to their stereotyped and fast developmental cycle, invariant cell lineage, and the ability to identify the expression pattern of any molecule in the entire nervous system to single neuron resolution. We first focused on innexin-19 (inx-19), a gap junction channel that has been previously suggested to play important roles in neuronal maturation, and characterized its downregulated expression pattern across post-embryonic development in single neuron resolution. Next, we characterized the locomotor behavior across each stage of post-embryonic development in wild type vs. inx-19 null mutant animals using the WormTracker. Despite high inx-19 expression in early development, we found that inx-19 mutant animals only exhibited defects in locomotion in old adults. To investigate this further, we used the Auxin Inducible Degron tool to control inx-19 function with spatiotemporal precision. We found that specifically inhibiting inx-19 function in early larval stages but returning to normal function in adulthood still impaired locomotion specifically in old adults. Currently, we are investigating the mechanisms by which dysregulation of electrical synapses early in development contributes to defects in neuronal function in aged adults, which will help us to better understand underlying mechanisms of neuronal aging and to identify potential novel therapeutics for neurodegenerative disorders.

Abstract Name: Physiological and Behavioral Effects of Salinity on Two Species of Intertidal Snails

Calcifying organisms such as marine snails need calcium and carbonate to build and maintain their shells. The total alkalinity (TA) is highly dependent on carbonate species like carbonate and bicarbonate. The TA and salinity of the ocean vary together because the same processes that increase one also increase the other, and vice versa. TA will have a smaller carbonate concentration as it decreases with salinity, so there will be less available for the snails to use. Thus, shifts in salinity may impact shell-dwelling organisms' ability to maintain and build new shell, or make behavioral shifts to reduce the impact of the salinity. I will investigate

the proposed effects of salinity on two marine snails: Littorina littorea and Ilyanassa obsoleta collected from Chincoteague Bay, Virginia. These snail species play an important role in the bay ecosystem. L. littorea is an herbivore whereas I. obsoleta is a predator; both are prey for many bay organisms. They are both estuarine snails that live in a habitat with high salinity fluctuations throughout the day and year. However, both species may utilize behavioral strategies to avoid suboptimal conditions. To determine the physiological and behavioral effects of salinity on these two species, live snails and empty shells will be exposed to four different salinities. Resulting differences in weight, size, morphology, shell composition, and shell strength will be recorded for approximately four months. We predict that each species will display reduced shell growth at lower salinities unless behavioral shifts allow them to mitigate these effects.

Abstract Name: A Look at University Student Engagement and Connection in and its Impact on At-Risk First-Year Students Residing in Housing and Residential Life at Middle Tennessee State University

This study investigates how at-risk freshmen that are residing in Housing and Residential Life connect with MTSU's campus and feel a sense of belonging versus those that do not reside in Housing and Residential Life. Housing and Residential Life is the center of student engagement and students are expected to feel a sense of connection more than those that do not live in university housing. This study will look at what other university Housing programs are doing for student support and connection, what MTSU does for student support and connection, and the leadership in university Housing. College students, especially at-risk college students, are at risk of dropping out of school and not being connected academically or emotionally. Middle Tennessee State University (MTSU) Housing and Residential Life (HRL) also currently has a little under 3,000 students residing in university housing. One of the ways that students feel connected to campus is by student engagement in the residential halls. Housing staff put together programs for residents to attend, residents live so close to one another, MTSU Housing puts together Living-Learning communities for residents based on interest and major, and other areas of student affairs connect with Housing and Residential Life. Because Housing has many ways for students to be connected to campus well, students that are residing in Housing and Residential Life may feel more connected than students that commute to school. Connection to campus is one of the most important things a student can do during their time on campus. Not every student is going to feel connected to campus. However, if residential life students feel more connected than commuters, it could not only impact students' connections but also lead to helping more “at-risk” students feel connected and attempt to help them be successful academically, socially, and emotionally.

Abstract Name: Toward an LGBTQ-Inclusive Russian Language Classroom: Contexts, Models, and Materials

This presentation will share insights derived from ongoing research that considers avenues toward developing more LGBTQ+-inclusive pedagogies within the context of Russian language teaching and learning in the United States. Despite notable strides in recent years to support teaching and learning about more diverse identities in the Slavic field, it is evident that contemporary textbooks for Russian language pedagogy fall short in fully representing LGBTQ+ lives. There remains a lack of readily accessible pedagogical materials designed to assist both learners and instructors in seamlessly integrating these diverse identities into the Russian language classroom. This presentation will introduce several LGBTQ+ inclusive teaching strategies that have proven effective in second language classrooms, providing practical suggestions for how Russian language courses could adopt or adapt these practices for our own cultural contexts. Drawing upon successful practices from other language disciplines, there will be an analysis of the most frequently used methods for inclusive language practices in gendered language and how these practices can be presented to students in the classroom. Furthermore, the presentation will delve into the intricacies of Russian grammatical gender, shedding light on how the queer Russian-speaking community has customized the language to embrace a broader spectrum of identities. This presentation will conclude by sharing with participants a set of resources to use in the classroom setting to include LGBTQ+ identities in novice, intermediate, and advanced level conversations about biographies, relationships, marriage, and families.

Abstract Name: Florida Government and data Scientists on rising sea levels

Rising sea levels are a growing problem in coastal regions in Florida, and there are many climate change challenges that scientists and local governments have to face today to maintain a clean and safe environment for the people who live within the tropical regions of Florida. Climate change threatens to enhance coastal flooding and saltwater intrusion into water supplies along regions around the southern United States. The rise in water on sea levels around the coast is expected to be one of the most socially and economically disruptive challenges as the temperatures in Florida keep rising. The water disruptions risk the people around Florida as floods occur during late springs and hot summers, ranging from day-to-day challenges of delivering essential services to planning for large-scale population shifts inevitable with the loss of habitable land. Infrastructure providing necessary water services to treat water waste, control stormwater runoff, and transport are considerably vulnerable to rising sea levels and intensifying existing flooding hazards. Without adaptive measurements in place, rising sea levels could lead to population shifts similar to the great migration, as residents move from inundated areas that are not exposed to water. Although federal and state governments can play key roles in shaping primary climate policy, sea level rise(SLR) has created localized risks that can only be addressed in profoundly local political environments. As a result, coastal cities and counties in Florida face increasing pressure from the general public, media, and credit markets to develop strategic plans addressing rising sea-level risks. To plan risks effectively, local governments developed procedures to break their complex problems down into politically tractable solutions.; yet despite the significant dangers that the coastal governments had to face from rising seas, there had been relatively little research conducted on how they strategically could plan to prepare for risks...

Abstract Name: Empowering non-native English speaking students: Nurturing self-efficacy for writing

Research on self-efficacy for writing at the college level is a relatively limited area of study. The current study explores the effects of an upper-level undergraduate writing-intensive Health Communication course on students' self-efficacy for writing. The purpose of this study was to identify strategies for improving self-efficacy for writing, particularly among underrepresented groups, as the study population was majority female, Hispanic, non-native English speakers, and first-generation college students. Student's self-efficacy for writing was measured using the Self-Efficacy for Writing Scale (SEWS) which was administered twice; once at the beginning of the semester and once at the end. Results showed statistically significant differences in students' pre- and post-self-regulation and writing convention scores (15% and 10% increase, respectively). These scores suggest major improvement in students' self-reported abilities for writing mechanics and the regulation of their writing process. Subsequently, two focus groups were conducted to gain insight into how students' self-efficacy for writing was affected by the class content, assignments, instructor feedback, and classroom environment. Implications of low self-efficacy on writing performance and strategies for enhancing self-efficacy for writing are discussed and should be considered for implementation by educators.

Abstract Name: Viewer Affinity for Live Sports Broadcast Innovations

The NFL is one of the most popular sports leagues in America. In the first two weeks of the season, NFL games are averaging 17.5 million viewers per game. The way NFL games are consumed is changing with the advent of new broadcast techniques that may cater to audiences with different levels of football experience. My research aims to evaluate the response of viewers from various football knowledge bases to new camera angles being used in NFL broadcasting. The traditional broadcast angle shows the two teams on the line of scrimmage and depicts the players' movement up the field as horizontal movement across a viewer's screen. The new camera angle dubbed "All 22", shows the field from behind the view of the offense, making the downfield movement of players appear as vertical movement on the viewer's screen. The reviews of the "All 22" camera angle have been mixed. Some viewers enjoy the new camera angle, as it allows them to see plays unfolding from the offense's perspective and the defense's response to specific movements. Other viewers say that the new angle is disorienting, especially to viewers who are not as familiar with the intricacies of football. This study will gauge the viewers' affinity for the new camera angle using data from individual interviews complemented with data from eye-tracking software used while watching plays from both camera angles. The use of eye-tracking can indicate feelings of stress, interest, or confusion upon viewing certain material. Conducting interviews and tracking the eye movements of participants who are avid and casual football viewers provides insight into how and when to use this camera angle during broadcasts. Furthermore, this study will indicate if the new camera angle is inviting or isolating to viewers new to the sport, which could have implications for viewership trends.

Abstract Name: In-Between an Ocean and a Hard Place: Exploring Sojourning Southern Chinese Diaspora in the Pacific and West Indies (1830-1910)

Current scholarship has described Chinese immigration through their search for gold in California or barred entry into the US by the Exclusion Act of 1882, briefly mentioning the extent of their assimilation or assuming permanent settlement in their respective areas. However, it fails to examine the Caribbean and US as a sojourning society like their Southeast Asian counterparts. With anti-government suspicions and rejections of overseas Chinese back into their homeland coupled with exclusionary policies in the US, sojourning Chinese found themselves in a state of estrangement - no citizenship, no rights, nowhere else to go. This group exhibits a particularly interesting perspective of immigration as a temporary state who longs to return to their homeland or at least support their families abroad. This "in-betweeness" of overseas Chinese sprouts various complications regarding their national identity as well; an experience altered and affected by immigration of any means, which too is largely overlooked by scholarship, hiding between paragraphs or through brief mentions in sentences.Thus, this research examines the ideas of a sojourn society's willingness to return home. Southern Chinese migration to the United States, Hawaii, and the Caribbean are going to be chronologically explored in the Modern Period to help contextualize their migration outward, starting from the period of the gold rush in California towards the height of Chinese exclusion in the US using colonial letters from respective plantations and personal narratives. This research will also explore the complicated nature of overseas Chinese's national identity - how exclusionary policies, treatment of Chinese immigrants, and China's rejection/acceptance of their "citizens" directly impacted immigrating Chinese from 1882 to the early 1900s. This research offers various ways to reframe the discourse of immigration and migrant experiences and helps contextualize the presence of large Chinese enclaves throughout North and South America.

Abstract Name: Astrocytic Contribution to Motor Recovery After Spinal Cord Injury

Spinal cord injury results in loss of motor, sensory, and autonomic functions. Astrocytes, a cell type in the central nervous system, react to injury in a process called astrogliosis that impacts repair. At the site of injury, reactive astrocytes form an astrocytic scar that yields neuroprotective effects. Impaired formation of this scar

causes increased tissue damage along with worsened motor recovery. Our lab identified leucine zipper-bearing kinase (LZK) as a key activator of astrogliosis that promotes wound healing after spinal cord injury in mice. This project examines the effect of astrocyte-specific LZK gene manipulation on hind-limb motor recovery following spinal cord injury. To determine the role of LZK on functional recovery post-injury, a complete crush was performed at thoracic level T8. Hindlimb function was measured using i) Basso Mouse Scale, an open field test that assesses gross motor function; and ii) regular horizontal ladder test that measures skilled stepping over 2 months after injury. Analysis demonstrated decreased function following LZK gene deletion. Decreased gross and fine motor function improvement was seen for the LZK-knock out when compared to the control genotype, suggesting that LZK is necessary for functional recovery. This is further suggested through increased gross motor function observed for the LZK-over expression when compared to the control genotype. Further research must be done to determine the role of LZK-over expression in fine motor recovery.

Abstract Name: Determining Specificity in a High-Quality Library of Pervasive Binding Proteins

Antibodies, renowned for their precision in antigen (i.e. binding target) recognition and specificity, exhibit limitations as specific-binding therapeutics due to their large size and complex structures. To overcome these drawbacks, alternative protein scaffolds with stringent binding specificities and smaller sizes are explored through protein library design. This study focuses on the mammalian central calcium-regulating protein calmodulin (CaM) as an alternative scaffold. In the cell, CaM recognizes and binds to hundreds of cellular targets to transmit calcium signaling. Previous work from our group has shown that introducing diversity into this highly-conserved sequence is tolerated to generate a large, high-quality protein library of synthetic CaM. Characterization of over 77 randomly selected sequences confirmed that individual sequences can be overexpressed in bacteria and purified. Additional structural characterization showed conformation differences amongst individual members upon the binding of calcium, and different protein folding stabilities in the unbound (apo) form. Our hypothesis posits an inverse correlation between stability in the unbound form and increased binding specificity with novel targets. To test this hypothesis, we selected three CaM variants (P7, B7, and B9) with reduced apoprotein stability compared to wild-type (WT) CaM, and three variants (K4, P5, and B6) with enhanced apoprotein stability and measured changes in binding specificity through rodent brain pull-down assays. In addition, we provide binding data comparing selected variants to a single target peptide from KCNQ1. Our data show that members with decreased apoprotein stability lead to increased binding specificity and affinity, thereby supporting our overall hypothesis. The outcomes of this investigation with this model protein, yield new insights into protein library design of alternative scaffolds with increased binding recognition and specificity, to help accelerate discovery and development of protein-based tools for research and the treatment of diseases.

Abstract Name: Identification and Prevalence of Batrachochytrium dendrobatidis on Amphibians in Ohio

Amphibians are in a severe decline worldwide making them the most threatened group of vertebrates. Batrachochytrium dendrobatidis (Bd), a fungal epidermal pathogen, is a major cause but little is known about the occurrence of chytrid in the Midwestern United States. The goal of this research is to assess the prevalence and strains of Bd at the Primmer Outdoor Learning Center (Logan, OH) and the Stratford Ecological Center (Delaware, OH). Amphibians were live-trapped and hand caught during ten sessions at the swamp wetland and streams at Primmer, and a pond and two vernal pools at Stratford, during Spring and Summer 2023. Ninety-six total swab samples were collected at Primmer and Stratford from amphibian species including spotted (Ambystoma maculatum), small-mouthed (A. texanum), southern two-lined (Eurycea cirrigera), northern dusky (Desmognathus fuscus), and eastern red-backed (Plethodon cinereus) salamanders, and American toads (Anaxyrus americanus), spring peepers (Pseudacris crucifer), western chorus frogs (P. triseriata), American bullfrogs (Lithobates catesbeianus), and northern green frogs (L. clamitans melanota). To date, DNA has been extracted and real-time qPCR testing has been performed for 94 swab samples. TaqMan assays consisted of TaqPath BactoPure master mix, primers ITS1-3 Chytr and 5.8S Chytr and probe Chytr MGB2, and Taqman Exogenous Internal Positive Control reagents. Preliminary results show that 4.9% (3/61) of samples from Stratford and 15.2% (5/33) from Primmer were positive for Bd from a western chorus frog, northern green frog, and a spotted salamander from Stratford, and two southern two-lined salamanders and three northern dusky salamanders from Primmer. Additional extractions, qPCR, and digital PCR analyses are ongoing, and samples that test positive will be DNA sequenced to determine the strain of Bd. This research contributes to our understanding of amphibian biodiversity and disease surveillance in Ohio, and can help inform management and conservation efforts in the Midwestern USA.

Abstract Name: Creation of U.S. Money by the Private Sector

According to the U.S. Constitution, can U.S. money be issued by any entities solely in the private sector? The answer is no. Article 1, Section 8, Paragraph 5 of the U.S. Constitution states, “The Congress shall have Power … To coin Money, regulate the Value thereof, and of foreign Coin, and fix the Standard of Weights and Measures.” Paragraph 18 further states, “To make all laws which shall be necessary and proper for carrying into execution the foregoing powers.”Since U.S. money is currently being created and circulated by the private sector, under the auspices of the Federal Reserve, this process is in violation of the Constitution. The Federal Reserve is not a government organization. It is a private cartel of 10 powerful private banks, each of which has the sole responsibility of earning a profit for its investors. The function of earning a profit interferes with the function of working on behalf of the public. Consequently, the U.S. is currently experiencing a pricing structure that harkens runaway inflation. There are no elected officials in the Federal Reserve who are responsible to the American public. The methodology of the Federal Reserve is opaque. It was originally created under fraudulent circumstances in 1913.Historical precedent described from scholarly research verifies the unconstitutionality of private creation of U.S. money. Research methodology will consist of proof from numerous case studies which confirms the thesis. The conclusions will show that U.S. money can only be created and circulated by the Congressional branch of the U.S. Government. These conclusions

will be discussed in the context of historical experience with current evidence of the danger of this private system of money creation to the American public and the world, as was evidenced in 2008.

Abstract Name: Struggling Readers: Action to Improve Comprehension

In the intermediate grades, reading comprehension greatly impacts student's ability to understand what they are reading. When evaluating a student's reading performance, 90% accuracy is an indicator that the text is an appropriate level for a student. Accuracy is determined by how many words are read incorrectly while the student is reading orally. The methodology of action research will be used to explore the validity of the following hypothesis, "Will the application of reading strategies improve reading comprehension?"A sixth-grade multilingual learner (ML) who attends an intermediate school will be the focus of this study. This student's reading level is currently evaluated at the third-grade level. Although the student can read simple chapter books, they need continual practice reading with more complex text. To support the student to meet 90% accuracy for reading comprehension, five specific reading strategies will be implemented. After the student has been assessed to determine appropriate reading level text, 1) The student and the teacher will meet four times a week for 15 to 20 minutes for a total of six weeks, 2) teacher will preview words in the text with student, 3) student will read aloud to the teacher, 4) student will orally summarize what is being read. Lastly, to measure if the student's reading comprehension has improved, they will write a summary of the content in 2-3 sentences. With continual support using these strategies, the student will be able to transition to a more complex text.

Abstract Name: Accusations and AMLO: Legitimizing Femicide Responses Through Political Discourse

How might a presidential administration respond to severe public criticism concerning its reaction to the brutal slaughter of women across the country? This research analyzes how the language patterns of the Mexican presidential administration attempt to justify the political action taken to address femicide, the intentional killing of women based on their gender. In other words, how does the political discourse produced by the Mexican president and his administration from November 2018 to December 2020 in commenting on cases of femicide in Mexico endeavor to legitimize accused policy inaction? Utilizing a critical discourse analysis framework, the term 'femicide' is searched within Mexican presidential administration press conference transcripts from November 2018 to December 2020, providing 57 that discuss this specific form of violence. The femicide-related sections of each of the 57 transcripts are analyzed for recurring discursive patterns in responses to media questions on the administrative response. This study finds that the administration attempts to establish policy legitimacy and minimize culpability by conflating femicide with

other crimes, signaling federal virtue and progress, deflecting attention away from bureaucratic responsibility and toward other involved parties, and generalizing descriptions of response strategies. A quantitative assessment involving the numerical tallying of the four strategies across the 57 transcripts exposes the extensive use of these discursive moves during the time period studied. These findings supplement the understanding of the relationship between discourse and policy as well as political responses to public dissent and violence as initially outlined in previous scholars' studies of normative discourse and the positioning of discourse as both a theory and a method. Further, these findings provide vocabulary to better identify and interrogate rhetorical legitimization and intimate how to navigate the complicated dynamic between the bureaucracy and the people.

Abstract Name: Air Force Relevant Cold Injury Induces Release of Microvesicle Particles Which is Downregulated by Treatment with Tricyclic Antidepressant Imipramine

The Department of the Air Force has the greatest United States Military presence in the Arctic region with assets in Alaska, Greenland, and around the world, and the Air Force continues expansion and development of operational capabilities in the Arctic region in pursuit of vigilance, deterrence, and defense from foreign threats. Warfighters in the Arctic region and other subarctic regions are at high risk for cold injury including frostbite and hypothermia. One of the most significant pathologies associated with frostbite is inflammation and its consequences including ischemia, necrosis, and self-amputation. Previously, the Travers group has shown that the lipid mediator Platelet-activating factor (PAF) was biosynthesized and released by cells undergoing cold injury. Moreover, many environmental stressors (heat, UVB radiation) which also produce PAF also generate subcellular microvesicle particles (MVP). The goal for these studies was to define if cold injury results in MVP generation and release and whether cold injury effects on MVP release were PAF-Receptor (PAFR)-dependent or -independent. Using the human keratinocyte-derived cell lines HaCaT, KBM (PAFR-), and KBP (PAFR+)we find that cells undergoing Air Force relevant cold injury released MVPs consistent with the release of PAF and that MVP release appears to be PAFR-independent (though more studies need to be carried out to confirm this). We also tested if experimental cold injury to porcine skin explants resulted in MVP release, and if tricyclic antidepressant imipramine which blocks MVP releasing enzyme acid sphingomyelinase is a down-regulator of MVP release. Ultimately, these studies provide the first evidence that cold injury results in MVP release. Future studies will define roles of PAFR and acid sphingomyelinase in MVP release as well as the pathologic consequences of MVP release in the setting of cold injuries.

Abstract Name: Assessment of a Polyethylene Glycol Based Bivalent Bacteriophage Treatment for Pseudomonas aeruginosa and Staphylococcus aureus in an In Vitro Tissue Model

Bacterial infections caused by Staphylococcus aureus and Pseudomonas aeruginosa are becoming harder to treat due to the rise of deadly antibiotic-resistant strains of these microbes. These bacteria are often responsible for common skin infections including surgical wounds, burns, and diabetic foot ulcers. Bacteriophages, naturally occurring viruses that kill bacteria, present a promising alternative to traditional antimicrobials. This study will evaluate duration of treatment, time of application, and dosage for a polyethylene-glycol (PEG) bacteriophage cream containing two specific bacteriophages: S. aureus bacteriophage 75 and P. aeruginosa bacteriophage PP7 (bivalent). This will be achieved by applying the bivalent ointment to an in vitro porcine skin model that simulates a skin infection. Bacterial presence will be quantified through colony counts at the conclusion of each trial. Results will reveal that varying dosage, treatment duration, and application time will influence this therapy's efficacy. It is expected that high-dose treatments delivered shortly after inoculation will show the largest reduction in bacterial growth. Optimizing dosage and timing of this bacteriophage therapy is important for future clinical application on real patients and could present a valuable alternative to traditional antimicrobials.

Abstract Name: Portraits of Prostitution: An examination of sex work and working-class women's experiences in Progressive Era New York City (1890-1920)

Despite its dangers and degradations, prostitution paid more than the so-called “clean” labor that kept working-class women living below the poverty line. This poster reconstructs the social geography of prostitution to reveal another disturbing inequity in the wage-labor market during the industrial economy’s maturation. Black women, who already experienced the least opportunity in the urban workforce, were similarly disadvantaged as sex workers. Unlike most fair-skinned women who benefited from the safeguards and, sometimes, even modern business practices, that defined brothels and dance halls, most women with dark complexions were forced to initiate sexual encounters on the streets or from the windows of their own lodgings. These findings are visualized through charts demonstrating the recorded complexions of sex workers in addition to recorded situations and locations of solicitation according to investigative and arrest affidavits from the Committee of Fourteen and Committee of Fifteen. Finally, there is a graph comparing weekly earnings from sex work and those from “clean” labor from the findings of a 1913 study conducted by the Bedford Hills Reformatory and establishes that sex work was a common occurrence for working-class women of this time. This research builds on the findings of Kathy Peiss, George Chauncey, and Elizabeth Alice Clement by presenting a more racially and ethnically diverse portrait of prostitution in turn-of-the-century New York.

Abstract Name: Investigating Solar Wind Conditions of Mars through MAVEN Observations and Validation of the AWSoM Model for Solar Wind Magnetic Fields

The Mars Atmosphere and Volatile Evolution (MAVEN) mission has been pivotal in advancing our understanding of the Martian upper atmosphere and its interactions with the solar wind. Previous MAVEN findings underscore the substantial impact of solar wind conditions on plasma dynamics within Mars' magnetosphere. However, a persistent challenge lies in the absence of a consistent solar wind monitor in the upstream region of Mars' magnetosphere, hindering real-time information acquisition within the planet's plasma environment. This project addresses this critical gap by focusing on the validation and assessment of the Alfvén Wave Solar Atmosphere Model (AWSoM), a solar wind model developed at the University of Michigan. The primary objective is to evaluate the model's effectiveness in predicting solar wind Interplanetary Magnetic Field (IMF) conditions, including both polarity and magnitude. The validation process involves a meticulous comparison of AWSoM's simulated outputs with solar wind data obtained directly from the MAVEN mission. Employing rigorous evaluation metrics such as mean squared error and dynamic time warping, the study aims to quantify the agreement between AWSoM's simulations and MAVEN's observational data. Building on previous comparative studies conducted with solar wind data from MESSENGER, this project extends the scope of inquiry, contributing valuable insights to the broader field of solar activity and solar wind IMF. Furthermore, the methodologies and results presented in this study are anticipated to play a pivotal role in informing future research endeavors and spacecraft missions, particularly those directed towards Mercury, such as the Bepi-Colombo mission.

Abstract Name: Perspectives on Walking Curriculum from Educators, Caregivers, and First Graders: A Two-Part Qualitative Study

Walking curriculum is a pedagogical practice in P - 12 education wherein educators take students out of the classroom on a walk with a curricular focus. As such, walking curriculum is considered a form of environmental education that connects students to the natural world and to their local community and encourages ecological imagination (Anderson, 2017; Fettes & Judson, 2011; Judson, 2020). In the first part of this study, we interviewed 19 educators (P-12) from the United States, Canada, Chile, Australia, and Singapore about their perceptions of walking curriculum. In our analysis of the data (Braun & Clark, 2021), we found five themes. First, all participants noted multidimensional benefits to being outside, particularly increased focus and attention. Second, most of the participants articulated that going on walks was good for them as teachers. Third, the participants use walking curriculum for multiple purposes. Fourth, all the participants felt that walking curriculum is an inclusive practice, even one that promotes equity. Finally, the participants shared how going on walks connected students to each other and to the land. In the second part of this study, we focused on a first-grade teacher and her students (N = 10) who go on walks every morning. During the 2022-2023 school year, we completed 40 hours of observations with the teacher

and students, and we conducted interviews with nine students and five caregivers. We developed five themes based on interviews and observations with the students and four themes based on interviews with caregivers. Given the many longstanding and common barriers to environmental education (e.g., Ham & Sewing, 1988; Kim & Fortner, 2006), walking curriculum is a means to get students outside the classroom, increasing the likelihood that they connect with nature, place, and peers while also covering typical curricular content and practicing various academic, social, and emotional skills.

Abstract Name: Contextualizing George Orwell: How Orwell's Life Experiences Influenced his Most Famous Novels

George Orwell is one of the most celebrated authors of the 20th century. His most famous novels, Animal Farm and 1984, serve as insightful commentaries on the horrors of totalitarianism. These two books have been studied extensively and incorporated into public and political discourse since his death in 1950. Contemporary Right-wing and Left-wing leaders and pundits both continue to reference the concepts and language in Orwell’s books to support their respective stances on various issues. Additionally, they have been presented to high schoolers and college students as simplified anti-Communist novels or pro-capitalist propaganda during the Cold War. However, Orwell’s work outside of these iconic novels has been given far less attention. This research project contextualizes Orwell’s work with his life and examines the way his political ideologies changed as a result of his experiences. Special focus is given to Orwell’s stint as an imperial policeman in India, his time spent as a vagabond in working-class England, and his experience in the Spanish Civil War. I argue that Orwell’s participation in the Spanish Civil War was a turning point in his life, exposing him to the authoritarian nature of Stalinism and solidifying his identity as a democratic socialist. This research illustrates that the common oversimplification of Animal Farm and 1984 is problematic as it fails to acknowledge Orwell’s commitment to socialism and his criticism of Western imperial powers. I contend that Animal Farm was intended to be a warning about the corruption of revolution rather than revolution itself and 1984 was written with the intention of warning Westerners about the potential for totalitarianism in their own countries, while also addressing totalitarian regimes of his day.

Abstract Name: Identifying ZYG11A, HS6ST1, and DIO2 gene expression in green anole lizards (Anolis carolinensis)

Green anole lizards (Anolis carolinensis) exemplify certain behavioral changes depending on whether they are in their breeding or non-breeding season. During the breeding season, these lizards display sexual behaviors such as head bobbing and flashing their dewlap and these behaviors do not occur during the non-breeding season. Our question is to determine at the gene level what might contribute to these behaviors being apparent in the breeding season and not the nonbreeding season. We are testing three candidate genes, ZYG11A, HS6ST1, and DIO2 for their expression during the breeding and non-breeding season in the anole brain. ZYG11A is both a promoter and enhancer gene and HS6ST1 plays a role in angiogenesis. DIO2 converts thyroid hormone T4 into the active version, T3, which plays a role in metabolism. Our research project is to evaluate whether the expression of these three genes is altered seasonally. We designed specific primers for our genes and tested them via PCR and gel electrophoresis. We obtained our results by performing a quantitative PCR (qPCR) test. This allowed us to analyze and determine if there is any significant difference in gene expression between breeding and non-breeding seasons in males and females. From these tests we will learn how these genes may play a role in behavior changes during the breeding and the non-breeding seasons.

Abstract Name: Determining the Efficacy of a Decitabine Analog, 4’-thionucleoside, in the Sensitization of Glioblastoma Cells to Temozolomide.

The dysregulated epigenetic landscape in glioblastoma (GBM), a malignant primary brain cancer, presents an avenue for improving treatment options. DNA methyltransferases, particularly DNA methyltransferase 1 (DNMT1), induce hypermethylation of tumor suppressor promoters, leading to altered gene expression and tumor growth. Treatment with the hypomethylating agent, decitabine, can inhibit DNMT1’s epigenetic gene regulation. Prior reports determined that pretreatment with decitabine sensitizes glioma cells to standard of care DNA damaging agent, Temozolomide (TMZ). Investigators at Southern Research developed a 4'-thionucleoside analog (4’-T-Nuc) as an effective DNMT1 inhibitorthan decitabine. We hypothesize that 4’-T-Nuc will be more effective than decitabine in the sensitization of glioma patient-derived xenografts (PDX) to Temozolomide. Utilizing Jx39P and D456 PDX models, we treated over a 7-day period with either hypomethylating agent (Decitabine or 4’-T-Nuc) at concentrations spanning 1nM to 5uM. In a separate assessment, Jx39P were pretreated for 48hrs with 4’-T-Nuc (160 nM), then subject to a singular treatment of TMZ (4μM). Cell Titer Glo was used to measure cell viability through ATP production. 4’-T-Nuc was determined to effectively reduce relative cell viability when compared to decitabine. In Jx39P, 4’-T-Nuc was significantly more effective in reducing cell viability alone and as a dual agent with TMZ. Future plans involve assessing 4’-T-Nuc's ability to extend the survival of mice with orthotopic brain tumors, determining its efficacy in TMZ-resistant GBM PDX models, and evaluating the impact of both hypomethylating agents on DNA damage and repair pathways. Our data collectively suggests that 4’-T-Nuc merits further investigation as a potential standalone anti-GBM agent.

Abstract Name: Molecular Dynamics Study of the Two-State Serine Protease APEH

APEH is a serine protease responsible for the degradation of acylated proteins. In doing so, it helps to regulate the proteome and maintain cell health. APEH activity has been proposed to have anti-inflammatory, anticancer, and anti-dementia activity. Published work has shown that tea extracts can activate APEH; however, specific chemical activators or allosteric binding sites on APEH are unknown. Previous molecular dynamics studies have also shown that the catalytic serine residue can occupy an active and inactive state, effectively turning the enzyme on and off. Taken together, the previous work suggests that APEH may have allosteric regulation. In this study, the multi-state catalytic serine in APEH is studied using molecular dynamics simulations to better understand the on and off states. We predict that the higher the probability the serine is in the active position, the more active the enzyme will be. These results are compared to monomeric serine proteases to highlight differences. Additionally, the effects of docking small molecules found in tea extracts on APEH's active-inactive state distribution will be discussed. This may help to establish a link between small molecule binding and protein activation.

Abstract Name: Construction of a Genetically Encoded Oligopeptide FRET Sensor

Forster Resonance Energy Transfer (FRET) experiments offer a powerful means to assess biomolecular structural changes through alterations in fluorescent spectra. Leveraging the significant conformational shift observed in Periplasmic Oligopeptide Binding Protein (oppA) upon ligand binding, we employed Golden Gate Cloning to insert a FRET pair of fluorescent proteins into opposite sides of oppA's hinging mechanism. Our study builds upon the success of FRET-based sensors developed for analytes like glucose and calcium, utilizing the unique characteristics of periplasmic binding proteins. As with other periplasmic binding proteins, oppA undergoes a substantial hinge motion upon ligand binding, offering an ideal framework for FRET sensor construction. This presentation discusses the successful implementation of Golden Gate Cloning in engineering a FRET sensor for oligopeptides and explores the sensor's accuracy in measuring various peptide fragment concentrations. By combining genetic engineering and fluorescence spectroscopy, our work introduces a promising avenue for the development of biosensors with diverse applications.

Abstract Name: Politics of The Hood: An Analysis of Hip Hop Lyricism

Hip-hop culture and the rap genre were created by youth from poor Black and Brown neighborhoods in the 1970s as an escape from the dangerous reality they were living in and to provide a means of expression. As these communities continued to experience discrimination, such as police brutality and racial profiling, hip-hop grew in popularity, becoming one of the few outlets of self-expression that did not result in real-life consequences. While Hip-hop culture and rap serve as entertainment, this paper will argue that Blacks used the genre as a tool for documentation, organization, and self-expression in response to oppression and discrimination. This research is based on secondary sources that provide a historical background of events, including the invention of mass incarceration and the "War on Drugs," which affected the Black community and the beginning of hip-hop. It will also include an analysis of primary sources focusing on hip-hop and racial discrimination to contextualize the circumstances under which these artists created these songs. This study will also analyze specific songs, such as "Changes" by Tupac, Public Enemy's "Black Steel in the Hour of Chaos," and N.W.A's "F*** the Police," to view how hip-hop artists used the art as a form of protest against racism in America. The purpose of this study is to demonstrate that hip-hop as well as rap lyrics were created for self expression and not just for the spread of mere violence, but rather to avoid violence by using the power of their voices

Abstract Name: Finding Harmony in Design: Exploring the Connection of Music and Architecture Through Proportion

Both music and classical architecture have a strong foundation in proportion. Further research shows that the same systems of proportions are found in both areas. Common chords found in music can be translated into proportions found in architecture. For example, the octave has the same proportion as a 2:1 ratio. While there is a clear relationship, the question remains: does understanding one help in understanding the other? Does understanding music make one a better architect? Can designers benefit from musical instruction? To answer these questions, a comparative survey was conducted asking participants to determine which visual proportion best matched the sound heard. These questions range from basic chords and rectangles to a more complex comparison of the Fibonacci sequence to the golden ratio. The survey also asks about participants' background in both music and architecture, as well as general demographic questions. The demographics of the current survey are limited to students and faculty attending BYU and Utah Valley University, but further studies will provide a more comprehensive result. To analyze the results, a comparison will be conducted on the percentage of individuals who were correctly able to recognize the same proportions visually and audibly. This will then be cross-examined with the demographics, comparing those who have a background in music and/or architecture to those who do not. The expected result is that those familiar with one of the previously mentioned fields will better recognize proportions in both music and architecture. If this is proven true, it will show that having a background knowledge in multiple fields will help to create a more well-rounded and capable individual. It will provide insight on how to become better in one's chosen field.

Abstract Name: Balance and Jump Dynamics as an Indicator for Musculoskeletal Injury Risk In Collegiate Hockey Players

Hockey players must maintain dynamic balance to adapt quickly to the game's dynamic elements, stay on their feet longer, and perform skills like skating and stick handling more effectively. Poor dynamic balance, reduced jumping ability, muscle strength, and incorrect landing patterns can contribute to an increased risk of musculoskeletal injury in athletes. METHODS: A single force plate protocol was used to assess unilateral balance and jump dynamics in 31 male (21.7±1.1 yrs.) and 24 female (19.9±1.1 yrs.) collegiate hockey players. Unilateral balance and asymmetry were measured via the center of pressure (COP) and weight shift control asymmetry (%) and single-leg balance via two trial sets on the force plate. Jump height (in.) and jump shift (%) were measured via four counter-movement jumps tracking COP and ground reaction force (GRF) release from the force plate via vertical velocity(m/s). Injury risk classification was stratified derived from the most recent jump, balance, and stability scans used the base athletic population model. Group comparisons (sex) were made using one-way ANOVA. RESULTS: Maximal jump height and shift were higher in the male hockey players (19.2 ± 1.9in. vs. 13.6 ± 1.4in., p<0.05) and (2.7±6.2%. vs. 2±8.27%). The unilateral balance mean was lower in male hockey players (52.6 ± 8.7 vs. 55.9 ± 7.1), while the percentage of balance asymmetry was lower in female hockey players (3±1.3% vs. 0.2±1.6%). Injury risk classification was higher in female hockey players (3.2 ± 0.9 vs. 2.7 ± 1.2, p<0.05).CONCLUSION: Males recorded significantly larger values for jump height, an increased percentage of jump shift, and balance asymmetry. However, increased variances in female balance and jump dynamics led to a higher injury risk classification.

Abstract Name: Ethnofiction Through Contemporary Narratives: Combining Digital Archiving with Creative Storytelling

Ethnofiction through Contemporary Narratives is a research and writing workshop class at California State University, Fullerton. Through project-based learning and direct mentorship, we research Black, Indigenous, People of Color (BIPOC) and LGBTQ+/feminist history, tracing 1960s to present time. We write weekly creative responses and read one another's writing, proceeding through a series of exercises to add density and texture to ethnographic description by including attention to scene, character, historical events, situations, and dialogue. To identify how past and current history and virtual storytelling practices relate to social privileges, power relations and the future, students learn how to use virtual storytelling elements and apply open-source resources (i.e., virtual timelines, storymaps, 3D captures) within multimedia literary projects produced over one semester.In this panel, three students who completed this class will share their research process, digital

storytelling outcomes and how this led them to re-present history in literary forms including an immigrant testimonio, re-presentation of Korean mythology, and Latinx sci-fi. We will collectively discuss the following questions: How do ethnofiction and the digital humanities impact storytelling? How does this form of creative archiving preserve ethnic and gender narratives, re-present history and re-imagine futures? What questions does ethnofiction raise about BIPOC, LGBTQ+ and women's history and the possibility of reclaiming stories through contemporary narratives? Who should tell these stories?

Abstract Name: Studying antibiotic resistance in Enterococcus with a One Health approach

One health is the connection between animals, humans, and the environment. Our study uses this concept to understand community-acquired antibiotic resistance using Enterococcus as a model. In an urban environment, animals have a great potential to be a reservoir for antibiotic resistance genes (ARG). Urban environments also contain a great deal of pollution from businesses and transit. Metal pollution places pressure on bacteria, leading to the development of metal resistance genes (MRG) and ARG. We hypothesize that wildlife exposure and MRG in an urban environment have a strong correlation with community-acquired antibiotic resistance.Enterococcus is a gram-positive bacteria found in the gut of humans and animals and has a high potential to transfer between these populations. Our study uses wildlife sampling, MRG, and ARG identification, as well as the comparison of antibiotic-resistant Enterococcus strains of human and wildlife origin collected in metro Detroit. A total of 140 rodent and bird fecal samples were collected, giving 268 positive Enterococcus isolates. Antimicrobial Susceptibility Testing was performed for 16 antibiotics using Sensititre plates. Multidrug resistance was demonstrated by 17% of isolates. The samples had the most resistance to lincomycin (89.55%), followed by quinupristin/dalfopristin (32.84%) and nitrofurantoin (17.54%). Cadmium resistance was found in 76 (28%) of wildlife samples. So far, 35 (46%) of these samples have been identified as Enterococcus faecalis. Further species analysis is in progress for the remaining samples. Eighty-one clinical samples were recovered from VRE patients at Henry Ford Hospital. All tested clinical samples were multidrug-resistant, resistant to at least eight antibiotics. 74% were found to have Cadmium resistance. Further analysis is underway to compare animal and human isolates on Enterococcal species distribution and molecular subtypes.

Abstract Name: How has racial disparities in the criminal justice system contributed to mass incarceration?

Mass incarceration, a complex and profound concern, exacerbates racial disparities, necessitating an examination of the root causes. The United States criminal justice system consistently demonstrates racial inequity. This becomes evident when black men experience incarceration rates four times higher than their white counterparts. This disparity persists across socioeconomic status and beyond that, necessitating urgent rectification. Progress in the past two decades has led to an overall decline in incarceration rates, with the most significant reduction observed among the Black prison population. Reforms in drug-related law enforcement, charging, and sentencing, particularly in urban areas housing communities of color, have contributed to this positive shift. Despite this positive shift, racial biases persist beyond the statistical representations, perpetuated by public perceptions and influencing policy actions, resulting in disproportionate impacts on black individuals. This paper explores the complex relationship between racial disparities and mass incarceration in the United States. By utilizing a comprehensive methodology, including literature review, data collection, and analysis drawing from scholarly journals, firsthand experiences, and public responses, it sheds light on the multifaceted issues surrounding the criminal justice system. Racial disparities within the system significantly contribute to mass incarceration, posing profound implications for civil rights, public trust, and community well-being. The hypothesis that racial disparities in arrests, sentencing, and implicit bias contribute significantly to mass incarceration highlights the necessity to address these issues and promote an equitable criminal justice system. The paper aims to promote impactful discussions and interventions to rectify systemic problems, ultimately fostering a more just and inclusive society.

Abstract Name: Antifungal Mechanisms of Action by Dendritic Cell Lysosome Proteins

Cryptococcus neoformans is an opportunistic fungal pathogen that primarily affects immunocompromised individuals and can cause cryptococcal meningitis. Approximately 152,000 cases of cryptococcal meningitis occur annually in HIV/AIDS patients, leading to 112,000 yearly deaths. Very few antifungal drugs are available to treat cryptococcal infection, and those are ineffective or toxic. In addition, fungal pathogens such as C. neoformans have become resistant to many types of treatment. Previous studies in our lab showed that proteins from the dendritic cell (DC) lysosome have antifungal activity against C. neoformans, including NOSTRIN, human neutrophil elastase (HNE), matrix metalloproteinase 25 (MMP25), myeloperoxidase (MPO), and coronin. In this study, we tested the antifungal activity of the compound NOSTRIN, one of the DC lysosomal proteins that has been known to exhibit these antifungal properties. We tested NOSTRIN against the C. neoformans strain H99 using different concentrations of the drug and calculated the minimum inhibitory concentration (MIC). Then, fluorescence microscopy was used to examine structural changes in C. neoformans following treatment. Results showed that NOSTRIN had a similar result compared to MICs performed with the antifungal drug Amphotericin B, with NOSTRIN around 0.25 ug/ml and Amphotericin B around 2 ug/ml. In addition, fluorescence microscopy showed that fungal cells treated with NOSTRIN are releasing intracellular contents following incubation, indicating damage to the fungal cell wall or membrane. In future studies, we will continue to examine NOSTRIN and other antifungal DC lysosome proteins by microscopy and using cryptococcal mutant libraries in order to identify their mechanism(s) of antifungal activity. By researching the presented topics, we hope to gain a better understanding of the effects that these proteins have on C. neoformans, which could potentially lead to more effective therapies for cryptococcosis.

Abstract Name: My Language, my Country: Study of Language and National Identity Across Ireland and The United States

The present research explores the relationship between language and national identity between Ireland and the United States as it relates to hegemonic positioning in Gramsci's World Systems theory. From the perspective of linguistic composition, the United States and Ireland hold conflicting relationships between language and national identity. In the United States, citizens prioritize pro-English sentiment toward American identity that fails to account for the nation's growing linguistic diversity. On the other side, revitalization efforts by the Irish government to preserve Irish Gaelic after decades of linguistic censorship struggle to promote citizens' support regarding the importance of the language to Irish identity. The following research studies the respective populations' attitudes to language and whether speaking these languages makes them truly American or Irish. The 2013 National Identity III survey conducted by The International Social Survey Programme was used to examine these relationships by running tests between participants' country nationality to the participants' response to the level of importance that the respective language (English/Irish Gaelic) has on being truly American or Irish. Study outcomes as they relate to World Systems theory point to a larger importance of English to American nationality compared to Irish Gaelic to Irish nationality due to the two countries' positions within the cycles of hegemony and the fluctuations of power each language has within their hegemonic positions.

Abstract Name: Musical Systems with $\mathbb{Z}n$ – Cayley Graphs

It is well-established that music theory uses mathematics to explain how music is created. The chromatic scale and pitch frequencies can be explained by modulo 12 arithmetic and geometric ratios. Using group theory, we interpret concepts from Western music theory. We show that in $\mathbb{Z}12$, chords, scales, the circle of fifths, and the first species of counterpoint can be explained using a Cayley graph with respect to generators 3 and 4. Using $\mathbb{Z}12$ as a model, we generalize to $\mathbb{Z}n$ where n is a product of two relatively prime numbers. Most major and minor chords can be constructed using paths on the oriented Cayley graph, beginning on the root of the chord. The circle of fifths can be explained by adding both generators at once. The unoriented Cayley graph gives way to a weaker form of counterpoint, with minimum distance elements forming a set of consonant elements. Then, we create partitions of consonant and dissonant elements using affine transformations to create a full generalization of counterpoint. We assume equal-tempered tuning for various $\mathbb{Z}n$ systems. As application, we have written code in Maple to hear chords, scales, and counterpoint in these musical systems.

Abstract Name: Stopping the Willow Project on Social Media: An Exploration of the Social Problems Process in a Sub-Environmental Issue

From casual sexism to catastrophic terrorism, social problems (SPs) are prevalent in vast ways all throughout society. Those relating to environmental and climate crises have and will continue to affect communities across class, gender, race, and geographic location. The Social Problems Process (SPP), a sociological theoretical model, encompasses an in-depth examination of the stages a SP passes through in efforts to achieve remediation. This project aims to explore the SPP of the environmental sub-SP of fossil fuel continuation and dependency as demonstrated by the Willow Project (WP). The WP is an accepted policy that allows for intensive oil drilling in environmentally vulnerable landscapes. This will result in exasperating current climate conditions, both locally and globally, by its contributions to climate change. The aim in exploring the WP here is to better understand the SPP in contemporary SPs and the role of social media. The present study uses qualitative content analysis, emphasizing frequency and themes, of WP related Instagram posts. A total of 44 posts were collected and analyzed across two account categories: activist/educational (n=5) and news/informative (n=5). Approximately 86% of the analyzed posts were collected from the activist/education account category (n=38). Primary themes derived included (1) taking action, (2) animal/local environmental consequences, (3) Biden contradiction, and (4) policy details/overview. Contrastingly, the news/informative account category produced minimal coverage prioritizing contextual information. These findings present as supporting evidence for the WP sub-SP passing through the initial three stages of the SPP (claimsmaking, media coverage, and public reaction). Pattern analyses reveal fearmongering tactics, assumption of audience's environmental knowledge, political framing tendencies, and an emphasis on animal impacts. This work contributes to filling in the literature gap exploring SPs within social media atop the acute focus on the connections between environmental SPs, public perception, and today's youth.

Abstract Name: Connexin 43 Expression in Large Artery Endothelial Wound Healing

Impaired endothelial cell (EC) wound healing in blood vessels is a primary contributor to vascular stent failure and coronary thrombosis. Therefore, endothelial wound repair is essential for improving vessel patency and patient survival rates. It is essential to identify the regulators of normal endothelial healing and understand how these factors are dysregulated when healing is impaired. RNAseq data from McDonald et al. 2018 in non-injured vs regenerating murine EC in vivo revealed a significant increase in expression of gap junction protein connexin 43 (Cx43) throughout the EC healing process. Cx43 has been implicated in other tissue types as a regulator of wound healing and yet was primarily thought to be absent from large artery EC.

This injury induced upregulation indicates a role for Cx43 in EC healing. To study this, we developed a novel model of EC wound healing in mouse carotid arteries. Mouse carotids undergo ligation for a period of one minute resulting in EC denudation injury. Immunofluorescent imaging of the injured mouse carotid arteries revealed punctate staining indicative of Cx43 containing gap junctions in regenerating EC. To more quantitatively measure protein level expression changes in injured EC, mouse carotids were flushed with lysis buffer to isolate and collect EC for western blotting. The resulting samples expressed vascular endothelial cadherin, a marker for EC, without expressing smooth muscle marker, transgelin. Western blotting of injured mouse EC revealed increases in Cx43 protein expression that correlate temporally with EC healing. Macrophage specific Cx43 knockout mice were used to insure that increases in Cx43 expression were not due to macrophage recruitment to the injury site. Future investigations will focus on understanding the role of Cx43 in the EC healing process. To accomplish this, we will measure the rate of endothelial healing in endothelial specific Cx43 knockout in mice compared to littermate control.

Abstract Name: Testing the Antidiabetic Agent Acarbose in Mice with Renal Carcinoma: A Diet-Based Approach to Cancer Treatment

Immunotherapies are the standard of care for renal cancer patients, but only ~50% of patients respond to treatment. Because renal cancer cells use glucose as an energy source to sustain their proliferation, our lab studied the connection between diet and renal cancer using acarbose, an FDA-approved glucoregulatory agent that prevents the breakdown of complex carbohydrates into glucose, reducing the amount of sugar that makes it into the bloodstream after eating. In lean mice with renal tumors from the Recna renal carcinoma cell line, past research in the lab confirmed that acarbose blunted blood glucose elevation after meals and reduced renal tumor growth in a CD8 T cell-dependent manner. When acarbose was combined with anti-PD-1 immunotherapy, spontaneous lung metastases were significantly reduced. However, obesity and type-2 diabetes – characterized by high blood glucose – are common comorbidities in renal cancer patients and tend to result in worse clinical outcomes. Thus, to emulate clinical patients, we worked to develop a BALB/c mice model that would reflect both obesity and high blood glucose by using a standard high-fat diet plus streptozotocin, a toxic chemical that kills insulin-producing pancreatic beta cells. We found that using this approach, it was possible to generate mice with either obesity or high blood glucose, but not both. Low-dose streptozotocin produced unregulated type-1 diabetes, reducing body weight and survivability. After this experiment, we used acarbose and found it ineffective at reducing renal tumors and spontaneous lung metastasis in obese mice on a standard high-fat diet alone and a high-fat diet containing low levels of complex carbohydrates. Surprisingly, acarbose was also ineffective at slowing renal tumor growth in mice fed a high-fat diet containing starch. Future studies will examine how ACA interacts with other cancer cell lines and how obese mice respond to immunotherapy with acarbose.

Abstract Name: The Nature of Artificial Intelligence: How AI Can Be Used As a Tool in Design

Artificial intelligence has evolved into a powerful yet misunderstood tool very quickly over the last couple of years. Utilizing various AI softwares such as ChatGPT, Stable Diffusion, ahrefs, and Mid Journey, “The Nature of AI” examines AI’s application as a tool for designers and artists, specifically looking at its role in translating across different mediums. The core of the research centers on showing the comparison between the subjectivity of human interpretation to the stark objectivity of AI descriptions. This research initially grew from the project “Journals of Epistemology” in which extensive research in the New York public archives lead to creating visual imagery from archived journal entries with no visuals. This evolved into multiple projects with a commentary on how machine learning algorithms synthesize information, versus how humans naturally synthesize information. When seeing the images the viewers are presented with a layered experience. They witness the subjective overlay of human emotions alongside the algorithmically generated descriptionsThe research as a whole raises questions about the nature of interpretation, the role of emotions in art, and the boundaries between human and machine understanding. It provides insights into the inner workings of AI, showcasing practical applications in the design domain and contributing to a deeper understanding of how AI can be utilized to foster communication and creativity. This approach highlights not just improving our understanding of AI's capabilities but also how easily technology blends with the natural creativity of design.

Abstract Name: The Effects of Foot and Knee Kinematics on Knee Kinetics in Youth Baseball Pitching

Of injuries that keep MLB and MiLB baseball pitchers benched for the longest time, meniscal tears rank tenth and kept pitchers out of play for up to 438 days. Since they are defined as overuse injuries, reducing mechanical load at young age is crucial in preventing meniscal injuries. This study investigated stride leg foot and knee kinematics influencing peak knee adduction moments during youth baseball pitching. Forty youth baseball pitchers who were active on a team roster and injury free for the past six months participated (15.25 ± 1.21 yrs, 72 ± 9.6 kg, 1.77 ± 0.06 m). Participants pitched maximum effort fastballs for strikes at regulation distance. Pitching motion was collected at 100 Hz using an electromagnetic tracking system. Knee kinetics were calculated using an inverse dynamic method in MotionMonitor. The peak knee adduction moment was extracted between stride foot contact (SFC) and ball release. Foot progression angle, knee abduction angle, and flexion angle at SFC were obtained. Multiple regression was conducted to examine the relationship between foot and knee kinematics and knee adduction moment. The overall prediction model was statistically significant (F(3,37) = 8.60, R2 = .41, p < .01). The analysis revealed that knee abduction/adduction angle (β = -1.8, p <.01) and knee flexion angle (β = 1.5, p <.01) at SFC were predictors for the peak knee adduction moment, but foot progression angle was not (β = -0.7, p =.06). Our work shows a relationship between increased knee abduction angle at SFC and the increased peak knee adduction moment in youth baseball pitchers, which may result in increased compression force on the medial knee compartment. Correcting knee abduction at SFC using cues, strength, and neuromuscular training of the gluteus maximus

may reduce the peak knee adduction moment during the pitching motion, therefore reducing the risk of injury.

Abstract Name: Examination of the Role of MAPK Activity on Placental Formation in Vitro Using Stem Cells

Mitogen-activated protein kinase kinase kinase 4 (MAP3K4) phosphorylates and activates several MAP2K (mitogen-activated protein kinase kinase) enzymes, including MAP2K3, MAP2K4, MAP2K6, and MAP2K7. Upon activation, MAP2K3/6 phosphorylate p38, MAP2K4/7 phosphorylate JNK, and MAP2K1/2 phosphorylate ERK. We hypothesized that the activation of these enzymes promotes placental and fetal maturation, prompting examination of these pathways. This study investigated wild-type and MAP3K4 kinase-inactive mouse cells in vitro in multiple biologically independent experiments. Trophoblast stem (TS) cells were treated with either DMSO (-) or 3 μM of CHIR 99021 for 96 hours. We measured the activity of p38, JNK, and ERK using polyacrylamide gel electrophoresis and Western blotting. We found that the p38 and JNK mitogen-activated protein kinase (MAPK) pathways were induced during differentiation of wild-type TS cells to syncytiotrophoblast (SynT-II) cells. In contrast, activation of the ERK MAPK pathway was reduced upon differentiation. MAP3K4 kinase inactivation resulted in a failure to activate JNK or p38 MAPKs and the inability to form SynT-II cells. Together, these data suggest a key role for MAP3K4 activation of JNK and p38 in the formation of the SynT-II cells of the placenta. Future studies will assess the activation of MAPK signaling in vivo during placental development.

Abstract Name: Effects of Beaver-engineered Wetlands on Biodiversity at Ogden Nature Center

The American beaver (Castor canadensis) is known to play an important role in ecosystem engineering, increasing community diversity in and around the streams where they create their dams (Wright et al., 2002). Wetlands formed by beavers are key habitats that increase water retention and foster animal populations that are in decline. To study the effect of beaver engineering supporting wildlife populations in more urban environments, 16 camera traps were placed along streams and canals in the Ogden Nature Center (ONC) to characterize differences in species number, distribution, and occupancy, comparing between areas directly adjacent to sites of beaver engineering and areas where water flow was not modified. Data were collected at 8 sites along two waterways in the ONC, between 25 May and 22 June 2023. Data collection sites were characterized as either beaver modified, or unmodified (control) areas. Twenty-one vertebrate species, including 15 species of bird were documented in the camera traps (6 more birds were documented but could not be identified at the species level). Beavers were documented at 4 of the 8 locations, most frequently at

one of the control locations. Preliminary analyses suggest that species richness and occupancy are significantly higher at beaver modified areas, particularly in waterfowl and racoons. A more quantitative assessment of diversity is underway and will be presented once complete.

Abstract Name: Stephen Greene's Narcissistic Mentality And How it Aided His Career

Greene was an artist, illustrator, a painter, and designer during the 1940s and 1950s, most famously known for his abstract paintings. This painter, forgotten over time, was seen as narcissistic and pretentious during his life. Greene, a mentally flawed individual, became well-known for his strange figure drawings and abstract paintings. Despite being viewed as an individual who tends to be difficult to get along with, this artist’s warped perspective proved useful in his artistic endeavors; through years of learning and experimenting, Greene has been able to transform his unique mentality into a notable feature of his artworks. Greene’s unique quirks were visible in his art- and hold up to this day. Through many interviews, others have learned that Greene is an artist who focused mostly on himself, rambled, and tended to be uncoordinated in his efforts. These qualities have disintegrated over time, leading to Greene maturing mentally and focusing less on his own appearances, but more on the artworks he’s created. Stephen Greene shows how his flaws have formed his art, working against him on some occasions, yet working for him creatively in unique and interesting ways. Stephen Greene was able to have many successes in his lifetime, learned from his mistakes, and never quite changed exactly who he is- while still creating unique and notable designs. Greene was able to teach many, learn from many, and mature plenty in his career.

Abstract Name: Mitochondrial Targeting: A Novel Approach to Optimizing Cytomegalovirus Treatment

Cytomegalovirus (CMV) is the leading cause of sensorineural hearing loss, the most prevalent form of permanent hearing loss worldwide. Effective CMV treatment requires long term administration of ganciclovir (GCV), which inhibits CMV replication but is toxic to neutrophils, an essential component of the immune system. GCV toxicity often limits treatment duration, risking permanent hearing loss in thousands of infants each year.Prior undergraduate students in our lab determined that 80% viral inhibition can be maintained with reduced GCV concentrations when combined with an antiviral flavonoid therapy (QP188) in a mouse fibroblast cell model. QP188 consists of a hydrophobic flavonoid with antiviral and antioxidant properties, quercetin, encapsulated in Poloxamer 188 (P188), an FDA approved surfactant utilized as a drug delivery vehicle. This prior research also demonstrated that P188 targets the mitochondria of mouse fibroblast cells

but was unable to determine the if the mitochondrial affinity of P188 provided any benefit in combinatory CMV treatment.After extensive literature review, I learned that the mitochondria plays a significant role in CMV infection. CMV exploits host mitochondrial function, promoting viral infection by generating excess reactive oxygen species, altering apoptotic (programmed cell death) pathways, and manipulating cellular metabolism. Thus, I predict that interactions between P188 and the mitochondria of CMV infected cells improved CMV inhibition. Thus, current work is focused on understanding the role of Poloxamer 188 in antiviral treatments by assessing the effects of P188 on healthy and CMV infected mouse fibroblast cell models and comparing the delivery of quercetin in dimethyl sulfoxide (non-specific delivery) to QP188 (mitochondrial targeted delivery). Preliminary results show that P188 stimulates mitochondrial activity in healthy cells, as assessed using the MTT assay to measure cell metabolic activity, suggesting that P188 plays a more active role in the inhibition of CMV replication beyond its use as a drug delivery vehicle.

Abstract Name: Interdisciplinary Approaches to Studying Climate Change: The Development of a Web-Based Closed-Loop Temperature Control System for an Aquatic Tank

The study of the effects of climate change on indicator species like intertidal mussels can indicate the health of ecosystems, but studying mussels in their natural habitat can be costly and labor intensive. This project set out to design an automated system to manage the study of mussels through the collaborative efforts of an electrical engineering and computer science team. The objective of the computer science team was to design a web application for climate researchers that can deploy automatic heat ramp interventions, centralize data collection, and provide time-delineated visualizations of the data. The web application is built upon the Next.js front-end framework and the Prisma ORM PostgreSQL database system and is hosted on Vercel. Through these tools, the user can store, access, and communicate data, specifically timelines, to and from the aquatic tank to initiate and monitor different experiments. In tandem, the objective of the electrical engineering team was to design a closed-loop temperature control system to provide a dynamic heat ramp to an aquatic tank, reflecting the temperature patterns of the intertidal zone. The system uses a Raspberry Pi to continuously monitor the temperature of the aquatic tank, activate an aquatic heating rod when necessary, and communicate with the designed web app. Using pulse width modulation, the Pi can accurately heat the tank at different rates to mimic real-world sea-temperature data. The final combined system operates by seamless communication between the closed-loop temperature control system and the web application through both automated and user-prompted HTTPS requests. The presentation will demonstrate a running trial where the web application sends a timeline to the heat ramp device which then initiates an experiment and returns temperature data.

Abstract Name: Understanding the Impact of Rumination on Depression Among First-Generation and ESL (English as a Second Language) College Students

This paper dives into the unexplored relationship between rumination and depression among college students. Rumination, characterized by repetitive and self-focused thoughts, intensifies perceptions of inadequacy and failures, fostering a mindset fixated on past errors. This can influence confidence, belief in one's capacity to enact positive change, and can lead to heightened levels of depression. In studying these relationships, we focus the experiences of first-generation college students and those for whom English is a second language (ESL), as there is generally a gap of knowledge surrounding these students. Studies have revealed that first-generation and ESL students often grapple with imposter syndrome and language comfortability, which can significantly impact their mental health, specifically contributing to depression. Among first-generation ESL students, the toll of excessive rumination on mental health can be more prominent and lead to higher susceptibility of depression, compared to continuing-generation, non-ESL peers who face fewer complex challenges. Therefore, this research tests how rumination predicts depression and whether first-generation or ESL status moderates this relationship. To test these hypotheses, we collected data from 500 undergraduate students in a university in California's San Joaquin Valley. Each student completed surveys measuring rumination, depression, college generation status, and ESL. We hypothesize that those who have a constant amount of ruminative thinking will have higher levels of depression and that those who are first-generation and ESL students will show a higher associative relationship between rumination and depression.

Abstract Name: Optimizing in vitro Editing of SPP1, NXF2, LRH1 in Testicular Cancer Cell Lines

Various factors, such as exposure to environmental toxins or radiation, can cause DNA damage and further elevate the risk of cancer in individuals. Our research project centers on the development of a molecular toolbox to investigate gene function within a human testicular cancer cell line, SUSA, using CRISPR/Cas9 and SiRNA biotechnology. By leveraging the power of these, we can modify specific DNA sequences to eliminate or knock down gene function. We have selected three genes for our gene editing toolkit, Secreted Phosphoprotein 1 (SPP1), Nuclear Export Factor 2 (NXF2), and Liver Receptor Homolog 1 (LRH1), to explore their influence on cell cycle progression and cell death when their functions are disrupted. We designed primers to amplify the genes, along with guide RNAs to serve as essential directives for the Cas9 enzyme to cut the targeted genes. Our current focus involves observing the gene cuts in vitro before introducing the guide RNA and Cas9 complex into our cell lines through electroporation. Going forward, we will utilize real-time RT-PCR to confirm the successful depletion of gene expression, thereby enabling us to assess the resulting changes in the cell cycle after gene deletion in future cellular experiments. This approach promises to shed new light on the intricate relationship between gene function and cancer, advancing our understanding of these critical biological processes.

Abstract Name: How Manga Influenced Graphic Design

Japanese graphic novels, called manga, have remarkably impacted a variety of medias, such as video games, television, and the digital media, graphic design. In this paper, we delve into the profound impact of manga on graphic design, exploring how this unique medium has influenced specific design elements, including line quality, the integration of image and text, and the evolution of design styles. Furthermore, the evolution of design styles inspired by manga's genres has made graphic design a vehicle for conveying emotion, narrative, and aesthetics. Work from a few graphic designers influenced by the artistry of manga, specifically Mr. Tsuyoshi Kusano, will be showcased as well.

Abstract Name: Phonotaxis Plasticity & Approach Medium: Speed & Directionality in Female Frogs when Swimming vs Walking

During the breeding season, male Eastern Gray Treefrogs (Hyla versicolor) form large choruses in woodland ponds to advertise for mates. Females select mates by listening for the male’s call and moving towards the chosen male guided by his call, a behavior called phonotaxis. Climate change may dry up parts of their habitat, which may affect mate choice and reproductive success of the frogs. We tested the hypothesis that the approach medium (land/water) affects phonotaxis behaviors. Because frogs ultimately lay eggs in water, we predicted that phonotaxis is more accurate/faster when females approach the male in water compared to on land. To test the effects of approach medium on phonotaxis behaviors, we conducted acoustic playback experiments in the lab, taking advantage of the fact that female frogs approach a speaker playing an attractive call like they would approach an attractive male at the pond. Females were tested in a “water” treatment (testing arena was a pool filled with water), and in a “land” treatment (arena was dry pool). We filmed the trials and recorded the following data: (1) distance of first jump towards the speaker, (2) angle of first jump relative to speaker location, and (3) time it took females to reach the speaker. Females took wider first jumps when starting their approach in water, but approached the speaker with similar accuracy and speed in both environments. This suggests that frogs can adjust their phonotaxis/mate choice behavior in response to environmental change altering the relative proportions of land and water in their breeding habitat.

Abstract Name: A Proposed Model Addressing Food Insecurity and the Wellbeing of International Students at Missouri State University

International students can face numerous hardships including culture shock, language and communication barriers, increased homesickness, feelings of isolation, and increased stress within both their personal and academic environments. In addition, food insecurity amongst the international student community can cause harmful effects on their physical and mental health, eventually impacting their academic success in higher education. This paper proposes a collaborative model between international services and an on-campus food pantry to expand food distribution aimed toward addressing the specific needs of international students. Missouri State University, a midsize, midwestern public university focused on public affairs, poses as a model for concerns and solutions surrounding this issue. Further, a literature review will provide an understanding of the effects of food insecurity on international students as well as the cultural impacts of pursuing higher education abroad.

Abstract Name: The Seven Trumpets - Using Music Composition to depict religious texts surrounding the Great Tribulation

The Great Tribulation is stated to be a seven-year period that is to occur following the rapture, but prior to the second coming of Christ. In the Book of Revelation, seven trumpets are sounded, one at a time, to cue apocalyptic events seen by John of Patmos in his vision. The trumpets are revealed after John sees a vision of the great crowd from every tribe and nation standing the throne offering worship to the lamb of God. Each trumpet will be blown by a different angel, however the angels remain unnamed, only depicted by the events that follow them.The first trumpet brings upon devastation to the Earth itself.The second trumpet shall be targeted towards the seas.The third trumpet casts a deadly effect onto the water supply which brings upon mass death to many people.The fourth trumpet attacks the realms of space, affecting the sun, moon, and the stars.The fifth trumpet (first woe) releases Satan, described as locusts, with the power of demonic influences.The sixth trumpet (second woe) brings an army of 200 some odd million angels to form a demonic army which will bring death to one third of all remaining people on Earth.The seventh, and final trumpet (third woe), is considered to be the announcement of Christ's reign and return to the throne as king of the heavenly world.The piece, scored for trumpet ensemble, is centered around the themes presented in each of the chapters from the Book of Revelation that dicusses the Great Tribulation. Each of the seven movements depicts the scenes that transpire as each of angels sound off their calls upon the Earth. Movement one serves as the opening call as hails of choas begin on Earth. (Movements two - seven to be completed at a later date).

Abstract Name: Reagan's Immigration Crisis

One year after refugees were granted the right to “non-refoulment”, the Reagan Administration started their “inditement-at-sea” program which stopped Haitian boats before they reached U.S. soil and sent them back to an authoritarian dictatorship where they faced risk of persecution. The purpose of this research is to understand how official discourse during the Reagan Presidency reflected the two distinctly different treatments of Cuban and Haitian immigrants. Despite being aware of the political, anti-democratic, situation in both countries, the Reagan Administration fought to make it more difficult for these two groups to seek legal and political protections while also demonstrating policies that favored Cubans over Haitians. Securitization theorists suggest that Cubans and Haitians were viewed as a threat to national and economic security which was increased by tensions due to the Cold War, while scholars who adopt a more humanitarian approach highlight the social-colonial, racialized, and nativist views pertaining within Reagan's official discourse and immigration policies. To understand how the Reagan Administration framed differential policies toward Cubans and Haitians, this research paper carries out an interpretive discourse analysis of legislative policies, Reagan’s diary entries, the Reagan Archive Immigration Files, and National Security Council meeting minutes and memos. Reoccurring themes in the primary and secondary sources were coded into categories such as anti-immigration discourse, pro-immigration discourse, anti-communist discourse, negative representations of Haitian relations, positive representations of Haitian relations, negative and positive Cuban relations, among others. The results of the study showed that Reagan's official discourse on Cuban and Haitian refugees had a significant impact on immigration policies. By conducting this analysis, the study aims to shed light on how the administration justified its immigration policies towards these two groups which could set a historical precedent into immigration policy and possibly lead into a broader cycle of U.S. immigration “crisis” and reform.

Abstract Name: Surface Modification of Metallic Alloys

Diffusion coatings offer an effective method to modify metallic surfaces. This can be achieved through a process known as halide activated pack cementation that involves vapor deposition and solid state diffusion. Typically, a single element is deposited in this process; however, depositing two or more elements simultaneously may be useful to achieve multiple performance improvements. In this study, pure elements and selected alloys were chosen as substrates onto which chromium and silicon were co-deposited. Chromium is expected to provide corrosion resistance while silicon is likely to improve the erosion resistance, thereby providing dual benefits in a single process. The coatings were characterized using X-ray diffraction as well as optical and scanning electron microscopy. Hardness measurements were also performed. The results will be presented and discussed, with a focus on the relationship between alloy composition and coating characteristics.

Abstract Name: Evaluation of Dielectrophoretic Response of Naïve and Drug-Resistant Melanoma

Modern day cancer treatment relies on a cycle of chemotherapy and removal of cancerous tissues. Due to the mutating behavior of cancer cells, however, this procedure may leave behind adapted cells that have acquired a resistance to chemotherapy lying in remission. During this time, these drug-resistant cells may also circulate around the body, spreading the affliction and metastasizing in the organism. This chain of events propagates the medical cancer cycle by requiring more chemotherapy and more excision, continuing until total remission or death. Effective measures to evaluate chemotherapeutic efficacy and assess drug-resistant cells will reduce the work and cost during treatment. Current evaluation methods have shortcomings; biomarking requires custom signaling agents for each type of cancer and each type of drug, limiting its applicability, while the evaluation of cultures from a patient's cancer is time intensive. An attractive alternative to these practices is the use of dielectrophoresis (DEP) to discriminate cells by their electrophysiological profile. DEP is selective without the use of biomarkers, and single-cell DEP response can be monitored instantaneously. This response is dependent on cell phenotypic features such as morphology and composition, notably membrane folding and glycosylation. Therefore, monitoring the highly selective DEP response may enable assays acute to biophysical differences between drug-resistant and non-resistant melanoma cells. To work towards a methodology that can discriminate between drug-resistant and non-resistant melanoma cells, cell specific DEP spectra will be obtained for both cell types using DEP field-

flow fractionation, enabling the comparison of DEP response to applied frequency. In addition, spectral differences of melanoma cells will be investigated after exposure to chemotherapeutic agents. The expected differences in DEP spectra, related to cell physical properties, may inform on mechanisms related to cell drug response. Uncovering correlation of DEP response and drug resistance may improve individual patient treatment outcomes.

Abstract Name: Mesoporous nanoassemblies as delivery agents and high-quality tracers for magnetic particle imaging of lungs in a mouse model

Superparamagnetic iron oxide nanoparticles (SPIONs) are tested for various theranostic applications. Structural alterations of these nanoscale particles can result in changes in their physico-chemical properties, further emphasizing their tailored use in nanomedicine. Therefore, we hypothesize that the self-assembled ordered architectures would increase surface area within its pores for hosting therapeutic payload, and promote their imaging capabilities for magnetic particle imaging (MPI). In this study, mesoporous nanoassemblies (MNAs) of SPIONs were synthesized using a simple solvothermal method. Characterization was performed using X-ray diffraction, transmission electron microscopy, magnetometry, porosity and surface area measurements, optical emission spectroscopy, dynamic light scattering, and zeta potential. Next, their surface was coated with a cationic polymer, polyethylenimine, which enhances aqueous stability and generates a cationic surface to facilitate complexation with negatively charged. Compared to their conventional spherical counterparts, their assembled structure provides larger surface areas for molecule complexation. For MPI tracer performance evaluation, agarose phantoms of varying iron concentrations were imaged, and a linear relationship between signal intensity and corresponding concentrations was exhibited. Additionally, these MNAs exhibited 2-fold increase in their signal intensities when compared to commercial spherical SPIONs VivoTrax®. Cellular uptake and biocompatibility were evaluated with lung epithelial cell line (A549), revealing the MNAs as cytocompatible. As intended for MPI-guided drug delivery to lungs, investigations of delivery performance and lung localization post-inhalation in CD1 wildtype mouse using MPI monitoring is ongoing. Using a laboratory nebulizer, the MNAs were aerosolized, administered to the airstream of mice and monitored for two weeks. Afterwards, mice will be sacrificed and lungs will be harvested for further histological examinations of iron content, distribution within lung tissue and localization in epithelial cells. By the end of this study, we intend to validate the use of these MNAs in mouse models as they hold strong promise for theranostic applications for lung disesases.

Abstract Name: Investigating the Role of Neuregulin 1 (NRG1) Signaling in the Functionality of Rat Luteal Cells

Alyssa Rodriguez1, Saswati Banerjee2, Indrajit Chowdhury3 1Department of Biochemistry & Chemistry, Spelman College, Atlanta, Georgia 2Department of Physiology, Morehouse School of Medicine, Atlanta, Georgia 3Department of Obstetrics & Gynecology, Morehouse School of Medicine, Atlanta, Georgia The corpus luteum (CL) is a transient ovarian endocrine gland and develops from an ovulated dominant follicle in the ovary. The preovulatory surge of pituitary luteinizing hormone (LH) at ovulation and differentiation of residual follicular granulosa cells (GCs) and theca cells (TCs) with the disappearance of the basement membrane between GCs and TCs is responsible for luteinization of the ovulated dominant follicle. CL growth and differentiation are tightly regulated by survival and cell death signals, including endocrine (LH), intra-ovarian regulators, and cell-cell interactions. Neuregulin 1 (NRG1) is a small peptide and a member of the epidermal growth-like factor family that acts through the erythroblastoma (ErbB) family of receptors. Interestingly, NRG1 roles in CL are unknown. Therefore, we examined the NRG1 expression in rat CL and its role in rat luteal cells (LCs). LCs were cultured and treated with or without exogenous NRG1 in a dose-dependent manner for 24 hours. The total protein was isolated and analyzed for various markers under these experimental conditions. In further studies, ovaries from adult female pregnant rats were collected, fixed, and immunostained for the spatial and temporal expression patterns of NRG1 and ErbB receptors in the CL. Our preliminary results suggest that NRG1 and ErbB receptors are differentially expressed in CL during pregnancy. Whereas in vitro, exogenous NRG1 treatment promoted activation of ErbB signaling and supported LC proliferation. Thus, NRG1 signaling may support CL growth and differentiation. Abstract Name: Recombinant expression of the kinase domain of atypical MAPK4

Mitogen-activated protein kinases (MAPKs) are crucial in regulating biochemical signaling pathways in cells. These pathways typically control gene expression, cellular growth, and survival. It is especially important in carcinogenic outcomes due to abnormal MAPK signaling being linked to enhanced cell proliferation and resistance to apoptosis. Accordingly, several proteins participating in these pathways have been targeted by various cancer drugs. Interestingly, some members of the MAPK family remain relatively understudied despite the family of kinases being well-studied and well-characterized. This project focuses on an atypical MAPK, MAPK4. Unlike the other MAPKs, the roles of MAPK4 remain largely unknown. Similarly, the structure of MAPK4 remains to be determined. In addition to attempting to understand its biological roles, MAPK4 has also been shown to be involved in breast cancers, which provides impetus to study this protein. In this project, we attempt to express the kinase domain of MAPK4 recombinantly. The construct was designed based on AlphaFold2 structure prediction. Recombinant expression in E. coli was attempted first by varying expression conditions. Interestingly, no significant change in expression levels were observed. However, purification remains to be a challenge. As an alternative, insect cell expression is also being pursued by generating a bacmid that encodes for MAPK4. This preliminary work is critical to better understand the structure and function of MAPK4 as well as to establish screening pipelines for the identification of MAPK4 inhibitors which can be used in cancer therapy.

Abstract Name: GROWTH: Global Review of Factors in Whole-child Motor Development

Objective: Spontaneous movements, such as arm waving and leg kicking, observed in infants are not only adorable to watch but also hold significance in the child's motor development. The transition from these movements to crucial motor skills like reaching and walking is influenced by various environmental and individual factors (e.g., home environment, caregiver interactions, etc.). To gain a comprehensive understanding of the relative importance of these factors in shaping early motor development, we are conducting a systematic literature review.Methods: Our review process consists of two levels. In level one, we performed an EBSCO search of journal articles published from 2000-2023, utilizing specific search criteria and keywords related to motor development. This initial search yielded 84 relevant studies. In level two, we employed a systematic coding manual to meticulously review and extract information from the study purpose, method and results. We coded for factors under assessment, study design, participant age, characteristics, measurement methods, analysis techniques, and findings.Results: Preliminary analysis of our ongoing review reveals that environmental factors are studied more often than individual ones. Cross-sectional studies dominate the research landscape, with typically developing infants and premature infants being the most commonly studied population.Conclusions: The insights derived from this systematic review will not only facilitate the identification of connections within existing literature but will also provide a robust framework for future research aimed at determining the critical factors influencing motor development. This framework is particularly essential, considering the relevance of these factors in atypical development, such as Autism Spectrum Disorder.

Abstract Name: Understanding How Interpersonal Social Support Can Alter Perceived Stress and Blood Pressure Among African American Women

Introduction: Previous studies have shown that perceived stress has been associated with an increased risk of elevated blood pressure (BP). However, few studies indicate how social support can influence perceived stress and BP. Therefore, this study hypothesized that social support would moderate the relationship between

perceived stress and BP among Black women.Methods: Fifty Black women (Mage=38 years) completed the Perceived Stress Scale (PSS) and the Interpersonal Social Evaluation List (ISEL). The PSS measures potential stressful situations and the ISEL measures social support through appraisal, belonging, and tangibility. Two BP readings for systolic (SBP) and diastolic (DBP) were averaged for each participant. Linear regression models determined the relationship between perceived stress, social support scores, and BP. Results: PSS score was not associated with DBP (B=-.325, p=.243,95% CI [-.879, .229] or SBP (B=-.789, p =.105, 95% CI [-1.749, .170]). ISEL also did not predict DBP (B=-.649, p=.271, 95% CI [-1.822, .524] or SBP (B=.003, p=.997, 95% CI [-2.042, 2.048]). Lastly, no moderation effect was observed for PSS and ISEL on DBP (B=-.009, p=.167, 95% CI [-.022, .004] or SBP (B=-.013, p=.245, 95% CI [-.036, .009]). Conclusions: These findings are contrary to what has been reported previously in the literature. This may be due to a small sample size (n=50). As this study is an ongoing pilot study, the preliminary evidence may differ with a larger sample size. Continued research is needed to understand how social support can reduce stress-related cardiovascular disease risk.

Abstract Name: Modulation of Synaptic AMPA-Glutamate Receptors by Polysialic Acid: A Potential Therapeutic Strategy for Ameliorating Neurological Disorders

The α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic (AMPA) subtype of glutamate receptors is a crucial mediator of fast excitatory neurotransmission within the mammalian central nervous system. Precise regulation of AMPA receptors is essential for normal synaptic transmission. Numerous endogenous molecules play pivotal roles in modulating the functional characteristics of AMPA receptors. One such molecule is polysialic acid (PSA), a highly negatively charged carbohydrate covalently attached to the neural cell adhesion molecule (NCAM), which is prominently expressed in hippocampal synapses. Although previous research has demonstrated that PSA-NCAM can influence the single-channel properties of purified and reconstituted AMPA receptors, its impact on native synaptic AMPA receptors has remained unexplored.In this study, we employed the isolation and functional reconstitution of synaptosomal AMPA receptors in lipid bilayers to investigate the effects of PSA on synaptic AMPA receptors. Our findings revealed that PSA, in a concentration-dependent manner, exerts several noteworthy effects on AMPA receptors. It enhances the single-channel open probability, prolongs the mean open time, and reduces the mean closed time of these receptors. Notably, the well-known AMPA receptor desensitization blocker, Cyclothiazide, was unable to block the effects of PSA. This implies that PSA can modulate AMPA receptor channel properties independently of desensitization blockade, a phenomenon observed in certain pathological conditions.Taken together, our results indicate that PSA enhances the single-channel activity of synaptic AMPA receptors. Beyond reducing the rate of desensitization, PSA appears to potentiate AMPA receptors through alternative mechanisms. A comprehensive understanding of the dynamics of the interaction between PSA and AMPA receptors holds the potential to expand the utility of PSA as a small molecule therapeutic compound in various disease states characterized by AMPA receptor dysfunction.

Abstract Name: Osmotic performance of the mussel Mytilus galloprovincialis across increasing salinities

Climate change is a major contributor to causing drastic changes in ocean salinity, temperatures, and acidification. Mussels like the species, Mytilus galloprovincialis, act as biological indicators of environmental changes and studying effects of abiotic stress (i.e., heat, salinity) on mussel metabolic rate provides a metric for understanding changes in energy demand under stress. Climate change is predicted to increase precipitation rates which may alter seawater salinity exposing mussels to hyposalinity. However, there is little information about the osmotic stress tolerance of M. galloprovincialis in the face of climate change. Thus, the goal of this study was to determine the effect of variable salinity on the metabolic rate of M. galloprovincialis from two different sites as a predictor of climate change effects on marine invertebrates. Mussels (N = 300) were collected from Marina Del Rey and Ballona Creek, CA and exposed to 7 days of salinity stress (ranging from 5-40 ppt). Metabolic rate was measured following stress exposure and an osmotic performance curve was developed across all tested salinities. Results showed prime mussel metabolism at the average ocean salinity (34 ppt) and reduced metabolism under exposure to salinity extremes (5 and 40 ppt). Although Ballona Creek seawater variation is more variable than Marina del Rey, we did not identify a difference in metabolic rate between sites. Thus, our study suggests that M. galloprovincialis mussels exposed to hyposalinity will be energy limited and this may influence mussel survival under future climate change scenarios.

Abstract Name: Introduction to Disability and Critical Race Theory for Pre-Professional Educators and Clinicians

Students of color are disproportionately overrepresented in disability diagnoses, leading to placement in segregated, more restrictive classrooms, limited access to the general education curriculum, and reduced academic and occupational opportunities after graduation. Scholars studying the compounded effects of systemic racism and ableism in education note the limited instruction of these issues in pre-professional, higher education. The central aim of this project is to elucidate the intersections of race and disability in the delivery of educational services to school-age learners with communication disabilities who require extensive support to make progress on their academic curricula. Under the advisement of knowledgeable faculty, this author conducted a literature review to inform the creation of two 30-minute introductory course modules. The modules utilize Disability and Critical Race Theory as an underlying framework to educate pre-professional educators and speech pathologists on historical and contemporary knowledge of the interrelationships of race and disability in education. We will first pilot the two-course learning modules by

inviting undergraduate and graduate students from CSUF to complete the modules on Canvas. The participants will take pre- and post-test module evaluations using Qualtrics-delivered surveys to determine the modules' social validity and to critique speed, flow, and content usefulness. The modules offer practical tools for addressing educational, attitudinal, and practice barriers preventing students of color with disabilities from maximizing their educational and life potential. These modules will begin conversations within university departments responsible for graduating students likely to interface with the public and provide human service. We believe this is one step toward increasing awareness of the disproportionality of race and dis/ability in pre-professional education.

Abstract Name: Noise Affects Quality of Care Given by Nurses

Problem:Excessive noise in healthcare settings, such as call bells and loud machines, negatively affects patient care by impacting nurse concentration levels and increasing stress. This can result in lower quality of care and higher burnout scores among nurses.Purpose:This study aims to identify effective and noninvasive strategies to reduce noise levels in the Intensive Care Unit (ICU). By implementing interventions, the goal is to alleviate nurse stress and enhance the quality of care provided to patients.Method:The study utilizes a cross-sectional research approach conducted in four different acute care settings across two southern California hospitals. An anonymous survey consisting of eight questions was administered to gather initial grievances from nurses before implementing any changes. Participants were assured that no identifiable data would be collected or shared, ensuring complete anonymity.Innovation and resulting change:The pre-intervention survey involved 150 participants, with 135 being nurses and 15 holding supervisory positions. Among nurses, 68.1% agreed that the unit was too loud, and 64.4% felt uncertain about the availability of support from supervisors. Among supervisory staff, 73.3% believed the unit was too loud, and 66.7% were unsure how to access appropriate resources for implementing changes. Common concerns included training, improved/new technology, and staffing issues.Limitations:Limitations of this study include the small sample size, the use of a cross-sectional research method, and the time required to implement changes within the hospital.Implications and significance of the findings:Based on the data analysis, noise reduction interventions can lead to improved patient outcomes by reducing nurse stress. These findings have implications for research, practice, leadership, and education, emphasizing the importance of addressing noise as a contributing factor to nurse well-being and the quality of patient care.

Abstract Name: “Phantom or Reality”: Women’s Liminality in Fin-de-Siècle Gothic Short Stories

This project seeks to examine the evolution of the Female Gothic genre by analyzing how the prevalence of spectral figures in fin-de-siècle ghost stories by women writers serves as a symbol of women’s liminal status and transparency in the patriarchal world. My research extends recent scholarship by Diana Wallace, Vanessa Dickerson, and Ellen Ledoux, who are redefining the Female Gothic genre by studying how women writers complicated and expanded on traditional Gothic tropes found in early 18th and 19th century feminist literature. Using their work as a foundation, my project centers on three understudied short stories by women authors including Lettice Galbraith, G.M. Robins, and Rosa Mulholland from the collection Avenging Angels: Ghost Stories by Victorian Women Writers (2018). With the combined application of feminist criticism and historical research on the Victorian occult, this inquiry creates a dialogue between scholarly and literary texts to ask: How did fin-de-siècle women writers reimagine conventional Female Gothic tropes as a means of resisting patriarchal archetypes that deemed women as vulnerable, irrational, helpless beings? How did the popularity of the ghost story and emerging beliefs about the supernatural and the occult provide a space for women to exert agency in their writing? The conclusion to this study finds that the recurrence of liminal ghostly figures in fin-de-siècle short stories serves both as a representation of women’s liminality and inferiority in the domestic sphere and as a means of rebellion within itself. Women in these stories display agency when they enact revenge, disrupt the male household, and resolve ghost hauntings to avenge their own oppression and uncover the dark and hidden realities behind women’s experience in the home, which often figures as a domestic carceral.

Abstract Name: Designing StoX-Net: A Deep Neural Network Leveraging Emerging NVM Technology for Efficient In-Memory Computing

Crossbar-based in-memory computing (IMC) has emerged as a promising platform for hardware acceleration of deep neural networks (DNNs). However, the energy and latency of IMC systems are dominated by the large overhead produced by peripheral analog-to-digital converters (ADCs), which consume up to 60-80% of chip area and energy. Methods of limiting ADCs’ costs, such as sparse DNNs or aggressively-quantized training, do not fully take advantage of the speed and parallelism offered by IMC. To address the ADC bottleneck, we propose training a DNN model to capitalize on emerging non-volatile memory (NVM) technology’s capability of converting analog signals to binary values, eliminating IMC’s sole reliance upon the ADC. Specifically, we propose to implement stochastic processing of array-level partial sums (PSs), leveraging the probabilistic switching of spin-orbit torque magnetic tunnel junctions (MTJs). To mitigate accuracy loss, we develop PS-quantization-aware training that enables backward propagation across stochastic PS throughout bit-streamed and bit-sliced operations. Additionally, the network is trained using heterogeneous sampling lengths at MTJs, where multiple samples allows for accurate stochastic conversion. Our proposed PS processing eliminates the costly ADC, achieving significant improvement in energy and area efficiency. Compared to similar studies, we see up to a 0.5% increase in accuracy on classification tasks with a 130x lower energy-area-delay-product (EADP) seen at the hardware level.

Abstract Name: The Effects of Alcohol Consumption on Alzheimer's Disease, a Systemic Approach

Alzheimer's Disease (AD) is a detrimental neurodegenerative disease that can develop over time due to Tau tangles and Amyloid Beta (AB) plaques that causes neuronal death and thus hinders cognitive function. Recent studies have shown a positive correlation between alcohol abuse and AD development. We hypothesize that the alcohol metabolite, acetate, may play a role in the development of AD. Acetate can be converted to Acetyl-coA a metabolite that induces acetylation, a protein translational modification. Taken together, high acetate concentrations, due to alcoholism, can promote acetylation of liver proteins and mitochondrial reprogramming resulting in liver dysfunction. HEPG2 liver cells were treated with increasing concentrations of acetate (0, 0.5, 1, 2.5,5, and 10 mM) and analyzed within 24 and 48 hours of treatment. MTT, Trypan Blue, and Western blotting experiments were done to analyze the effects of acetate on HepG2 cells. No major changes were shown regarding HEPG2 viability or cell death. However, acetylation measured through western blotting showed an upregulation trend with increasing concentrations of Acetate. Acetate treatment also showed an upregulation trend for mitochondrial proteins like COX IV and Citrate Synthase. However, proteins like glutamate dehydrogenase showed an upregulation but then a downregulation at higher concentrations. Overall, increases in acetylated proteins and mitochondrial reprogramming may play a role in liver dysfunction that ultimately leads to AD development.

Abstract Name: Investigating the Tumor Interstitial Fluid Extracellular Vesicles Repertoire in Vivo

Metastasis is the major cause of suffering and death for patients who were diagnosed with cancer. Extracellular Vesicles (EVs) resident within Interstitial fluid (IF) of the tumor tissue microenvironment plays an essential role in cell-cell communication processes driving tumor progression. Tumor IF EVs are an unappreciated source of information surrounding a tumor that could provide insights into mechanisms that aid tumor immune escape and metastasis. We developed a method to isolate the IF from an excised tumor without damaging the underlying tissue cellular morphology. Our team discovered that the key mitophagy initiator molecule, PINK1, is exported into an EV in vivo. It has been shown that the tumor suppressor p53 is tagged for degradation by PINK1. We hypothesize that p53 is exported into PINK1+ EVs to aid tumor formation. To test this hypothesis, we used the syngeneic BALB/c animal model and injected 106 4T1 triple

negative breast cancer cells into the mammary fat pad. After 14 days, N=5 mice were treated with anti-PDL1 and N=5 were treated with a loading control. After 48 hours, the animals were sacrificed. tumor IF collected, and EVs were purified by centrifugation. We performed IHC on the metastasis against F4/80, CD206, Ly6G/C, CD11b, Arginase-1, and PINK1 to determine mitophagy level and the immune cell infiltrate. We found PINK1 and phospho-p53 were elevated in the IF EVs. By IHC and mass spectrometry we found that the treated tumors had greater immune cell infiltrate such as markers for neutrophil degranulation and T-cell activation indicative of the drug treatment's effect on the tumor. In conclusion, we have developed a MS analytical workflow which eavesdrops on the tumor pre- or post-treatment state using IF EVs as a novel tumor biomarker. Moreover, we identified a potential pro-tumor adaptation mechanism through the PINK1/p-p53 EV secretion.

Abstract Name: Simulating Multifunctional Nano-Optic Surfaces for Higher Efficiency Solar Energy Conversion

Solar irradiance, while abundant, poses challenges for traditional photovoltaic cells due to limitations in capturing specific wavelengths, storing energy, sensitivity to incident angles, and addressing bandgap mismatches. In response to these challenges, thermophotovoltaics has emerged, converting heat into electricity by utilizing thermal radiation from a high-temperature source to excite electrons in a photovoltaic cell. Additionally, metasurfaces positioned ahead of solar cells have been explored as alternative sources that absorb incoming solar energy, undergo heating, and subsequently emit an optimized spectrum for efficient low bandgap solar cell utilization.In this project, we employ the open-source simulation tool S4 (Stanford Stratified Structure Solver) to refine the design of a metasurface absorber/emitter for thermophotovoltaic applications. Utilizing the S4 Python API, we conducted an extensive parameter sweep, varying structural dimensions, frequencies, and incident angles to comprehensively explore the design and optimize performance. Guided by analytical calculations, the metasurface functions as a highly efficient filter, selectively transmitting wavelengths within the bandgap of the underlying germanium dielectric while reflecting most inefficient wavelengths. Notably, this selective transmission occurs with minimal polarization dependency and sensitivity to incident angles, ensuring consistent performance across varying conditions. The precision of our exploratory simulations closely aligns with analytical solutions, validating the accuracy and reliability of the S4 tool as an accessible alternative to expensive commercial solvers.

Abstract Name: The Psychology Behind Political Ads: The Use of Social Identity and Intergroup Emotions Theories

During an election, people are asked to make decisions about candidates. How do people make decisions? What influences these decisions? Research in psychology, specifically the social identity theory and intergroup emotions theory, has found that people make decisions based on group interests. Social identity biases can also lead to bad decision-making and loss. To what extent do political ads use social identity theory and intergroup emotions theory? Content analysis will be used to analyze 40 political ads from four presidential elections: 2008, 20012, 2016, and 2020. It is important to understand these theories and how they relate to political ads because it can lead to a better understanding of how and why political ads work. This thesis will contribute to the research because there has been research done on the theories and political ads separately, but no study conducted on how the two intertwine. I expect to find the political ads include cues that tap into group identity to influence voters because these theories have been shown to influence how people make decisions.

Abstract Name: Fluoride-Ion Batteries: Next Generation Sustainable Batteries to Lithium-Ion Batteries

Lithium-ion batteries (LIBs) are central in modern life, where they are found in products from smartphones to laptops to electric vehicles. The demand for efficient and sustainable batteries is higher than ever, with the predicted depletion of lithium sources after the year 2050. As an alternative to LIBs, next-generation fluoride-ion batteries (FIBs) are now being studied since fluorine is more abundant than lithium. This was a 6-month mentee-mentor internship at Caltech, the Caltech Connections program, an outreach program that pairs graduate students and postdoctoral scholars from Caltech as mentors with undergraduates from local community colleges. The topic of research is Lithium-Ion batteries and Fluoride-Ion batteries. The research methodology includes; solid-state synthesis, materials characterization, electrochemical analysis, in-situ/operando capacity measurement, fabrication of battery-cast electrodes, crystallography and material visualization, and structural analysis. Conclusions and future work are; LiCoO2 (95% wt) electrodes were produced through solid state grinding and mixing, which were then punched into half-inch electrodes, the lithium battery coin cell was assembled in an Argon glove box, the specific capacity of the battery was measured by charging/discharging the battery, BiF3 crystal structure is currently being studied to evaluate the material to make BiF3 electrodes, future work includes assembling a coin cell battery with BiF3 electrodes.

Abstract Name: Examining the Task Differences of Hispanic Americans' in the 21st Century Labor Market

Social movements address discriminatory treatment and marginalization experienced by groups of individuals. The Chicano Civil Rights Movement and 2006 Immigration Reform protests are no different. These social movements emerged from shared marginalized experiences Hispanic Americans faced in the United States. The movements inspired socially mobilized events, including the East Los Angeles Walk-Outs and a Day Without Immigrants strikes. Like many social movements, the Chicano Movement and 2006 Immigration Reform highlighted serious conflicts within our government and society; however created, an empowering spotlight for Hispanic Americans. One part of the Chicano Movement was to push for curriculum changes that would give students more choices to pursue non-stereotypical occupations. The research analyzes the labor market outcomes of Hispanic Americans, several decades on from the social movements to examine how persistent occupational segregation is. Using data collected from the American Community Survey, we examine occupational differences between Hispanic Americans and Non Hispanic Americans, focusing on the task components of their jobs.

Abstract Name: Psychedelic Social Media: The Rhetorical landscape of Ketamine Therapy in Georgia

Studying the rhetoric behind psychedelics has been an important feat for researchers, as it impacts science, policy, and communication between researchers and the landscape of psychedelics. Although not a classic psychedelic, ketamine therapy is an emerging type of therapy with promise for treating multiple conditions. e.g., depression, anxiety, and mood regulation, due to its ability to affect neurotransmitters like antidepressants. -(1A, 1B). However, due to the stigma around the drug, there are social side effects to consider. It's an almost inaccessible drug for marginalized populations in Georgia that could benefit from ketamine therapy who also stand against higher rates of stigmatization. Specifically, people who aren't able to access it due to shortage, geographic location, price or knowledge of it. Our analysis will use insight on clinics in Georgia, a state known for conservative laws. And allow the reader to conclude a thorough understanding of the rhetorical strategies surrounding these clinics websites and social media to their audience. Our hypothesis is that ketamine therapies are inaccessible for people with lower income.

Abstract Name: The Functional Impacts of Mutant Pacs-1 on Neuronal Morphology

Pacs-1 Syndrome is a rare neurodevelopmental disorder that causes neurodevelopmental delays, seizures, and craniofacial dimorphisms. Pacs-1 syndrome is caused by a genetic de novo mutation that is localized in the Pacs-1 protein that is used for transport in the trans-Golgi network(TGN). PACS was found in a study in 1998 that unveiled that this protein’s function was in the TGN to direct the localization of phosphorylated furin. PACS-1 has since been found to have a role in regulating calcium flux and genomic stability. In this study, we

aim to use C.elegans to model human Pacs-1 syndrome and examine the functional impacts of an R to W change in the neurons.Through investigating the well characterized mechanosensory neurons within C.elegans labeled with a transgenic marker, we intend to uncover the functional impacts of mutant Pacs-1 on neuronal morphology. Prior experiments have shown that certain Pacs-1 mutants from two other genes exhibit defective neuronal morphology. Utilizing this information we want to discern other types of mutant PACS-1 genes on the neuron structures. The goal for our study is to contribute to better understanding the functions of the Pacs-1 proteins and its functional relevance on mutant Pacs-1 in the nervous system.

Abstract Name: Improving Physical Activity in Rural and Older Cancer Survivors

Background/Study Purpose: Higher physical activity levels have been associated with lower cancer-related mortality as well as all-cause mortality rates. Those living in rural areas have less access to exercise opportunities; and therefore, lower physical activity levels. The purpose of this study was to implement a 12-week virtual exercise program to increase moderate-intensity physical activity among older cancer survivors living in rural areas. Methods: Rural, elderly cancer patients were recruited to join the study. Baseline measurements of activity were taken for 7 days using an ActiGraph device worn on their dominant wrist with a Velcro strap and a Fitbit device to monitor step counts. The patients participated in a 12-week virtual exercise program. Immediately post intervention, activity was monitored for an additional 7 days to examine the changes in moderate physical activity from pre-intervention to post intervention. Results: Paired samples t-test indicated a statistically significant increase in light-intensity physical activity (minutes per day) from baseline ($M = 157.71$; $SD = 46.01$) to post intervention ($M = 178.24$; $SD = 65.58$), $t(9) = 2.31$, $p = .047$. There was no statistically significant increase in moderate-intensity physical activity from baseline ($M = 107.57$; $SD = 46.46$) to post intervention ($M = 120.35$; $SD = 50.76$), $t(9) = 2.25$, $p = .051$. There was no vigorous-intensity physical activity captured at baseline or post intervention among the participants. As by step counts measured by Fitbit, paired samples t-test indicated a significant increase from baseline to post intervention, $t(9) = 2.60$, $p = .029$. The average increase in daily step counts was 997±1214 steps. Conclusions: The virtual exercise intervention was effective to increase light-intensity physical activity but not moderate-intensity physical activity among older, rural cancer survivors. The current preliminary analyses included $n = 10$, and data collection is ongoing for another 40 participants to be included.

Abstract Name: Development of a Biocatalytic Platform for Scalable Synthesis of Muconic Acid

Ring-cleaving dioxygenases (RCDs) are a class of enzymes responsible for selectively breaking open the ring of benzene derivatives to provide a carbon source for microorganisms in bioremediation. RCDs produce highly conjugated acids and aldehydes that can be used as building blocks for organic synthesis. Numerous studies have documented the activity profiles of various RCDs, but few have focused attention on isolation of the enzymatic products. Our research aims to synthesize these ring-opened products on a milligram to gram-scale. To achieve this goal, we sought to develop a scalable enzymatic method for the synthesis of muconic acids using the well-studied RCD CatA. To develop an efficient and economical approach to muconic acid synthesis, we analyzed various enzymatic preparations, including whole E. coli cells and clarified lysates harboring the enzyme CatA. Experiments on analytical and preparative scale demonstrated that clarified cellular lysates provided efficient access to the desired product with high turnover numbers and commensurate high product yields. Furthermore, we developed a non-chromatographic purification method for muconic acid isolation, reducing organic solvent use and improving the sustainability of our approach.

Abstract Name: The Unspoken Population of the U.S: The Homeless Population

Homelessness has emerged as a nationwide human rights violation. Homelessness is stigmatized with criminalization, violence, and aggressive policies that violate, rather than protect, the rights of the people involved. How much federal attention and aid is being directed to this issue and why are the U.S. homelessness rates rapidly increasing each year throughout the nation? The methodology includes an in-depth analysis of percentages of homeless residents across the nation and which of those are being financially supported by government organizations and state authorities in their current crisis. It explores risks (both physical and emotional risks) that are consecutively taken by America’s deprived residents in order to survive. America’s homelessness problem only seems to continue increasing. Our nation’s civilians have a negative stereotype engraved in their minds that a homeless person is someone who has some sort of addiction that caused them to lose their jobs and now lack money and shelter. Thoroughly examined research demonstrates that there are multitudes of other reasons that cause homelessness. Anyone can become homeless. Research suggests that as a society, we need to educate ourselves more about this sensitive issue in our communities. We are all guilty of staring off into the opposite direction of someone begging for food or money in the street while sitting inside our cars. We are guilty of misjudging someone’s current financial or living situation. Homelessness is not spoken about enough, society tends to keep this topic on the down-low or below radar so it doesn't seem like we as a society don't care about our needy civilians. This study proves that not enough attention or aid is being provided to American homeless residents, and basic human rights are currently being violated.

Abstract Name: ‘Music is how I translate my life’: Exploring the Identity Work of Non-Men in Musical Practice

How do non-men use music to construct identity? I explore the process of making music as a site for the construction of gender identity- music and identity are co-created in the act. I analyze the construction of identity and the self through 16 qualitative in-depth interviews with participants who identify as non-men. All participants in this study had experience with music-making, with backgrounds from diverse scenes and styles. Participants’ responses illustrate that music making is a practice in identity construction. Music making offers individuals an avenue for reflection and engagement with gendered norms. The musical practices and meanings that are ascribed to them affirms the identity work that non-men enact in musical spaces. Furthermore, their practices have the potential to take up struggles for agency that disrupt gendered norms and hierarchies. Music is used to resist gendered norms through strategies of resistance and redefinition, allowing for spaces of possibility. I analyze these themes in non-men’s use of sound, voice, and persona in their musical practices.

Abstract Name: Gone Without Saying Goodbye

Between the years 2002 and 2008, Colombia was affected by a scandal called "Los Falsos positivos". This scandal involved innocent civilians being presented falsely as guerrilla fighters and being killed, to inflate the appearance of government success. The poem, "Falsos Positivos (Su Voz)", explores the aftermath of a victim of the "Falsos Positivos" scandal. It is from the perspective of a young boy who was killed, talking to his mother. He is trying to tell her to not look for him or wait for him to come home for dinner because he has been killed and will never come home again. This painting shows the mother who is waiting at the front door for her son to come home. In the painting, the son (as a ghost) is off in the distance waving to his mother. She cannot see him because he is dead, and she still thinks that he will be returning back home. I learned about the deception, violation of human rights, and major systemic issues within the Colombian government. I would like to continue to learn about the long-term effects on the victims and their families, and how the Colombian government is being held for the heinous crimes that they committed. I selected this topic because although it was a significant scandal in history, it was something that I had no idea about before taking SPAN 3570. Although I have no personal connection to the scandal of "Los Falsos Positivos", I see the importance of learning about and remembering how a selfish political decision made by the government altered the lives of those living in Colombia forever.

Abstract Name: Perception of Peer Criticism at Different Academic Levels on a College Campus

This study emphasizes the value of expressing a diversity of opinions and cultivating an environment that encourages constructive and inclusive discussions on sensitive topics. Our study explores how students' perceptions of peer criticism influence how comfortable they are at expressing a range of opinions on college campuses. Students at the University of Minnesota Rochester responded to a quantitative research survey to assess their levels of comfort with self-expression and concerns about peer criticism on non-controversial and controversial topics related to gender, politics, race, religion, and sexuality. The findings reveal nuanced differences in the reluctance and concern of students at different academic levels to engage in these discussions. Students taking lower-division courses are more reluctant to discuss topics related to religion, race, and non-controversial topics, and are most concerned about peer criticism when discussing race, sexuality, gender, and non-controversial topics. Students taking upper-division courses are more reluctant to engage in discussions about gender, sexuality, and politics, and are most concerned about peer criticism when discussing politics and religion. The findings suggest that, while students may be concerned about peer criticism, this does not always dictate their willingness or reluctance to discuss the topic. The findings provide insight into the evolving attitudes, concerns, and comfort levels among students across various topics and academic levels. Regardless of a student's reluctance to speak up or concerns about peer criticism, efforts should be made to encourage students to confidently navigate complex subjects, fostering meaningful interaction with professors and peers. While the research itself does not explain these variances, the insights provided have implications for administrations and educators seeking to create an inclusive and supportive campus environment that encourages expression and a diversity of opinion.

Abstract Name: Investigation of Antibiotic Resistance & Microbial Contamination in Urban Water Samples

This study investigates antibiotic resistance in urban water sources across Rochester, MN. Rochester has a variety of water sources, among which we investigated Zumbro River, Foster Arends Lake, and Cascade Lake. Of note, both lakes are former gravel-mines converted in recent years to public recreational parks. It is not unusual for the swimming beaches at the two lakes to be closed due to elevated bacterial counts that exceed safety guidelines. Multifactorial and confounding reasons govern the elevated bacterial counts such as

fecal contamination from the abundant bird population and input of feces from dog swimming areas. Bacterial introduction via feces and other mechanisms can contaminate the local water sources with antimicrobial resistance genes. If these genes are located on plasmids, these genes can readily be shared by horizontal gene transfer and contribute to greater local resistance across bacterial species. For this study, water samples were collected from both man-made lakes and the Zumbro River. Using serial dilutions of water samples, bacteria were cultured on trypticase-soy agar plates including antibiotics, spectinomycin, chloramphenicol, ampicillin, and enrofloxacin. The prevalence of antibiotic resistance was determined by tabulating colony-forming units and extrapolation to bacterial counts per mL of source water. Interestingly, the water samples collected from the river revealed the greatest abundance of antimicrobial resistance. This aligns with the public wastewater facility moving treated wastewater into the river, which includes resistant genes to a diversity of antibiotics that are understood to be elevated in hospital wastewater and neighboring sewage systems, as Rochester is home to multiple hospitals. Ongoing research may contribute to identifying possible locations of greater concern regarding water quality and antibiotic resistance. We hope to expand testing of our local water sources for contamination to include antimicrobial resistance. We are committed to better understanding and improving the quality of local water resources.

Abstract Name: Locust of Control: Modeling Locust Motion as a Markov Process

An accurate model of locust motion would be an invaluable tool for reducing the economic and agricultural impact of locust swarms. Emergent structures in the collective motion of locusts suggest that their directional movements are not simple random walks (or hops). To develop a next-simplest model, we analyze locust motion as a discrete sequence of direction-independent motion states: stationary, walking, or hopping. In line with other contemporary models of locust motion, we propose that these states can be effectively modeled as a Markov process. We test that hypothesis by evaluating a Markovian model for videos capturing nearly 20,000 individual locust trajectories at 25 frames per second. The sojourn time, a key characteristic of random processes, measures the length of time elapsed between state changes. Under our null hypothesis that locust motion states are a Markov process, we expect: (1) that the distributions of individual sojourn times within a given state follow a geometric distribution; and (2) that the distribution of state changes within all non-overlapping, equal-duration segments of the data follow a Poisson distribution. Using goodness-of-fit tests, we compare the distributions of empirical data to the expected distributions. We find sufficient evidence to reject our null hypothesis on timescales longer than 6 frames. In the context of Poisson variables, his suggests that locusts' motion states may be independent of their neighbors but not independent of their own histories. Additionally, an algorithm was developed to evaluate the relationship between the frame rate and the shortest possible sojourn time. Though further research is needed, our results suggest a need to account for time variance in agent-based modeling of locust motion.

Abstract Name: Ubiquitination of xCT: Impacts on The Protein's Stability, Turnover Rate, and Localization

System xc- imports cystine and exports glutamate. Its presence on the plasma membrane has been shown to increase directly with oxidative insults. Ubiquitin, a small protein, is directly involved in the trafficking and degradation of numerous proteins within cells and has been shown to bind to System xc-. Moreover, upon oxidative insult, protein ubiquitination increases. However, it is not understood how ubiquitination of the transporter impacts its activity. Therefore, the objective of this project is to directly assess how ubiquitination affects the protein's stability, turnover rate, and localization in the context of oxidative stress. We expressed System xc- in COS7 cells transfected with increasing levels of ubiquitin and observed a decrease in xCT expression and increase in xCT turnover rate. However, we also observed an increase in membrane localization. Ultimately, this work will allow us to better understand the mechanisms by which System xc- activity is regulated under oxidative stress.

Abstract Name: Exploring the role of the ancient and ubiquitous protein: Jagunal homolog 1

Jagunal homolog 1 (Jagn1) is a transmembrane endoplasmic reticulum (ER) protein that cycles between the ER-Golgi interface. Jagn1 is highly evolutionarily conserved and expressed in the vast majority of eukaryotic cells. Jagn1 cannot be placed in a protein family, but its tetraspanning topology and presence of sorting motifs suggests it may "escort" cargo proteins in both retrograde and anterograde directions between the ER and Golgi. Jagn1 was identified in a screen of lethal mutations in D.melanogaster and was shown to be essential for protein trafficking during egg development. Later studies demonstrated that humans with homozygous JAGN mutations exhibit Severe Congenital Neutropenia (SCN) due to impaired neutrophil maturation. SCN neutrophils have enlarged ERs, suggesting an ER to Golgi trafficking defect. In addition to neutropenia, patients present with systemic symptoms unrelated to immune system functioning. This suggests that Jagn1 plays an essential role in some key cellular process(es). To understand the molecular mechanism of Jagn1, we aim to identify interacting proteins as well as effects of Jagn1 absence on cellular function. We have generated Jagn1 constructs tagged with the BirA* biotin ligase, that when supplemented with biotin, will biotinylate neighboring proteins. Putative interactors have been identified and binding affinity to Jagn1 is being assessed. We have also generated three Mouse Embryonic Fibroblast (MEF) knockout cell lines, each with a differentially truncated Jagn1. Preliminary analyses indicate that these cells display defects in adhering to/and spreading on plastic after plating. This correlates with observed defects in surface-localized integrin-a5 and establishment of paxillin-containing focal adhesions. Live imaging assays have shown defects in cell movement, adhesion, and polarity in comparison to wild-type MEFs. This suggests Jagn1 may facilitate trafficking of integrins and/or extracellular matrix proteins to the cell surface. This is relevant in context of maxillofacial, musculoskeletal, and neurological defects observed in SCN patients.

Abstract Name: Win-Win Opportunities: How Diversifying Farm Operations can Lead to On-Farm Environmental and Economics Gains

Existing research on farm diversification practices tends to focus on the accompanying environmental benefits, such as improved soil health, more effective weed and pest management, and increased biodiversity. Yet, less attention has been devoted to the economics of these practices. This project aims to determine the profitability of two farm diversification practices, cover crops and a more diverse crop rotation, in comparison to a typical corn-soybean rotation in rural western Wisconsin. This analysis was done with USDA data on the costs, yields, and selling price of corn, soybean, and rye. The data was then aggregated with information from literature, surveys, field experiments, and local experts to determine reasonable and conservative estimates of the financial effects of implementing a simple rye cover crop or adding rye into the crop rotation. This showed that diversification practices are less profitable in year 1 (short-term) than the corn-soybean rotation, but both are more profitable in year 5 (long-term) compared to the corn-soybean rotation. Also, both practices help reduce the economic losses that occur during a drought. Since every farm is managed differently, the exact results found in these analyses cannot be expected on every farm, but the results highlight the general economic trends associated with these two diversification practices.

Abstract Name: Definition Through Distance: Animals as the Sartrean Other

This essay examines animals and their place as “the Other” in Sartrean literature. In Being and Nothingness (1943), Sartre by and large centers his writings around human consciousness in establishing our experience of the Other, or the engagement with a free and independent consciousness beyond our own. Animals are notably absent in this analysis. Scholar Florence Burgat notes that Sartre had little interest in incorporating animals on the grounds that they do not share a human consciousness. I argue, however, that by holistically considering his conception of the Other, we can read Sartre against himself regarding animals. Pairing the nuance of our experience with the Sartrean Other alongside John Berger’s discussion of anthropomorphism and its effects on human-animal relations, I suggest that we encounter animals in such a way that they resemble human consciousness and are thus the Other. Further, holding this to be true, we might receive “the look” from animals when considering how they perceive us and the world around them—in doing so, we become an object to their subject. It is precisely in this objectification that we experience the look. The value of these questions lies in Steve Martinot’s analysis of Sartre’s position. He claims that the look is a way of communication or dialogue between independent consciousnesses, a reciprocal cycle of objectification and subjectification wherein relations are constructed, defined, and maintained. Relying on Martinot’s claim, I extend this notion to human-animal relations and hold that by experiencing them as the Other and thus receiving the look, we engage in a form of dialogue which positions us to better examine ourselves and our own relationships to animals.

Abstract Name: Exploration of Medical Mistrust Amongst African Americans and Arab American Youth

This research examines two large overlooked minority young adult groups in America who experience racial discrimination in healthcare. This paper argues that the effects of trust in a provider are associated with medication adherence, continuity of care, improvements in self-reported health, and decision making when seeking care. Racial discrimination in health care access and quality of care has resulted in a long standing and ongoing medical mistrust of healthcare providers and the health system for many racially demean groups. Adolescents and emerging adults are very important considering youth are beginning to become more independent and are taking on greater responsibility for their own health care. Medical mistrust studies have predominantly been studied in adult populations, but there has been a huge gap in the research studying medical mistrust in youth which is where early intervention can clearly be beneficial. Due to mutually dependent challenges that minority youth face such as racial discrimination, environments with social disadvantages, and medical mistrust they often have social complexes. With this being said minority youth often have a lot of involvement with health care systems from multiple different access sites, but this leads to them often failing to achieve positive health outcomes. To gauge medical mistrust, surveys will be given to minority youth between the ages of 16 to 18 years old and 19 to 25 years old in clinic settings and in the community. The population the survey will be given to will include African American and Arab American youth in metro Detroit, Hamtramck, and Dearborn. There are studies that look at the concept of adolescent trust in their providers, and also how it relates to the youths' health outcomes. It's shown that youth with higher levels of trust in their provider consistently receive more chronic illness care than those who receive medical mistrust.

Abstract Name: A benchtop route from elemental Se to superior thermoelectric β-Ag2Se

β-Ag2Se is a remarkable material for thermoelectric applications, but enhancing its performance through doping techniques has remained a challenge. Over the past years, research has been devoted to interstitial, vacancy, and substitutional doping into the parent β-Ag2Se structure, aiming at tuning the material's charge and heat transport properties to enhance thermoelectric performance. The transformation of β-Ag2Se into a-Ag2Se at ~134°C and the low solubility of dopants are the main obstacles for the doping approach. Here, we will discuss our efforts to develop a facile, safe, scalable, and cost-effective benchtop approach to successfully produce pristine and metal-doped β-Ag2Se at near room temperature. This research will display our progress in creating a safe, straightforward, and inexpensive synthesis procedure to obtain pure and metal-doped β-Ag2Se at near room temperature. Our research will also address our progress in enhancing the electrical and thermal transport properties of β-Ag2Se upon metal-doping – resulting in an increase in zT from ~0.65 (pristine) to ~1.30 (metal-doped β-Ag2Se) at 120 degrees Celsius. Additionally, we will compare the results of different metal dopants and the trends we discover. In conclusion, this new proposed synthesis procedure offers a new route to create β-Ag2Se of the highest caliber with negligible energy input while investing in superior energy sources.

Abstract Name: Retrospective Analysis of Auditory Processing and Comorbid Disorders

This retrospective analysis delves into the intricate relationship between Auditory Processing Disorder (APD) and Language Processing Disorders (LPD). Through a comprehensive review of existing literature, clinical case studies, and diagnostic methodologies, this study seeks to explain the underlying connections, shared characteristics, and potential causal factors between these two neurodevelopmental conditions. The analysis highlights the challenges in accurately diagnosing APD and LPD due to overlapping symptoms and variability in presentation. Additionally, the study explores the implications of misdiagnosis or co-occurrence of these disorders on individuals' academic, social, and emotional well-being. By synthesizing findings from diverse sources, this analysis contributes to a deeper understanding of the complex interplay between APD and LPD, paving the way for improved assessment strategies, tailored interventions, and enhanced support for individuals experiencing these challenges.

Abstract Name: Cultivation of bacteria from PCB-contaminated sediments PCB Degradation

Polychlorinated biphenyls (PCBs) are toxic chemicals popularly used in electrical manufacturing companies from the 1930s - 1970s. PCBs, colloquially known as ‘forever chemicals’, are known to cause significant health concerns and are notoriously difficult to remove from an environment. PCBs are currently banned in the US; however, they can still be found in the environment due to improper disposal methods. This research aims to better understand ecological networks, genomic novelties, and potential bioremediation of microbes from PCB-contaminated environments. Microcosm cultures were developed to resemble the original conditions of the environmental samples, containing PCB-contaminated mud from Woods Pond, Lenox, Massachusetts, and filtered pond water with three different treatments: aerobic, anaerobic, and anaerobic with the addition of sulfate. These cultures have been growing for five months, showing signs of active microbial metabolism (e.g., rust patches in sediment gas production). The microcosms were used as inoculum for agar containing PCBs, and 30 PCB-tolerant colonies were isolated, with some belonging to known PCB-degrading taxa of Paenibacillus, Clostridium, Rhizobium, Methylversatalis, and Sphingobacteria. Future analyses will be conducted to (a) identify the microbial diversity within the microcosms via 16S rRNA amplicon sequencing, (b) explore the metabolisms within the microcosms, and (c) further characterize the isolated PCB-tolerant bacteria. This data will aid further research to determine if and how these microbes metabolize PCB compounds.

Abstract Name: A Compositional Analysis of Aged Latent Fingerprints Post-Rehydration

Fingerprints are a widespread means of identification and are commonly used in forensic practice. However, the ability to develop fingerprints decreases over time due to rapid evaporation as a fingerprint ages. Our previous research has shown that rehydration is an effective method that enables the development of high-quality aged latent fingerprints on non-porous surfaces. Unfortunately, the scientific process allowing for fingerprint rehydration was unknown and, without a mechanistic understanding of the process, the method therefore could not be implemented in forensic laboratories. The purpose of this project was to identify what specifically occurs when a fingerprint is rehydrated so that this novel methodology can be utilized in forensic laboratories and defended in a court of law. Fingerprints were deposited and aged (evaporated) on a glass substrate before rehydration for 30 minutes at 80-85% relative humidity in a sealed humidity chamber. The fingerprints were imaged under a microscope at 4x and 10x magnification after deposition, evaporation, and rehydration to assess what was occurring at the rehydration interface of the fingerprint. Protein and lipid dye stains were used to assist in the microscopic identification of the rehydration component of the fingerprint. Results indicate that there are trace amino acids located in the rehydration interface of the fingerprint that are rehydrating and restoring the fingerprint to its depositional condition. Though additional research is necessary

to identify the specific trace amino acids present in the interface, this research has important implications in both enabling the widespread implementation of this method in forensic laboratories and satisfying the admissibility requirements for rehydrated fingerprint evidence into a courtroom. Furthermore, when implemented in forensic laboratories, this method will enable latent fingerprints from cold cases to be rehydrated to their original ridge width and analyzed using present technology and databases, therefore enabling the possible resolution of these cold cases.

Abstract Name: Commissioning the timing of the GBO Outrigger telescope for the localization of fast radio bursts

The construction of the Canadian Hydrogen Intensity Mapping Experiment (CHIME) Outrigger at Green Bank Observatory (GBO) was just recently completed in the spring of 2023. CHIME and the Outrigger have been outfitted to detect fast radio bursts (FRBs), mysterious transient radio pulses of unknown origin. In order to detect and locate these FRBs, we implement very-long-baseline interferometry (VLBI) which effectively creates a telescope with a dish the size of the distance between the two telescopes. To implement VLBI, clocks at each location have to be paired accurately in order to document the different arrival times of the signal in each location. As well, this accurate pairing will assist in triangulating the location of FRBs, identifying the galaxy of origin and their location within that galaxy. Ensuring the atomic and GPS clocks at the GBO site are operating at a certain level of precision is essential to the implementation of VLBI. The task at hand is ensuring that the Outrigger is in sync with the CHIME telescope in British Columbia, Canada, down to the nanosecond (10-9 s). By calculating the Allan Deviation and the Tau Shifts of the clocks at GBO we have been able to test the effectiveness of the clocks and diagnose issues and current shortfalls at the Outrigger. Currently, we are progressing toward reaching the desired level of calibration to begin sub-milliarcsecond detections.

Abstract Name: The Significance of Preserving Historic Architecture While Promoting Progress

History can be defined as the study of change, adaptation and progress. Life as we know constantly changes from the way we learn to how we create buildings. It is important to mention that people do not only create history, but so do their creations. The question is why preserve it and what purpose does this serve in a progressing environment? This research features first-hand insight on how a specific historical site stays up to date with society while paying tribute to its complex upbringing. In this presentation, we will take a look into

Darlington School, a private historical institution that has presented several points of discussion that highlight the significance of preserving historic architecture while promoting progress. Darlington School's motto is: “Wisdom more than knowledge, Service beyond self, Honor above everything.” Wisdom is gained through experiences by trying new things and reflecting on the process of how those things came to be. In order to serve someone effectively, you must look inward and identify what kind of energy you are putting forth, and adjust so that you affect others in a positive way. To honor is to pay respects to someone or something higher beyond yourself because of what they are and the purpose they have served. It feels as if this motto not only represents the students, but the history of the building itself for the purpose it’s served over the years. Given this information, we will dissect an interview from an alumni who shared their experience being a student here by discussing the school’s history, the physical appeal and the community built internally and externally. With this approach, we expect to ultimately define the purpose for preserving historical buildings while promoting progress.

Abstract Name: Only Murders in the Paper: How Publications Enthralled Chicago, Elevated America's First Serial Killer, and Evaporated Public Interest

This project seeks to determine how the American public, especially that of Chicago, reacted to and engaged with the rapid reports following the H. H. Holmes murder case of the late 1890s. Existing conducted research emphasizes Holmes as an individual, while brushing over the broader context surrounding the public’s response to the horrors, arrest, trial, and execution. I analyze the public’s reaction primarily via newspaper articles following the case’s progression, including the dramatic use of yellow journalism and frequent publication dates. My most-consulted sources include newspapers from Chicago, Los Angeles, and Atlanta, as well as Holmes’s autobiography, written during his incarceration. This research connects the pedestal of a prolific serial murderer’s legacy to its foundation. Holmes has gained lasting notoriety for his deeds, but the public who survived, remembered, and followed the case have faded from collective memory and academic research. Holmes’s legacy remains as America’s first serial killer, a title that encapsulates much of the theatrics surrounding his reputation. Yellow press riveted audiences, sculpted the public response, and forged Holmes’s image. I conclude that the citizens of Chicago and elsewhere were incredibly invested in the H. H. Holmes case. It was only after the final resolution that public interest evaporated, rendering their reactions obsolete in the minds of researchers, when it is the very same public interest that elevates characters like Holmes to their pedestals in the first place. A focus on that aspect of this episode will provide greater insight into how historical events are often created, remembered, and forgotten.

Abstract Name: Radical Misogyny, Insidious Trauma, and Amber Heard: Reviewing The Fascist State of

Minds Cultivating Male-Supremacy

Utilizing Ann Cvetkovich's An Archive of Feelings: Trauma, Sexuality, and Lesbian Public Cultures as a primary source, this paper seeks to gain a critical understanding of female-specific trauma, reviewing the notorious defamation trial of Amber Heard versus Johnny Depp. I will examine this trial using two terms – "insidious trauma" and "radical misogyny" – that I believe best encapsulate the situation created out of the live-streamed trial and the reactions on social media, namely X and TikTok. Most effective in Cvetkovich's explorations here is employment of "insidious trauma" – engendered with its earliest meanings by Laura Brown — made insidious by the lack of outrage given toward the act of violence in its wake and support toward the victim. The term, as argued by both authors, can do powerful work as the traditional usage of trauma/PTSD "cannot do justice to the traumatic effects of a sexism that does its work precisely by being constructed as normal" (163). Critical in rejecting universalizing readings of trauma, insidious trauma ousts the moments of reified patterns of intolerance toward a female or feminized Other that infiltrates everyday experience and into a space for critique and social change. My term, "radical misogyny," which will be parsed through in depth, makes misogyny radical in the same way that trauma can become insidious: through minimal response, perhaps even normalized entirely. These terms lie at the heart of my feminist-based research, alongside the work of psychoanalyst Christopher Bollas, namely using what he describes as "the fascist state of mind," which I argue stands at the basis of our misogyny-based society. Amber Heard's situation as publicly displayed is exactly what epitomizes the traumatic treatment of the female subject, the archive and impact of which will circulate forever in the digital age.

Abstract Name: Understandind the Social Norms of Generation Z and the Generational Dependency of Online Media

In past forms of research, there has been a common occurrence of a decline of mental and social standards in society that is connected to a person's dependency on internet resources. More specifically, members of Generation Z, the generation that was born with some form of technology in hand. This generation is the most recent community to be influenced by the new trend of technological innovations. The most prominent outlet that has affected Gen Z and swayed their social demeanor is online media. Studies have been conducted on this group and their dependency on social media to understand their mental stability, self-esteem, and independence compared to previous generations. This concept is especially prominent throughout the COVID-19 pandemic. I propose to demonstrate how the social norms of Generation Z have been influenced by online media, leading to their dependency on internet resources and shift in social demeanor. My research will enlighten my readers about the repetition of generational downfalls as well as guide my readers to understand that the things people absorb online can impact their behavior in the real world. I have scoured through many scholarly articles to unravel varying reasons as to how instances from the past have reshaped Generation Z to behave the way they do today. We are going to discuss why people are so reliant on gaining satisfaction from online outlets despite the shift in society's social demeanor. Regardless of the evolutionary technological devices, humanity will only be able to advance so far with our lives online before it's too late to turn back to what's important for us in the real world. With this demonstration of how the social norms of Generation Z have been influenced online, I will establish why their dependency on Internet resources should not be considered an impossible hurdle to overcome.

Abstract Name: Religious Precedents for Consumerism in the American Cattle Meat Industry: Islam and Cultured Meat

Commercialized cultured meat and Muslim meat markets are both currently experiencing periods of growth, expansion, and influence, especially in the western world. New developments in bioengineering and technology at large continue to demand the attention of consumers. This accelerating commercialization of cultured meat implores the adaptation of religious laws onto its consumption, especially by faiths that are perceived as stricter in their dietary guidelines, such as Judaism and Islam. The present study aimed to discuss possible solutions to the debate of cultured meat within Islam and provide a prospective foundation for the product's augmentation within western Muslim communities. The study consolidated and analyzed various peer-reviewed sources regarding religious statutes in Islam in relation to stances on meat, technological modernization, as well as the potential for unprecedented producer benefit, broader product options, and other religious implications in global markets. Sources were synthesized and compared alongside each other to construct a coherent conversation. The study found that some arguments opposing cultured meat warned against "playing God" by obtaining meat from means that may be seen as unnatural. Conversely, arguments that favored permission of cultured meat highlighted the options of serum, growth media, and cell harvest processes that are animal-product free, as well as perceived promotion of Islamic principles of animal welfare, environmental welfare, and self-health. This review proposed Islamic justification for the consumption of cultured meat by utilizing various conceptual categories, criteria for the acceptance of cultured meat into western Muslim diets, and the potential monetary gain achieved by producers who implement halal practices into their products and businesses at large.

Abstract Name: Exploring the Impact of Sex-Biased Dispersal on Genetic Diversity and Gene Flow in Moose (Alces americanus)

Moose (Alces americanus) are particularly at risk from environmental alterations and anthropogenic disturbance due to their size and resource requirements. Population monitoring and habitat management are vital for conservation efforts which promote the longevity of healthy individuals. Populations located in Northeastern Quebec, Western Quebec, and South of the Saint Lawrence River offer a favorable region to examine sex-biased dispersal among moose. Molecular approaches provide insight into how sex-biased dispersal influences genetics within populations of interest. We used a publicly available single nucleotide polymorphisms (SNPs) data set and the software program GenALEx to analyze the role of sex-biased dispersal on moose genetic variability, gene flow and connectivity. DNA was extracted from the hair and tissue of 317 moose and genotyped at 136 SNP loci. The pairwise population Fst values facilitated understanding of connectivity between the populations of interest. Genetic differentiation was lowest between

Northeastern and Western Quebec suggesting gene flow between the two populations. Evidence of male-biased dispersal included 1) higher genetic differentiation in females relative to males and 2) a tendency for males to be genetically assigned to populations other than the ones where they were sampled. These findings align with previous research suggesting the mammalian tendency toward male-biased dispersal. Further understanding of the movement dynamics of moose populations will improve conservation strategies. This will ultimately benefit the management of a fragile species in an environment that is rapidly changing.

Abstract Name: The Impact of Foregrounding on Aesthetic Experience: An Analysis of Real-Time Responses to Sonnets

The Digital Humanities and Literary Cognition Lab (DHLC) at Michigan State University is conducting an interdisciplinary study of sonnets that examines the similarities and differences in the aesthetic pleasure that English majors and non-English majors experience while reading poetry. In the study, participants were tasked with highlighting moments they found aesthetically pleasing in green and aesthetically displeasing in red. The lab compiled and graphed this qualitative data to visualize the cumulative highlighting patterns of both participant groups (English and non-English majors) and then compared them. When analyzing the graphs, we found that the trends between the two groups were more similar than initially hypothesized. Our presentation will discuss the study with a focus on the moments where foregrounding devices were prevalent and how these affected the aesthetic responses of our participants. Foregrounding theory argues that certain literary devices, such as metaphor and imagery, are “foregrounded”—in a sense, the expression and effect of the text is prioritized over its literal meaning, thereby capturing reader attention. Our study aims to recognize why people are attracted to foregrounding devices, specifically in terms of a positive response. This poster examines multiple moments that prompted frequent aesthetic pleasure highlighting across both groups and attempts to explain why moments of foregrounding are closely tied to an aesthetic response. Devices such as metaphor, personification, alliteration, imagery, and ambiguity appeared the most frequently across popular words and phrases, suggesting that these tools’ ability to foreground language is an essential element to their capacity to produce pleasurable aesthetic effects.

Abstract Name: Reduction Of PCID2 In Breast Cancer Cells Decreases Mesenchymal Markers And Upregulates Epithelial Markers

Breast Cancer is the leading cause of cancer death among women due to tumor recurrence and metastasis five years after a lumpectomy. Epithelial to mesenchymal transition (EMT) is important for cancer cell migration and invasion, and ultimately metastasis. Activation of the Wnt/B-catenin signal transduction pathway activates downstream targets Snail 1&2, Zeb 1&2, and ZO-1 which are transcription factors that trigger EMT. High expression of the protein PCID2 in Colorectal Cancer (CRC) is associated with larger tumors, increased cell migration, and activation of the Wnt pathway, increasing EMT markers. Because metastasis is a key factor in breast cancer associated deaths, we decided to determine if PCID2 expression also contributes to epithelial to mesenchymal transition and breast cancer progression. Western blots were preformed to assess if siRNA knockdown of PCID2 impacted B-catenin expression, downstream EMT transcription factors like Snail 1&2, Zeb1&2, and ZO-1, and subsequent decreases in epithelial markers E-cadherin and claudin, or increases in mesenchymal markers N-cadherin and Vimentin. Decrease in PCID2 caused decreases in some EMT transcription factors, such as ZO-1, Slug, and B-catenin. Loss of PCID2 also decreased mesenchymal markers and increased epithelial markers, indicating a potential role for PCID2 to normally drive EMT. Future work will include migration assays to assess the effect of PCID2 in breast cancer cell migration and invasion. Understanding the role of PCID2 in breast cancer cell metastasis can potentially lead to development of targeted therapies, to inhibit these cellular processes in the hopes of decreasing breast cancer metastasis and patient death.

Abstract Name: Generating CRISPR Mutations in the ASYMMETRIC LEAVES1 Gene of Arabidopsis

The goal of this study is to create new mutations in the ASYMMETRIC LEAVES 1 (AS1) gene of Arabidopsis using CRISPR technology. AS1 is a myb domain transcription factor that represses the KNOX genes, a group of genes involved in maintaining an undifferentiated cell state. AS1 binds to the chromatin remodeling protein Histone Repressor A (HIRA). In animals, HIRA is involved in the permanent suppression of proliferation genes required for early development. The interaction between AS1 and HIRA provides clues to how AS1 maintains suppression at the KNOX genes; however, we must be careful applying what is known in animal systems to plants because there are key differences between the two during development. Most notably, plant development occurs throughout the lifecycle, and unlike animals, plant cells more readily un-differentiate and re-differentiate. We are working to create new AS1 CRISPR mutants to better understand the structure and function of the AS1 protein and how it physically interacts with HIRA in plants. We are currently screening plants for the presence of mutations in the AS1 gene. This work will allow us to better understand how genes are regulated during cellular differentiation during leaf development.

Abstract Name: Thermal Decomposition of Tetra-ethoxy-silane by VUV-PI-TOF Mass Spectrometry

Organosilanes have recently become a subject of interest for research due to their unique properties as organic molecules. Organosilanes are hydrophobic, water-repelling, making them useful for surface coatings; they also help stabilize fuels which result in reduced emission of pollutants. The purpose of our research is to study the flash pyrolysis of tetra-ethoxy-silane and its relevance to fuel combustion as well as chemical vapor deposition (CVD). In CVD, the primary focus is on the success that a gas precursor has with respect to how well it will coat a surface (no impurities). Pyrolysis of tetra-ethoxy-silane (TEOS) was achieved by using the vacuum ultraviolet photoionization mass spectrometer. This method helps ionize tetra-ethoxy-silane and allows for fragments to be detected at a detection chamber, which are then translated into a mass spectra. Our work has demonstrated that the pyrolysis of tetra-ethoxy-silane generates silicon dioxide of high-purity which is useful in the surface coating of silicon dioxide films. In a similar way, the fragments of TEOS have been shown to act as combustion catalysts in fuels, which release less harmful pollutants. Overall tetra-ethoxy-silane has been successful in its fuel and surface coating applications. However, the costs of this organosilane make it difficult to set as an eco-friendly fuel. Through mass spectrometry TEOS can be analyzed in order to identify important chemical properties that may be shared with other organosilanes, which are more cost-efficient. Furthermore, the pyrolysis of TEOS has helped in coating SiO2 thin films, which is indicative of other surfaces that may be compatible for coating such as ceramics.

Abstract Name: Exploring Intracellular Mechanisms of Action of Coral- and Sponge-Derived Bioactive Compounds with a Survey of Sustainable Technological Advances for the Drug Discovery Pipeline.

Background: While marine metabolites from deep-sea corals and sponges represent a treasure-trove of therapeutic potential, including anti-tumor, anti-fungal and anti-viral benefits, roughly ~5% of such marine invertebrates have been thoroughly investigated for their production of bioactive metabolites and their mechanism of action. Additionally, there lacks sustainable methods to maintain deep-sea coral and sponge populations to support the drug discovery pipeline. Purpose: Our study goal was to systematically identify deep-sea corals and sponges off the Western Coast of Florida to identify their marine metabolites, potential interactions with mammalian cells, and technological advances that could sustainably support their bioactive compound production and contribution to the drug discovery pipeline. Research Methodology: Using the National Oceanic and Atmospheric Administration portal, we curated deep-sea coral and sponge entries within a ~100,000 km2 segment of the U.S. Exclusive Economic Zone off the Western Coast of Florida. PubMed was utilized to decipher the current understanding and gaps across a subset of these sessile organisms pertaining to their natural products and mechanisms altering cytoskeleton, protein trafficking, and signaling pathways. Since exploitation of such marine organisms could disrupt the marine ecosystem leading to supply issues of limited bioactive compounds, we surveyed methods and technological advances that would be necessary for sustaining the drug discovery pipeline. Conclusions: Approximately 2% of NOAA coral and sponge entries were found at depths <50m, 29% ≥50 to <200m, 31%, ≥200 to <1000m, and 38%, ≥1000 to 3000m. Purified metabolites were found to deregulate microtubules and actin filaments, induce ER stress, and activate PI3K/AKT/MAPK, JAK/STAT, and EGFR. Optimal techniques were identified for bioactive compound production, primarily through specific aquaculture and in-vitro cultivation systems. Collectively, our efforts support future research in identification of marine-based natural products and their mechanism of action to develop novel drugs and therapies, while preserving our natural ecological community.

Abstract Name: Gender and corruption: mapping knowledge production in UN conference spaces

The link between gender equality and anti-corruption work has slowly been established over the last few decades in scholarly, practitioner and activist spaces. Corruption greatly undermines progress in gender equality as women tend to be less economically independent and more reliant on public services where their proximity to corruption is enhanced. Additionally, because corruption tends to thrive in male dominated patronage networks, women do not reap the same benefits as men. At the same time, when the relationship between the two is acknowledged by policymakers, women are often treated as "political cleaners" or a one-stop solution for achieving gender equality and getting rid of corruption. Other activists and practitioners, on the other hand, consider more intersectional solutions that mainstream gender justice into an anti-corruption framework. Scholar-practitioners are playing a key role in defining the field of gender and corruption, particularly through knowledge production (research) and activism at UN conferences. This study explores the work of scholar-practitioners in shaping knowledge production through transnational connections and interactions with global development regimes. This project maps the field of gender and corruption through consulting first-hand knowledge of experts in the field at two critical United Nations conferences: the UN Commission on the Status of Women (UN-CSW) and the UN Convention against Corruption (UN-CAC). By identifying patterns between how anti-corruption versus gender experts define the problem, this study identifies room for overlap and how solutions in the two fields can be linked.

Abstract Name: Modeling the Exit of Cranial Nerves Through the Skull in Canines

3D-printed models are increasingly used as supplemental materials in anatomy education, seeking to address financial and ecological concerns of using animal specimens while offering an interactive experience. 3D-printed models allow students to more easily observe spatial relationships between anatomic structures while avoiding the destructive nature of dissection. A new 3D-printed model of the canine brain and skull was designed to help veterinary medical students better visualize the spatial relationship between the cranial nerves originating from the brain and the foramina (holes) of the cranium through which they exit. The clear material allows students to view the cranial nerves passing through the skull, something that is visually obscured in a wet specimen. The brain with its cranial nerves can be removed from the skull, offering a dynamic and interactive experience. While the 3D model is not a replacement for wet dissection, it augments learning by presenting typical canine neuroanatomy that students can revisit and compare against unique specimens.This research project exemplifies an iterative design process for developing an accurate and detailed learning aid in anatomy education. The model was constructed in Maxon ZBrush using anatomy text references and hands-on dissection experience to ensure accuracy. Additionally, a plastinated brain specimen and skull were scanned using novel 3D scanning software, and served as the base for the final digital model. Initial prototypes were test-printed with inexpensive material and the final model was fabricated using clear resin for the canine skull and dyed flexible resin for the neural components. User testing was conducted with students and faculty in veterinary medicine, scientific visualization, and lay audiences to collect feedback on the design and anatomic accuracy. The final 3D-printed model will be used in veterinary neuroanatomy courses with the opportunity for a future experimental study to evaluate this model as an educational tool.

Abstract Name: Characterization of Npas1+ Interneurons in the Mouse Dentate Gyrus

The dentate gyrus is a region of the hippocampal formation that is critical in learning, memory, cognition, and spatial recognition. Within the dentate gyrus, GABAergic interneurons, which release the neurotransmitter gamma-Aminobutyric Acid (GABA), are highly heterogeneous with multiple subtypes that have not been well characterized. These interneuron subtypes provide synaptic inhibition that enforces neural activity of the principal granule cells and dynamically gate the flux of information from the cortex.Goals of the project are to study a novel class of interneurons (Npas1+) and to understand their morphological and electrophysiological properties and how they contribute to the activity of the principal cells of the dentate gyrus. There are numerous Npas1+ cells within this region, but they have yet to be differentiated into existing classes. By determining physiological, morphological, and molecular expression characteristics of these cells, this fundamental information can be used to explore the functional relationships of these interneurons and the inhibitory role they play in cognition, memory, and higher brain function. Mouse hippocampal slices will be used to characterize the morphological and physiological features of Npas1+ interneurons as well as their molecular marker expression to determine differentiation from classified groups of interneurons in the area.GABAergic interneurons exhibit abnormal function in a range of neurological diseases, but it is unknown how specific subtypes contribute to normal dentate gyrus function. Results from this project will provide a new understanding of the contribution of different GABAergic interneurons to normal information processing that will shed light on circuit dysfunction in diseased states.

Abstract Name: Identifying a Cryptic, Invasive Species of Toad Under the Genus Rhinella

My project aims to determine which cryptic species of cane toad of the genus Rhinella has become established as an invasive species in Florida. A cryptic species complex occurs when there is more than one species that appear identical but are actually two or more genetically-distinct species. For this project, I set out to 1) Determine which Rhinella species has invaded and become established in Florida and 2) Determine the likely geographical origin of the founding population(s). To accomplish this, I extracted DNA from the livers of over 144 cane toads from 12 different locations, developed and conducted polymerase chain reaction (PCR) protocols to amplify ~400 base pairs of the cytochrome b (cytb) locus, and completed Sanger Sequencing of PCR products. Subsequently, I used Geneious to trim and align reads, and create a gene tree using both recovered sequences and publicly accessible Rhinella cytb sequences published from previous studies. To date, I have successfully recovered 3 distinct cytb haplotypes from 14 individuals across 5 different Florida populations. All 3 recovered sequences cluster with previously published R. horribilis sequences from southern Mexico, indicating this is the Rhinella population in Florida likely arose from a single founding population of R. horribilis from south Mexico. By determining what invasive Rhinella species is present in Florida, we hope to gain insight into their invasion history, provide information to inform

best practices to avoid future invasion events, and determine possible impacts this species is having on Florida ecosystems.

Abstract Name: Determination of Total Hardness Levels in Milwaukee Waterways and Instrument Comparison

Water hardness affects the alkalinity of water, which can help reduce water toxicity. However, excessive hardness can harm plant and animal life. pH levels are also important in determining nutrient intake capacity for both plants and animals. Any changes in pH levels can have a significant impact on their ability to absorb nutrients. The alkalinity of water can help reduce the harmful effects of toxicity on plants and animals since they have specific preferences for their environment. This study aimed to compare the flame atomic absorption spectroscopy and titration methods to determine the most effective and straightforward method for measuring total water hardness based on factors such as workload, waste production, and ease of use. Water samples were collected from three different sites on the Kinnickinnic River in Milwaukee, WI, and analyzed using both methods. Although flame atomic absorption spectroscopy was more expensive, it provided similar results to the titration method. Flame atomic absorption spectroscopy was found to be simpler, faster, more accurate, and non-toxic, making it the better option.

Abstract Name: Family Visits to a Children’s Museum

Children's museums are purposefully designed to cultivate hands-on learning experiences, providing a welcoming space for the inquisitive minds of children. These visits not only foster shared opportunities for young children and their adult partners but also serve as a focal point for observing the intricate dynamics of family interactions within the museum setting. The current study aimed to explore family visits to a children's museum by observing the ways families navigate through a full visit, gaining insights into adult motivations to attend, and understanding their perceptions post-visit.To explore the nuances of family visits, data were gathered from 20 randomly selected families at a Midwestern children's museum. These participants engaged in a comprehensive full-visit observation. During the visit, caregivers were asked to complete a survey to assess motivations to visit the museum and beliefs about play. Participants were also invited to complete a post-visit interview approximately one week after the observation to provide their insights about the visit.Visits lasted an average of 107 minutes including time spent in each exhibit with collaborative decision of movement patterns in the museum. Top motivations focused on the child’s experience, quality family experiences and learning. Play was endorsed for healthy brain development, enhanced imagination, and

problem-solving. Post-trip interviews yielded themes of the children’s museum as a trusted space, opportunities for socialization, and opportunities to learn about the child.Findings highlight the appreciation families have for children's museums, recognizing them as trusted spaces that provide exceptional experiences. The emphasis on play aligns with the adult perception of the museum as a 'yes space,' empowering children to engage in self-directed play while caregivers observe. Ultimately, this study underscores the pivotal role of children's museums in promoting holistic child development and strengthening family bonds in a supportive and enriching setting.

Abstract Name: Early Adulthood Perceptions: The Effects of Priming & Gender on Implicit Ageism in the Fitness Industry

Previous research in the fitness industry has shown that in order to increase one's life span, exercise is vital to maintain health and quality of life (e.g., Jin & Harvey, 2021). However, despite increases in longevity and productivity, older adults are likely to be stigmatized by younger generations in places such as fitness, social, and medical settings (e.g., Kimuna et al., 2005). Therefore, this study will examine how contextual priming impacts implicit ageism among traditional undergraduate psychology students and their feelings towards working with older adults in the fitness industry. This study will also examine how gender may impact the perceptions traditional undergraduate psychology students have towards elders within the fitness industry. A sample of 159 traditional undergraduates (ages 18 to 24 years) were recruited through the California Lutheran University SONA Systems. Participants were first randomly assigned to one of four contextual priming conditions: 1) positive-male, 2) positive-female, 3) negative-male, 4) negative-female and then completed an online survey via Qualtrics on implicit ageism, attitudes towards working with older adults in fitness, and demographic information. The study will use a between-subjects two-way ANOVA to compare the effects of contextual priming and gender on implicit ageism and attitudes towards working with older adults. The data is currently undergoing analysis.

Abstract Name: Hermit Crab Foraging Under Different Conditions

Foraging is important for animals because it allows them to grow, reproduce, and have energy for other activities like movement and predator avoidance. We tested the foraging behavior of the hermit crab Pagurus longicarpus under acidic conditions to better understand their response to ocean acidification. The experiment consisted of a Y-maze (a maze of three arms that form a “Y” shape), with a food pellet and rock placed at

opposing ends of the maze to see how effective the crabs were at finding the food. The goal was to compare the time it took for P. longicarpus to find the food, using both their visual and chemosensory ability, under control and acidified (pH 7.5) conditions. We had a secondary goal of determining whether vision or chemosensory ability plays a larger role in hermit crab foraging. We found that neither acidic conditions nor darkness impeded the foraging ability of P. longicarpus, as they were very efficient at finding the food (correct decision ~80% of the time) and took a similar amount of time in both treatments. However, when we filled the entire Y-maze with water with the odor of food (to mask chemosensory cues), crabs were largely unsuccessful at finding the food even when they could see the food pellet. Therefore, we concluded that chemosensory abilities play a larger role than vision in foraging this hermit crab species. The foraging ability of the hermit crab, Pagurus longicarpus, shows that they can adapt under various conditions, such as acidity. Still, more research has to be done to determine the limit of these abilities and assess potential limits to the scale (distance) of their chemosensory abilities. Our results suggest that hermit crabs are relatively resilient to environmental changes and could remain important shallow-water scavengers even in changing ocean environments.

Abstract Name: Harrie A. Vanderstappen's Legacy: Exploring his Impact on Students, the Smart Museum, and the Discipline

Harrie A. Vanderstappen was a professor at the University of Chicago from 1959 to 1991. Vanderstappen’s tenure includes his chairmanship of the Department of Art from 1965 to 1970, a pivotal time during which the Smart Museum of Art was constructed. Given the broad scope of his three decades of work, my research maps Vanderstappen’s effect on the formation of the Smart Museum, teaching at the University of Chicago, and Chinese art history. To explore this, I examined his personal papers in the University of Chicago Library Special Collections, exhibition and object files, catalogs, and publications from Vanderstappen and his colleagues. I learned that though his primary role was as university faculty, Vanderstappen was nevertheless a central figure in the development of the Smart Museum, his department, and discipline. As an educator, he harnessed the Smart Museum of Art as a teaching institution, pairing the close viewing of art with his connoisseurial approach to teaching. Coupled with his expansive interests across Asian art, Vanderstappen's foundational contributions to the study of Chinese painting and sculpture guided the museum’s acquisition strategies and developed the Smart Museum and the University of Chicago’s strength in East Asian art. As faculty-curator, he worked with donors to raise funds and assemble the Smart Museum’s uniquely strong teaching collection of Chinese and Japanese paintings. This research begins the Smart Museum’s self-reflective work undertaken in its 50th anniversary year and traces Vanderstappen’s role in the development of contextual methodology in the Western study of Chinese art.

Abstract Name: An Analysis of the Efficiency of Hospital Pricing

Starting on January 1st, 2021, the Hospital Price Transparency Rule mandated hospitals to provide a public database containing gross charges, discounted cash prices, and payer-specific negotiated prices for their items and services. Before this law, prices were not transparent, meaning patients could not shop for hospital services based on price. This lack of available prices likely meant hospitals did not compete on price, potentially resulting in inefficient pricing. Prior research has found that prices hospitals charge can vary dramatically across hospitals for particular services without being explained by differences in quality. The aggregated dataset Turquoise Health Price Transparency Scorecard from Turquoise Health provides access to the cost of healthcare in the United States using publicly available data disclosed by hospitals as a result of the Hospital Price Transparency Regulation. I use this data to determine the relationship between hospitals characteristics, competition, and price markup as related to their degree of non-compliance with the regulation. I find that hospital characteristics and market characteristics are associated with whether hospitals willingly comply with Hospital Price Transparency Regulation and the degree to which they comply. In a regression model adjusting for these characteristics I will determine the relationship between how concentrated a hospital's market is, their price markups as measured by the difference between cash prices and list charges, and how their compliance was scored by Turquoise Health. Price transparency may be a necessary but not sufficient mechanism to lower hospital prices and healthcare spending. The transparency will empower patients and give them more control over their healthcare spending, but these findings can result in policy that could lead to a sufficient increase in competitive behavior, which would drive down the burden of healthcare spending for consumers and the U.S.

Abstract Name: Health and Lifestyle Behavioral Changes To Prevent Myocardial Infarction (MI): Mixed Methods Approach To Understand Secondary MI Prevention

Cardiovascular diseases are the leading causes of death globally and about 200,000 individuals experience their second myocardial infarction yearly. There is a lack of understanding about how lifestyle and behavioral changes can prevent secondary myocardial infarction a year in the United States. The objective of this study is to use a mixed methods approach to understand how individuals who have made lifestyle behavioral changes to prevent their secondary myocardial infarction. Surveys and interviews consisted of questions about the participants' health behaviors and health history. Demographics, background information, and lifestyle behavioral changes were measured using Qualtrics. Valid and reliable tools such as the Healthy Lifestyle Screening Tool, were utilized. Semi-structured interviews will be conducted with willing participants after survey completion. Quantitative associations of self-reported behaviors and thematic analysis were performed. Based on preliminary results, we found statistically significant associations between the severity of the first heart attack and willingness to change lifestyle behaviors (p>0.05). Additionally, thematic analysis reveals three main themes for preventing secondary myocardial infarctions; eating healthier, consistent exercise routine, and maintaining body weight. When connecting the qualitative and quantitative data, the three main themes were more consistently expressed when the severity of the first heart attack was greater (p>0.05). These findings suggest that behavior change is more likely in individuals who survived a more severe heart attack. Themes of eating healthier, maintaining a consistent exercise routine, and keeping a healthy body weight are expected to be common amongst the interviews, but more prominent among those with more severe heart attacks. With this knowledge, individuals can be better educated on preventing myocardial infarctions.

Abstract Name: Condition Monitoring of Induction Motor Using Vibration Signals and Machine learning Classification

This study addresses a crucial aspect of industrial operations by delving into the root causes of induction motor mechanical failures through vibration data analysis and classification using a machine learning algorithm. The primary goal is to enhance cost-effectiveness by exploring the feasibility of employing a single vibration sensor for detecting multiple failures in induction motors, offering a low-cost solution that is particularly advantageous for small enterprises, ultimately improving productivity.Traditional induction motor defect detection methods often involve multiple expensive sensors such as vibration, temperature, pressure, and humidity sensors. Previous studies primarily relied on the Riemann series for vibration analysis, based on the Gap metric in the Riemann, but the proposed method seeks to improve performance and accuracy in fault diagnosis. By investigating the frequency of vibration signals from a single sensor and utilizing machine learning for categorization, the approach provides a more accessible and interpretable solution. The incorporation of a confusion matrix with the machine learning algorithm enhances user-friendliness and accuracy in analyzing and interpreting vibration data, providing quick insights into the motor's state.The research methodology involves analyzing vibration signals from an induction motor in both normal and faulty states, including perfect condition, shaft imbalance, fault in the linear module's ball screw, and bearing defect. AutoML and Scikit-learn machine learning algorithms leverage a dataset of around 1000000 rows generated by the induction motor to establish a robust classification method for recognizing common motor failures using a single vibration sensor. The resulting model boasts an F-measure of 0.9978, a recall of 99.58%, and a precision of 99.795%, showcasing its effectiveness in classifying induction motor failures. This approach presents an innovative and cost-effective solution for industrial operations, demonstrating potential benefits for enhancing overall efficiency.

Abstract Name: Reconstituting Full-Length Mitochondrial Fission Protein 1, Fis1, and Assessing Its Inhibitory Role in Pancreatic Cancer

Mitochondrial fission is the process by which mitochondria divide and is necessary for organelle segregation into daughter cells during cytokinesis. Excessive mitochondrial fission has been linked to increased tumor growth in many cancers, including pancreatic cancer. Pancreatic cancer is one of the deadliest cancers in the U.S., with a 5-year survival rate of 10%. The project goal is to advance a novel therapeutic route against pancreatic cancer by targeting mitochondrial fission proteins. Inhibition of mitochondrial fission, either

genetically or pharmacologically, blocks oncogenesis. Dynamin-related protein 1 (Drp1) performs mitochondrial fission and is recruited to sites of fission by mitochondrial fission protein 1 (Fis1). By inhibiting Fis1, which is three times more upregulated in pancreatic cancer than Drp1, mitochondrial fission is restricted. We have developed pep213, a novel peptide inhibitor, that inhibits Fis1 and prevents mitochondrial fission. However, pep213 was designed to block a version of Fis1 that lacks its transmembrane domain that anchors it to the outer mitochondrial membrane (Fis1ΔTM) and has not been tested in vitro against Full-length Fis1. We hypothesize that inhibitors designed against Fis1ΔTM will have an enhanced affinity for membrane-anchored Fis1. To this goal, Full-length Fis1 was successfully reconstituted in a detergent micelle. We then tested the hypothesis that Cy5-Drp1 would have an enhanced affinity for Full-length Fis1. Using microscale thermophoresis, binding affinities of Cy5-Drp1 to Full-length Fis1 suggest that Full-length Fis1 binds better with Cy5-Drp1 than Fis1ΔTM. Nuclear magnetic resonance (NMR) also revealed chemical shift perturbations of residues in the Full-length Fis1 regulatory arm region compared to Fis1ΔTM. Pep213 was also analyzed using NMR and circular dichroism. We then tested how inhibited Fis1 impacts pancreatic cancer cell proliferation by using cellular proliferation assays and discovered that pharmacologic inhibition of Fis1 by pep213, and not a control peptide, in mouse pancreatic cancer cells reduced cell proliferation by 75%.

Abstract Name: The Use of Auditory Data and the Role of Machine Learning as a Diagnostic Tool for Early-Onset Alzheimer’s Disease

Alzheimer's Disease (AD) is a chronic neurodegenerative disorder characterized by irreversible cognitive decline. Symptoms of AD can develop years before clear clinical manifestation, leading many patients to start treatment later. Current diagnostic treatments typically can only be performed years after the disease's onset. A way to measure the cognitive decline affiliated with AD is by detecting specific patterns in speech, such as repetition of words, duration of words, clarity of speech, and articulation, since language impairment is a common symptom of AD.Machine learning (ML) techniques have emerged as promising non-invasive tools by using vocal pattern detection to provide a more accurate diagnosis of early-onset AD. ML algorithms offer the ability to analyze large and complex datasets capable of integrating multiple sources of information, including clinical, genetic, neuroimaging, and auditory data. However, some challenges include the need for extensive and diverse datasets, knowledge of how to interpret different ML models, and integrating multiple data sources into global databases to be shared with various investigative teams and clinicians.This project focuses on the auditory data from the DementiaBank repository (https://dementia.talkbank.org/access), which was used to train the ML algorithm during some preliminary analysis. Our focus was the preprocessing stage to ensure that the file formats could be transformed into a form the algorithm could use. The ML model used was able to identify patterns, extract meaningful features, and then apply them to predict future outcomes. Through the use of ML and future collaboration with medical professionals, we expect to have a trained program with at least 80% accuracy. With our current results, we plan to integrate other clinical data files, including imaging, into the pool of datasets to ensure a more robust system for a more accurate and precise diagnosis.

Abstract Name: Artificial Intelligence and Healthcare: A Legal Perspective

Through its ability to rapidly interpret complex data sets, Artificial Intelligence and its advancements are dramatically reshaping the world as we know it. My project explores the technical, legal, and policy debates surrounding AI's role in the healthcare sector, which presents significant potential benefits, such as personalized patient treatment and improved hospital communication. AI's emergence in health care poses an ethical conundrum. On the one hand, it offers a powerful tool that can potentially save thousands of lives through expediting healthcare processes, revolutionizing the healthcare industry on an international level. On the other hand, AI still has its own issues to resolve. AI has raised questions such as patient consent/privacy, bias in algorithms, and whether full AI integration in healthcare is desirable or even possible. Examining AI's role in healthcare from a legal perspective opens up a 'Pandora's Box' of legal contradictions and ramifications, such as the potential to conflict with existing laws like HIPAA and the data privacy concerns of patients. The controversial debates regarding clinical decision supports and jurisdiction over electronic health record systems would be key themes in the conversation of AI in healthcare from the perspective of the law. My project will mine existing primary sources--such as legal commentaries, debates over state legislation and regulatory policies, and technical studies--while also using Interviews with prominent AI experts to further understand the nuances of new technology and historically established fields of healthcare. AI is bringing in a new era to healthcare that offers unprecedented potential for patient care and operational effectiveness, while simultaneously raising complex ethical dilemmas and legal issues that require navigating a new paradigm to ensure patient safety, overcome algorithm bias, and work with existing legalities.

Abstract Name: Developing a Novel Method for Counting and Identifying Water Molds in Field Samples

Water molds (Oomycota) are aquatic multi-host pathogens that infect many species of amphibians and aquatic invertebrates. Established methods for counting eukaryotic microbes, such as hemocytometry are time consuming and difficult to use with field samples. We developed a method for the quantification of reproductive propagules (zoospores) responsible for water mold transmission between hosts using Microwell Plates (MWP) and selective media. We compared measurements of five concentrations of water mold zoospores created from serial dilutions, using a hemocytometer and our MWP method. There was a close relationship between hemocytometer counts and MWP counts, giving us confidence that MWP provided accurate and precise counts of zoospore concentrations. When we tested water samples from local wetlands, the MWP method was effective and precise. To confirm that the growths on MWP are our target species of water mold, Saprolegnia ferax, molecular methods of identification using specific probes and primers in a quantitative polymerase chain reaction (qPCR) were designed and will be tested. This method will allow ecologists to identify and count a common pathogen of many aquatic organisms.

Abstract Name: NGO Reports vs. Reality: Indigenous people's real-life challenges

Indigenous people in Peru face socioeconomic and environmental challenges. Given the scholarly debate about NGOs imposing agendas in developing countries, this project aims to see if the NGO reports addressing indigenous challenges actually resemble the individual experience of Quechua speakers – the predominant language among indigenous Peruvians. This study draws on previous research addressing discrimination based on ethnicity in Latin America, and the transnational movement of environmental protection of indigenous land. Furthermore, this research will contribute to the debate about NGOs' imposition of environmental agendas in developing countries. This project hypothesizes discrepancies between NGO reports emphasizing environmental challenges and indigenous individuals' real experiences who prioritize more socioeconomic inequalities over environmental protection. The study will use thematic coding to find the six main issues according to NGO reports. These six main topics will serve as the basis for formulating open-ended questions to conduct 45-minute interviews with ten Quechua speakers. This research aims to assess if NGOs impose an agenda over vulnerable populations. Primary data will help to close the gap between NGO reports and real life challenges to allow researchers to explore policies on how to address the specific issues individuals report instead of following external agendas.

Abstract Name: Persistent Exposure to Subinhibitory Levels of Alkyltrimethylammonium Bromide Compounds Reduce Bacterial Sensitivity and Promote Antibiotic Cross-Tolerance

Alkyltrimethylammonium bromide (CTAB) compounds are a common subgroup of quaternary ammonium compounds with broad-spectrum antimicrobial activity that are used as the active ingredient in many cosmetics and personal care products. Given the abundant use of these products, CTAB compounds are frequently in contact with microorganisms on the skin and opportunistic pathogens on hard surfaces. To investigate the impact of persistent subinhibitory CTAB compound exposure on bacterial species of human and public health importance, we repeatedly exposed Corynebacterium xerosis, Staphylococcus epidermidis, Staphylococcus aureus, Klebsiella pneumoniae, Escherichia coli, and Pseudomonas aeruginosa to subinhibitory concentrations of purified C16TAB, C12TAB and C10TAB. While bacterial sensitivities to CTAB compounds were directly related to alkyl chain length, CTAB tolerance and antibiotic cross-resistance were preferentially observed for C10TAB and C12TAB-acclimated bacteria and mediated by efflux pump activity. Opportunistic pathogens were significantly less sensitive to CTAB-inhibition and more likely to

increase CTAB-tolerance in response to persistent CTAB exposure, as compared to the commensal species. These results suggest that persistent exposure to subinhibitory levels of CTAB compounds can enhance antimicrobial tolerance and antibiotic cross-resistance, which may render these antimicrobials ineffective at the directed use concentrations. Reassessing the formulation of CTAB-containing products, particularly those that are not rinsed off after application, is recommended.

Abstract Name: Data Discrepancies in the Missing and Murdered Indigenous Peoples Crisis- How Do We Get the Real Numbers?

According to reports by multiple government agencies, there is a disproportionately high number of unsolved missing persons and unsolved murder cases among Native Americans. One barrier to addressing this problem is that there are discrepancies in the number of missing persons reported among various agencies. Not only do different agencies report different numbers, there also appears to be an issue of underreporting to the critical databases that consolidate this information. For example, the FBI only has 43 listed open cases involving Native Americans, while the Bureau of Indian Affairs (BIA) has 40 open cases. From these two federal databases, only two names overlap. While the BIA has acknowledged that this is a “crisis,” there is a public perception that this problem is being ignored. As a result, individuals have taken it upon themselves to track missing persons, typically on websites. A resident of the Blackfeet reservation, Drew Landry, created the "Montana Missing Indigenous Persons Reporting Portal," in part because "what it [the website] does is, they can ignore it, but we can make them [police] look bad if they don't do anything." As of September 2023, however, only two people were listed, compared to the 25 people reported by NamUS for the state. Clearly, action is needed to ascertain how many indigenous people are missing if these cases are to be solved. While individual efforts like Landry’s appear well-intentioned, they raise the question of whether this will help or make the problem worse. The aim of our study is to 1) identify all individually run websites, and 2) attempt to match their data to the closest approximation of official data across all relevant government databases. Additionally, website content will be analyzed to determine goals and intentions of each effort and characterize these as positive, neutral, or negative toward governmental efforts.

Abstract Name: Perceived Implications of Generative Artificial Intelligence on Human-Interaction and Skill Development in Higher Education

This research paper presents the findings of a qualitative and quantitative mixed methods study, which aimed

to investigate the specific generative AI tools used among students at California State University, Long Beach (CSULB). The study incorporated both quantitative and qualitative responses, encompassing approximately the responses of 150 participants. The present study focused on assessing the frequency of utilization of these AI tools and their perceived influence on social and academic skill development and proficiencies. During the data collection, coding, and interpretation phases of the study, significant relationships emerged between students' perspectives on these generative AI tools and their impact on academic and social skill development, as well as their interactions with human educators. The students' discussions revolved around several key themes, including the role of generative AI tools in their preferences regarding modalities of education, academic and social skill acquisition, and fostering relationship-building with peers and faculty. Future studies can explore the significance of acquiring relevant AI-related skills for prospective job market success. These findings highlight the evolving landscape of education and the multifaceted implications of generative AI tools on student development and their educational experiences. The findings and outcomes of this survey will be presented and discussed.Keywords: Generative AI, artificial intelligence, digital learning, human interaction, higher education, college student, skill development

Abstract Name: Memorializing Genocide in Bosnia and Herzegovina: Collective Memory and Reconciliation

Since the Holocaust, human atrocities like genocide and ethnic cleansing, have taken center stage in memorialization efforts across the world in order to unite affected communities. After the genocide between 1992 and 1995, a fragmented Bosnia and Herzegovina took on the task of remembering those they lost to the war and memorializing the events themselves as lessons for the future. In this three-month transdisciplinary qualitative case study, the researcher utilized ethnographic field notes, semi-structured and structured interviews with museum curators, and participant observation to explore different memorialization efforts across Sarajevo, Bosnia and Herzegovina's capital. The study found that the majority of memorialization efforts appear to be directed at the Bosnian Muslim community as well as tourists. Furthermore, the research suggests that, while memorializing the Bosnian genocide aims to mitigate genocide denial, in doing so, it may alienate Bosnian Serbs by representing them as the enemy or perpetrator in collective memory. Based on these findings, the author suggests rethinking and restructuring memorialization strategies in museums dedicated to the Bosnian genocide to include the Bosnian Serb population. It is suggested that through a collective memorialization strategy that includes Bosnian Serbs and Croats, who also suffered during the war, differences across constituent ethnic groups might be reconciled without compromising the central narrative. This research might thus benefit the different ethnic communities in Bosnia and Herzegovina, as well as the scholarly discussion on post-conflict transformative justice.

Abstract Name: Localization of a DNA enzyme-catalyzed redox reaction to fluorescent DNA condensates: the art of molecular programming using deoxyribonucleic acids

Biochemical microreactors have the capacity to organize chemical pathways and separate their respective molecular products. Host cellular condensates show great promise in customizability and programmability in this respect. The goal of this research is to create condensate systems with DNA-based enzymes localized to specific layers in order to catalyze biochemical reactions. Fluorescent DNA nanostars were engineered, each featuring a 4-arm structure with varied arm lengths of 15, 20, or 25 base pairs and sticky ends at the terminus. Some DNA nanostars were designed with the sequence for a DNAzyme extended from Arm 4. DNA nanostars were annealed by heating to 95°C for 10 min and then slowly cooled at a rate of 1°C per minute (microscale) or in a 95°C water bath placed in a Styrofoam box overnight (macroscale). Formation of fluorescent DNA condensates with up to 50% DNAzyme attached to Arm 4 was confirmed through fluorescence microscopy, and a colorimetric peroxidation reaction was carried out on the functionalized DNA condensates. DNAzyme-catalyzed peroxidation was achieved on microscale and macroscale DNA condensates / 50% DNAzymes. Peroxidation was localized to a single layer of a 2-layer bulk condensate system, indicated by a color change in the layer containing DNAzyme, and optimization of this process is an ongoing area of research. Toehold-mediated strand displacement was used to turn off the DNAzyme-catalyzed reaction and thus achieve a programmability. Adding anti-strands prior to annealing disrupted the integrity of the DNA condensate, but it did not displace or unfold the DNAzyme and thus hinder its activity. Overall, significant progress toward localizing a biochemical redox reaction to a single layer of a 2-layer DNA condensate system was made, and strategies to turn off this reaction were tested, laying the groundwork for future experiments to achieve programmable DNA condensate systems.

Abstract Name: Influence of Various Drying Techniques on the Anti-nutrient Properties of Powdered Beetroot (Beta vulgaris) in Kenya.

Beetroot (Beta vulgaris) is a nutrient-dense root vegetable with numerous beneficial properties to the body. However, it may also contain anti-nutrients that can inhibit nutrient absorption. It is mostly consumed fresh because of its high perishability. Beetroot season typically spans from late March to April through to July after which the root vegetable becomes scarce. To resolve the seasonality problem beetroot can be converted into longer-lasting products in dried powdered form. This study investigated the effect of different drying procedures (sun, solar, and oven) on the anti-nutritional factors (oxalates, phytate, and nitrate) of powdered beetroot. Oxalates were extracted using HCl and their levels were subsequently determined through titration with potassium permanganate. Phytate and nitrate were determined using the UV spectrophotometric technique. All samples were analyzed in three replicates. Results obtained showed no significant difference in the nitrate content across the different drying methods (sun, oven, and solar). The different drying methods did not produce nitrate levels higher than 3.7 mg/kg, the maximum limit recommended by WHO for nitrate to act as a nutrient in the human body. Fresh beetroot had the lowest nitrate levels. There were no significant variations in the levels of oxalate with the highest level obtained in the fresh sample (0.296 mg/100g). Overall, drying increased the phytate content of beetroot with the highest level (0.086 mg/100g) attained with

solar drying. The results obtained in this study indicate that drying beetroot does not amplify the anti-nutrient factors in the vegetable powder, hence it is safe as a preservation method.

Abstract Name: A Comparative Study of Data Visualization Tools

In data visualization, there exists a challenge to imagine any data's representations in more than three dimensions. However, real-world data often consists of several features, most likely higher than three. The purpose of this research is to explore higher dimensional datasets in the content of science and commerce, along with the utilization of visualization techniques used by practitioners. In particular, we use dendrograms produced by hierarchical clustering methods for the tree diagram. Additionally, we introduce a supplementary technique known as the Traveling Salesman Problem (TSP) to create temperature-based visual heatmaps of reordered dissimilarity matrices to produce visualizations of high dimensional data and analyze their ability to communicate the structure of the data in a clear and easy-understanding manner. The principal component analysis (PCA) and t-SNE are other optional methods to reduce the higher dimensional data to lower dimensional, facilitated using the "R" programming tool. These dimensional-reducing tools are reliable for datasets with several attributes. However, it is significant to recognize that they still can perform visualizations of each dataset while losing some information, but we experiment to minimize the missing detail of the data. The primary source of study takes away from the dissertation document focusing on seriation methodology. The dataset used in this study ranges from two to over sixty dimensions including both numerical and categorical types of data points with the label column. After the analysis, the expected result should provide a clear example of when and how each technique can appropriately apply to different dimensional datasets. The ability to convert computing numbers of the dataset into meaningful insight is what we anticipate in the performance evaluation.

Abstract Name: Perceptions & Policy: Views on U.S. Capital Punishment in Southeastern Europe

In the global conversation surrounding the death penalty, the perceptions of U.S. capital punishment echo far beyond its borders. As the world scrutinizes the human rights implications of this practice, a unique lens focuses on Southeastern Europe's views and the potential lessons it holds for U.S. policymakers. This transdisciplinary qualitative study challenges the common narrative of a "broken" criminal justice system and reframes it as an intentional form of structural violence, disproportionately impacting marginalized groups. Delving into the multifaceted perceptions of the U.S. death penalty among Southeastern European policymakers and legal officers, the study aims to provide tangible recommendations for U.S. policymakers engaging with capital punishment's human rights implications. Undertaken during a three-month internship

with the Regional Anti-Corruption Initiative from September to November 2023, this study combined participatory observation, interviews, and surveys to explore the pivotal themes of education, transparency, and cross-country knowledge exchange. This research yields significant findings illuminating the factors shaping these perceptions, underscoring the critical role of transparency, corruption, and the rule of law in the justice system. The study's findings not only complement the ongoing debate on capital punishment but also offer pragmatic and timely recommendations for U.S. policymakers. It advocates for a more equitable and just society by acknowledging the urgent need to address the complex issues surrounding capital punishment.

Abstract Name: The Association between Working Memory and Psychopathy among Young Adults

The purpose of this study was to examine the relationship between psychopathy and working memory (WM) in non-institutionalized young adults. Previous research suggested that general psychopathology could meaningfully predict WM capacity (Hoppenbrouwers et. al., 2013). If these findings replicate over time, and additional third variables are factored out as non-significant predictors, it may suggest that inferior WM capacity may raise the risk for developing psychopathology. We hypothesized there would be a negative relationship between psychopathy and WM capacity and that sex would moderate this relationship.Sixty undergraduate students completed our study which was comprised of the following: a demographics questionnaire, the Triarchic Psychopathy Measure, and two common WM tests (i.e.,"Forward Digit Span" [FDS], "Backward Digit Span" [BDS]).We found that males had significantly lower WM scores as compared to females on both WM tests (FDS [p = .04), BDS [p = .05]). However, there was not a significant difference in psychopathy scores between males and females (p > .05). In testing our first hypothesis, we found a trend towards significance for the relationship between psychopathy and FDS scores (r[59] = -.391, p = .072), but no relationship between psychopathy and BDS scores (p >.05). Next, we tested whether sex moderated the relationship between psychopathy and WM (i.e., our second hypothesis). We identified a significant moderating effect of sex on the relationship between psychopathy and WM, measured by FDS scores (t[57] = -2.21, p =.03, CI.95bootstrapped [-0.49, 0.02]). That is, the associations were significant for males but not females.Our findings identified that higher levels of psychopathy in males are associated with lower WM capacity, replicating previous findings for institutionalized samples. This suggests that WM capacity is inversely correlated with psychopathy even among a population that scores lower than institutionalized samples on psychopathy measures.

Abstract Name: The Effects of Chinese Foreign Direct Investment in Sub-Saharan Africa

Sub-Saharan Africa has become a focal point in the international community, as billions of dollars of foreign direct investment (FDI) flow into the region each year. China is one of the largest and most controversial investors in this part of the world, but how is Chinese FDI in Sub-Saharan Africa different from FDI from the rest of the world? To tackle this question, I conduct both an empirical analysis as well as country case studies. First I ask, does Chinese FDI have a different impact on GDP growth in Sub-Saharan African countries compared to FDI from the rest of the world? To answer this question, I use cross country regressions. Using Chinese FDI data into 48 Sub-Saharan African countries from 2003-2019 as well as controls, I analyze if Chinese FDI and FDI from the rest of the world has any significantly different impacts on GDP growth. This study uses panel regression analysis with fixed time and country effects. Results describe that a 1 percent increase in Chinese FDI into the region is associated with a 0.024 percent increase in GDP growth, 1.5 times the amount of GDP growth as FDI from the rest of the world. I then conduct case studies looking into Ethiopia, which receives some of the highest inflows of Chinese FDI into the region, and Senegal, which receives an average amount of inflows of Chinese FDI. Analysis of the policies these countries have with China as well as how the FDI flows into different sectors may shed light on this difference of effects in Sub-Saharan Africa. This study offers literature on FDI efficiency that may contribute towards policy decisions surrounding how FDI can be made more efficient in how it flows into Sub-Saharan Africa.

Abstract Name: Additive Manufacturing for Lightweight Tube Design: Maximizing Length and Load Efficiency

This research initiative focuses on the application of additive manufacturing techniques to design lightweight tubes with an emphasis on maximizing both length and load efficiency. The project challenges participants to employ innovative approaches in material selection, structural design, and manufacturing processes to achieve tubes that are not only lightweight but also capable of efficiently bearing substantial loads over extended lengths. The competition encourages exploration of cutting-edge additive manufacturing technologies, including 3D printing, to realize intricate designs that balance structural integrity with reduced weight. Contestants are tasked with pushing the boundaries of traditional tube design, exploring new materials, and leveraging advanced manufacturing methods to optimize length and load-bearing capacities. Key evaluation criteria include the overall weight-to-length ratio, load-bearing efficiency, feasibility for production, and potential real-world applications. Participants will have access to state-of-the-art additive manufacturing technologies, fostering an environment of innovation, collaboration, and knowledge exchange. The significance of this research lies in its potential to revolutionize lightweight tube design for various applications, from aerospace to automotive industries. By maximizing both length and load efficiency, the project aims to contribute to advancements in additive manufacturing and provide sustainable solutions for industries requiring lightweight, high-performance tubes. Anticipated outcomes include groundbreaking tube designs that showcase the capabilities of additive manufacturing in optimizing length and load-bearing capabilities. Overall, this research represents a crucial step towards the development of lightweight structures with enhanced functionality and efficiency.

Abstract Name: Queering Mobility: An Intersectional Analysis of the Experiences of (Im)mobility of LGBTQIA+ International Students in Los Angeles

Literature on LGBTQIA+ international students pursuing higher education in the U.S. has highlighted that, although studying abroad presents an opportunity for their sexual and gender identity development, they are still subjected to discrimination on their college campuses. In this research, Crenshaw's framework of intersectionality has been crucial in analyzing how their overlapping identities shape their experiences of discrimination. However, there is a research gap in understanding their experiences outside their campuses. This study explores the experiences of mobility of LGBTQIA+ international students in Los Angeles. Specifically, how their identities shape their physical movement through the urban area, especially the queer spaces within it. By using flyers and snowball sampling, this study conducted interviews and cartographic exercises with 3 UCLA international students who self-identify as LGBTQIA+. The study showed that students' international status, country of origin, class, gender, race, and sexuality intersect to impact their forms and experiences of mobility in Los Angeles. First, it demonstrated that their predominant forms of mobility, public transport and walking, limit their physical exploration of Los Angeles. In addition, negative experiences of discrimination and harassment led to their limited mobility, and even immobility. Second, this study also demonstrated that although Los Angeles was initially perceived as an opportunity for sexual and gender identity development, experiences of discrimination in "formal" queer spaces, such as gayborhoods and university organizations, have led to their limited participation in them. Instead, international students engage in the informal "queering of space" for the safe expression of their multiple identities. In this way, this study explored how the intersectional identities of queer international students impact their experiences in their host urban areas, to be used as a source for the creation of university programs and services that support these students' diverse needs.

Abstract Name: After-Death Communication: Alleviating Death Anxiety and Facilitating Mourning

This paper investigates the role of after-death communication (ADC) in the mourning process, integrating diverse cultural and psychological perspectives. It explores spontaneous contacts with deceased individuals, which vary in form from physical to ethereal, and how these contribute to coping with loss. This study examines key concepts such as death anxiety and the formation of continued bonds with the deceased while underscoring cultural variations in these experiences. Utilizing a thorough review of literature, including cultural and psychological studies, this research paper highlights contrasting cultural views on ADC. It notes that some cultures, like the Kagwahiv and Cambodian, discourage continued bonds and maintain strong taboos against ADC. Findings reveal that ADC significantly reduces death anxiety and often enhances belief in an afterlife, offering comfort beyond religious or spiritual contexts. ADC is identified as a conduit linking religion, spirituality, and culture, aiding in forming continued bonds and lessening death anxiety. The conclusion underscores ADC's universal relevance in processing death, transcending cultural and religious

barriers. This study advocates for personal interpretations of death and the use of continued bonds to avoid complex grief. It suggests that ADC, as a form of continued bond, not only diminishes death anxiety but also supports a healthy mourning process, preventing complex grief. This paper calls for an open-minded approach toward death and mourning, recognizing ADC as a natural and beneficial aspect of the human experience with death.

Abstract Name: Assessing the Efficacy of Different Methods in Chloride and Copper Testing

Road salts used in Milwaukee during the winter to melt ice are considered a threat to local waterways. Therefore, Alverno College has been monitoring the concentration of chloride ions in three different parks along the Kinnickinnic river and sharing this information with Milwaukee River Keepers to monitor Milwaukee water quality. Additionally, copper was monitored as it can affect local fish life at concentrations higher than 0.20 mg/l. Formerly, chloride was studied using silver nitrate titrations which create significant amounts of hazardous waste. As such, an ion selective electrode was used and the results using both methods were compared. In order to test for copper concentrations, the method of atomic absorption spectroscopy was used. The findings show that ISE could potentially be the new method to test for chloride ions in future research. Copper concentrations were found to be higher than the recommended amount which is something to consider to start monitoring further.

Abstract Name: Design and Implementation of Kawaii (Cute) Companion Robots by a Cross-cultural Team

As robots are increasingly used to help people across the globe, it is important to design these devices to curate positive experiences for a broad range of people. For example, among student populations, who are susceptible to high levels of stress and anxiety, mental health has become a significant concern in countries including the United States and Japan. This presents the opportunity to design robots with the intent of fostering companionship, which may help with mental health. We present a collaborative effort between Japanese and American university students, funded with a National Science Foundation Grant, to design and

implement Kawaii (Japanese cuteness) companion robots through in-person collaboration. The long-term objective is to investigate whether the perceived cuteness of these robots contributes to increased user satisfaction across cultures. Over seven weeks, we researched the Japanese concept of Kawaii and its application in design. During this time we also designed Kawaii and non-Kawaii virtual companion robots and evaluated the initial designs, including analyzing the design team's response to the designs using electroencephalograms (EEGs) and heart-rate variability sensors. Utilizing these results, we revised the initial designs and then implemented them using Blender, a 3D Printer, and an Arduino-controlled Zumo robot. The robots were designed to have "Kawaii" and "non-Kawaii" attributes through visual, auditory, and mobile design elements. Therefore, some robots were more "Kawaii" than other robots due to variations in the design. Through designing, implementing, and evaluating user-response to "Kawaii" companion robots, we gained a deeper understanding of Japanese culture and cross-cultural collaboration. We will present our cross-cultural design process, the robots we designed, and data that shows how college students responded to the various designs through follow-up surveys.

Abstract Name: Foot-Care Initiative

Project PurposeThe purpose of this project was to increase awareness among the unsheltered community on foot health since this is an issue that is prevalent within the community. Our goal was to provide essential information regarding foot care and foot hygiene products to our unhoused neighbors in Flagstaff. BackgroundUnsheltered individuals are forced to commute mainly by foot, walking between 10 to 15 miles daily and sometimes even more. People experiencing homelessness are up to 65% more likely to develop foot-related injuries including infections and cold-related injuries like frostbite. This is due mainly to constant exposure to the elements, specifically cold and wet weather, and a lack of access to hygienic resources such as dry, warm clothes and foot care products.MethodsWe collaborated with the Community Assistance teams of Flagstaff (CATs) to work on their mobile hygiene bus to provide foot hygiene products to unsheltered people with limited access to improve foot conditions. We developed, assembled, and distributed informational material, such as wound care and exercise cards, and hygiene care kits containing foot care materials. We measured baseline awareness of foot hygiene among the target population with pre-surveys. Post-surveys were given to bus workers to assess whether foot hygiene awareness increased among the target population.ConclusionPre-survey data detailed that only 12.5% of unsheltered individuals surveyed had received foot hygiene kits in the past and only 18% of those surveyed had received any foot care information. Following our intervention, foot hygiene awareness among program recipients increased by 100% demonstrating program effectiveness.

Abstract Name: Exploring the Influence of Simultaneously Learning Two Foreign Languages on Preservice Teachers' Identities: A Narrative Study

This narrative research aims to describe the relationship between concurrent learning English and French as foreign languages and its impact on the identities of two fifth-year preservice teachers at a foreign language undergraduate program at a Colombian public university. Rooted in the constructivist paradigm, this study attempt to understand and describe the intricate layers of identity construction within this unique educational context. It seeks elucidate how the participants interpret their realities while navigating the dual path of obtaining linguistic proficiency and learning pedagogical abilities. To delve into the participants' narratives, storytelling is used to clarify their experiences and interpretations of the influence of learning to foreign languages and the pedagogical aspects associated with learning how to teach under professional identities. The purpose of this study is to explore the perception of identity throughout the preservice teachers' educational journey. Data was collected through classroom observations, reflective journals, a language portrait silhouette instrument, and semi structured interviews. The presentation showcases preliminary findings through a thematic chronological narrative, encompassing personal, social, and educational settings. It unveils experiences related to learning and teaching foreign languages, shedding light on their identity re/shaping process. Among the findings this presentation highlights the transformation of participants from introvert to extrovert and leader behaviors, the influence of foreign language teaching training on self-perceptions, and the revelation that while personal perception and core identity remain unchanged, new emerging facets compliment and strengthen the core identity. Acknowledging potential limitations arising from the reduce sample size and the inherit subjectivity and individual stories, the study underscores the necessity of investigating identity development in the context of foreign language preservice teachers.

Abstract Name: Relationship identification between triggers and changes in the brain and the overall human electrophysiology during migraines

Migraines are neurological conditions that affect a major portion of the world, and occur more frequently in women while a decent portion do occur in men. This research aims to reinforce that migraines have environmental triggers, establish that migraines cause changes in the brain's electronics and the body's overall electrophysiology, and define the relationship between the changes and the triggers. The hypothesis is that there is a relationship between environmental triggers and specific electrophysiological changes in the brain and the overall human electrophysiology. The population will be the young adults of Embry-Riddle Aeronautical University, and the sample size will be determined using the aforementioned gender split between female and male as well as the Sample Size for Known Population equation. Several general health, neurological, and psychological factors will be taken into consideration when making the selection of the samples, including but not limited to, the level of fitness, daily habits, sex assigned at birth, current identity of sex, age, past treatments, other diagnosis, and more. Throughout the study, the participants will fill out several surveys about their daily habits, any migraine episodes, and any possible triggers. Additionally, the participants will undergo several tests with an Electroencephalogram (EEG), Electrocardiogram (ECG),

Galvanic Skin Response GSR, and pulsometer to accurately record their electrophysiology, then they may undergo the same test during a migraine so that differences in their electrophysiology can be noted. These changes will then be correlated to their triggers, and the research team will determine if there are patterns between the corresponding changes and triggers across several different participants.

Abstract Name: Chemical Defenses in the Seeds of Pioneer Plants

The seeds of pioneer plants are known for their prolonged survivability in the soil seed bank until there is a transition from low light to high light intensity that triggers their germination. The persistence of these seeds suggests that they possess forms of chemical defense against microbial pathogens. Isolating and identifying compounds with antimicrobial activity informs drug discovery efforts. It also helps to understand the role of pioneer plants in the ecosystems in which they are found. Phytolacca rivinoides, a pioneer plant common in the Costa Rican rainforest, is related to the American pioneer plant, Phytolacca americana. Extracts from the seeds of both species show antifungal activity. This research seeks to identify the compounds responsible for chemical defense against fungi in the seeds of these two pioneer plants. With greater access to seeds from Phytolacca americana, our research efforts focus on this species. Methanolic extraction is used to isolate compounds of interest from the seeds. Preparative HPLC is used to separate the components. 1H-NMR, 13C-NMR, and LC/MS are used to determine the structure of the unknown components. To date, the regioisomers Americanin A and Isoamericanin have been separated and identified from the seed mixture using these methods. The anti-fungal properties of these and additional isolated compounds will be analyzed using bioassays. The results from this study will then be extended to identify the antifungal components of P. americana's Costa Rican counterpart, Phytolacca rivinoides, to analyze the commonalities in chemical defense between the two pioneer plants, and to understand the role of pioneer plants in the rainforest ecosystem.

Abstract Name: Income, Education, and Fear: Investigating Socioeconomic Status and Percieved Threat of AI

As artificial intelligence (AI) technologies continue to rapidly evolve and display capabilities across several different industries, potential fears and negative perceptions of job displacement among some non-specialized positions and concerns of use in daily life arise (Dodel, 2019). These sentiments, which have long paralleled technological advancement in the automation of service and labor industries, returns to the forefront for many individuals who may foresee themselves interacting with AI technologies they may not be familiar with in the near future (McClure, 2017). Research of these kinds of human-AI interactions and the concerns held by individuals could possibly influence a host of areas pertaining to the development and implementation of AI for future consumers, especially for individuals reluctant towards use of the technology due to fear (Nimrod, 2021). Further in regards to economic effectiveness, research findings may be applied to current and future employee perceptions of job quality and security (Kortman et al., 2021). Understanding these interactions may also prove useful for addressing the possible stresses and health effects associated with significant changes to economic and cultural factors (Pankaj, 2018; Shoss, 2022). This study investigates the relationship between the socioeconomic status of an individual and their perception of the capabilities of AI as a possible threat to society, specifically whether low socioeconomic status predicts AI as more threatening. The data for this study will be sampled from the general US population through a panel service and ANOVA tests of group differences will be employed to determine whether different socioeconomic groups perceive AI differently. The findings of this study will be used in determining the effect to which these fears are held, who they are held by, and whether future research into this niche area may be worthwhile.

Abstract Name: A Multi-Modal Machine Learning System to Determine Fatality Information and Infrastructure Damage after Natural Disasters

Earthquakes and natural disasters have become frequent and severe due to climate change, demanding efficient and rapid emergency response. Traditionally, governments use systems such as PAGER to estimate an earthquake's destruction. However, it requires manual retrieval of official reports which suffer from time delays and bias. Recently, social media such as Twitter have become hotspots for reporting and communication during disasters, producing large volumes of information. This study designs a multi-modal machine learning system to automatically extract real-time multi-lingual data from social media to numerically quantify fatalities and infrastructure damage after a disaster. For text classification, the method uses a 2-model approach with fine-tuned XLM-RoBERTa models and leverages the few-shot learning abilities of GPT-J to extract the number of deaths, injuries, and locations. For image classification, the method uses a 2-model approach and transfer learning with InceptionV3 to categorize images by type of infrastructure and damage severity. The models are trained on images and text collected from CrisisMMD, CrisisNLP, and web scraping. Images were categorized into bridges, buildings, and roads via data-labeling platforms. The XLM-RoBERTa models achieved an accuracy of 96% and 94% and InceptionV3 achieved accuracies of 93% and 89%. The system was evaluated and deployed on social media and news data from earthquakes in Haiti (2021) and the Philippines (2022). Using timestamps of social media data, the system created graphs of the death tolls and infrastructure damage over time, yielding promising results and reliable information for deploying the method in real time to ensure a rapid and efficient emergency response. `

Abstract Name: Examining the Brand Identity of the Oxnard Performing Arts Center: Supporting Non-Profit Organizations in a Competitive Market

Brand identity can help differentiate non-profit organizations in a competitive market where non-profit organizations have been growing exponentially, creating scarce levels of engagement, volunteers, and charitable giving. The present study aimed to evaluate the Oxnard Performing Arts Center's (OPAC) brand identity through community members' awareness of this non-profit organization and ratings of the activities it hosts. Through an extensive review of the psychometric properties of existing brand identity measures, there was a total of 8 different measures utilized in the survey with domains emphasizing themes such as usefulness, brand commitment, and likeability. There was 111 participants. An independent samples t-test was conducted to assess potential differences among racial/ethnic groups and types of OPAC events. Compared with other racial/ethnic groups, Hispanic, Latinx, and/or Chicanx participants reported significantly higher likeability ratings whereas Black/African American participants reported significantly lower brand association ratings. Additionally, participants who strongly associated OPAC with visual and performing arts had significantly higher usefulness ratings, higher affect ratings, and higher sincerity ratings than those who associated OPAC with other events. An ANOVA test was also employed to examine whether the likeability scores differ based on how people perceive OPAC's status (i.e., non-profit, for-profit, run by the city of Oxnard, two or more options selected), which resulted in a significant macro-level effect. Post-hoc tests showed that those who believed OPAC is non-profit had significantly higher likeability scores than those who believed that it's a for-profit organization. Also, those who made two or more selections had significantly higher likeability scores than those who believed OPAC is a for-profit organization. It is recommended that OPAC host more events that cater to the Black/African American community (e.g., Juneteenth celebrations), increase/promote OPAC's visual and performing arts events, and highlight OPAC's non-profit status in their logos and informational booths.

Abstract Name: The Colonial Dilemma: Hispanismos in post-Americanization Puerto Rican Literature, Culture, and Politics from 1930 to 1960

The Americanization period of Puerto Rico, which intended to indoctrinate the Island towards mainstream American culture, created a politically charged identity complex amongst major cultural leaders. Transitioning from a Spaniard colonial regime from 1492 to 1898 to an American colonial domination from 1898 to the present day, Puerto Ricans have continuously struggled to define a national identity outside colonial boundaries. After the Americanization period ended, many literary figures began to attach to the past Spaniard regime as a way to differentiate themselves from an American colonial discourse. Such inverted dynamic provided a framework for literary studies to understand the peculiar development of themes in Puerto Rican literature after the arrival of the United States, focusing on topics like La Gran Familia Puertoriqueña. Although past scholarship has exhaustively addressed the influence of this inversion in cultural production, little to none have addressed how such inversion laid the groundwork for 'whitening' ideologies within post-Americanization Puerto Rican cultural nation-building. Through a literary analysis of

compositions by Emilio Belaval, José de Diego, and Luis Llorens Torres, alongside a brief sociohistorical analysis, I pinpoint discriminatory politics amongst decolonial national discourses in Puerto Rico rooted on the premise that Puerto Ricans are strictly European-descent subjects. These literary figures supported a racially homogenizing, patriarchal Puerto Rican identity as a decolonial attempt. I specifically identify hispanismos, which I categorize as an unbending devotion through figurative language to Spaniard identities that disregards African, Native, and diasporic Puerto Rican communities. The results obtained guide the forthcoming scholarship to examine the influence of such exclusions in the nationalist portrayal of Puerto Rican identity.

Abstract Name: Assessing Long-Term Social Consequences in Adult Zebrafish Embryonically Exposed to Ethanol

Zebrafish (Danio rerio) have been frequently used in neurobehavioral research, demonstrating how social behavior and brain development may be affected by prenatal alcohol exposure. Fetal alcohol syndrome (FAS) is the extreme form of fetal alcohol spectrum disorder (FASD) as a result of alcohol consumption during pregnancy, resulting in known birth defects and developmental disabilities. Zebrafish remain an ideal model organism for understanding alcohol-induced neurobehavioral disorders manifested in FAS because of their low cost, small size, and prominent external development. They share a highly conserved nervous system and 70% of orthologous genes with humans, making developmental and behavioral studies comparable. Complex social behaviors such as shoaling allow for observation of social function due to ethanol (EtOH) exposure. Male (n=20) and female (n=20) Tg(ETvmat2:GFP) zebrafish were exposed to 1% EtOH at 4 hours post-fertilization (4hpf) and tested for shoaling preference. EtOH or Ctrl treatments were followed by a 3-chamber open swim preference tank, recorded and analyzed live using digital video cameras and the Ethovision tracking software, which produced heat maps for analysis of swimming patterns. Results showed that both untreated control zebrafish and EtOH-treated zebrafish preferred to swim near the shoal side of the tank. Zebrafish treated with EtOH generally shoaled vertically, while the control generally shoaled horizontally. Future studies will be conducted to increase the sample size of both control and EtOH-treated fish and observe if the incorporation of a previously established or newly introduced shoal influences results.

Abstract Name: Latino Growth in Woodbridge, Virginia: The Possible Implications for U.S. Politics

A case study, “Immigrants, Politics, and Local Response in Suburban Washington,” explains how Prince William County’s (PWC) population rapidly increased between 2000 and 2006 (Brooke, Audrey & Jill 2009). Beyond the population of PWC tripling in just a few years, it has been known as one of the nation’s top counties for Latino growth (Brooke, Audrey & Jill 2009). Within Prince William County is Woodbridge, a suburban area of nearly 45,000 residents (Brooke, Audrey & Jill 2009). When looking at the Census data of Woodbridge from 2000 to 2020, with the demographic changes alone, it can be inferred there has been and will continue to be a change in Latinos' influence in the area. This project analyzes socio-demographic and economic changes in the Latino community in Woodbridge, Virginia. The research summarizes the literature on Latinos in U.S. politics and society and looks at the changes in Woodbridge to seek possible implications from such changes. Applying many research findings to the socio-demographic and economic characteristics of Latinos in Woodbridge, we identify ways such changes affect their’ political power and influence, mobilization and targeting by elites, and political participation in the area. This research is crucial, considering the growth of the Latino community in the United States. More than ever, Latino engagement can play an essential role in shaping society. In 2019, there were 60.6 million Hispanics in the U.S. Last year, the Census Bureau estimated that Hispanics make up 19% of the U.S. population. The findings from this research will motivate activists and groups to seek ways in which more engagement can be encouraged, ensuring our policies and leaders are representative of society. By looking into the possible effects of Latino growth in one specific neighborhood, we can see what to expect on an at-large level as similar changes emerge nationally.

Abstract Name: Lemons, Mining, and the Sicillian Economy: Arguments for the Origins of the Mafia

This paper investigates the origins of the Sicilian mafia during Italian unification (1848 - 1871). By exploring how trade during this time boosted the economy after the fall of feudalism (1817), I will use historical scholarship and primary sources to study the mafia as a business. More specifically, I will focus on how the citrus trade in individual Sicilian ports led to the mafia’s creation through the societal need for private protection and money management. I will also analyze how Sicilian sulfur exportation provided the necessary capital for the mafia to form a lasting legacy. My paper aims to show that the mafia was created as an economic enterprise subsidized through the citrus and sulfur trades. The reasons for the mafia’s continued success will be revealed through a historical and business analysis of the mafia’s establishment.

Abstract Name: An Investigation of DBD Plasma-Water Interaction Applicable to Wound Healing

In this study, the plasma-water interaction phenomenon was investigated. Non-equilibrium DBD plasma can be used for wound healing and sterilization to help millions of patients. However, the interaction of plasma with the wound is complicated and requires more understanding. When it interacts with water, plasma radicals react with water molecules. Plasma jets contain reactive oxygen and nitrogen species (RONS) as they entrain atmospheric air ejected out of the plasma torch. This study investigated what happens to water as RONS interact with it. A DBD plasma torch was operated at 10-12kV/30-40kHz on argon at 10SLPM to produce a plasma jet of about 20-30mm long. Input power was measured using two 1000:1 voltage probes and was found to be between 10mW and 20mW, depending on the operating conditions. The first set of experiments investigated the impact of plasma on DI water. The plasma exit was kept 30 mm above the surface of water, which was in a beaker placed on a lab jack. For 30 minutes of plasma exposure, there was a 54% decrease in pH value towards the acidic side. In addition, we are planning to analyze the various radicals that may appear as a result of plasma-water interaction. These include OH, O3, H2O2, NO3-, and NO2-. The analysis of radicals required a calibration curve that can be used to depict the concentration of each RONS at different wavelengths in the UV-VIS spectrum. A standard set of data must be determined for each radical by measuring absorbance at varying concentrations. In this work, we will present our calibration curve. Absorption spectroscopy was conducted to identify the absorbance of the radicals at each concentration. Preliminary results are obtained and are being reconfirmed. Full results will be presented at the conference.

Abstract Name: Machine Learning Approaches for Predictive Modeling of RNA Structures and Chemical Reactivity Profiles

The RNA polymer is an essential molecule for gene expression performing various biological functions. Folding of RNA on itself creates the secondary structure of RNA. The structural motifs of the secondary structure of RNA are important for gene transcription, translation, and splicing. Consequently, understanding the secondary structures will not only allow us to understand the role of RNA in diseases but also it will aid in the identification of potential therapeutic targets. Although predicting RNA structures remains challenging due to limited data and computational constraints, Machine learning, such as neural network models with its ability to be trained on large datasets, has emerged as a powerful tool in molecular biology with the ability to accurately predict RNA secondary structure. These models are more predictive than traditional bioinformatics methods, allowing for more accurate and detailed predictions of RNA folding. In the current

study, the data was taken from Kaggle that incorporated multiple variables from 1,118,5113 RNA sequences. The Jupyter notebook was employed to develop a machine learning model that used a Convolutional Neural Network (CNN) for this study. Traditionally, CNNs are a deep learning model primarily used for image processing tasks. It consists of convolutional layers that apply filters to input, pooling layers that reduce dimensionality, and fully connected layers that perform classification or regression tasks. In summary, the model uses the Adam optimizer with a learning rate of 1e-3, and the Mean Squared Error loss function. In the current work, the Convolutional Neural Network showcases notable efficacy, achieving a mean absolute error of 0.28. Its thoughtfully crafted architecture, encompassing 9 layers, incorporates key components such as dropout layers to mitigate overfitting. With a focus on image processing tasks, the model emerges as a potent tool for scientists across diverse domains, exemplifying robust performance and meticulous optimization.

Abstract Name: Analogs of Irbesartan as GDP-Bound K-RAS Inhibitors for Targeted Cancer Therapy

KRAS (Kirsten Rat Sarcoma Virus) is a proto-oncogene involved in cell proliferation and division. It is mutated in approximately one-fourth of all cancerous tumors. We aimed to block GDP-bound KRAS' function, which is the inactivated version of the protein, which may help prevent malignant transformation in precancerous states. We tested the binding affinity of various small molecules using UCSF Chimera and Autodock Vina. We hypothesized that the addition of electron acceptors to the molecules would increase hydrogen bonds, thereby increasing thermodynamic favorability. We formed this hypothesis after docking several small molecules to GDP-bound KRAS and noticing that molecules with favorable free-energy binding affinities usually formed more hydrogen bonds with amino acid residues. Most of the small molecules that we tested were Benzimidazole derivatives; certain derivatives, such as methiazole and fenbendazole, have been found to inhibit KRAS-mutant cells. Given the mortality benefit seen with some benzimidazole derivatives, such as the Angiotensin II receptor blockers, we also investigated if one such drug, Irbesartan, and its analogs had a strong affinity for KRAS. Herein, we report a novel modification to Irbesartan that resulted in an increase in silico binding affinity for KRAS.

Abstract Name: Potential for Native Species in Grand Canyon's Novel Riparian Forests

Water releases used to optimize hydropower production from Glen Canyon Dam have increased baseflow in Grand Canyon which allowed invasive tamarisk tree (Tamarix spp.) to establish on its historically barren sandbars, introducing a completely new ecosystem to one of the most well known stretches of the Colorado River. This new forest provided many benefits to wildlife, especially for endangered migratory birds. In 2001, tamarisk beetles (Diorhabda carinulata) were introduced to the United States in an attempt to quell the widespread tamarisk invasion and unexpectedly expanded into Grand Canyon by 2009. Since then, the canyon's tamarisk canopies have experienced almost a 30% reduction that is likely to continue, negating the new benefits to wildlife. While the situation introduces a large risk that this novel ecosystem will collapse, it also provides an opportunity to reshape Grand Canyon's new riparian forest as a novel, but native-centered, ecosystem. The Fremont Cottonwood (Populus fremontii), a keystone native riparian tree, is unique in the magnitude and variety of benefits that it provides to humans, wildlife, and river form. The tree's reproduction depends heavily on its seeds being transported downstream by large spring floods. These floods only occur during high flow experiments (HFE's) that are synced with large sand influxes from the Paria River, a tributary, to rebuild sandbars used by rafters for campsites. Here, we use USGS water elevation data and a literature review of regional cottonwood characteristics to explore how strategic adjustments to HFE designs can potentially promote cottonwood germination in Grand Canyon, continuing the benefits to local wildlife and migratory species while transitioning to a riparian forest that is resistant to damages from the tamarisk beetle.

Abstract Name: Using a Genetic Circuit to Understand the Antibiotic Resistance Mechanism of small RNA MicF

Antibiotic resistance has been an increasing issue in treating bacterial infections. Small RNAs (sRNAs) can quickly regulate various biosynthetic pathways within bacteria based on changes in their environment. Our research focus lies with the sRNA MicF, and its contribution to configuring antibiotic resistance in Escherichia coli. In the presence of antibiotics, E. coli produces MicF as a stress response. MicF then decreases the expression of the outer membrane protein OmpF, preventing the passage of antibiotics into the cell. The objective of this project is to understand how sRNAs, like MicF, influence antibiotic resistance in E. coli by accurately detecting concentration changes when exposed to different environmental conditions. To accomplish this, we constructed a synthetic gene circuit that detects MicF. The proposed circuit is composed of three parts: MicF sensing, amplification, and detection. The circuit components are encoded on plasmids, which are then inserted and expressed in E. coli. Direct complementary binding of MicF to the sensing component of the circuit causes downstream events that lead to the expression of the reporter gene, green fluorescent protein (GFP). GFP is produced in the presence of MicF whereas in the absence of MicF, the opposite is true. Circuit function is assessed based on fluorescence and optical density readings of the cells. After testing different combinations of the MicF sensing and amplification portion, we identified two that expressed GFP in the presence of MicF with high dynamic range. We performed a quantitative analysis of the detection of MicF by testing two circuits with different concentrations of MicF to determine their sensitivity. Our next step involves incorporating the amplification component of the circuit to further increase the circuit sensitivity. With increased sensitivity in detecting MicF, the circuit will allow us to investigate various environmental triggers of MicF and their influence on the antibiotic resistance mechanism.

Abstract Name: When Racial Attitudes Take Flight: Passenger Perceptions of Airline Employees

This study investigates racial and status-based attitudes among airline passengers towards Black and White male pilots and flight attendants. Drawing on a sample of participants (N = 162), the study employs an Evaluative Priming task and uses a video for participants to rate competence and warmth. Results indicate that participants harbor more negative implicit attitudes towards Black flight attendants compared to their White counterparts, with Black pilots also facing a significant bias. Surprisingly, the study reveals a nuanced impact, as warmth perceptions are affected by race condition, but not status condition. The findings underscore the persistent racial biases within the airline industry, emphasizing the need for targeted interventions to address these biases and promote inclusivity. This research contributes to understanding implicit attitudes in a specific occupational context, shedding light on potential areas for intervention and fostering a more equitable workplace environment.

Abstract Name: Sex differences in the ability of exercise to attenuate methamphetamine-induced monoaminergic neurotoxicity

Methamphetamine (METH) use is a major public health concern. Upwards of 14.7 million people in the U.S. report having tried METH. The use of METH is highly problematic due to the acute effects of the drug, including psychosis and aggressive behavior, as well as the long-term consequences including neurotoxicity, cognitive deficits, and addiction. One well-known rodent model of METH use utilizes binge administration, resulting in long-lasting damage to monoaminergic nerve terminals. Notably, individuals who use METH are more likely to develop Parkinson's disease, suggesting dopamine loss as a consequence of METH use. Exercise is well known for its beneficial physiological effects and cognition-enhancing properties and has been investigated in the context of neurodegenerative disease. While METH-induced neurotoxicity has been modeled in many species, these studies have largely excluded female subjects. Here we examined sex differences in the ability of exercise to attenuate METH-induced neurotoxicity. Male and female Sprague Dawley rats were dosed with comparable neurotoxic regimens of (+)-METH-HCl or saline. Beginning 1, 7, or 30 days after injections, animals were then subdivided into one of two exercise conditions, voluntary exercise or sedentary control. In males, at all three delay time points, 3 weeks of voluntary running after a METH binge protected against METH-induced dopaminergic neurotoxicity. Surprisingly, females showed no such beneficial effect of exercise demonstrating critical sex differences in the ability for exercise to attenuate METH-induced neurotoxicity, as evidenced by variability in degree of damage to dopaminergic nerve terminals. These results highlight the necessity of including sex as a biological variable in methamphetamine neurotoxicity studies going forward.

Abstract Name: Effect of Void Ratio on Slopes Subjected to Post-Earthquake Rainfall

It is known that slopes that have undergone an earthquake may fail if subsequently subjected to rainfall.

Previous studies have found correlations between the rate of the infiltration of the water and both the intensity of the rainfall and the density of the slope materials. In this study, the effect of varying void ratio in soil subjected to an earthquake and then rainfall was studied to quantify the relationship between void ratio and seepage velocity. Four numerical models with void ratios between 0.89-1.2 were built in GeoStudio 2023 and subjected rainfall after an earthquake. All of these models were subjected to the same earthquake loading conditions. The seepage velocity was found to depend on the location at which it was measured and the void ratio of the slope material. Specifically, as the void ratio increased, the seepage velocity was seen to increase. The seepage velocity was typically higher within the inclined portion of the slope than at the head (top) of the slope mass. Finally, the seepage velocity decreased as the depth from the ground surface to the point of measurement increased.

Abstract Name: The Effect of Post-Earthquake Rainfall on Slope Stability and Deformation

It is known that intense, and prolonged rainfall increases the chances of a landslide; and although there have been studies done on landslides caused by post-earthquake rainfall, few studies have specifically analyzed how the amount of rainfall directly affects a slope. By analyzing the numerical correlation between post-earthquake rainfall on slope stability and deformation, the ability to predict landslide risk from rainfall will increase. This study looks at how varying rainfall intensities affect slope stability and deformation by analyzing seepage velocity, soil swell, and the slope's factor of safety. The slope geometry and soil properties for the finite element model were based on calibrated numerical models. The model was subject to horizontal sinusoidal motion with a frequency of 3 Hz and a peak ground acceleration of 0.1g. The models were subjected to rainfall intensities ranging from 0.50 – 8.00 cm per hour. As rainfall intensity increased the seepage velocity throughout the entire slope increased. However, the seepage velocity was not uniform. For all rainfall intensities, the seepage velocity decreased as the water went deeper into the slope. This result indicates the densification of the soil as depth increases. Similarly, as rainfall increases soil displacement at the head of slope increases. The combination of increased soil swell at the head of the slope and the low density of soil near the surface indicates that an increase in rainfall intensity directly decreases the slope's stability.

Abstract Name: The Role of Nuclear Hormone Receptor daf-12 in C. elegan Post-Embryonic Neuronal Development

While significant advances have been made regarding the process of neuronal development during embryonic stages, there is a gap in knowledge pertaining to the mechanisms that control post-embryonic neural development and maturation. Preliminary evidence suggests that vitamin D and its cognate vitamin D receptor (VDR) play important roles in these areas. VDR serves as an interesting candidate to examine as it responds to environmental stimuli by binding to nutritionally derived ligands, while its regulation is also under tight control by intrinsic genetic regulatory pathways. This project aimed to identify the mechanism by which VDR controls post-embryonic neuronal development and maturation. To examine this relationship, the temporal expression pattern of daf-12, a homolog of the VDR in C. elegans, was examined to single neuron resolution in the C. elegans post-embryonic nervous system using a GFP-tagged expression reporter, generated using CRISPR-Cas9. This showed that daf-12 was most highly expressed pan neuronally in the second and third larval stage, with the highest expression being seen in ciliated sensory neurons throughout life. Once these critical stages were established, the locomotory behavior of worms carrying the wild-type daf-12 gene were compared to that of daf-12 mutant worms. With movement being closely tied to neuronal development, the observed juvenile behavior in daf-12 mutant worms support daf-12 being involved in the regulation of neuronal maturation. More broadly, the preliminary data gathered in this project aims to advance our understanding of neuronal development and how dysregulation of gene-environment interactions can contribute to neurodevelopmental disorders such as intellectual disabilities or autism spectrum disorder.

Abstract Name: The Construction and Functions of Value Arguments in Scientific Literature of the SARS and COVID-19 Pandemics

The scientific community is a unique rhetorical ecosystem which has been a longtime subject of rhetorical analysis. Scientists act as speakers by communicating their findings, as audience by judging the validity of new research published in journals, and as teachers by training students to write in ways considered acceptable by the larger field (Overington, 1977). Several scholars have investigated the ways scientists establish the value of their work through writing and argue for its inclusion in the body of knowledge accepted by the community. In particular, Fahnestock and Secor (1988) studied the uses of the stases, a technique in which rhetors focus their argument on a particular topic or question. Carter (2016; 2021) continued this work, defining three classes and seven functions of value arguments in the introductions of scientific papers and comparing the rhetorical moves favored by authors in a sample of publications in various fields and journals.This research investigates the effects of public crises on scientists' rhetorical strategies in the introductions of published papers. Value arguments in fifteen published papers each from scientific literature published during the SARS and COVID-19 pandemics were classified and compared to those analyzed by Carter (2021). Though both corpuses rely mainly on implicit value arguments, which connect the subject to a topic which is understood to be important, the pandemic literature uses more value arguments which situate the research topic within the larger crisis and rely on the audience's own understanding of the situation. In total, this investigation demonstrates continuity over a period of decades in scientists' rhetorical responses to crises and suggests that the nature of the rhetorical situation profoundly impacts scientific value arguments. These insights have the potential to further understanding of the ways scientific knowledge is constructed and improve the rhetorical education of novice and seasoned scientific writers alike.

Abstract Name: Regulation of neuromuscular development in C. elegans by an epidermal growth factor-like transmembrane protein.

Epidermal growth factor promotes the development of many tissues, including neurons and glial cells. In mammals, epidermal growth factor receptor signaling coordinates the development and function of neuron synapses. Previous research suggests that epidermal growth factor-like proteins promote synapse development. Using the Caenorhabditis elegans (C. elegans) neuromuscular junction, we have identified a transmembrane epidermal growth factor domain-containing protein that reduces synapse formation. Using fluorescent synaptic markers, we observed that mutant animals produce more synapses and have an increase in neuromuscular activity. Although expressed in multiple tissues, this epidermal growth factor-like protein is only required in the epidermis of C. elegans to reduce synaptic connectivity of motor neurons. To reveal the underlying molecular mechanisms, we investigated potential functional domains beyond the epidermal growth factor domains. We identified a critical carboxy terminus peptide that is essential for protein function. Based on predicted protein interaction motifs, we performed an RNA interference-based screen and identified two genes that contain complementary interaction domains. Knockdown of one of these genes recapitulated the phenotype caused by mutations in the epidermal growth factor-like protein. Knockdown of the second gene restored development to normal in the epidermal growth factor-like mutants. These results suggest our RNAi screen has uncovered a new positive and negative of this epidermal growth factor-like signaling pathway. We propose that this epidermal growth factor-like signaling pathway mediates an interaction between the epidermis and motor neurons to prevent excessive synapse formation at the neuromuscular junction.

Abstract Name: Fiber Amplifiers for Directed Energy Applications

Using the power of photons, one can drive and maneuver objects in space with light. The first phase of achieving this goal lies in developing small scale photon propulsion systems on Earth. Directed energy systems are any systems that direct energy to a target, and in this project it is accomplished using a Direct Photon Driver (DPD). A DPD specifically refers to the delivery of photon energy to a target. The light source comes from a laser beam which can be used to change the momentum of a photon upon reflection from a target to “push” said target. For the project’s initial development, the target will be a Low Earth Orbit (LEO) wafer satellite. The directed energy system will use a phased array, which is an array of emitters whose radiation pattern can be tailored by adjusting the phases of each emitter. These emitters contain a pre-amplifier, which raises the signal level at the input of an optical receiver, and power amplifier, which converts a low power signal to a high power signal. By increasing the power of multiple laser beams and manipulating

them to meet at the wafer satellite, the energy of photons is amplified as multiple light waves constructively interfere with one another. Furthermore, the satellite outputs its own light beacon which communicates with the emitter’s light in the Earth’s atmosphere. This combined light is sent back to the phased array and decoded where it can then be used to adjust the emitters position and steer the satellite.

Abstract Name: Testing the Capability of the Keith Terry Palen Observatory Telescope to View Exoplanets

We conducted a comprehensive observational study using the 18-inch telescope at Weber State University's Keith Terry Palen Observatory to observe a variety of exoplanetary transits. Our primary objective was to assess the instrument's capabilities in detecting subtle changes in brightness, particularly during exoplanet transits. This methodology, although initially applied to exoplanets, can potentially extend to other celestial objects, such as variable stars and asteroids.Our observations encompassed both confirmed exoplanets archived by NASA and suspected exoplanets or exoplanet candidates identified through the TESS survey. This broad spectrum of targets allowed us to evaluate the telescope's sensitivity and precision in detecting various low-percent brightness changes.

Abstract Name: Alteration and Hydrothermal Fluid Provenance in the Lima Segment of the Peruvian Coastal Batholith

Plutons emplaced in the shallow crust (<5 km depth) are likely subject to subsolidus alteration due to hydrothermal fluid flow from sources as varied as meteoric water, metamorphic water, magmatic water, and seawater. We present a description of alteration patterns and mineral δ18O values that document the origin of the hydrothermal fluids that affected tonalites, monzogranites, and diorites belonging to the Lima segment of the Peruvian Coastal Batholith (PCB). The PCB is a ~2000-kilometer-long magmatic arc related to the subduction of the Nazca plate underneath the South American plate during the Cretaceous and early Tertiary. These Lima segment plutons intruded Permian-to-Cretaceous oceanic crust and andesites that formed after attenuation of the preexisting continental crust (e.g., Bahlburg et al., 2006). Host rocks were metamorphosed to epidote and chlorite-greenschist facies. Thin section observations revealed moderate to extensive alteration of biotite to chlorite as epitaxial overgrowths and plagioclase to sericite. Myrmekitic textures in plagioclase

along with calcite, sericite, and epidote alteration along cleavage planes and within cores of crystals are additional evidence of alteration by external fluids. These mineral assemblages suggest hydrothermal alteration at shallow crustal depth (~350°C). Equilibrium δ18O values for coexisting quartz (+7.5 to +9.7‰), plagioclase (+5.9 to +7.5‰), K-feldspar (+5.5 to +7.2‰), and hornblende (+4.7 to +6.6‰) indicate a magmatic source for some fluids. However, δ18O values for biotite (+2.9 to 5.4‰) are out of isotopic equilibrium and are evidence for the involvement of low latitude meteoric-hydrothermal waters.

Abstract Name: The effect of B-alanine on the rate of axolotl limb regeneration and digit formation and the expression of tgf-B1.

Axolotls can regenerate tissues after damage or loss. Tissue regeneration proceeds through three stages: wound healing, dedifferentiation, and redevelopment. B-alanine enhances carnosine production, leading to a variety of physiological roles, such as buffering pH in muscle cells, aiding in reducing muscle fatigue and allowing muscle to rebuild at a faster rate. This study aims to examine the effect of B-alanine on limb regeneration and digit formation while analyzing its effect on the expression of tgf-b1. Tgf-b1 is expressed during the first two stages, aiding in cell proliferation and dedifferentiation. Cox3, a housekeeping gene is constitutively expressed, served as the control. To determine expression levels, limb tissue was sampled at Time 0 (“T0”, non-regenerating tissue) and 72 hours after initial amputation (“T72”, regenerating tissue). After T0 amputation, B-alanine was injected subcutaneously into the abdomen, RNA was immediately extracted from T0 samples and converted into cDNA, and expression of tgf-b1 was analyzed using RT-qPCR and gel electrophoresis. A second injection was administered 12 days after initial amputation, which served as T0 for recording the rates of limb and digit regeneration. Image-J was used to assess growth, and digit formation was evaluated by initial appearance of distinct webbing between digits. We hypothesized that the addition of B-alanine would increase tgf-b1 expression levels and enhance limb regeneration and digit formation. Our study showed that B-alanine did not significantly increase the expression levels of tgf-b1 at T72. Furthermore, while injections with low concentrations of B-alanine had a positive correlation with the formation of digits and limb regeneration rates, statistical analysis indicates limb regeneration rates were not significantly different from the control. On the other hand, injections with high concentrations of B-alanine decreased in regeneration rates during wound healing, suggesting that too much b-alanine may be inhibiting axolotl wound healing.

Abstract Name: The Relation between Perceptions of Diversity and Cohesion in Teams: Results from an In-Lab Descriptive Study

Perceived diversity refers to the extent that team members view themselves as similar or different, based on a variety of demographic characteristics. When group members see their teammates as being part of their in-group or out-group, this can impact how cohesive the team ends up being. Individuals may feel most comfortable with people who they perceive as similar to themselves, which has implications for the emergent relationships that form with group members. Accordingly, the purpose of the current study was to analyze how perceived diversity similarity influences cohesion within teams. We chose to examine the relation between cohesion and three forms of perceived demographic similarity: race/ethnicity, sexual orientation, and political preference. We hypothesized that perceptions of demographic similarity, across the board, would be positively correlated with cohesion. To test our hypothesis, we conducted a study using 103 research participants who were brought into the laboratory to complete creativity and decision making tasks in teams ranging in size from three people to six people. At the end of sessions, participants completed survey-based measures of perceived team diversity and cohesion. To analyze our data, we ran a correlation analysis using SPSS. The results of our analysis indicated that our hypothesis was not supported. We suspect this was potentially due to the relative strength of other factors, such as personality, in determining team cohesion, as well as the relatively liberal/open-minded nature of our sample. We did, however, find a strong correlation between different forms of perceived diversity that, while not connected to our hypothesis, merits further investigation and discussion. Namely, there was a significant relationship between perceived racial/ethnic diversity and perceived political diversity that we theorize occurred due to the common perception that these two variables are correlated in American culture. Implications, limitations, and future directions will be discussed.

Abstract Name: Mirror, Mirror: Models for Contemporary South Indian Womanhood through a Ninth-century Hindu Saint

Andal was a Hindu poet and saint who lived and wrote in the 9th century. Among the twelve South Indian poet-saints called alvars who composed Tamil-language devotional poetry to Vishnu between the 8th and 11th centuries, Andal is both the only woman and the most prominent in contemporary ritual practice. Her two poetic compositions are centrally important to the South Indian Vishnu-centered, or Srivaishnava devotional tradition. They are also noted for their vast differences in voice: the oft-recited Tiruppavai articulates a vow centrally concerned with women's auspiciousness, while the less-engaged Nacciyar Tirumoli offers an intimate image of Andal with strong themes of rage, desire, and sexuality. The tensions generated by these disparate voices have invited numerous scholarly and popular assessments of Andal's character, but less academic attention has been given to devotees' daily engagements with the poet-saint and the implications those interactions have for their lives beyond ritual contexts. During seven weeks of ethnographic research in South India, I traced how elite Srivaishnavas engage and imagine Andal, and explored ritual, familial, and expressive contexts in which she is prominent. Building upon 15 formal interviews, dozens of informal dialogues, and many hours of participant observation in Hindu temples, I

argue that the expressive dichotomies represented by Andal's two poetic works encourage distinct interpretations of her identity which are variously deployed to sustain or negotiate the boundaries of traditional womanhood. Additionally, I suggest that upper-caste Srivaishnavas, through idealized understandings of Andal, construct two broad-based models of womanhood structured by opposing emphases on transgression and devotion, unrestrained sexuality and wifehood, and literary content and signification, as well as the degree to which gender shapes who Andal was and what she wrote. I give special attention to classical Indian dance or bharatanatyam, a popular medium through which women embody these models as Andal.

Abstract Name: Studying the acoustic end behavior of the flue organ pipe

The musical acoustics research group at Rollins College has spent the last few years investigating the acoustical behavior of organ pipes. Early 2023 Moore et al. used an optical system (TESPI) to image sound waves in a flue organ pipe and found an unexpected internal node as well as an exponential decay of sound pressure outside of the tube. This was surprising as sinusoidal decay was expected in order to complete the standing wave based on all literature on the subject. The goal of this research was to further investigate the findings of the previous work using acoustical measurements as opposed to an optical system. This work focused on the 3D modeling and design of custom built organ pipes. Then, using a MircoFlown sound intensity probe, measurements of acoustic pressure were taken inside and outside the end of a 3D printed organ pipe. Comparisons between the optical results and acoustical results will be presented.

Abstract Name: How National Ideals Affect the Teaching of World War One History in North American High Schools: A Comparative Study of Canada and the United States

This study aimed to add to the growing body of research analyzing how the political cultures of different regions are manifested in educational curriculum, particularly the history of World War I. I utilized secondary textbooks from four states in the United States, Massachusetts, California, Texas and Florida, and two provinces in Canada: Ontario and Alberta. The purpose of this project was to analyze how traditionally liberal states and provinces, such as California, Massachusetts, and Ontario, teach history compared to traditionally conservative states and provinces such as Texas, Florida, and Alberta. The political climate regarding education in certain states and provinces has been changing even within the past few months and it is always beneficial to know what students are being taught and being able to compare that information to

past studies. This research is important because the United States and Canada can work together to fight the weaponization of education.

Abstract Name: Radar Signature Precursors to Tornadic Development in Squall Line Thunderstorms in Southern Wisconsin

In recent events such as the March 31st event of 2023, southern Wisconsin has experienced abundances of squall line thunderstorms and tornadoes. Wisconsin and surrounding areas are more prone to seeing QLCS thunderstorms, as compared to supercell thunderstorms. QLCSs present a variety of associated hazards during the time they occur, like the ability to produce strong straight line winds. While this can be threatening, different challenges associated with predicting tornadic development from QLCS thunderstorms. QLCS thunderstorms are less likely to produce a tornado and tornadic development is more difficult to detect on radar. In addition, QLCS thunderstorms present significant challenges to warning lead times and warning operations. This project examines a total of 22 days, 10 days in the Milwaukee County Warning Area that had at least 2 or more tornado reports on these days, and 12 days that a tornado was not reported but received at least 25 hail and wind reports combined. Radar data is accumulated from NEXRAD Archive Access site and then further analyzed through GRLevelX software. Level 2 products were used to examine reflectivity, velocity, and correlation coefficient products. The radar signatures associated with these storms are analyzed and the evolution of these storms through Milwaukee County Warning Area is examined further. Forward motion with these storms and their lifecycle will be spatially significant in mesovortex and QLCS development. Radar precursor signatures to tornadic mesovorticies may contain convergence zones, especially along the leading edges of these storms. Notably, the identification of updraft/downdraft convergence zones and velocity over time may help overall to improve warning lead times and warning operations.

Abstract Name: Working Memory Capacity as Differentiated by Linguistic Category

PROBLEM/PURPOSE: A previous study assessed the impact of multilingualism on working memory capacity (van den Noort et al., 2006). The study found that working memory capacity may be larger in a person's native language than their second language. However, the languages were from the same linguistic group. The authors suggested conducting the same study with multilingual participants from different linguistic groups (DLG, e.g., English versus Arabic). Our research tested the following hypotheses: 1.) Can we replicate the original study with participants who speak English and French (i.e., same linguistic group

[SLG]); 2.) Working memory capacity differences will be greater for multilingual participants who speak languages from DLG's. PROCEDURE: We conducted our study in two locations: Rabat, Morocco (n = 30) and Duluth, MN (n = 30). In Rabat, our participants spoke Arabic and English (i.e., DLG). In Duluth, our participants spoke French and English (SLG). Working memory was assessed with the standard forward (FDS) and backward (BDS) digit span tests.RESULTS: For those who are multilingual within the SLG (i.e., French and English), we found a significant difference in working memory capacity (t[29] = 8.32, p < .001, r2 = .704). In Morocco, we found significant working memory differences between Arabic and English (DLG's), as well (t[29] = 2.94, p = .006 r2 = .229). Our second hypothesis assessed whether there was a larger absolute difference in working memory capacity when comparing languages in the SLG (i.e. van den Noort study) to languages in DLG's (in Morocco). The original study found a larger effect size for differences in the SLG (r2 = .416), as compared to our Moroccan DLG participants (r2 = .229). CONCLUSIONS/IMPLICATIONS: Our findings suggest, that regardless of where the languages are learned, working memory capacity differences are greater between SLG languages as compared to DLG languages.

Abstract Name: Wood Type Printing and Its History

Wooden movable type or wooden type printing is one of the oldest and most used variations of printing that continues to fall in and out of fashion over the years. This printing variation was known in certain areas in different periods. But after some time, when printing was in high demand, people turned to the wooden type over its counterpart in, the metal type. The reason for that is the wooden type, unlike many others, is easy to carve ornamentation in and the most inexpensive to replace when needed. Another reason the wooden type was preferred is that the wood made it cheaper to have large-scale fonts without costing as much as the metal variety would have. So in all, the wooden type was an easy-to-use and more inexpensive method that came and went with the times.

Abstract Name: Designing HerStory

Throughout the history of the design canon, many women's achievements that came to pass were not seen or discussed. This essay will talk about the stereotypes these women faced, how they overcame them, and any other challenges they faced. The design world now strives to allow equality no matter the gender or race of a person, which was the opposite of how it was then. This essay dives into showing the challenges faced by women in their times to achieve equality, including gender bias and stereotypes. Throughout history, women like Ellen Raskin fought against what society thought of them to find a place in the design field. The discussion extends toward lesser-known women in design like Evelyn Ramsay Carey, Bertha M. Boye, and

Josephine St. Pierre Ruffin, who were instrumental in their help with the women's suffrage movement. Ruffin founded the Women's Times newspaper and challenged the status quo while giving black women a voice. On the other side, Carey and Boye use their mediums to showcase their opinion on women's suffrage. Despite these challenges, women fought a long and hard to get to where they are now in the design field. Even today, there is still history about all of the women in design being discovered or even just an already-known designer being credited for a previously unknown work. With all of the effort put towards identifying these designers, anything uncovered is another significant step toward the design canon being reevaluated. If it was not for those women who fought long and hard, who knows what the design field would look like today?

Abstract Name: Examining the Negativity Bias in College Students with Depressive Symptoms: An ERP Study

The present study aims to understand the differences in emotional information processing between individuals with low depressive symptoms (LD) and high depressive symptoms (HD) using electroencephalography (EEG). Previous research has demonstrated that individuals with depression have blunted responses towards positive and negative stimuli, which is called the Emotion-Context Insensitivity Hypothesis (ECI). Comparatively, in healthy individuals, negatively valenced stimuli have more impact on one's psychological state than positive or neutral stimuli. This sensitivity to negative information is referred to as the negativity bias. By measuring event-related brain potentials, previous research has displayed that the negativity bias emerged during early information processing among healthy individuals. In this study, we hypothesize that people with high depressive symptoms would be less likely to exhibit the negativity bias compared to their counterparts. To test this hypothesis, 33 college students, who were not taking any medication, were asked to passively view 135 happy, sad, neutral, angry, and fearful facial expressions taken from the NimStim Face Stimulus Set in a random order while their brain waves were recorded. The depressive symptoms of the participants were assessed using a modified version of the nine-item Patient Health Questionnaire (PHQ-9). The participants were divided into two groups (N=15; LD and N=18; HD) based on their PHQ-9 scores. The results of the current study supported part of the ECI hypothesis. It was found that the HD group displayed blunted affective responses towards the sad condition in the right hemisphere of the brain but not for the happy condition. The implications and significance of the current study were discussed.

Abstract Name: Heavy metals in Eastern Oysters (Crassostrea virginica) and their impact on condition

Estuaries are among the most impacted coastal systems and provide habitat for oysters. Louisiana is a hotspot for human activities such as shipping, fishing, tourism, and oil and gas industry, all of which pollute the marine environment. Organisms like the Eastern oyster, Crassostrea virginica, can serve as biomonitors for local pollution because they are filter feeders and bioaccumulate pollutants such as heavy metals. The aim of this study is to analyze which heavy metals are found in C. virginica around Terrebonne Bay, LA and how those metals vary with proximity to human activities such as shoreline development, shipping, and oil and gas production. Additionally, we investigated if there is a correlation between heavy metal concentration and overall oyster health, measured as a condition index. The number of manmade shoreline structures (any type) and oil and gas structures are each correlated with lead concentrations in oyster tissue. Only arsenic and barium concentrations in oyster tissues were negatively correlated with oyster condition. Oysters collected from Bayou Petit Caillou, LA had both the highest total heavy metal concentrations and the highest condition index, while the oysters collected from the Houma Navigation Channel had the lowest condition index. These findings suggest other factors beyond heavy metal load affect oyster condition. The Houma Navigation Channel was the only site where the oysters were collected from the marsh platform, where conditions are hotter and drier. Understanding more clearly how these and other factors impact oyster condition are crucial to understand to better protect oyster reefs and fisheries as coastal pollution worsens.

Abstract Name: Regulation of Biguanide Metabolism in Pseudomonas mendocina

Metformin is a top-prescribed synthetic pharmaceutical used as a blood glucose-lowering drug for type II diabetes, but is only partially metabolized by the human body, and not completely removed in some WasteWater Treatment Plants. Consequently, metformin, and its transformation products, guanylurea and guanidine, are major anthropogenic pollutants, and have been identified in national and international waterways. The presence of guanidine carboxylase, guanylurea hydrolase, and the enzymes involved in the metformin degradation pathway facilitate the complete degradation of metformin to carbon dioxide and ammonia in the bacteria Pseudomonas mendocina strain MET. The purpose of this study is to investigate the environmental and physiological conditions that regulate the production of these enzymes in order to further our understanding of the degradation of guanidine and biguanide compounds. P. mendocina was grown in a medium containing biguanidine compounds as the sole nitrogen source. mRNA was extracted from these cell cultures and used to perform RT-qPCR, in which mRNA was converted into dsDNA, amplified, and quantified using the fluorescent dye, SYBR green. Results indicated that guanidine carboxylase genes were upregulated in the presence of guanidine, guanylurea, or urea and downregulated when exposed to alternative nitrogen sources. Upstream regions of sequences encoding guanidine carboxylases in P. mendocina were analyzed using bioinformatic programs to predict possible regulatory elements. Two riboswitches that bind free guanidine and promote gene expression were identified upstream of guanidine carboxylase genes in P. mendocina MET and P. mendocina GU. This novel understanding of the genetic regulation of guanidine carboxylase advances our understanding of metformin and guanidine degradation, as well as aid in the development of biotechnological remedies to remove these compounds from the environment.

Abstract Name: Mechanical Properties of Organic-Inorganic Composite Films: Compressive Resistance of Flexible vs. Rigid Organic Components

A series of organic-inorganic composite films composed of close-packed, alkanethiol-capped gold nanoparticles and dithiol crosslinking molecules were assembled upon the air-water interface within a Langmuir trough. The mechanical properties of films were assessed by the Langmuir isotherm, yielding measurements of minimum collapse pressures and structural responses to collapse. The results of this study address the specific role of nanoscale materials components, further enabling the rational design of nanoarchitectures with specific chemical, physical, and mechanical properties.

Abstract Name: The Effects of COVID-19 On College Student Stress and Resources

This research is the last in a three-part series that studies how students were impacted by Covid-19. Grounded in Hobfoll's Conservation of Resources Theory (1989), this third study measures whether the relationships between stress and resource loss still hold true while exploring additional research questions about the differing impact between gender, and student level as the world shifts back to a "new" normal in 2023. In comparing the key hypotheses across the three years, support was found for a strengthening relationship across time between resource loss and stress. Likewise, the negative relationship between stress and the outcomes of physical health, psychological health, and well-being were found to be supported across time with one exception of insignificance in 2022 for the relationship between stress and physical health. Overall, there were no significant differences in average reported stress across the student yearly samples; however, there were decreases in the overall average net resource loss from 2021 to 2022, but no significant difference from 2022 to 2023. Women consistently reported significantly greater stress levels and net resources losses than men, demonstrating a differential negative impact of the pandemic for women. However, the stress gap between both genders decreased from 2021 through 2023. Additionally, upperclassmen reported significantly

higher stress levels and increased net resource losses during the heart of the pandemic in 2021 and 2022, compared to underclassmen. However, those differences disappeared in the 2023 sample, suggesting a return to a parity of experience. The three-year study provides insight to universities and employers on how to better support college students. This knowledge can be used to generate support through mentoring, time management programs, and networking events to make up for the losses students encountered. The research can serve as a foundational piece for both future research and historical purposes.

Abstract Name: Title IX: Has Women's Athletics Really Progressed?

There has been a dramatic movement of girls and women into sport since the inception of Title IX in 1972, but has women's athletics really progressed since then? Title IX prohibits discrimination based on sex or gender in any educational program or activity receiving any type of federal financial aid. There have been many successes since 1972 from equal opportunities in intercollegiate athletics to protecting survivors who report sexual harassment and misconduct. The percentage of female collegiate athletes rose from 15% in 1972 to 44% during the 2020-2021 school year. But women's sports receive only 5% of media coverage, girls drop out of sports at twice the rate of boys by the age of 14, and the number of women coaching collegiate women's sports decreased from 90% in 1972 to only 41% in 2020. The high school participation rate is 11 times greater than what it was when Title IX was passed, but even with this increase girls participation rates today are still not as high as what boys' participation rates were back in 1971-1972. This research mainly focuses on athletics and the inequalities regarding participation rates, lack of female coaches, lack of females in leadership positions, and the minimal media coverage that women's athletics receives. I reviewed and analyzed various credible sources such as academic papers, journals, and websites over the course of six months to form conclusions. These show that there are underlying systemic gender equity issues in society and specifically in women's athletics that demonstrate that society has not progressed much since 1972. Data has shown that when women's sports are made available on media, they are extremely popular. Title IX does not fix gender inequality or sexual harassment and much progress is still needed until equality is prevalent in society.

Abstract Name: Green Synthesis of Gold-Palladium Nanoparticles Using Upland Cress: Synthesis and Characterization

Previously, the green synthesis of gold and silver nanoparticles using upland cress (Barbarea verna) has been achieved. This study explored the potential in synthesizing gold-palladium alloy nanoparticles. Upon

successful synthesis and characterization using UV-vis spectroscopy, the analysis confirmed that the initial solution exhibited a peak at 438 nm for samples containing pure palladium, which is characteristic of the presence of Pd2+ ions; however, this peak diminished as synthesis progressed, indicating the formation of Pd-containing nanoparticles. For samples containing gold only, an absorbance peak between 500-600 nm can be seen increasing in prominence as time progressed, indicating production and growth of nanoparticles. Regarding the samples with both palladium and gold, the characteristic features of each pure palladium and gold absorbance values can be observed as a combination with skewing proportionate to the ratio of palladium and gold. The successful synthesis of gold, silver, palladium, and now gold-palladium alloy nanoparticles using upland cress demonstrates the versatility and potential of this green synthesis. By leveraging the unique properties of upland cress, researchers can continue to develop environmentally friendly and cost-effective approaches for metallic nanoparticle synthesis.

Abstract Name: Refuting Censorship: Using World Literature to Develop Empathy, Perspective, and Critical Thinking

This research paper is meant to answer the question “why is world literature important?” It was expected that this study would confirm that censorship of world literature deprives people of important knowledge and skills. The research addresses the importance of world literature (specifically fictional literature) for its functions in developing people’s perspective, skills in independent thinking, cultural values, and empathy.Often, those who argue in favor of censorship are afraid of literature’s power to disseminate values to readers. When values are in opposition to the values that an individual holds, they view the texts as blasphemous or a danger to their way of living. Literature does in fact transmit values to readers, challenges the status quo, and exhibits model behavior. However, the analysis of literary texts using the diversity of other texts has been shown to increase critical and independent thinking skills. In the classroom, methods of reading against the grain, the common ground method, and the California English language arts framework are some of the ways students are taught to recognize the messages and values of a text without taking them on as their own. It is essential to utilize world literature in the classroom to get students to a level of critical thinking appropriate in a university classroom, and it is important in developing an understanding of the world in which they live in.This research builds on existing conversations of literature’s importance, taking from research papers, studies, and articles. Ultimately, what was discovered is that world literature should not be censored, as it is essential to the development of empathy, world knowledge, and critical thinking. It is applicable to arguments made for the use of world literature in education, to create educated arguments against censorship, and to be built on for future study.

Abstract Name: Design and Development of Inhibitor of Gut Microbiome Metabolite Associated with Development of Alzheimer's Disease

Recent investigation for understanding the mechanism by which altered gut-brain axis impacts the central nervous system has received significant attention. The alterations in the gut microbiome termed dysbiosis has been observed to be associated with neurological conditions. In cognitively impaired elderly patients and transgenic rodent models of Alzheimer’s disease (AD), gut dysbiosis has significantly positive correlations with AD pathology including cerebral amyloid beta depositions. The gut microbiota catabolism of dietary nutrients (primarily L-carnitine, choline, and phosphatidylcholine) induces an increase in Trimethylamine (TMAO), which is oxidized by hepatic Flavine monooxidase 3 (FMO3), to trimethyl-N amin oxide (TMAO). Interestingly, higher concentrations of TMAO have been reported in diabetic and Alzheimer’s disease patients. Recent findings have reported that TMAO promotes brain aging and cognitive impairment. Moreover, we have observed higher levels of hepatic FMO3 and TMAO in the brains of Alzheimer’s disease mice (3xTgAD), and type 2 diabetic (db/db) mice. However, there are currently no inhibitors for FMO3 available. Therefore, in the current study, we investigated the design and development of novel FMO3 inhibitors in silico using the Schrodinger computational modeling software. In our investigation, we discovered that the asparagine 78 residue is highly conserved and an important residue for FMO3 activity. We then developed a library of compounds with ranking potential for inhibiting FMO3. Many of these compounds were synthesized and tested using FMO3 hepatic microsomes. The development of this assay was critical for the advancement of our compounds. Our assay focuses on measuring the conversion of TMA to TMAO by HPLC. Conclusion: We predict that our inhibitor will reduce TMAO levels in our animal models. Second, our FMO3 inhibitor will reduce blood glucose levels and gut dysbiosis.

Abstract Name: Analysis of German First World War Propaganda through Film

The effectiveness of German propaganda during the First World War has been largely debated since the conclusion of the war. Over the course of the war Germany, like many other nations, was attempting to understand the most effective way to sway public support for and the endurance of the war. German propaganda policy was lacking in the early stages of the war, but over the course of the war, they learned how to create effective propaganda policies that allowed them to continue fighting the war, even past the point of societal exhaustion. When tracking the evolution of the German film industry, the same trends are evident with the use of the motion-picture becoming increasingly common as the war progressed. The delay in the use of film as a propaganda medium was caused by the infancy of technology, but the increasing use and gradual centralization of film infrastructure allowed film to play a key role in late war propaganda. However, the far-reaching effects of film as a propaganda medium were limited with how late the centralization and bolstering of the film industry came. The impact of the investment into the film industry by the German government, created a foundation that allowed the German film industry to flourish well into the Weimar years. It is impossible to measure the impact that propaganda has on a society, as there is no tangible measurement for the effects persuasion has over the masses. In my research I focus on the unparalleled insight that the films provide us into the aims and methods of the propaganda campaigns of the Imperial Government, rather than the effects the films as a propaganda medium on society.

Abstract Name: Identifying the role seed mucilage plays in seed germination under drought stress

Drought significantly impacts farmers by causing water scarcity, leading to reduced crop yields and poor pasture conditions. Insignificant water availability disrupts agricultural activities, threatening the livelihood of farmers and affecting the overall food supply chain. Through this experiment we hope to gain an upper hand in the war against drought. Goal: This experiment is designed to expand knowledge of seed mucilage's impact on germination success under drought stress. The information obtained could lead to improving the agricultural industry, thus creating a more sustainable future. Seed mucilage can be defined as a gel-like, often sticky, substance that surrounds the seed when exposed to water. This understudied plant function is known to encourage seed dispersal, protect germination ability after passing through animals' digestive tracks, create symbiotic relationships through helpful bacteria who make mucilage its home, and protect the seed under drought conditions. Hypothesis: Seed mucilage increases germination success under drought stress. Plants selected to participate in the study must meet the following criteria: 1.) Displays potential for sustainability impact. 2.) Little/no existing mucilage research. This ensures a unique, goal-oriented research project encouraging the creation of a more sustainable world. The experiment involves: 1.) Dividing seeds into three groups: control (ideal conditions), heat stress, and drought simulation. 2.) Demucilaging half the seeds. 3.) Allowing time to pass so the seeds can germinate 4.) Compare germination success in demucilaged and unmodified seeds. For each variation of condition, the exact amount of water, temperature, sunlight exposer, humidity, etc. will be predetermined by the researchers to ensure the best results. The results of this experiment will determine how much of an impact seed mucilage has on germination success. The results will lead to a greater understanding of the understudied but important process known as mucilage synthesis, hopefully bringing us one step closer to a substantiable world.

Abstract Name: Infectious Disease RNA Structure Analysis Via Nuclear Magnetic Resonance

As observed in the recent Covid-19 global pandemic, infectious diseases can catastrophically affect our species. While vaccine research is unequivocally a crucial aspect of combating the effects of infectious diseases, the development of antivirals and antibiotics is highly important as well. Therapeutics that specifically work to mitigate already infected individuals are valuable for populations that lack either widespread vaccine accessibility or vaccine acceptance. Mapping the structure of pathogen RNA is vital so that drugs can be developed that specifically target its physical makeup. To achieve this goal, Nuclear Magnetic Resonance (NMR) spectroscopy can be utilized to interpret the physical structure of RNA. The RNA that I studied was a small fragment of Dengue virus. Primarily present in South America and the Middle East, Dengue viral infection can manifest with fever, nausea, body aches, and rash. While a primary

infection is often mild, contracting a second strain of Dengue can uniquely lead to more serious complications including hemorrhagic disease and hemorrhagic shock. The purpose of my experiment was to verify the accuracy of the computer-generated structure by comparing it to the RNA sample's imino proton region. Despite the findings of the one-dimensional analysis, the combined results of the experiments revealed that the original computer-generated RNA structure was inconsistent with spectroscopy results. One possible explanation is that the fragment of Dengue RNA could have multiple conformations associated with its structure. Further research involving the mapping of its three-dimensional structure is needed to come to a more specific conclusion.

Abstract Name: The Effects of Gender and Parents' Perceptions on Children's Science Identity

This study evaluated children's science identity and effects of parents' beliefs about their own and their child's science identity. Previous research suggests parents have an impact on the way children see themselves. Additionally, gender can influence how children describe their abilities, especially within the STEM field. To expand on this, the current study examines whether parent's belief of their child's science ability would impact the way the child rated their own science identity and whether child's gender impacted this relationship. The study sample included 422 parent-child dyads who completed an online questionnaire. Children were between 8 and 13 years of age. Based on regression analysis, there was a significant positive relationship between the parent's belief of child's identity and the child's own science identity. There was also a small, yet significant, difference in how parents rated their child's science identity depending on the child's gender. Specifically, parents tended to give lower child science identity scores if their child was female. However, a subgroup analysis showed that this difference was only significant for fathers, whereas mothers' child ratings tended to be more related to their own science identity. In addition to this, girls generally rated their own science ability lower than boys did. Therefore, this study supports the prior findings regarding children's identity and parental influence, while expanding to include new relationships involving gender. There tends to be a large gender gap in the STEM-related occupations and this study offers insights into possible explanations for it. This research also shows the importance of parents in addressing the STEM gender gap, since children are shown to value what their parents believe about their capabilities. Interventions should focus specifically on boosting fathers' awareness of their personal biases and subconscious tendencies that may hinder their daughter's scientific identity and career plans.

Abstract Name: Visualizing Holocaust Testimony

With the end of direct survivor testimony, the transmission of Holocaust memory becomes complicated by its mediation through the voices and narratives of subsequent generations. The need to confront how the Holocaust has shaped the contemporary global landscape seems more urgent than ever. While the Holocaust may seem like history, there has been a shocking rise in antisemitic violence since the end of World War II. Thus, this project has important implications for the study of contemporary expressions of intolerance and prejudice. Recent Holocaust testimony has expanded to include the hybrid genre of Holocaust graphic novels and memoirs. A newly published collection of graphic stories, But I Live, is an innovative approach to Holocaust representation – facilitating a polyphonic dialogue among scholars, survivors, and graphic artists. But I Live, edited by Canadian Holocaust scholar Charlotte Schallié, consists of three chapters narrated by four adult child survivors and illustrated by three comics artists. The book concludes with scholarly historical accounts of the role of Nazism in rupturing the lives of these narrating survivors. Our project reflects on the ways in which Holocaust testimony is negotiated through these multi-generational, overlapping voices and perspectives. But I Live moves from individualized experiences of survivors to a historical account of the collective mass destruction of lives and communities. Specifically, we examine the impact of the survivor-witness relationship on representing Holocaust testimony in the third chapter of the volume, titled "But I Live," and its unique approach to the transmission of traumatic memory. We examine further the ways in which comics artists, in reinscribing survivors' narratives, create a visual testimony to memory by recreating the material landscape of trauma. Together, these voices raise important questions about forms of testimony and witnessing as well as the future of Holocaust representation in K-12 educational curricula.

Abstract Name: The Anti-Metastasis Mechanism of Cucurbitacin B on Non-Small Cell Lung Cancer Cells

Abnormal, uncontrolled growth and cell division form tumors where cancerous cells can break away and move into the bloodstream spreading to other parts of the body in a process called metastasis. Metastatic cancer cells can dissociate from neighboring cells and become individual migratory cells by altering the cell adhesion repertoire. Earlier studies identified cucurbitacin B as an anti-metastasis agent where the actin filaments in cancer cells appeared severed and aggregated upon cucurbitacin B treatment. This study utilized human non-small cell lung cancer (NSCLC) to understand the effect of cucurbitacin on cell adhesion by western blotting. First, consistent with the earlier result, NSCLC cells treated with cucurbitacin B showed a significant decrease in beta-actin protein, a component of the actin filament. Surprisingly, we saw no change in tubulin protein, a component of the microtubule cytoskeletal system, indicating that cucurbitacin B targets the actin system specifically. Cucurbitacin B also caused a significant decrease of N-cadherin, a known pro-metastasis protein, and an increase of E-cadherin, a known anti-metastasis protein but, had reflected no changes of OB-cadherin, an adhesion molecule that was expressed at high level in the bone-metastasized prostate cancer cells, in cucurbitacin B-treated NSCLC. Finally, we observed that MAPK signaling activity had increased three times but the STAT3 pathway activity decreased slightly. Our results begin to reveal the molecular mechanisms of the anti-metastasis activity of cucurbitacin B and suggest the close association of the MAPK and STAT3 signaling pathways with NSCLC metastasis.

Abstract Name: Strategies Used in Minnesota for the Unwinding of Medicaid Post-Public Health Emergency: July 2023

The public health emergency (PHE), declared in January 2020, allowed for continuous enrollment in Medicaid–a provider of healthcare coverage for roughly 72.5 million low-income and disabled Americans, which includes 1.5 million Minnesotan residents. The conclusion of the PHE removed this provision and enrollees are required to reapply for and resume yearly re-enrollment in Medicaid. The suspension of continuous enrollment in Medicaid is commonly known as the "unwinding." Due to the complexities of Medicaid and the unwinding, hundreds of thousands of Minnesotan residents may be without insurance post the unwinding. The purpose of this project was to understand the strategies used in implementing the unwinding of Medicaid in Minnesota. A standardized eight question interview tool was used to gather information regarding policy and strategy implementation for the unwinding period from eight public or private facilities and healthcare personnel in Minnesota. Public data from news publications, current literature, and non-profit, non-partisan health policy organizations was analyzed. The findings indicated that Minnesota's unwinding is led by the Department of Human Services and is implemented at the county level. State agencies are partnering with stakeholders such as insurance companies, social organizations, and healthcare facilities, to ensure that enrollees maintain health insurance. The common theme drawn from interviews was that strategies and communication are implemented inconsistently resulting in a fragmented approach to the unwinding in Minnesota. While it is premature to determine the effectiveness of strategies implemented in Minnesota's unwinding, the findings and data suggest that Minnesota's unwinding may have deleterious effects on individuals, healthcare organizations, and public agencies and that there are opportunities for more communication between state and county-level implementers. The next steps are to share the findings with interviewees and public and private social agencies. The authors will continue to monitor the unwinding in Minnesota.

Abstract Name: XBMAL1 and XPERIOD1 effects on Metabolism during Xenopus laevis animal cap differentiation

Circadian genes comprise a transcriptional translational feedback loop that regulates gene expression and metabolism over 24 hours in adult cells. For example, circadian genes control the concentration of NAD+ in a cell. BMAL1 and CLOCK transcribe Nampt which increases the concentration of NAD+, while PERIOD1 inhibits transcription of Nampt by BMAL1 and CLOCK and decreases the concentration of NAD+. Xenopus laevis embryos have no circadian rhythm, but the genes that control circadian rhythm are still expressed during embryonic development. In embryonic stem cells, these genes have been shown to affect a metabolic shift from glycolysis to oxidative phosphorylation during differentiation. Our overall goal is to determine the role circadian genes play in mesoderm specification and differentiation. Currently, we are testing whether a metabolic shift is detectable during early induction and specification of mesoderm in Xenopus laevis. To do this, we dissect pluripotent cells from the animal pole of Xenopus blastulae (animal caps) and treat with 10ng/ml activin to induce mesoderm. Then we measure glycolysis (ECAR) and oxidative phosphorylation

(OCR) over 12 to 24 hours using the Agilent Seahorse Xfe96 Analyzer. Unexpectedly, we observed a decrease in both ECAR and OCR after nine hours of activin induction. We hypothesize that circadian gene expression during this time affects the pool of NAD+ in the embryo, which can influence both epigenetic gene expression and metabolism. Our next experiment is to test whether CRISPR knockout (KO) of xPeriod1 and xBmal1 influence changes OCR and ECAR during mesoderm induction and specification.

Abstract Name: Changing the Communication for a Changing Climate: Effects of Climate Change Communication on Identity, Emotions, and Mobilization

A specific communication style and subsequent emotional response may best mobilize people interested in climate change mitigation efforts compared to people who are less invested in the issue. This study attempted to determine the most constructive emotions to evoke in climate change communication for diverse groups of people in a way that encourages pro-environmental behavior. Roughly 1100 participants surveyed were randomly assigned to one of three groups: a “fear” condition, a “hope” condition, and a control condition. All participants were asked a series of questions about their demographics, identities, values, and environmental attitudes. Following these sections, they watched a brief video to induce the corresponding treatment emotion. Finally, they indicated their likelihood of doing a range of self-reported behaviors related to minimizing climate change. Participants who had higher levels of climate change belief, concern, and motivation were expected to respond with increased pro-environmental behavior under the fear condition. Conversely, those with lower levels were expected to be more likely to respond with pro-environmental behavior under the hope condition. However, with our treatments and sample, only the hope condition seemed to mobilize participants near the middle of the identity distribution. Another important discovery was that the more impactful participants found the treatment video they watched, the higher the likelihood that they responded with pro-environmental behavior, regardless of the treatment condition. Additional analyses are being explored to further examine the interactions between identity, emotions, and mobilization. These results suggest that scientists, politicians, and other messengers must differentiate between various levels of climate change belief, concern, and motivation within peoples’ identities when communicating the need for action. They also point at the need to be conscious of which emotions, and the intensity of those emotions, arise in their audiences to make adjustments to what communication practices promote pro-environmental behaviors.

Abstract Name: Birth of the Magic Baby: An Exploration of Motherhood and Anti-Abortion Sentiments in Young Adult Fiction

A new literary trend is being born in the young adult fiction genre: the female protagonist and her Magic Baby. In this trope, young, white, economically stable female protagonists in relationships have an unplanned pregnancy that jeopardizes both the mother's and child's life. After the mother prioritizes the child's life, she is rewarded with a beautiful, supernaturally gifted baby. The birth, idealized qualities of the Magic Baby, and the baby's relationship with their mother reveal harmful anti-abortion sentiments; an obligation to keep the baby despite dangers to the mother's life due to the child's future potential, a glorification of life-endangering birth, and the idealization of self-sacrifice in motherhood that devalues the woman. Under the lens of anti-abortion and abortion arguments, the interpretation of novels containing The Magic Baby, Breaking Dawn, A Court of Silver Flames, and The Scarlet Letter, in conjuncture with peer-reviewed research papers based on teen pregnancy portrayals, stereotypes in young adult fiction, and how stories influence people, will be guiding the analysis. Overall, these extremely popular novels set a disturbing precedent by portraying unrealistic, dangerous, and anti-abortion expectations and valued qualities of motherhood, influencing young women's perceptions of motherhood. The "Magic Baby" model of the perfect mother comes at the expense of real women.

Abstract Name: Unearthing Inequity: an Exploration of Women Farmworkers Struggles In the Shadow of Racial Capitalism and Environmental Racism.

California agribusiness generates billions in profits annually, making the state the nation's top producer.However, the commodification of agriculture imposes a significant burden on the people who play an integral part in this success. Female farmworkers, in particular, are a vital but often marginalized group within this labor force.In this paper, I investigate how the intersection of race, gender, and labor influences the experiences of female farmworkers in California, focusing in particular on their working conditions and the impact of environmental hazards on their well-being. Using racial capitalism as a theoretical framework, I examine the ways in which women farmworkers encounter gender-specific challenges within the agricultural industry. By providing a more nuanced view of the challenges women face while working in the fields, this paper contributes to broadening the conversation around gender equality, labor rights, and environmental racism.

Abstract Name: Using DNA Nanodevices to Characterize Ion Levels in the Golgi Apparatus

In the pursuit of understanding and treating human diseases, there is a growing need to shift focus from cellular-level problems to a more detailed exploration of individual cellular compartments, known as

organelles, and their impact on human health. One crucial organelle is the Golgi apparatus, often referred to as the “post office” of the cell. Its primary role involves editing, tagging, and exporting proteins to prepare them for use in regular cellular functions. Malfunctions in the Golgi are implicated in various neurodegenerative diseases like Alzheimer’s, Parkinson’s, and Huntington’s, as well as conditions outside the brain such as osteoporosis, cardiac arrythmia, and colon cancer. The ionic environment within the Golgi plays a vital role in maintaining its biogenesis, yet our understanding of the key ion channels responsible for the production of proteins within the Golgi remains poor, with most candidate genes unknown. In the Krishnan lab, DNA-based fluorescent indicators have been developed to quantify potassium and pH levels in the Golgi. However, the ionic content of sodium and calcium remains undiscovered. Our study aims to characterize these sodium and calcium levels within the Golgi, providing a foundation for understanding the ion channels crucial to its function. To achieve this, we utilize our lab’s innovative DNA nanotechnology, employing ion sensors conjugated to double-stranded DNA (dsDNA) molecules. The dsDNA serves as a modular scaffolding that incorporates localization sequences to specifically target the Trans-Golgi Network (TGN), fluorescent sensors tailored for each ion of interest, and a normalizer dye for ratiometric imaging. These DNA nanodevices offer customizable sub-cellular resolution, enabling the investigation of organellar ion levels in a manner not previously explored due to a lack of proper technology. Our research promises to unravel essential insights into Golgi ion channels, which has enormous implications in the fields of cell biology and drug development.

Abstract Name: Stuttering Prediction with Machine Learning

Addressing stuttering is an important problem. It affects the quality of the affected person’s life. If machine learning algorithms can be designed to detect stuttering in audio files containing speech, there is great potential for helping people with stuttering communicate better. Automatic Stuttering Identification Systems are computer-assistive aids that help speech pathologists identify stuttering, often using machine learning models trained on audio samples of stuttering speech data. Recently, there have been some labeled (stuttering types) speech datasets made available to the public. The Sep-28k and FluencyBank datasets collectively account for 32,000 three-second audio clips containing labels on whether stuttering is present or not. This paper models the data using a variety of machine learning models: Decision Trees, Random Forest, Gradient Boosting, XGBoost, and CatBoost. We conducted different empirical case studies, including predicting an individual stuttering type; predicting different types of stuttering with one model; and predicting the presence or absence of any stuttering speech at all. The modeling features consisted of mean and root-mean-squared (rms) values of arrays from the Librosa Python package that analyzes audio data. We developed a novel feature, max_gap, which was the largest gap in the intensity vs time data, meant to find long pauses within the audio data files. The best accuracies were obtained with the XGBoost and CatBoost models, when trying to predict prolongation and sound repetition. Model accuracies computed on the test data are about 80%, which is competitive to some more advanced models. Both the prolongation and the sound repetition favored the tonnetz_rms feature in the models. The novel max_gap feature introduced in this paper was the most important feature for predicting the block stuttering type, which is intuitive because block stuttering involves a long pause in the stutter’s speech. Future work includes modeling with additional data sets and deep learning.

Abstract Name: Perfected Love in the Present Day: T.S. Eliot's Adaptation of Revelations of Divine Love in Little Gidding

In the final poem of Four Quartets, Little Gidding, T.S. Eliot seeks to invite his readers into a pursuit of meaning analogous to his own. Eliot's poem demonstrates that his search was undertaken partially through the writings of medieval Christian mystic Julian of Norwich. In T. S. Eliot: An Imperfect Life, Lyndall Gordon notes Eliot's belief in poetic form as a conveyor of meaning (390), shown by countless revisions of the poem, and suggests that Julian contributed the "transcendent calm"(391) present in Little Gidding. Naturally, Eliot values poetic structure and the tone of Julian's text, but these points in isolation do not fully capture the mystic's influence on Little Gidding. In Revelations of Divine Love, Julian of Norwich presents the spiritual journey as one beginning with a divine Call from God. This call elicits trust and love, which expand as one prays and eventually experiences divine revelations. The journey concludes with perfected Love found in God. Writing prior to secular modernity, Julian anticipates that her audience already desires this perfect Love and writes to intensify that desire. Centuries later, T.S. Eliot, living in war-torn, post-Enlightenment England, writes to a society which values rationality and sees no perfect Love in the midst of violence and fragmentation. Eliot recognizes that without an intellectual entry into a spiritual journey, his readers will never be moved to greater desire, prayer, or perfect Love. Therefore, Julian's text contributes more than tone; Eliot merges her description of the approach to God with a profound intellectual analysis of modern alienation. His poetry thus unites thought and feeling to provoke spiritual desire within a modern secular audience.

Abstract Name: Inhibitory Control and Race as Predictors of Unsafe Shooting in Children: Implications for Firearm Safety Interventions

Guns are the leading cause of death for children ages 1-19. Limited research exists on how children learn to use firearms safely. Within a larger study, children 10-12 years old were randomly assigned to receive either firearm safety training or nutrition education. The broader intervention involves 5 visits: baseline, two trainings, post-training, and follow-up. At baseline, participants complete inhibitory control tasks (prize bin, draw-a-circle, money choice) in addition to a hunting simulation. During the hunting simulation, participants view 8 different shooting scenarios, 4 of which are considered unsafe. It was hypothesized that children with low inhibitory control would display more unsafe shots at baseline than children with high inhibitory control. A total of 97 participants were included in present analyses (Mage=11.30, %Male=63.90, %White=68.0). Preliminary correlations showed that only prize bin was significantly associated with unsafe shots taken during the hunting simulation (r=-0.22, p=.03). An independent samples t-test determined that unsafe shooting differed based on race, such that black children took significantly more unsafe shots than white

children, t(92)=-2.31, p=.02. A linear regression included each inhibitory control variable as a predictor, race as a covariate, and unsafe shooting as an outcome. The model was statistically significant, F(4, 87)=2.66, p=.04, and both the prize-choosing task (p=.04) and race (p=.02) significantly predicted unsafe shots.

Abstract Name: Generation of Thiols via Pyridoxal Phosphate- Dependent Pathways Maintain Redox Homeostasis in Absence of Disulfide Reduction

Research conducted in the Schmidt Lab focuses on the reduction of cellular oxidants through thiol oxidation, particularly under conditions of significant oxidative stress. Investigations focus on the role of sulfur-containing methionine and cysteine amino acid metabolism in maintaining cellular redox balance. To quantify whole sulfur flux through metabolic pathways, we employ in vivo isotopic tracing in mouse models, enabling direct comparison between normal liver and mutant livers lacking the antioxidant enzymes Thioredoxin Reductase-1 and Glutathione reductase (TR/GR null). These models, exemplified by TRGR-null livers, are relevant for studying oxidative stress conditions that enzymes, cystathionine β-synthase (CBS) and cystathionine γ-lyase (CSE), can both form and cleave carbon-sulfur (C-S) bonds of amino acids including cystathionine, serine, cysteine, homocysteine, and others. Here we assessed the functionality of these enzymes present in a pathway that generates cysteine from cysteine via an initial C-S bond cleavage in Wildtype (WT) and TRGR-null mice. Our hypothesis suggests that complete knockout of these pathways in vivo should be non-viable, highlighting their relevance. Utilizing isotopically labeled amino acids, we traced sulfur, carbon, and nitrogen atoms from cystine or serine. These labeled amino acids were infused via jugular catheters in WT and TRGR-null mice, with half of the mice from each genotype receiving the inhibitor aminooxyacetate (AOAA) to block PLP-dependent enzymes CBS and CSE. Mass spectrometry was used to quantify heavy cystathionine, cysteine, and glutathione containing products. Tissue analysis revealed a significant reduction in production of antioxidant systems in animals treated with AOAA. This reveals the crucial role of CBS and CSE in maintaining cellular redox homeostasis under stress conditions wherein disulfide reductases become deficient.

Abstract Name: Bridging the Divide: A Comprehensive Analysis of the Implementation of Opportunity Investment Funds to Combat Inequality in Development.

The lack of development in lower-income areas is a pressing concern in Middle Tennessee. Despite overall economic growth in the region, significant economic disparities persist, with some communities failing to equally partake in this progress. This deficiency in lower-income areas exacerbates socioeconomic

disparities, restricting residents' access to quality education, healthcare, and job opportunities. Consequently, this perpetuates a cycle of poverty and hampers the region's potential for comprehensive economic growth and community advancement.In this research endeavor, my primary objective is to discern promising investment opportunities within funds that have demonstrated success in fostering development. By scrutinizing both nationwide successes and failures, I aim to pinpoint the key variables exerting the most significant influence on the outcomes of such initiatives. This exploration is designed to unravel the intricacies of economic conditions, local policies, community engagement, and effective fund management. The ultimate goal is to distill these findings into actionable insights, gauging their adaptability and applicability to the distinctive landscape of the Middle Tennessee area. Through a comprehensive analysis, I aspire to offer targeted recommendations for potential investment avenues, underpinned by a nuanced understanding of the region's specific challenges and opportunities. This research seeks not only to identify universal success factors but also to tailor these insights to the unique context of Middle Tennessee, ultimately contributing to informed and strategic investment decisions in the pursuit of sustainable development.

Abstract Name: Exploring Economic Methods to Synthesize Wood Biochar for Energy Storage Devices

While the world has made significant investments to increase the production of renewable energies, the materials used to store those energies still rely on fossil fuel-derived activated carbons, coming from materials such as coal and petroleum residues. As these materials are non-renewable, it is imperative that new and sustainable materials are found. Biochar, thermochemically transformed biomass in the absence of oxygen, presents a promising alternative with high surface area and tunable surface chemistry desirable for electrochemical energy storage. We investigated economic methods for producing bur oak biochar to replace the standard activated carbons as electrode materials for supercapacitors. Three synthesis methods were evaluated based on their operating temperatures, mass yield, setup cost, ease of use, and performance in supercapacitor electrodes: a top-lit updraft gasifier, the distillation of wood, and a biochar kiln. The resultant biochars were utilized in fabricating electrodes for coin-type supercapacitors and tested for their specific capacitance, cycling stability, and electrical conductivity. The gasifier demonstrated the best electrode material, with a specific capacitance of 70.14 F/g, cycling stability of 97.37% after 250 cycles, and an internal resistance drop of 55.80 Ω (all tested at a 0.5 mA charging current). This is close to commercially available carbons (83.55 F/g, 98.99%, 93.00 Ω), and outperforms the kiln (40.79 F/g, 123.03%, 239.8 Ω) and distillation methods (20.57 F/g, 97.72%, 112.2 Ω). The gasifier also possessed high operating temperatures (>550℃), low setup costs (~$50), a mass yield of 18.84%, and user-friendly operation. Future endeavors will focus on optimizing the gasifier biochar composition, exploring diverse wood species, and identifying more sustainable chemical activation agents.

Abstract Name: Potential Role of Adenovirus E4 11k Protein Toward the Inhibition of Interferon-beta Expression During an Infection

Adenoviruses are double-stranded DNA viruses that cause common upper respiratory infections. Early viral proteins will generate an ideal environment to promote viral replication. An early viral protein, E4 11k, has multiple functions, including the redistribution of PML nuclear bodies and cytoplasmic p bodies, leading to a potential alteration of their functions. The cell will attempt to respond to viral infection through nucleic acid sensors, such as RIG-I, that will induce type I interferon transcription, which can lead to an inhibition of viral replication. Retinoic-acid inducible gene I (RIG-I) is a viral RNA sensor that activates a signaling cascade to stimulate a type I interferon response. DEAD-box helicase 6 (Ddx6) was recently shown to bind to RIG-I to enhance its functions. E4 11k has been shown to colocalize with and bind to Ddx6, causing Ddx6 to go into aggresomes. Influenza and EV71, single-stranded RNA viruses, have also been shown to interact with Ddx6, leading to the modulation of RIG-I. Therefore, we hypothesize that E4 11k is binding to Ddx6 to modulate RIG-I, leading to a decrease of expression of interferon-beta. Human cells were infected with an Ad 5 wild-type virus and an E4 11k deleted virus for 12, 24, 30, 36, and 48 hours, and RT-qPCR was performed to evaluate expression of RIG-I and interferon-beta. When the expression of RIG-I and interferon-beta was normalized to GAPDH, an internal control, we found that a biphasic expression of both RIG-I and interferon-beta was present during the wild-type infection with peaks at 24 and 36 hours post infection (hpi) and decreases at 30 and 40 hpi. When E4 11k was not present, a similar expression pattern occurred; however, there was a sustained increase of interferon-beta expression present after 36 hpi, suggesting that E4 11k is necessary toward the reduction of interferon-beta expression.

Abstract Name: Application of Eye-Tracking for Fingerprint Examination

In latent fingerprint analysis, examiners compare the patterns and minutiae points between a known and unknown fingerprint to conclude the relationship between the two prints. To accurately present their results in a court of law, there must be established error rates for this process. However, the methods by which an examiner views features within a pattern are not currently understood, meaning the effectiveness or error rates of their reasoning process cannot be assessed. The purpose of this project was to contribute to the understanding of how fingerprint comparisons are completed and, in doing so, explain the validity and reliability of feature-comparison methods in fingerprint examination. To accomplish these goals, Gazepoint, a computer-based eye-tracking system, was mounted below the computer monitor and used to analyze the gaze pattern of examiners. Study participants viewed a set of ten latent fingerprints of variable difficulty and development technique before conducting a standard forensic examination. Once the examination was completed, the examiner was prompted to conclude identification (match) or exclusion (nonmatch). Heat maps created from the data were overlaid to assess similarities in comparison between examiners while fixation maps were used to identify the specific features examiners used as focal points. The expected

outcome of this project is to explain the validity and reliability of feature-comparison methods in fingerprint examination. Preliminary results showed that participants took about 16 minutes to complete the test set, or about 92 seconds per comparison. Comparison times were affected by the development technique used. For example, Fingerprints developed via WetWop took longer to compare than those developed with black powder. In addition, the false positive rate was assessed at 0.5%. However, this project only assessed novice examiners and therefore continued research is necessary to assess expert examiners and compare pattern examination techniques between the two.

Abstract Name: Upconversion and Downconversion Luminescence in Ln:Yb:Y3NbO7, Ln = Er, Tm

The photoluminescence of co-doped Y3NbO7 was investigated. Er3+ and Tm3+ were used as the activators and Yb3+ was used as a sensitizer. Six different phosphors featuring different doping levels of Er3+ and Tm3+ were prepared. Er3+ and Tm3+ had doping levels of 0.2, 2, and 20 mol %. The doping level of Yb3+ was kept constant at 20 mol %. In this project, we sought to understand how varying the concentration of Er3+ and Tm3+ doping impacts photoluminescence of the phosphors at room temperature. Polycrystalline samples were synthesized via solid-state reactions. The phase purity of the as-prepared samples was probed employing powder X-ray diffraction (PXRD). Using spectrofluorometry, downconversion and upconversion luminescence was examined. We first monitored the emission of the phosphors under UV excitation (i.e., downconversion). Er3+/Yb3+ co-doped phosphors are green emitters, whereas Tm3+/Yb3+ co-doped phosphors exhibit a blue color. The potential of using these phosphors as NIR-to-visible upconverters was also investigated. Samples were excited with a 980 nm laser and emission monitored in the 400–850 nm range. Contrary to what was observed in downconversion, the Er3+/Yb3+ co-doped phosphors are yellow-orange emitters and the Tm3+/Yb3+ co-doped phosphors were NIR emitters. The Tm3+/Yb3+ co-doped phosphors showed weak emissions in the NIR. Altogether, we have shown that light emission properties of these phosphors can be modulated by changing the excitation source. Additionally, we discovered that Tm:Yb:Y3NbO7 is a NIR emitter under 980 nm excitation. We expect to exploit this feature to develop a phosphor suitable for bioimaging.

Abstract Name: Depression, Shame, Social Media, and Diet Culture Impacting Harmful Eating Behaviors

Harmful eating behaviors, characterized by eating patterns with potential physical, emotional, or social harm, have become a prevalent issue across demographics. The increase in harmful eating behaviors is fueled in part by societal factors, cultural shifts, and the prevalence of social media that often perpetuates unrealistic body standards. The rise in harmful eating behaviors holds a significant risk factor for the development of eating disorders raising concerns about the potential long-term consequences for individual's well-being. In light on this, this study aimed to assess the impact of the factors of social media, diet culture, shame, and depression on harmful eating behaviors, particularly within the context of Egypt. The study included 149 participants with 37 males and 112 females from various age groups. The data was collected from a questionnaire of 58 questions in 5 sections each section assessing one of the factors. The correlation analysis indicated that there is a significant impact between shame, depression, social media, diet culture and harmful eating behaviors. Two linear regression tests we're conducted. The first multiple linear regression (F(4, 138) = 28.133, p < 0.001, R2 = 44.9%) indicated that shame (Beta = 0.674, p = < 0.001) and depression (Beta = - 0.218, p = 0.005) were significant predictors in the of harmful eating behavior. The second linear regression F(2,145)=56.267, p <0.001, R2=43.7%) result showed that depressed people experience less harmful eating behaviors if shame is not in play (Beta= -0.194, p=0.008) . The results highlighted the importance of shame and depression above the other variables and highlights a complex relationship between the factors studied.

Abstract Name: Nurturing Future Scientists: Child Science Identity as a Moderator in Science Media Engagement and STEM Career Aspirations

According to the U.S. Bureau of Labor Statistics, STEM jobs are expected to grow 10% over the next decade. Research has demonstrated that growth mindset and gendered science identities predict a desire to work in STEM across various age groups. Research examining children's science identity as a moderating factor in their likelihood of engaging with science media is lacking. This study analyzes data from a national survey of 424 parent-child dyads fielded by Dynata in May 2023. Using OLS regression, we analyzed the moderating effect of child science identity on 8- to -13-year-old children's engagement with science media and their reported desire to work in science. Results show a child's perceived science value is the most consistent predictor of science engagement and STEM career interest. Girls have lower science media engagement, but gender does not predict STEM career interest. Notably, there is a significant moderating effect of child's science identity in both models. Child's science identity moderates relationships such that parent's perceived science value and child age are stronger predictors of science media engagement when children have a strong science identity, and gender is a stronger predictor when science identity is weak. However, parent growth mindset and child's perceived science value are stronger predictors of children's STEM career among children with weak science identity. These results indicate that strategies for fostering children's science engagement and interest in STEM careers may vary based on children's level of science identity. Promoting a belief that science is valuable and boosting parents' growth mindset is especially important among children with weak science identity. Particular attention should be paid to girls with weak science identity who are unlikely to use science media. Further research should track long-term effects of science identity, science media engagement, and STEM career interest on actual STEM career outcomes.

Abstract Name: A Student-to-Teacher “Thank You”: Effects of Expressing Gratitude on Subjective Well - Being

The Actively Caring for People (AC4P) Movement—www.ac4p.org—integrates humanism and behavioral science (i.e., humanistic behaviorism) to promote the occurrence of interpersonal acts of kindness or prosocial behavior. This ongoing research assessed the impact of expressing interpersonal gratitude on various mood states of students after they delivered a customized thank-you card (TYC) to the instructor of their university class. As a benefactor of personal gratitude, a research student delivered a TYC to his/her instructor after class. The benefactor, as well as a second randomly-selected student in the class (i.e., in a Control group), completed a mood survey before and after the lecture. The survey employed a Likert scale to assess 19 mood states (e.g., vulnerability, confidence, interest, and happiness) with regard to one’s current emotional feelings, evaluating each mood state from 1 (Untrue) to 10 (True). The TYC included a section for the benefactors to express personal words of appreciation to their professor/instructor. Qualitative analysis revealed uniformly positive emotions from all instructors and from each of the 64 participants who delivered a TYC. The quantitative analysis demonstrated a significant 36% increase in the students' overall positive mood states, after delivering a TYC to their professor/instructor, compared to the control group that showed no significant change in the mood states assessed. The results of this study support the notion that expressing interpersonal gratitude can enhance a person’s subjective well-being (SWB) across multiple mood states. This study also highlights the disturbing lack of interpersonal expressions of gratitude on our University campus, and the need to design and implement interventions to increase occurrences of interpersonal gratitude expressions as an evidence-based strategy for enhancing SWB. Thus, this research accentuates the significance of gratitude for the enhancement of interpersonal relationships and SWB, as well as the application of humanistic behaviorism to cultivate an AC4P culture.

Abstract Name: Causes of Depression for International Students Studying in the United States.

The purpose of this research project is to identify and investigate the causes and lifestyle factors affecting depression among undergraduate international students attending a regional comprehensive university in the Midwest. Given the unique circumstances and stressors faced by the students studying outside their home countries, international students experience high levels of depression. Depression can impact these students’ overall health and affect their futures. Current research shows the prevalence of depressive thoughts for international students and the universities need to take more action. This project is designed to examine the relationship between a series of demographic variables such as age, domestic and international support

systems, financial security, length away from home countries, and areas of studies and depression. Primary research consists of the completion of 50+ surveys to international undergraduate students ages 18 to 25 at a comprehensive regional undergraduate university–in the upper-Midwest. The answers will be evaluated using analytical and statistical methods. This project is designed to examine the relationship between depression and demographic variables such as age, domestic and international support systems, financial security, length away from home countries, and areas of academic study. At the conclusion, I plan to report my findings to the university leadership and provide recommendations to encourage the university to help international students be more social, keep in touch with their families regularly, meet new friends, and provide information about where to find help if they feel depressed or lonely, and help them overcome this situation and educate everyone else about their situation.

Abstract Name: Simulating charge and exciton dynamics on quantum computers.

Open quantum system dynamics has gained increasing research interest due to its direct applications to quantum dynamics in the condensed phase, transport properties, quantum biology, and quantum error correction. Recent advances have uncovered many intriguing phenomena, such as environment-assisted exciton transfer, coherence trapping, enhanced quantum entanglement, information backflow, emergence of noncanonical equilibrium states, topological state preparation by reservoir engineering, etc. At the center of theoretical chemistry are the developments of methodologies and computational tools for simulating charge transfer in solutions and heterojunctions, as well as exciton transfer in macromolecules and molecular aggregates. As many of these processes are quantum mechanical and non-Markovian in nature, classical computer simulations can be prohibitively expensive.Since the insightful suggestion by Feynman and the pioneering demonstration by Lloyd, numerous works have emerged in seeking efficient quantum algorithms for quantum simulations. However, the quantum computer simulations of open quantum systems are in the nascent stage of development. In this work, we present a novel quantum algorithm based on Kraus operators that capture the exact non-Markovian quantum effect at finite temperature. The implantation of the Kraus operators on the quantum machine uses a combination of singular value decomposition (SVD) and the optimal Walsh operators that result in shallow circuits. We demonstrate the feasibility of the algorithm by simulating the spin-boson dynamics and the exciton transfer in Fenna-Matthews-Olson (FMO) complex in photosynthesis. The Noisy Intermediate Scale Quantum (NISQ) machine results show very good agreement with the exact ones. The algorithm development along this line could leverage the advantage of quantum computers to simulate quantum systems that are beyond the reach of classical computers.

Abstract Name: Design and Mechanical Assessment of Novel Bird Claw Biomimicry Inspired Upper Limb Prosthesis Models

Biomimicry for mechanical design refers to incorporating the form and function of existing processes from nature into design elements. Adapting biomechanical principles from natural structures specialized for grasping into current research with 3D printed bionic hand designs may improve robotic dexterity in picking up a wider variety of objects, and limiting degrees of freedom and actuators can streamline mechanical design. Bird claws are an ideal inspiration for robotics because of their limited joints, reduced number of actuators, and smaller palm size. Species of birds' claw variations lend biomechanical advantages for grasping motions related to perching, climbing, and hunting and may provide improvements beyond a human-inspired structure for specific grasping applications. Different bird species' unique toe configurations offer different prehensile movements, which are biomechanically specialized for their environments and lifestyles. Recent literature has developed flying drone landing mechanisms inspired by bird claws, which this work builds upon.This research designed, manufactured, and mechanically evaluated two robotic devices with different toe arrangements: anisodactyl (3 in front x 1 in back), commonly found in birds of prey such as falcons and hawks, and zygodactyl (2 in front x 2 in back), commonly found in climbing birds such as woodpeckers and parrots. The evaluation methods for these models included a qualitative variable-object grasp assessment, which highlighted design features that suggest an improved grasp - a small and central palm, curved distal digit components, and a symmetrical digit arrangement. To support the incorporation of these design features into upper-limb prostheses, a quantitative grip force test was conducted to demonstrate the design approach met the minimum mechanical load capabilities outlined in ISO and ASTM standards for prosthetic devices. These designs and comparisons offer insights into how the biomechanical advantages of these models can be harnessed to optimize the grasping functionality of upper-limb prostheses.

Abstract Name: "Beyond the Classroom: The Broader Socioeconomic Impacts of Secularism in France's Education System on Europe's Changing Demographics"

This research presents a comprehensive analysis of Laïcité, the French version of secularism, in the education system, contextualized within France's dynamically changing demographics. This mixed-methods study includes 25 in-depth interviews conducted in France with educators, policymakers, and students and an extensive online survey capturing a diverse range of the French population's perspective. The research specifically examines the impact of Laïcité on the assimilation of immigrants and diverse populations, set against the backdrop of evolving European identities and immigration patterns.A significant focus is on how recent notable laws, such as the Hijab Ban, and the rise of far-right, anti-immigrant sentiments in France, are influencing educational policies and practices. The research contrasts the differing American and French perspectives on education and social services, highlighting the unique challenges posed by the French context. The study delves into the complexities arising from the illegality of collecting demographic statistics in France, as well as the public's hesitation to adapt laws originating from the French Revolution. The research highlights how these factors impact the understanding and implementation of educational policies.By exploring these facets, the study offers a detailed view of secularism's socioeconomic

implications in French education, extending to broader European socio-political dynamics. It critically examines the interaction of Laïcité with public policy, international relations, education, and economics, providing insights into how these secular policies are perceived and enacted amidst a diverse and shifting population. Furthermore, the research evaluates the implications of these secular policies on the formation of a European identity, considering the continent's demographic transitions and the integration of diverse cultures within a secular framework. It aims to contribute to discussions on the alignment or discord between secular educational policies and a multicultural society, offering valuable perspectives for policy-makers, educators, and scholars in various disciplines.

Abstract Name: Investigating Gain of Function Toxicity in Alpha-1 Antitrypsin Deficient Alveolar Type II Epithelial Cells Using Induced Pluripotent Stem Cells

Alpha-1 antitrypsin deficiency “AATD” is one of the most severe hereditary causes of lung and liver disease, most commonly caused by the homozygous “Z” allele mutation in the SERPINA1 gene. SERPINA1 encodes for Alpha-1 Antitrypsin Protein (AAT), an important protein for the inhibition of the enzyme neutrophil elastase in the lungs. However, patients with AATD have decreased amounts of AAT circulating to the lungs as a result of misfolded “Z” AAT protein becoming trapped and accumulating in the liver. This loss of AAT function within the lungs leads to increased neutrophil elastase activity in the alveoli, causing tissue damage and predisposing patients to emphysema. In the liver, there is gain of function toxicity from the accumulation of polymerized AAT. We hypothesize that the accumulation of ZAAT protein in alveolar type II epithelial cells (AT2s) leads to ER stress and activation of the NF-κB pathway, further contributing to emphysema pathogenesis.We model AATD using homozygous mutant “ZZ” patient-derived induced pluripotent stem cells (iPSCs) and isogenic gene-corrected “MM” counterparts that have undergone directed differentiation to AT2-like cells (iAT2s). In order to quantify the expression of genes associated with cell stress, we carried out qPCR. To quantify the activation of the NF-κB pathway, we performed western blotting for phosphorylated IκBα and immunofluorescent staining for nuclear p65. Due to technical complications, the Western blot was inconclusive for phosphorylated IκBα. However, we found a significant increase in DNAJB4 and DDIT3 gene expression in ZZ iAT2s compared to isogenic controls. We also observed increased nuclear p65 staining in ZZ iAT2s compared to isogenic controls.Our results revealed increased expression of both cellular stress and NF-κB activation in our ZZ iAT2s compared to isogenic controls.These results suggest that endogenous production of ZAAT protein may injure AT2s through a toxic gain of function mechanism.

Abstract Name: The Effect of Cat's Claw Bark on Aggregation of hIAPP in Type 2 Diabetes

Type two diabetes (T2D) is a disease that occurs when the cells do not respond to the insulin created in the pancreas. Human islet amyloid polypeptide (hIAPP) is co-stored with insulin but is overexpressed and misfolded in T2D. Once misfolded, hIAPP forms amyloid deposits which lead to pancreatic β-cell death or dysfunction. Cat's Claw is a thick, woody vine that grows in the Amazon rainforest and the tropical areas of Central and South America. It has been used as a dietary supplement and treatment for Alzheimer's disease and cancer. The objective of this work aims to prevent hIAPP aggregation in pancreatic b-cells using extracted cats claw bark. Cats claw bark was extracted with ethyl acetate and filtered. MTT assay and cell morphology were examined to check for cell viability after the addition of hIAPP alone, cat's claw bark extract alone, and hIAPP and extract combined. Increasing amounts of hIAPP decreased cell viability, confirming the toxicity of hIAPP on RIN-m cells. Increasing amounts of cat's claw extract decreased cell viability as well but to a much lesser extent. hIAPP and cat's claw bark mix had no significant effect on cell viability, and the extract was not able to save the cells from the toxic effects of hIAPP. Different solvents can be used to extract cats claw bark in the future. Different concentrations of cats claw can also be tested with hIAPP to determine its ability to save the cells from hIAPP.

Abstract Name: Investigating the Effects of Trauma on the Resilience of Artsakh Students under the 2022 Blockade

In 2022, Azerbaijan orchestrated a blockade of the only road connecting the 120,000 ethnic Armenians in Nagorno-Karabakh, also known as Artsakh, with the outside world. While previous studies show the long-term and transgenerational effects of war on mental health, immediate effects on mental health were relatively understudied until recently. The 44-day 2020 Artsakh War (September 27-November 10, 2020) resulted in an estimated 5,000 Armenian casualties, displacement of half the Artsakh population, and ongoing captivity of Armenian prisoners of war. The purpose of the project is to see the correlation between resilience and levels of trauma experienced by students in blockaded Artsakh. To investigate this relationship, 16 college students participated in the anonymous completion of two online surveys based on the Brief Resilience Scale (BRS) and Impact of Events Scale-Revised (IES-R) validated questionnaires assessing trauma and resilience. The validated questionnaires could take anywhere between 3 minutes to 15 minutes. Preliminary results indicated that the trauma caused by the blockade was high enough to suppress the immune system functioning of 13 participants ($\bar{x} = 47.875$). Furthermore, trauma had a significant negative relationship with resilience, where the mean resilience of the participants equaled 2.83, which according to DSM-IV criteria is considered very low ($p = 0.0216$). Overall, the negative correlation observed between trauma and resilience suggests that individuals with higher levels of resilience may be better equipped to cope with the adverse effects of the blockade and experience lower levels of trauma. These results align with previous research that highlights the protective role of resilience in mitigating the impact of traumatic events on mental health and the well-being of the indigenous Armenian population of Artsakh.

Abstract Name: Examining Trait Anxiety Effects on Instrumental Avoidance Learning

Trait anxiety has been shown to be associated with differential responses regarding fear conditioning and avoidance learning. Additionally, individuals with fear anxiety have been shown to exhibit lower cognitive flexibility and react more sensitively and negatively to stressors than individuals with lower anxiety levels. As a result, due to higher levels of stress, trait anxiety may be associated with worse performance in terms of instrumental avoidance learning. Other studies have shown that anxiety is associated with increased sensitivity toward aversive stimuli, which may further affect performance in avoidance learning. This study aims to evaluate the effects of trait anxiety on instrumental avoidance learning. To analyze these connections, a total of 96 individuals were enlisted to fill out a set of questionnaires that were looking at how stressful experiences compared to individual personality traits affect instrumental learning. The questionnaires also measured their levels of discrimination exposure. Participants completed an aversive instrumental learning task, which involved pressing certain key responses in response to visual stimuli to avoid the presentation of an aversive sound stimulus. The results showed that there was a significant positive effect of trait anxiety on instrumental learning ($r = 0.234$, $p = 0.022$). Specifically, individuals with high trait anxiety had increased accuracy in task completion during the experiment. In addition, we found no significant correlation between other stress factors (early life discriminatory experiences) and task accuracy (ps > 0.617). The findings suggest that personality factors, including trait anxiety, can influence the learning behavior of individuals and hence serve as predictors of cognitive outcomes.

Abstract Name: Howard the Duck vs. the Modernity of Man: A Critical Analysis on the attitudes, and Metaphors in Howard the Duck

Steve Gerber created and published Howard the Duck from 1975 to 1979. The comic used satire to offer a social commentary of the times through the lens of an alien. Based on the comic series and placing it in context, I ask What does Howard the Duck communicate about the comic industry? And, what strategies did the creator of Howard the Duck use to affect the comic industry? To address that question, I analyze Howard the Duck issues #1, #16, and #21. The first issue is the characters first great big solo adventure that lays much of the groundwork Gerber would later explore and expand within the entire series. Issue 16 would be the first of Gerber's deviations from the standard and publish his own unfiltered thoughts through the medium on the medium. Issue 21 is Gerbers direct response to Disney's lawsuit, and details his clear frustrations, and disagreements with the company. Through genre and metaphoric rhetorical perspectives, I argue Steve Gerber was a visionary that was ahead of his time, he was frustrated with the medium, and sought to point it out within the pages of Howard the Duck. Comic books to tell the superhero story constructed the genre way back in 1932 with the publication of Action Comics #1 and the introduction of Superman, however times changed and the genre was not relegated to simple black and white storytelling rather than expanding on the realistic more complex nature of the character. Howard the Duck was the trailblazer that offered a shift in

heroic dynamics. On top of utilizing metaphors in satire to be able to highlight the issues that the industry had gotten comfortable on that was causing its own downfall.

Abstract Name: Epidemiological Examinations of COVID-19: A Literature Review of Forecasting Research to Improve Public Health Responses

The COVID-19 pandemic revealed many challenges that were often overlooked or never addressed. From how people learn in school, commute to different locations, socialize, buy groceries, and even how they access healthcare. Epidemiology is the study of infectious diseases which deals with the incidence, distribution, and possible control of diseases and other factors relating to health. The analysis of population health shapes how society responds to these diseases both biologically and socially. This is important as examining relevant resources on past, current, and developing epidemiological practice barriers, and their impact on not just COVID-19, but other diseases can help improve future responses. In this project, understanding the barriers of these epidemiology practices will be examined with a close look at how they impacted the COVID-19 pandemic. A literature review of sources since 2021 from the National Library of Medicine, including statistical, mathematical, and computational sequences aimed at describing, modeling, and forecasting the spread of diseases in these contexts will be utilized. Findings from the literature view suggest there are many factors that contribute to a lack of understanding on how to mitigate the spread of COVID-19 in public spaces. Examples include social determinants, access to health care, and misinformation. Implications of these findings suggest there needs to be a reform of how information is shared with the public to accomplish a more cohesive social and medical response to public health emergencies in the future.

Abstract Name: How does the yellow starthistle affect the surrounding soil moisture at Big Break Shoreline Regional?

Yellow starthistle (Centaurea solstitialis) is a highly invasive plant species in North America that poses a danger to agriculture, wildlife, and biodiversity. Despite its potential to overtake native species, little is known about its impact on soil moisture levels in invaded regions such as Big Break Regional Shoreline in Oakley, California. In this study, we aimed to investigate the impact of yellow starthistle on soil moisture in the park. We hypothesized that the plant absorbs more soil moisture than it needs due to its dry environment

origins (Mediterranean Basin). To test this hypothesis, we collected soil samples from locations with and without yellow star thistle and assessed their moisture content. Our statistical analysis revealed a significant difference in soil moisture levels across the three sites ($F = 47.73913$, $p = 0.000036$), indicating that yellow star thistle is associated with lower soil moisture levels. These findings have important implications for understanding the impact of this invasive species on its surrounding environment and for developing effective management strategies. However, our study has limitations as we only collected data across three sites and five points in time. Further research with more extensive data collection is needed to confirm our findings and to better understand the mechanisms by which yellow star thistle absorbs soil moisture.

Abstract Name: Detection and Suppression of Parkinson’s Disease Tremors

Parkinson's Disease affects over 10 million people globally, causing various motor problems, including tremors. A prototype device has been developed to automate the detection and suppression of tremors using Soft Robotics and granular jamming. The device works by detecting vibrations from hand movements, analyzing the frequency to confirm the presence of a tremor, and triggering a wrist cuff filled with coffee grounds. The vacuum-induced rigidity of the coffee grounds creates a rigid exoskeleton-like structure around the trembling hand, arresting the tremor. The device was tested by simulating tremors on a skeletal hand, and out of 50 trials, there was a 92% tremor detection accuracy and 100% suppression activation accuracy. The device reduced tremor-induced movement by 84.6%, making it an effective and non-invasive alternative to costly and invasive treatments like surgery and drugs. This innovation can significantly improve PD patients’ qualities of life at a low cost of under $25.

Abstract Name: Culture of Abundance Robs Consumer Satisfaction: An Analysis of the Paradox of Choice

The paradox of choice, initially proposed by Barry Shwartz in 2004, suggests the theory wherein an abundance of choice leads to diminished consumer satisfaction: a phenomenon counter to intuitive expectations. This paper employs a mixed method approach incorporating both quantitative surveys and qualitative interviews to gain deeper insights as to how the prevailing culture of abundance within the United States influences consumer satisfaction. Findings reveal that an expanded choice set can exert adverse impacts on purchasing behaviors, including decision fatigue and paralysis. Participants reported feelings of anxiety, overwhelm, and dissatisfaction when confronted with an ample array of selections, leading to a consequent heightening of regret and diminished contentment with their choices. Nevertheless, research indicates that the repercussions of choice abundance can be mitigated. Individual characteristics such as decision-making style and personality traits play a moderating role, with individuals exhibiting heightened

decisiveness and stronger desires for closure generally experiencing less susceptibility to the consequences of overload. Implications of the study underscore the importance for marketers to exercise caution regarding the harmful effects of extensive choice sets. Strategies to help enhance satisfaction may include reducing option size, extending guidance in decision-making, and offering pathways to simplify the buying process. Further research is suggested to explore the paradox in diverse cultural and contextual settings.

Abstract Name: Cardiomyocyte GSK-3β Interaction with Immune Cells: A Regulator of Inflammation

The role of cardiomyocyte glycogen synthase kinase-3β (CM-GSK-3β) in the adult heart is not fully defined. To investigate its role, an α-MHC promoter-driven, inducible CM-GSK-3β knockout (CM-GSK-3β-KO) model was utilized. Mice were subjected to a tamoxifen (TAM) chow diet for 2 weeks at 12 weeks of age, followed by regular chow for an additional 5 weeks. Post-TAM protocol, electrocardiography revealed reduced ejection fraction and fractional shortening in KO mice, indicating severe systolic dysfunction and dilative cardiac remodeling. Masson's Trichrome staining demonstrated increased fibrosis in the KO heart. Flow cytometry analysis revealed an elevated frequency of infiltrated CD45+ leukocytes and myeloid cells in KO mice, suggesting potential cross-talk between cardiomyocytes and immune cells. To validate these findings, a co-culture experiment was performed. Adult cardiomyocytes (CM) were isolated from CM-GSK-3β knockout and control mice following a 30-day washing period post a 14-day TAM diet. Isolated adult cardiomyocytes were cultured, and the supernatant or conditional media was collected post 48 hrs. Bone marrow (BM) cells were co-cultured in the conditional media to study the impact of CM-GSK-3β on myeloid immune cells. After 72 hours of co-culturing in the conditional media, immune cell polarization and inflammation markers were analyzed using flow cytometry and qRT-PCR. The results demonstrated that GSK-3β regulated inflammation on myeloid cells. The absence of GSK-3β in cardiomyocytes led to increased proliferation of immune cells, accompanied by a pro-inflammatory phenotype as evidenced by flow cytometry and qRT-PCR analysis.

Abstract Name: Utilizing Stereolithography to Engineer Multi-Well Systems for Organoid Culture

Organoids and three-dimensional spheroids are multicellular aggregates that can model the complexity and physiology of tissue architecture and organs in vitro. Multicellular organoids and spheroids have become a standard in tissue engineering, serving as highly applicable tools in bioengineering, drug development, and

investigating the effects of disease on cellular phenotypes and function. Specifically, we developed hepatic organoids that co-aggregate primary hepatocytes with non-parenchymal cells, such as fibroblasts, to study and model liver function. To diminish the heterogeneity during organoid and spheroid formation, we utilized photolithography to build a polydimethylsiloxane-based (PDMS) multi-well system that can accommodate the organoids. However, one substantial challenge that remains in organoid biology is ensuring the spheroids' survival over extended periods of time. Facilitating an environment conducive to their physiology is crucial since organoids are prone to detaching from their wells or losing their spherical shape. This poses a problem for studies requiring the model to be functional for multiple weeks or months. Using stereolithography (resin printing), we gained greater control over the design and specifications of each well and developed a more suitable environment for the generation of spheroid aggregates. By optimizing the dimensions and geometry of the multi-well system and applying this system to hepatocyte-fibroblast spheroids, we observed that this created a more stable environment for the organoids. Compared to previous multi-well systems, the optimized system increased the duration of the spheroid's lifespan over this period. Furthermore, we observed significantly higher albumin secretion levels over prolonged durations in the hepatocyte organoids of the optimized multi-well system. This demonstrates the versatility of resin stereolithography as a technique in engineering three-dimensional organoid systems and presents an opportunity for modifying and optimizing this multi-well system for culturing different types of organoids.

Abstract Name: How Do Social Essentialist Beliefs Predict Learning Motivation among First-Generation College Students?

Social essentialism refers to the belief that the categorization of individuals into social groups (such as gender and race) reflects innate, meaningful differences in people that are distinct and unchanging. Holding essentialist beliefs can result in prejudice and discrimination such as racism, sexism, and classism. However, little research has investigated the predictors of essentialist belief and its impact on academic motivation, particularly in first-generation college students. The current project aims to examine how first-generation status shapes essentialist beliefs about social class among college students. We will recruit 146 KSU undergraduate students from SONA. Participants will complete an online survey measuring social essentialist beliefs, academic motivation, and psychological well-being. We hypothesize that compared to non-first-generation students, first-generation college students will endorse lower levels of essentialist beliefs about social class because of their ongoing effort to alter their social status and the lived experience that accompanies their identity. Additionally, we anticipate that those with lower essentialist beliefs would have stronger academic motivation and better psychological well-being. Findings from this study could provide insight into contributing factors of essentialist beliefs and prejudice.

Abstract Name: Is Wealth Maximization Better Than Profit Maximization in Businesses

The Profit maximizing rule is a fundamental part of running a business that has been around for so long. In addition to profit maximization, wealth maximization is a more modern concept that has become a crucial component of businesses that is beneficial in building a business up and promoting longevity. In this paper, I will gather a large sum of data and information highlighting profit maximization and why it is vital for businesses to implement it. I will also do the same regarding wealth maximization and its benefits. The benefits of both the profit maximization rule and wealth maximization in businesses have been tremendous and have helped mold the economy to this day. Using the data, statistics, and other information I have gathered from various reliable sources, I will determine which of the two business assumptions is better for the overall success of a business. The profit-maximizing ideal is still vital in businesses today and will continue to be that way for a long time. Along with the maximizing profit-maximizing assumption, wealth maximization will continue to enhance a business. It is just a matter of which business assumption will be proven to be the most beneficial to the success of a business.

Abstract Name: Taking a Bite of the “Feedback Sandwich”: Investigating Order and Ratio of Feedback

We receive feedback every day (Mory, 2004), however, feedback does not always improve our behavior

(Bangert-Drowns et al., 1991). In this study, we aim to examine whether the content and format of feedback affects its efficacy. Instructors are taught to use the “feedback sandwich,” defined as a critical statement (i.e., constructive feedback) surrounded by two positive ones (Procházka et al., 2020). While there is some evidence supporting its use, the reason for the feedback sandwich's efficacy remains unclear. Perhaps the mere presence of positive feedback improves performance or perhaps the 2:1 ratio is critical. Furthermore, perhaps giving positive feedback first “softens the blow.” The goal of the current study is to examine whether the effects of the “feedback sandwich” are due to the ratio and/or order of constructive and positive feedback. Undergraduate students (N = 160) will be randomly assigned to receive constructive feedback in a 2 (positive feedback before or not) x 2 (positive feedback after or not) design resulting in four conditions: constructive feedback (C), constructive and then positive feedback (CP), positive and then constructive feedback (PC), or feedback sandwich (PCP). The feedback is given in the context of a writing task, with students receiving feedback after a first writing task and before a second one. We are measuring uptake of constructive feedback, self-esteem, writing anxiety, and self-efficacy. Data collection is ongoing. We plan to conduct a series of 2 (positive first) x 2 (positive second) between-subjects ANOVA on all outcomes. We expect both order and ratio of positive to constructive feedback to matter for feedback uptake, self-esteem, and self-efficacy. If these hypotheses are supported, we will highlight the importance of the feedback sandwich for enhancing uptake of constructive feedback in educational settings and workplaces and provide evidence for its mechanism (i.e., higher self-esteem and self-efficacy).

Abstract Name: "Cool" Japan Strategy in Japanese Popular Culture: A Critical Analysis

What some consumers of Japanese media and pop culture may not know is that Japan’s current image is part of an official image-based endeavor spearheaded by the Japanese government. Following the fascist regime during World War II, Japan heavily industrialized, becoming one of the world’s leaders of industry. As the economy grew stagnant, the government made an intentional move toward becoming an intellectual property-based nation. Japanese pop culture revolutionized, which brings us to the present, where Japan has a largely positive image internationally. This is known as the “Cool Japan”, a PR Strategy, which began in 2002, for the purpose of exporting popular culture, and making Japan seem more friendly internationally. However, this pop culture is not “cool” for everyone. Our analysis of examples from “Cool Japan” in text in image is informed by a feminist approach, as much of the exported pop culture is misogynistic. Through critical analyses of various Japanese popular cultural products, one peels back the deep-rooted misogyny which outlines female depictions, indicating harmful trends of hyper-sexualization and pedophilic sensibilities. An exploration of positive and negative depictions of female bodies and gender presentation in pop culture exports—through a new historicist and feminist reading—reveals the contemporary cultural understandings which further large-scale patriarchal hegemony in the “cool” strategy. First, we provide a literature review and synthesis of existing research on Japanese pop culture trends. Second, we analyze several representative images of Japanese “cool” strategies through a feminist lens, specifically shōnen media, which tend to be the most popular. Finally, we analyze government documents from the Japanese Cabinet Office and the Nihon-Gatari-Sho guidelines for the “re-narration of Japan”. We demonstrate an evolution in the rebranding of Japanese pop culture, providing a fresh feminist analysis of images and documents not previously studied.

Abstract Name: Faster R-CNN for microscopic image analysis.

In modern biomedicine, cell analysis plays an important role in diagnostics, treatment planning, and research. Cell counting, the process of identifying the number of individual cells in an image, is an important step in cell analysis. Cell counting is often conducted manually by humans and is both time and resource intensive. This task becomes even more difficult due to cell overlap, non-uniform backgrounds, variations in the shape and size of cells, and different techniques of image acquisition. Moreover, the variability in cell counts per image presents a significant challenge, emphasizing the need for adaptable methodologies. Addressing this need, Convolutional Neural Network (CNN) models have emerged as crucial tools for advancing cell image analysis. CNN models are a type of deep learning model specifically designed for processing and analyzing large data, such as images. They use specialized layers that extract hierarchical patterns and features from an input image which improves accuracy in tasks like image recognition, object detection, and classification in comparison to traditional approaches. The goal of this research is to train and test a CNN model to accurately detect and predict the number of individual cells present in an image by employing Faster-RCNN, a CNN with region proposal. This work aims to improve automation and efficiency of cellular image analysis and test the potential of Faster-RCNN in biomedicine.

Abstract Name: 3D Reconstruction of an Axon Terminal in the Dorsal Striatum Releasing Both Glutamate and GABA from the Ventral Tegmental Area: A Study Using Correlative Light and Electron Microscopy

Introduction: The neurons that project from the Ventral Tegmental Area (VTA) to the Dorsal Striatum (CPu) are heavily implicated in reward pathways involved in drug use disorders. Recently, it was discovered that neurons from the VTA co-transmit glutamate and GABA neurotransmitters. It is known that cholinergic interneurons are common within the CPu but little is known how the VTA projecting neurons that co-transmit glutamate and GABA interact with the cholinergic interneurons within the CPu. The current study aims to determine the types of synapses a single VTA axon that releases glutamate and GABA makes on cholinergic interneurons in the CPu.Method: The study used correlative light and electron microscopy (CLEM) to investigate the aim. CLEM is a protocol that allows for fluorescent and electron microscopy images of the same section of tissue to be merged to label multiple neurons while visualizing the section in ultrastructural detail. We used vesicular glutamate transporter 2 (VGlutT2) to label glutamate, vesicular GABA transporter (VGaT) to label GABA, and choline acetyltransferase (ChAT) to label acetylcholine.Results: The single VTA axon that contains VGlutT2 and VGaT tags forms terminals that establish asymmetric (excitatory) synapses on ChAT-negative dendrites and dendritic spines. Also, the same VTA axon that contains VGlutT2 and VGaT

tags forms symmetric (inhibitory) synapses on a ChAT-positive soma. In the section of tissue, the axon interacted with at least nine different dendrites in the CPu.Conclusions: The single axon only interacted with cholinergic interneurons by forming symmetric synapses in the soma. The axon also interacted with at least nine different dendrites in the CPu, indicative of the modulatory power that a single axon from a single neuron has in the VTA to CPu circuit. Future research should replicate this study in other axons within this circuit to validate these findings.

Abstract Name: 3D-PRINTING AT THE POINT-OF-CARE: PATIENT-SPECIFIC PEEK ANKLE FUSION IMPLANTS FOR DIABETIC PATIENTS

Background: Failed total ankle replacements, ankle trauma, or destructive processes such as Charcot neuroarthropathy are just a few conditions that may be treated by ankle fusion (arthrodesis) surgery. However, post-treatment complications are common, with one cohort of diabetic ankle arthrodesis patients having a complication rate exceeding 75% due to issues such as infection and non-union which can lead to reoperation and, in severe cases, amputation. Current off-the-shelf ankle fusion cages fail to address the complex anatomies of ankle defects. Conversely, customized 3D-printed metal cages may pose challenges including metal allergies, cage subsidence, or long manufacturing times. Purpose: To address complex ankle defect anatomies in diabetic patients and to reduce implant manufacturing times, this study aims to define the design envelope for the development of patient-specific ankle fusion polyetheretherketone (PEEK) cages for 3D-printing at the point-of-care (POC). Methods: A dataset of patient CT scans with a primary cause of death of diabetes was analyzed to identify the smallest and largest ankle defects. These scans were segmented using CT segmentation software (DICOM to Print) to determine the size and shape of defects across various patient anatomies. The worst- and best-case cage designs were then modeled using nTopology and Geomagic Freeform software. Three-dimensional models of the cages were exported to 3D-printing slicing software (Simplify3D) for printing on a fused filament fabrication PEEK printer. Dimensional analysis and mechanical compression testing were conducted for each printed cage design. Results: Anticipated results from both dimensional analysis and mechanical testing are expected to confirm the printed cages' dimensions and strength of at least 3600 N (as per ASTM F2665: Standard Specification for Total Ankle Replacement Prosthesis), demonstrating promising results for clinical applications. Conclusion: This approach strives to shift current clinical standards for ankle fusion surgeries, especially in diabetic patients, through customized POC PEEK ankle fusion implants.

Abstract Name: Development of Preclinical Modeling Deep Brain Stimulation (DBS) Planning Software for Accurate DBS Electrode Placement

Deep brain stimulation (DBS) is an effective Parkinson's disease treatment. To target brain structures and place DBS electrodes accurately, preclinical preoperative imaging data requires subject-specific analysis. This study analyzed morphological brain differences in preoperative imaging data of rhesus macaque non-human primates (NHP) using anatomical and stereotactic neurosurgical software's electrode based coordinates. The Macaque Neuromaps Atlas provided coordinates for the dorsolateral subthalamic nucleus, a DBS target for motor movement regulation. By comparing Cicerone-generated STN coordinates for five NHPs with the reference Macaque NeuroMaps Atlas anterior-commissure STN coordinates, this study identifies significant differences of 14mm, 1.1mm, and 0.16mm in ML, VD, and AP coordinates, indicating a need for electrode relocation in DBS surgeries with software. The development of a user- friendly GUI with a DBS chamber can be integrated in 3D Slicer to meet Cicerone users' visualization needs. The study emphasizes accurate DBS electrode placement in preclinical models and improving DBS trajectory planning using Cicerone. DBS placement based on the Macaque NeuroMaps Atlas presents a detrimental impact on DBS surgical outcomes. Cicerone users will benefit from locating other brain structures through further developments of a 3D Slicer extension.

Abstract Name: The Weekend Warrior Effect: Consistent Intermittent Exercise Induces Persistent Cognitive Benefits

Our previous studies demonstrate that brief, 2-day reintroduction to exercise following a sedentary period can reactivate cognitive benefits, providing evidence for a molecular memory window where cognitive benefits are maintained. Here, we examine whether intermittent exercise (the weekend warrior effect: 2 days of exercise a week) displays similar or distinct cognitive benefits as previously examined with 14 continuous days of exercise. To test this, we used an Object Location Memory (OLM) task with sub-threshold training conditions to examine three distinct groups of mice: one with 14 consecutive days of voluntary wheel running (VWR), one with 2 days a week for 7 weeks (intermittent), and one with only 2 days (control). The results demonstrate that both continuous and intermittent exercise parameters similarly facilitate hippocampus-dependent memory compared to the 2-day exercise control group. To further assess the duration of these benefits, mice were provided with a 7-day sedentary period (brains were collected 1-hour post OLM for qPCR). Results demonstrate diminished benefits in continuous exercise and maintained benefits in intermittent exercise. Further, compared to continuous exercise, intermittent exercise mice exhibited elevated levels of Acvr1c and Bdnf in the dorsal hippocampus (critical genes for long-term hippocampal-dependent memory). Together findings suggest that consistent intermittent exercise persistently facilitates learning. Further, intermittent exercise may enhance the molecular memory window duration of exercise-induced cognitive benefits. Current work aimed at investigating the underlying epigenetic and molecular mechanisms allowing for the maintenance of exercise benefits on cognitive function will shine light on optimal lifestyle and therapeutic applications for cognitive enhancement.

Abstract Name: Sentimental Analysis using Machine Learning

In this digital age where everyone is on social networking platforms like Facebook, Instagram, and Twitter, opinions, and emotions expressed in these sites have been crucial for different entities. The information extracted can be used for business ideas, marketing, getting updated with recent trends, and communication. The feedback and ideas that people express on social media are also important for companies to boost their products or improve on drawbacks. For all these purposes, sentimental analysis can be used to analyze and evaluate users' attitudes and opinions from subjective texts. Sentiment analysis utilizes machine learning techniques and natural language processing (NLP) to identify the emotions behind texts. This involves pre-processing data, extracting crucial features/words, and evaluating polarity through diverse machine-learning algorithms. The process of sentimental analysis starts from unstructured data from the internet that includes spelling errors, sentence repeats are analyzed and removed. Significant adjectives are then chosen to categorize the data's polarity. Some researchers use polarity markings for each word/emoticon, aiding overall emotion determination. Feature extraction methods encompass Bag of Words, word embedding, word count, and noun count. Classification methods categorize data based on its features. We measure the performance of the classifier in terms of recall, precision, and accuracy. Machine learning algorithms stand out in this research due to their proven accuracy in various models. Sentimental analysis is an advancing field that can be used in most systems in this technological age assisting in good customer-company relationships, healthcare systems, crisis management, political analysis, marketing, and trading. Machine learning approaches constitute an essential part of sentiment analysis tasks. Hence, using the right approach with increased model performance measurements is essential to help us enhance the efficiency of sentimental analysis systems.

Abstract Name: Assessing the Dose-Dependent Influence of Acute Cocaine Exposure on Gcg Neuron Activity in the Caudal Nucleus of the Solitary Tract.

Glucagon-like peptide-1 (GLP-1), traditionally recognized for its role in glucose homeostasis and appetite, has emerged as a potential modulator of reward pathways in recent research, offering promise in understanding the neural mechanisms of cocaine addiction. Cocaine addiction poses a significant concern, with over two million regular cocaine users in the US, and its usage contributing to 20% of drug overdose deaths. Understanding these mechanisms can guide therapy development for cocaine addiction. Recent studies have highlighted the presence of GLP-1 receptors and GLP-1-producing cells (Gcg cells) in key areas of the brain associated with reward processing, such as the caudal nucleus of the solitary tract (NTS). Here we investigated the role of GLP-1 signaling on addictive behaviors, focusing on cocaine consumption.In a

behavioral assay, Gcg-GFP mice were randomly distributed into three experimental groups: 1) Saline, 2) 5 mg/kg cocaine, and 3) 20 mg/kg cocaine. 1.5 hours post-injection, the mice were transcardially perfused and their brains dissected. An anatomical characterization of Gcg cells in the NTS was performed. Post-perfusion, coronal brain sections, targeting the region of the caudal NTS, were cryosectioned using free-floating collection techniques. The sections were subjected to c-Fos immunohistochemistry, an effective method for mapping neuronal activation. The immediate early gene c-Fos, a molecular marker of neural activity, illustrated the brain regions activated by cocaine exposure. The sections were imaged using a Keyence BZX-800, and CellProfiler cell counting software was utilized to quantify Fos-positive nuclei and assess changes in neuronal activation. Analysis of this data establishes the impact of acute cocaine exposure on the activity of Gcg neurons in the NTS. Utilizing this data, future experiments could use chemogenetic transgenes to manipulate the activity of Gcg neurons to investigate their impact on cocaine-seeking behavior and the establishment of residual memories associated with cocaine exposure.

Abstract Name: Balancing Gender Equality and the Environment to Combat India’s Menstrual Waste Issues

In India, with over 355 million menstruating individuals, challenges persist for women in achieving proper menstrual hygiene management (MHM), crucial for gender equality. Despite governmental and NGO efforts, MHM schemes distributing plastic products contribute to a significant waste problem, harming the environment. To mitigate this, the government has installed incinerators in schools to balance product use with environmental concerns. Yet, a critical research gap questions the effectiveness and successful implementation of these incinerators. This project explores India's menstrual waste management, delving into incinerators' benefits and detriments as a disposal method for sanitary napkins. The goal is to scrutinize how stakeholders can address menstrual waste without compromising women's right to choose products aligned with their bodies. A comprehensive analysis of 12 menstrual health policy initiatives highlights gaps in the Indian context, while 54 in-person interviews with college students in Coimbatore unravel women's lived experiences with incinerators. The findings reveal a nuanced scenario, emphasizing the need for substantial improvements in policy development and implementation. The crux lies in reconciling gender equality and environmental sustainability, challenging the notion that they are mutually exclusive in addressing menstrual health. This research advocates for a holistic approach that transcends the dichotomy between personal choice and environmental stewardship, offering a clarion call for a more balanced and integrated strategy.

Abstract Name: "Vibe Check": Examining the Link Between Relationship Satisfaction and Life Goals

This study investigated the connection between life goals, individual well-being, and relationship satisfaction. Investigators hypothesize that partners with similar life-goal rankings will have higher relationship satisfaction levels. Previous research suggested that lack of similarity in partners' life goals is related to increased divorce rates. Conversely, perceived support for life goals within a marriage relates to increased marital satisfaction. Investigators did not find prior research that found a connection between differences in individuals' prioritization of life goals and couples' relationship satisfaction. As new approaches (e.g., Tinder) to finding a long-term partner are being developed, it is important to understand differences in partners' life goals and how they can influence the well-being of long-term relationships (e.g., families). The data can predict individuals' compatibility and well-being in relationships, which will help individuals form lasting, satisfactory connections. The study explores how partners prioritize their goals across seven domains: career, social life, immediate family values, hobbies and interests, religion and spirituality, healthy life choices, and forming personal and romantic relationships, and examines satisfaction and priority rankings between paired participants. The Couples Satisfaction Index (CSI) will be used to measure relationship satisfaction, and ranks for the life goals of individuals will be used to find critical differences in individuals' life goals prioritization. Investigators will compare different couples to examine the extent of similarity in their life goals ranking and relationship satisfaction. The findings will serve as a foundation for larger-scale studies to reveal crucial life goals to be ranked similarly between partners to make relationships more satisfactory. Additionally, the study may contribute a new theory on relationship satisfaction and the influence of life goals ranking to multiple fields in psychology, including family counseling, which will help people form healthier families.

Abstract Name: Studies on Diclofenac and its Metabolism

Drug induced liver injury (DILI), also referred to as drug induced hepatotoxicity, is a challenge to predict despite substantial preclinical and clinical testing. Several factors such as sex, age, weight, height, and BMI contribute significantly to DILI due to idiosyncratic reactions. There are various nongenetic and genetic factors that impact the way in which the body responds to xenobiotics. Due to the unpredictable nature of idiosyncratic reactions, it can be difficult to understand the detailed mechanisms of DILI. This project studies the metabolic degradation of diclofenac, a nonsteroidal anti-inflammatory drug, in order to gain a better understanding of its hepatotoxicity and its metabolic clearance. The involvement of liver enzyme cytochrome P450 responsible for metabolic degradation of diclofenac was studied. Various concentrations of diclofenac were incubated with rat liver microsomes. These microsomes are a rich source of cytochrome P450 enzymes. Following incubation, the samples were evaporated to dryness in order to isolate the amount of diclofenac remaining in the incubation mixtures. The loss of the parent drug was observed to determine toxic concentrations of diclofenac and its metabolic clearance. Quantitation of diclofenac was done using Thin Layer Chromatography (TLC) at various time points followed by UV-visible spectroscopy at 276 nm. Over the course of this study, a method for determining the metabolic degradation of diclofenac by rat liver cytochrome P450 was optimized. The metabolic degradation was followed from 5 minutes to 45 minutes. The percent loss of the parent drug was found to be 5%,10%, and 14%, at 5, 15, and 45 minutes respectively. It is believed that metabolic degradation continues beyond 45 minutes, and future studies are planned to follow degradation for extended time periods.Keywords: diclofenac, cytochrome P450, thin layer chromatography

Abstract Name: Tumor Phagocytosis by Macrophages in Prostate Cancer

While immune checkpoint inhibitors are effective in subsets of patients across multiple malignancies, their efficacy is limited in metastatic, castrate-resistant prostate cancer patients (mCRPC). mCRPC demonstrates a “cold” tumor microenvironment (TME) with a sparse immune cell infiltrate. This “cold” TME contributes to the lack of effectiveness of immune checkpoint inhibitors and immunotherapy. Tumor-associated macrophages (TAM), are key immunosuppressive myeloid cells that predominate the immunologically “cold” prostate TME. Within the TME, reprogramming TAM to work against prostate cancer cells could result in enhanced efficacy of immune checkpoint inhibitors. NLRP3 inflammasome is a complex of multiple proteins that activate the innate immune system and inflammatory response signals. Our laboratory discovered that ADT enhances NLRP3 expression within tumor-promoting M2 TAM. Using a small-molecule activator of NLRP3 (NLRP3 agonist), we propose to reprogram TAM, destroying tumor cells through phagocytosis. We hypothesize that the activation of NLRP3 will overcome TAM-mediated immunosuppression in ADT-treated prostate cancer, resulting in the sensitization of advanced prostate cancer to immune checkpoint inhibitors. Through conducting a phagocytosis assay, I aim to dissect the mechanism of how concurrent AR blockade and NLRP3 agonist (BMS-392959) treatment enhances phagocytosis of cancer cells by M2-TAM. I will also investigate NLRP3-primed phagocytic (NPP)-iBMDM expression of PD-L1 and CD86 following the treatment with ADT and NLRP3 agonists. My contribution to research with M1/M2-polarized immortalized murine macrophages will add to our understanding of the mechanistic basis of the NLRP3 inflammasome, crediting NLRP3 activation as a novel “macrophage phagocytic checkpoint” in advanced prostate cancer treatment.

Abstract Name: Review of Literature on the January 6th Insurrection

While working with Professor Valenzuela this Summer, I identified and read all the relevant literature that addressed political violence, anti-democratic behavior, elite messaging, partisanship, polarization, and racial consciousness. What follows is a theoretical synthesis of the literature and some potential research questions that come out of it. In terms of explaining the insurrection at the Capitol on January 6th, I will argue that those who participated had an underlying grievance surrounding their attachment to white identity which was activated by political elites through the construction of a narrative of a stolen election. Election fraud is the respectable veil for a deeper desire to protect white political power and priorities.Through historical analysis, Rachel Kleinfeld identifies 4 risk factors for electoral violence: highly competitive elections, partisan divisions based on identity, electoral rules that enable winning based on exploiting identity cleavages, and weak institutional constraints on violence. In 2020, the United States exhibited all four of these characteristics. While Kleinfeld (2021) gives us an explanation for why there was violence around the 2020

election, it does not help us identify why certain individuals were more likely than others to engage in political violence and undemocratic behavior. The popular explanation espoused by the right is that most people were at the Capitol to protest election integrity and the alleged fraud of Joe Biden and the Democrats. However, the literature suggests that even though 'election integrity' is the explanation, the far-right was actually motivated by a perceived attack on white identity and white power.

Abstract Name: Information Distortion of Visual Stimuli in Making Predictions

Decision makers often establish an early preference after being exposed to preliminary information about their choices—and this early preference can affect how subsequent information about choice options is processed. Importantly, such 'information distortion' can have a substantial influence on people's final judgments and decisions. In this study, we aim to test the role of information distortion when making predictions about future outcomes. Namely, we are testing whether people's initial predictions about potential outcomes can impact how additional prediction-relevant information is processed at a later stage—and how information distortion resulting from early predictions can impact final predictions.The study employs a paradigm involving visual stimuli as the primary or initial information presented as they are processed more fluently allowing for quick processing. Participants are presented with basic information about two artists and asked to make predictions about who won a prize. The art portfolios are equal in quality and different media (drawings, paintings, etc.) are presented at each trial and participants are asked for their evaluation of the art and prediction about the winner. We predict that after the first round of presentation of stimuli, participants would have a leading alternative that would influence their later evaluations and predictions about other media. Their initial preference would influence their judgment of other media and final prediction about who won the prize. This can also be tested with more real-world relevant contexts like looking at resume designs as the first information and predicting success of job application. This demonstrates how information distortion extends to a level beyond personal preferences, i.e., to factual analysis as well.

Abstract Name: Using Quantum Neural Networks (QNNs), Quantum Vision Transformers (QVT), and the Mathematical Morphological Reconstruction Algorithm (MMR) for Brain Tumor Detection

Brain tumors affect millions around the world, so detection is critical to helping doctors determine treatment. Currently, radiologists manually identify tumors through MRI (Magnetic Resonance Imaging) scans; however, this poses several limitations: it creates a heavy reliance on the experience of radiologists, has become increasingly costly and time-consuming, and is not as accessible to areas that lack the necessary resources and doctors. With the advancement of deep learning algorithms, a more accessible and efficient solution is possible. Given the existing research in classical Convolutional Neural Networks (CNNs) for tumor detection, Quantum Convolutional Neural Networks (QCNNs) and Quantum Vision Transformers (QVT) offer a promising approach to the problem. Mathematical Morphological Reconstruction (MMR), another image processing method, provides a relative metric for success in the QCNN, and is another classical alternative to CNNs. This research compares the accuracy and computational speed of the MMR, QCNN, QVT, and CNN algorithms to determine whether introducing a quantum aspect presents any noticeable advantage. To build these models, extensive datasets of MRI brain scans were collected. The MMR algorithm involved applying various techniques such as dilation, erosion, and skull stripping through OpenCV2's morphology functions. The QCNN algorithm utilizes quantum power to encode the data into a parametrized quantum circuit and apply convolutional and pooling layers. Futurewise, QVTS will be implemented with QCNNs for higher spatial understanding. So far, our results indicate that the MMR algorithm achieved up to 92% accuracy. These results will be compared with the accuracy of the QCNN, QVT, and CNN algorithms.

Abstract Name: A Correlation Analysis: Investigating the Gender Bias In High School Public Forum Debate

For the past few decades, there has been a clear difference in success between male and female debaters in high school and collegiate debate. The dominant explanation for this trend is gender bias – there are several gender stereotypes relevant to persuasive speaking such as brilliance, leadership, and assertion that can influence a judge's decision. While previous research focuses on the success disparity between males and females, speaker points have been untouched as a method of analysis. Speaker points are numerical values given to individual competitors by judges to assess their general speech and presentation throughout rounds. Previous research, however, has not focused specifically on the speaker points data and has also not controlled for representation. We use publicly available data from Tabroom to further study the gender bias in three of the most prestigious debate tournaments for high schoolers, using speaker points and overall representation as our metrics. The overall gender representation in entries is compared with the gender representation in Top 20 speakers to determine if an imbalance exists. In line with previous trends, it is highly likely that a gender bias is present in high school Public Forum debate, with male representation in the Top 20 speakers increasing roughly 6% to 8% from overall representation and vice versa for female competitors. Because speaker points are subjective, male speakers consistently receiving higher points than females compared to representation illustrates the general inequity in Public Forum debate.

Abstract Name: Association of Cyclooxygenase 1 (COX-1) rs4648298 and Cyclooxygenase 2 (COX-2) rs20417 Polymorphisms and Prostatic diseases Among Lebanese Males

Background: COX-1 and COX-2 genes encode prostaglandin-endoperoxide synthases (PTGS) isoenzymes,

involved in inflammation and possibly neoplasms. The genes are expressed in the prostate gland. Both genes have several polymorphisms. Here we examine the association of rs4648298 (A-G transition) and rs20417 (G-C transversion) polymorphisms and prostatic diseases. This research was approved by the Utah Valley University IRB. Materials and Methods: DNA was extracted from a blood sample of 56 healthy volunteers, 51 volunteers with benign prostate hyperplasia (BPH), and 61 volunteers with clinical prostate cancer (PCa). Genotyping was conducted through PCR-RFLP analyses. The restriction enzymes used were BaeGI (for rs4648298) and AciI (rs20417), respectively. Alleles with the restriction site were considered recessive. The association was inferred through statistical analyses of the distribution of the genotypes (BB, Bb, and bb or AA, Aa and aa), and allele frequencies among the controls and the affected groups. A p-value of ≤ 0.05 was considered significant. Results: The distribution of the genotypes is in Hardy-Weinberg equilibrium for all three groups. The b allele of the COX-1 gene is extremely rare (less than 3%), and no significant association between the B or b allele or BB, Bb, and bb genotypes and prostatic disease was observed. The a allele of the COX-2 gene is more common in the BPH group ($p=0.011$), but not the PCa group ($p= 0.472$) or the combined affected group ($p=0.068$) compared to the control group. Conclusions: There is no association between the rs4648298 polymorphisms of the COX-1 gene and prostatic diseases. The a allele of the rs20417 polymorphisms of the COX-2 gene is associated with higher risks of BPH and possibly PCa. The small sample size, sampling from one ethnic group, and the low distribution of the b allele in the Lebanese population are limitations of this study.

Abstract Name: A preliminary investigation on the association of the single nucleotide polymorphisms rs693 and rs10420331 of the APOB gene and prostate cancer

Background: The APOB gene encodes apolipoprotein B-48 and apolipoprotein B-100, which are major components of chylomicrons and LDL, respectively. Recent reports indicate an association between the single nucleotide polymorphisms (SNPs) rs693 and rs10420331 of the APOB gene and breast cancer. The APOB gene is expressed both in the breast and prostate gland to a nearly similar level. Breast and prostate tissues have lobular glands, and both tissues are sensitive to gonadal steroids. Here we investigated the association between the two SNPs and prostate cancer (PCa). This study was approved by the Utah Valley University (IRB #1013). Method: Blood samples were obtained from consented volunteers (50 years and older) who participated in a prostate disease screening campaign in Lebanon. DNA extracted from blood cells of 58 healthy subjects with no prostatic diseases and 44 subjects with confirmed PCa was genotyped by PCR-RFLP method. The restriction endonucleases XbaI and EcoRI were used for genotyping rs693 and rs10420331. Alleles with the restriction site were considered recessive. The association of the SNPs with PCa was tested by examining the differences in the frequency of the alleles (X or x, and E or e) and the distribution of genotypes (XX, Xx, xx, and EE, Ee and ee). A p-value of ≤ 0.05 was considered significant. Results: The distribution of the genotypes for both the SNPs is in Hardy-Weinberg equilibrium. No significant difference in the frequency of X and x alleles ($p=0.171$) and E and e alleles ($p=0.06$) and

distribution of the genotypes between the control and the affected group was observed. Conclusions: This preliminary examination showed no association between the SNPs rs693 and rs10420331 and prostate cancer risk. We are currently investigating a larger sample and included other prostatic diseases (including benign prostate hyperplasia) in this study.

Abstract Name: Women's Role in Shaping the Narrative of American History Textbooks, 1800-1865

Prior to the Civil War, history textbooks were an integral source of information about the American past to the public. Beyond conveying facts and figures, these books enabled writers to control the ideologies consumed by new generations of learners. The textbooks that surfaced during the first hundred years of the United States' existence provide a unique window into common beliefs of the time. They are widely understood to contain the creation story of America, casting the United States as a noble project launched by the European "discovery" of North America. This is especially true for textbooks authored by white women between 1800 and 1865, which enjoyed widespread readership, shaped standards for other history textbooks, and defined a broader sense of American identity.Although comprehensive studies of early American history textbooks have surfaced in the past decade, greater attention to the impact of women textbook authors is needed. In the early nineteenth century, educational reformers established numerous girls' schools across the United States, with over 180 such institutions founded between 1790 and 1830. As more women received formal schooling, they gained footholds in other areas of education, including the history textbook. Some women authors found immense influence in the educational community: their textbooks were read in multiple states, enjoyed numerous reprints, and, in the case of Emma Willard, were even copied by male authors. These women were heavily influenced by prevalent gender expectations casting women as civic and spiritual educators for their families. This study considers the contents of textbooks authored by women such as Emma Willard and Elizabeth Peabody, published between 1800 and 1865. Thorough analysis of textbook contents reveals abundant appeals to both civic virtue and providential support of Anglo-American colonization and expansion. These narratives created a distinct sense of American exceptionalism which was readily consumed by the public.

Abstract Name: Bacteria-Induced Internal Egg Hatching in Caenorhabditis elegans

The microbiome has been linked to many host-related health factors, including metabolism, immune function, and longevity. Mechanistically understanding how the microbiota impacts host physiological

processes can lead to the development of potential therapeutics. The genetic tractability of Caenorhabditis elegans makes it an ideal model organism to examine how bacteria impact host reproduction and life span. A lifespan experiment was conducted utilizing the wild-type C. elegans strain N2. These nematodes were raised on either Ochrobactrum BH3, a commensal microorganism found in their natural habitat, or E. Coli OP50, their conventional laboratory diet. The results indicate that BH3 induces a high percentage of internal egg hatching (28.0+9.8%), compared to a low percentage on OP50 (0.5+1.22%, p-value = .0001). This is a novel finding because previously pathogenic strains of bacteria have been reported to increase internal egg hatching but decrease life span. N2 was then screened with the CeMbio collection, a library of strains isolated from the natural C. elegans environment. This enabled the study to explore the role of bacteria in modulating reproduction and life span in manner physiologically relevant to C. elegans. Three additional bacteria that induce internal egg hatching were identified. This project explores the role of commensal bacteria in C. elegans reproduction and life span that might be conserved across other model organisms.

Abstract Name: Synthesis of N-Pyrazolyl and N-Benzotriazolyl Derivatives as Chelating Ligands for Ruthenium complexes

In this study we are preparing and studying 2,4- dimethylpyrazolynethylproponoate (L1), the symmetric (L3) and asymmetric (L4) isomers of N- benzotriazolylmethylproponoate, and their corresponding carboxylates. These are potentially hemilabile ligands that can coordinate to a metal through a heterocyclic nitrogen and/or an oxygen in the ester or carboxylate moiety. The solvent-free, catalyst-free Michael addition of 3,5-dimethylpyrazole with methyl acrylate resulted in the formation of an ester (L1) with high yields. L1 was allowed to react with tetrabutylammonium hydroxide (TBAH) to form the carboxylate anion (L2) of the ester as a viscous liquid. L2 was characterized using NMR and IR spectroscopy. L2 was allowed to react with RuCl2(PPh3)3 and the products were investigated with 31P NMR spectroscopy. These data indicate that the reaction yielded multiple products, which have yet to be separated and individually characterized. Under similar conditions, the Michael addition of benzotriazole with methyl acrylate yielded two isomeric esters (L3 and L4) which were separated by elution chromatography. When treated with TBAH, both L3 and L4 formed the corresponding carboxylates (L5 and L6). Treatment of these anions and the precursor esters with RuCl2(PPh3)3 is currently being investigated.

Abstract Name: Title: Impaired motor learning and molecular layer morphology changes in Rett syndrome mice with MECP2 deletion in Purkinje cells

Rett syndrome (RTT) is a severe autism spectrum disorder that primarily occurs in females. It manifests as cognitive and behavioral impairments, as well as repetitive behaviors, motor disabilities, and decreased social skills. RTT is caused by mutations in the MECP2 gene, which is situated on the X chromosome. Considering the role of the cerebellum in motor coordination and learning, we hypothesize that Purkinje cells, the principal neuron type in the cerebellum, are linked to motor dysfunction in mice with the absence of MECP2. In this study, we compared two mice groups: mice with MECP2 knocked out in Purkinje Cells (MECP2 PC cKO) and controls. The viability of the two groups was first confirmed using an immunofluorescence assay. We further examined motor learning by investigating classical eyeblink conditioning in which a signal light is paired with an air puff to generate a conditioned response. Our data shows that mice with MECP2 deletion in Purkinje cells exhibit impaired conditioned response, suggesting deficits in motor learning. We then trained mice in a forelimb-based motor task to monitor their performance in more difficult tasks beyond eyeblink conditioning. Lastly, immunostaining and western blotting were used to analyze the dendritic morphology and receptor density in the molecular layer of the cerebellum. Our data shows significant differences in the density of GluA1 and GluA2 AMPA receptor subunits between the control and knockout groups.

Abstract Name: Diet Change Over Time in the Ais Community of Cape Canaveral, Florida

Diet change over time is assessed for a Malabar II period (900 C.E. to 1565 C.E.) Ais Indigenous community in Cape Canaveral, Florida, at the Penny Plot site (8BR158). To this end, 7,760 faunal fragments were examined, with 1,876 identified at the species, genus, or family level. Through identification and analysis of faunal remains, it can be concluded that, while the amounts of overall remains left behind as a whole increased, there were no significant changes in the types of fauna utilized or patterns of consumption. This suggests that the indigenous people who occupied this site managed their food resources very effectively for a long period of time and likely passed on management strategies through generations to allow for plentiful food for years. The proposed resource longevity in this area corroborates with other precontact areas along the Southeast Atlantic coast of the United States, providing evidence that these indigenous coastal societies carefully sustained their resource supplies for centuries. This area of Florida has received little serious attention from scholars in the past, and through studying sites such as the Penny Plot site we are starting to paint a picture of precontact and colonial era Indigenous life in coastal Central Florida. Thus, we are better educating ourselves about the people who came first to Florida and their complex relationship with their surrounding environment, paralleling that of modern Floridians'.

Abstract Name: Convolutional Neural Networks for Density Map-Based Analysis of Adult Stem Cells Imagery

This research aims to investigate the use of deep learning methods for identifying and characterizing adult stem cells for nerve regeneration through chemical and electrical stimulation. Traditional methods of analyzing data from stem cell images can be time-consuming and subject to human error, making it challenging to derive accurate and consistent results. We propose using deep learning techniques to automatically identify and label stem cells in images with different staining methods and determine their boundaries and properties to address this issue. The deep learning approach is expected to enable faster and more accurate analysis of large datasets of cell imagery, providing a more comprehensive understanding of the behavior of adult stem cells under different conditions. Our proposed model uses a convolutional neural network (CNN) architecture to identify individual cells and place bounding boxes around them. We will train the model using a labeled image dataset collected at Iowa State University and evaluate its performance against attempted techniques. The trained model will help explore the possibility of electrical stimulation in modulating stem cell differentiation and potential applications for neural regeneration.

Abstract Name: Associations Between Religion and Mental Health

Research into the relationship between religion and mental health has grown dramatically over the past 50 years. The literature has demonstrated that religion can positively impact mental health by decreasing drug overdoses and suicide rates (Wojciechowska, 2021). However, it also revealed that religion can negatively impact mental health by fostering feelings of guilt and inadequacy (Ellison, 2014). This research investigated additional issues relating to mental health by exploring other connections between mental health and lifestyle factors. To do so, a questionnaire consisting of 76 multiple-choice and open-ended questions was developed using SurveyMonkey.com and delivered using Prolific.com. Prolific.com was also used to recruit 500 participants, restricted to U.S. citizens living in the continental U.S., 18 years old or older, and English-speaking. After an initial screening of the responses, the data from 44 participants were excluded from the analysis. All 500 participants were paid 3.00 USD for their participation. The initial analysis showed several significant findings. Using Chi-Square tests for independence, the responses to the question concerned with committing suicide and the responses to the question about being diagnosed with any mental disorders by a medical professional were found to be statistically significant (X2 (1, N = 456) = 49.141, p < .001). This may be because mental illness and thoughts of suicide are probably interrelated. The responses to questions about religion and mental health were not statistically significant. However, subsequent analyses may provide additional insights. The questions about mental health and religion may have been too general. Further research should address specifics of the religion, the extent to which participants believe in various aspects of their religion, and the depth of those beliefs. While specific results about religion and mental health were

lacking, other results from this study provide insights into the connections between mental health and other lifestyle factors.

Abstract Name: Do placebos have their effect because of cerebral laterality?

Layne Sherwood: sherw124@d.umn.edu United States, Minnesota University of Minnesota Duluth Psychology major Department of Psychology Faculty Mentor: Dr. Robert Lloyd This research project intends to explore the neurological basis of placebo effects. We hypothesize that the placebos differentially activates the left hemisphere. The right hemisphere of the brain mediates negative emotionality, such as pain. Research has shown that greater right frontal activity occurs as a response to watching films which elicit negative emotions. On top of this, people with damage to the right hemisphere tend to show manic symptoms, and inversely, people with damage to the left hemisphere show depressive symptoms thus illustrating that the right hemisphere mediates negative emotionality. To study this, participants are told that we are assessing pain thresholds of a medicinal plant extract. The experimental group is told they will be testing the effectiveness of a natural pain reliever, which is actually inert, and is applied to their hand. All subjects will be asked to hold a shock probe and to let go once it becomes too painful, but it is never activated. Neurological activity in the two hemispheres is computed by observing the power spectral density of alpha activity in frontal, temporal, and parietal homologues. The relative activity in the two hemispheres at these sites will be compared at baseline and during shock expectation. We hypothesize that lateralization of activity to the right hemisphere will increase with anticipation of shock, and that this shift in activity will be attenuated in the placebo group. Such results will help elucidate the neurological basis of placebo effects. Unexpectedly, multiple participants have reported feeling a shock from the probe, despite it having no ability to do so. This has shown us that suggestion can have a very powerful effect, especially in the context of this project.

Abstract Name: Understanding the Impact of ChatGPT on College Education: A Comprehensive Study

Recently, an artificial intelligence language model like ChatGPT has grown in popularity among college students, increasingly pervasive in higher education from academic tutoring to personal productivity. This comprehensive study will utilize information from academic papers found on Google Scholar and data collected among college students to analyze and assess the multifaceted impact of ChatGPT on college

education in terms of disciplinary perspectives, academic writing skills, STEM education, challenges in learning, ethical considerations, and the integration of AI tools in the classroom. By surveying students and educators, we analyzed how different majors use ChatGPT and its varying impact on the quality of academic writing, creativity, and critical thinking. Our research explored in-depth the perceptions of STEM students, assessing the unique challenges and benefits they encountered. We also discussed the ethical dimensions of using the ChatGPT, examining issues such as plagiarism and academic integrity. We further investigated the effectiveness of the tool in addressing specific academic challenges and compared it to traditional learning tools, aiming to gain insight into its broader impact on education. Moreover, we assessed the long-term impact of the ChatGPT on learning outcomes, exploring its effect on critical thinking development and overall academic success. This study ultimately presents educators with guidelines for responsible AI integration and advocates for the development of comprehensive institutional policies to navigate ethical considerations. Our findings provide educators, students, and policymakers with valuable insights into the dynamics of AI in higher education.This comprehensive study navigates the evolving landscape of ChatGPT in higher education, providing insights into discipline-specific dynamics, academic impacts, ethical dimensions, and the future integration of AI tools into formal educational settings.

Abstract Name: Examining the Effects of Walking Curriculum on Two Autistic First-Graders

Nature has positive effects on the mental, emotional, and physical wellbeing of children and adults. Nature-based learning (NBL) leverages these benefits to create an enriching and positive educational experience. Despite the evidence on the benefits of NBL, there is little research on its use with autistic students. Friedman and Morrison (2021) studied the effects of NBL with five autistic students, and they found that the students encountered affordances related to social and academic proficiencies. Additionally, the educators involved in the case study had positive outcomes. Friedman et al. (2023) also investigated practitioners' roles in facilitating NBL for autistic children. Four key themes were developed from interviews with practitioners from three countries, highlighting their active role in affirming and supporting autistic learners, while also uncovering the challenges faced by both autistic students and practitioners. Because school is often a stressful environment for autistic students, NBL offers an alternative way to support their social and academic needs. One form of NBL is called walking curriculum (Judson, 2020), which integrates outdoor walks with a curricular focus. My co-mentors and I are conducting a case study at an elementary school with one teacher and two autistic students in her class who go on walks every day. Our research questions are as follows: What are the effects of walking curriculum on autistic students? What affordances and challenges do autistic students and their teacher experience on walks with a curricular focus? What are caregivers' perspectives on walking curriculum with autistic students? Data collection includes interviews with the teacher, the two students and their caregivers, field notes on the walks, and document analysis. We will be collecting data from September 2023 until April of 2024, and we will use Braun and Clarke's (2021) reflexive thematic analysis to develop codes and themes.

Abstract Name: Furthering the Natural Language Processing Capabilities of Humanoid Robot Pepper through application of RLHF

Humanoid robots have the potential to revolutionize many aspects of our lives, from providing companionship, to assisting with tasks in the home and workplace. As they get older however, outdated software or hardware limit the utility which a humanoid robot provides. This project expands on the previously explored concept of integrating LLMs (Large Language Models)—to supplement and enhance the capabilities of such robots—by applying human-emotion analysis through RLHF (Reinforcement Learning with Human Feedback), and improving quality of response from such emotion detected. The subject of this project is the humanoid robot Pepper, by Softbank Robotics, a popular robot designed to interact with humans; however, due to its weak natural language processing (NLP) capabilities, it struggles to adequately articulate responses in human-robot conversation. Our previous approach incorporated PaLM2 into Pepper's existing system with the goal of improving the robot in conversation. A potential problem with the solution was the possibility of the LLM producing hallucinations which may confidently provide incorrect responses. By integrating RLHF, the robot is capable of determining the accuracy of provided responses from reading human facial features and modifying provided responses. The goal is that integrating RLHF into the robot's NLP system will significantly improve its ability to generate more coherent responses, leading to more natural human-robot interactions. Overall, this presentation will build upon the previous integration of PaLM2 by using RLHF to adjust responses. It's believed that the proposed approach can pave the way for developing more intelligent human-robot interactions in the future.

Abstract Name: AAV-progranulin gene therapy corrects phenotypes associated with progranulin deficiency up to one-year post injection

Frontotemporal dementia (FTD) is a common form of early-onset dementia and is characterized by neuronal dysfunction in the frontal and temporal lobes, resulting in progressive lingual and behavioral impairments. Mutations in the progranulin gene (GRN), which codes for the lysosomal glycoprotein progranulin, can cause FTD. Of the 70 identified pathogenic GRN mutations, the majority are loss-of-function, making AAV-progranulin gene therapy a promising approach for FTD. Previous work from my lab has demonstrated the effectiveness of neurotrophic AAV-mouse progranulin (AAV-mGrn) gene therapy in progranulin-deficient mice. Neurotrophic AAV-mGrn gene therapy can reverse lysosomal deficits, lipofuscinosis, and microgliosis observed in mice with complete loss of progranulin (Grn-/-) 8-10 weeks post AAV injection. However, the long-term effects have not been studied. To understand long-term effects of AAV-mGrn, Grn-/- mice were aged 6-9 months and then injected with AAV and allowed to age for 12 months prior to tissue collection. As a control, age matched Grn+/+ and Grn-/- mice were injected with AAV-GFP and allowed to age 12 months. To understand if AAV-Grn increases progranulin protein, we will use immunohistochemistry (IHC), ELISA, and western blotting techniques to measure the total amount of progranulin protein in brain regions as far as the cerebellum. To do this, we froze one hemisphere for ELISA or Western blot analysis and fixed the other hemisphere in 4% PFA for IHC. We hypothesize that there will be an increase in AAV-derived progranulin that leads to a correction in lipofuscinosis and gliosis phenotypes associated with progranulin deficiency using IHC for CD68 and Iba1. Together, these studies provide important data on the long-term effects of progranulin gene therapy up to one-year post injection.

Abstract Name: Assembling and testing an atomic force microscope to examine carbonaceous meteoritic fragments.

Atomic force microscopy (AFM) is a technique that can be used to analyze several properties of a sample's surface (e.g., optical, topographical, mechanical, chemical, magnetic and electrical properties) through non-destructive and accurate measurements with very high resolution at the nano- and micro-scales. In this work, we assemble and test an educational AFM system with different AFM tips and appropriate samples with the final goal of characterizing fragments of carbonaceous chondritic meteorites by examining their topography and mechanical properties, such as adhesion and hardness. These properties allow us to investigate what structures are on the surfaces of the samples and how they have stuck together. Our findings can provide

novel valuable evidence about how planets formed in our Solar System since carbonaceous chondritic meteorites are relics that date back to the origin of the planets. In addition, from a pedagogical point of view, this study was conceived as an undergraduate research project to expose students, in particular physics majors, to all the stages of an experimental scientific work.

Abstract Name: Method Development for the Extraction of Insensitive Munitions from Water

Insensitive munitions (IM) are compounds that can withstand a higher degree of stimuli without reacting. These compounds are used in military operations to prevent accidental, or enemy caused discharge of weaponry. 2,4-dinitroanisole, nitroguanidine, and nitrotriazolone are amongst the insensitive munition compounds. In addition to these IM compounds, after discharge they also develop the transformation products 2,4-dinitrophenol and 2-methoxy-5-nitrophenol. Although these munitions are beneficial to military operations they are left behind in the environment as small particles after detonation or discharge. These compounds are known to contaminate the ground or soil and various water sources. To investigate the harmful implications of these IM compounds a detection method must first be developed. The goal of this project is to create a method that can detect the IM compounds and their transformation products in water at high recovery rates. The goal will be achieved by using a solid phase extraction (SPE) process that is mix mode meaning it has reverse phase and anion exchange. First, the solid phase extraction recovery of the IM compounds will be tested in water. In addition, the solvents and resin will be tested and varied to improve overall recovery. Finally, recovered compounds will be analyzed through a previously developed liquid chromatography-mass spectrometry (LC-MS) method. As a result of the SPE testing, recovery of all the insensitive munition compounds is expected. The IM compounds are expected to elute through the chromatography column during the span of a 15-minute LC-MS run. In addition, the mass to charge ratios of the IM compounds are expected to be displayed on the mass spectrometry spectrums. This research is important because it will allow researchers to have a method for detecting these insensitive compounds in water. This research can eventually lead to the detection of other IM compounds that may reside in different mediums.

Abstract Name: TOBBACO USERS' PERSPECTIVE ON THE IMPACT OF COVID-19 PANDEMIC ON BEHAVIORAL AND CONSUMPTION PATTERNS IN A MIDDLE-INCOME COUNTRY: A QUALITATIVE STUDY

Purpose: To qualitatively evaluate tobacco users' perspective on the impact of the COVID-19 pandemic on the behavioral and consumption patterns within a middle-income country.Research Context: Brazil ranked third in the world in terms of total COVID-19 cases and deaths. Prior quantitative data showed discrepancy between consumptive pattern and higher chance of COVID-19 severity. It is relevant to research a broad set of tobacco products, both smoked and smokeless, which are common in low-middle income countries.Methodology: Participants involved were over 18 years of either gender and consumed tobacco products for a minimum of 12 months. Participants were recruited as a sub-sample of a survey study conducted nationally in Brazil. We conducted a qualitative study using focus groups with semi-structured interviews for data collection. We evaluated types of tobacco as well as health assessments and the use of the Fagerstrom test for nicotine dependence. The results of the focus group interviews were recorded and transcribed verbatim and took place 14 days apart from one another. Data were analyzed using an inductive content analysis.Results: The screening for unit of analysis resulted on two main themes; Theme 1: Behavioral and Psychological Factors Impacting Consumption and Theme 2: Consumption Patterns, Dependence, and Information. Negative changes in mental health, including increases in anxiety and stress levels, were identified as a potential barrier to quit during the pandemic. In addition, individuals in social isolation reported that the absence of social pressure was a facilitator to keep tobacco use and reduce motivation to quit. Despite showing awareness of nicotine usage in relation with COVID-19, stress with high-volume media contributed to increase in product.Conclusion: Discrepancies on consumption patterns were observed. Social isolation, awareness of nicotine usage, changes in routine, and absence of social pressure contributed to increase or no change in tobacco usage during COVID-19.

Abstract Name: Undergraduate Research for Learning from Public Spaces in Historic Cities

Successful public spaces in cities are key for enhancing social cohesion and improving health and safety. Learning from historic cities involves the development of representational and analytical tools aimed at capturing their essence as places of human interaction. The research reports mentoring undergraduate students for findings of the spatial analysis of twenty Adriatic and Ionian coastal cities, which addresses the question of how the network of public spaces calibrates different degrees of spatial enclosure necessary for creating successful social interactions. Cities in the littoral region include well-preserved historic centers that are renowned for the successful integration of urban squares into the urban fabric. For the purpose of this study, we define urban squares according to areas visible from key public buildings and measure the compactness and convexity of their shapes. We then plot the plaza shapes of all twenty cities in a two-dimensional matrix and classify them into groups that represent various degrees of enclosure and spatial interaction. The study discovers the existence of three main classes of plazas found in cities along The Adriatic and Ionian coastline, suggesting the effect of specific regional and national influences on urban form. On the one hand, the study develops analytical methods for capturing the degree of spatial enclosure of public spaces, and on the other hand, it suggests principles of contemporary urban design based on historical precedents

Abstract Name: CYBERBULLYING DETECTION SYSTEM USING MACHINE AND DEEP LEARNING

Internet use, particularly digital/social media and video games is growing daily. Everyone is becoming dependent on them from all ages and with many positive aspects, there are drawbacks as well, one of which is cyberbullying. Cyberbullying has effects on victims mentally, emotionally and physically. It includes low self-esteem, acting violently, despair, increased stress/anxiety, depression, self-harming/suicide, etc. Findings from this research study justify that it affects young people more which impacts their emotional development and overall safety. Real-time cyberbullying detection identifies and protects the target from further abuse and its effects. This study aids in determining the seriousness of the issue, and vulnerabilities that individuals can take advantage of to bully others. Additionally, understanding how various features for cyberbullying detection function assists in developing a strong and trustworthy system, making a healthy online community. Natural Language Processing (NLP) models assess the textual content, analyzing hashtags, and analyzing comments. Similarly, context in photographs is analyzed using Optical Character Recognition (OCR), which converts them into a machine-readable format for further examination. Deep Neural Network models, such as Convolutional Neural Networks (CNN), Long Short-Term Memory (LSTM), and Bidirectional LSTM (BLSTM). CNN is utilized for text/picture classification, LSTM is utilized for long-term dependency learning, and BLSTM expands the network's input by encoding data in both forward and backward directions. Classifiers like Support Vector Machine (SVM) and Naïve Bayes help in the detection of cyberbullying. A working cyberbullying detection system can detect cyberbullying on multiple platforms. With models being developed for different attributes providing results with high accuracy, the cyberbullying detection system contributes by leading us to a healthier online community.

Abstract Name: Predicting Cherry Blossom Day Using Machine Learning and Weather Data: A Comparative Study of Three Locations

The captivating phenomenon of cherry blossoms tree inspires our exploration into predicting their timing using advanced machine learning and statistical modeling. This project investigates regression models to predict the cherry blossom day of the year in three different locations around the globe (US, Japan, and Switzerland). Leveraging multiple data sources on weather and climate change (temperature distribution, number of climate incidents, humidity, rain, etc.), we developed predictive models to minimize the mean absolute difference between the predicted and the actual values. R/RStudio and tidymodels packages were employed to perform the analysis.

Abstract Name: Individual Differences in Prosody Sensitivity and Reading Ability: Insights from EEG Resting State Analysis

College readiness and career opportunities are heavily dependent on young adults' reading proficiency. However, recent data reveal that nearly two-thirds of twelfth-grade students lack the fundamentals needed to successfully navigate college-level reading materials. Converging evidence points to poor reading ability associated with difficulties perceiving speech rhythm cues, which include stress patterns in words. In addition, research suggests that such speech rhythm deficits may result from inefficient neural oscillations at 4-8 Hz (i.e., theta band) within auditory brain areas that fail to align with the prosodic information carried by speech. EEG in individuals with dyslexia is also associated with altered functional brain reading networks in the theta band. The current study aims to investigate brain oscillations, specifically examining whether individual variations in speech rhythm perception mediate the differences observed in the EEG theta band related to reading abilities. Participants (N = 60, 18 to 40 years of age) will be recruited from the Murfreesboro community. A 32-electrode EEG system will be used to record 8 minutes of their brain activity at rest (i.e., EEG resting state). Participants will also be administered standardized cognitive and reading assessments. By exploring the relationship between speech rhythm perception, theta neural oscillations, and reading proficiency, this study seeks to contribute valuable insights that may inform early interventions for enhancing the reading skills of individuals at risk for dyslexia. Addressing this gap in understanding is essential for creating a more inclusive educational environment and improving long-term outcomes for poor readers.

Abstract Name: Leading for Equity: Supporting Students in Accessing and Navigating the Academic Secret Menu

What is the role of offices of student research in leading for equity? This presentation focuses on the work of the Office of Student Research at California Polytechnic State University (Cal Poly in San Luis Obispo) and the ways in which this context has created opportunities to focus on equity and navigating the "Academic Secret Menu." This presentation will discuss context-specific recommendations that prioritize equity in student research programs. Part of the 23-campus California State University system, Cal Poly is a highly selective, predominantly white institution committed to a Learn by Doing pedagogy. Cal Poly has an

established history of undergraduate research. Given the scale of existing infrastructure to support student researcher activity at Cal Poly, the establishment of the Office of Student Research (OSR) was not motivated by a need to establish mentored student research programs. Rather, OSR is designed to make visible and challenge what the ReclaimingSTEM Institute calls the “Academic Secret Menu.” An Academic Secret Menu (also called a “hidden curriculum”) refers to information about the higher education system — including how student research and graduate education work — that some students have access to and others do not. In addition to increasing transparency of access to opportunities and addressing inequitable participation rates across student populations, OSR offers equity-focused professional development for mentors to guide, inspire, and elevate student research experiences; partners with campus entities to enhance existing programs; works to increase funding available to address variation across disciplines; provides professional development workshops for students that center the transformative impact of mentorship; and is developing, testing, and integrating meaningful metrics that measure outcomes and impact.

Abstract Name: Effects of Cyclization on Antifungal Peptoid Efficacy, Cytotoxicity, and Permeability

Cryptococcus neoformans and Candida albicans are two fungal pathogens responsible for lethal infections of brain tissue including cryptococcal meningitis and invasive candidiasis, respectively. The rising occurrence of antimicrobial-resistance in fungal pathogens in combination with the scarcity of safe and effective clinical antifungals necessitates the discovery of novel antifungal agents with blood-brain barrier (BBB) permeability. RMG8-8 and RMG9-11 are two linear peptoids, or peptidomimetic N-substituted glycines, that have demonstrated significant efficacy against these two fungal pathogens. While these linear peptoids have similar activity in vitro to current antifungals on the market, previous studies suggest that cyclization could improve efficacy through increased rigidity. The goal of this study was to compare the antifungal efficacy, mammalian cytotoxicity, and BBB permeability of RMG8-8 and RMG9-11 with their cyclic derivatives, RHS3 and RHS6. Antifungal efficacy of all four peptoids was evaluated in terms of minimum inhibitory concentration (MIC). The cyclization property of RHS3 and RHS6 did not yield significant antifungal improvement compared to parent compounds RMG8-8 and RMG9-11, though there were some instances of similar activity between parent and cyclic derivative. Mammalian cytotoxicity was evaluated against HepG2 liver cells and single donor human red blood cells (hRBCs). Though the linear parent and cyclic derivatives exhibited similar cytotoxicity against HepG2 liver cells, there was greater variability against the hRBCs as RHS3 was roughly twice as toxic compared to its linear parent, RMG8-8. Finally, the potential of each peptoid to cross the BBB was evaluated by a parallel artificial membrane permeability assay (PAMPA). Interestingly, both RMG9-11 and its cyclic derivative RHS6 exhibited high permeability across the artificial membrane while RMG8-8 and RHS3 did not. Overall, the data collected indicates that the effect of cyclization varies on a case-by-case basis.

Abstract Name: Exploring Techniques to Visualize Aβ Induced Changes to Primary Cilia

Alzheimer's disease (AD), a progressive neurodegenerative disorder, is one of the leading causes of death in the United States. AD is characterized by the accumulation of toxic Aβ plaques and hyperphosphorylated tau tangles; ultimately neuronal death. Primary cilia are immotile signaling organelles present in all eukaryotic cells including neurons and astrocytes. Defects in the primary cilia lead to ciliopathies, such being impaired neuronal development and cognitive domains, also compromised in AD. Previously in Dr. Saunders' lab, it was observed that in the presence of both extracellular and synthetic Aβ, primary cilia become disrupted. The purpose of this study is to determine if the localization of the cilia axonemal protein IFT88 is altered in response to elevated Aβ levels. Traditional fixation techniques are not necessarily adequate for investigating a wide range of cilia protein localizations. From previous experiments, we have an understanding that there should be an abundance of ARL13B and IFT88 positive cilia in the PFA treatment which is an established fixation method. To visualize IFT88 we tested two alternative fixation methods, a 1xPHEM treatment, and a 100% methanol treatment. To achieve this, 3T3 cells were cultured in the presence or absence of synthetic Aβ and fixed using PFA, 1X PHEM, or 100% methanol. Immunofluorescence techniques were used to visualize cells and their cilia. Under control conditions, methanol fixation resulted in highly visible IFT88 and ARL13B staining in primary cilia, while 1X PHEM fixation resulted in only IFT88 being visible. When exposed to Aβ, cells had dramatically decreased levels of both IFT88 and ARL13B staining. This study extends our previous findings by demonstrating that the ciliary membrane and axoneme receptors are disrupted after 24 hours of Aβ exposure.

Abstract Name: Root causes of homelessness in Marin County and prevention strategies

Even with increased prevalence of homelessness in the US, there is limited research that investigates circumstances that can lead to homelessness. This lack of understanding perpetuates the inequities in health and wellbeing, access to basic necessities, effective prevention strategies and meaningful policy changes. This qualitative analysis consisted of a total of 25, semi-structured interviews conducted in the Spring of 2023 by public health student researchers. Individuals (18 and older) who were seeking support from a local community partner (the Ritter Center) were interviewed. Interviews consisted of a verbal consent in English as well as a set of IRB approved questions about the participants life circumstances and background that may have led to homelessness. Transcribed interviews were coded and several themes emerged. After coding 25 transcripts, thematic analysis supports three main themes: abandonment, mental health struggle, and substance misuse. Abandonment appeared from personal stories from childhood where individuals experienced abandonment from their parents/family. In extreme examples, this was not just emotional

abandonment but led to legal foster care. Mental health struggles revealed depression, emotional abuse, feelings of betrayal, or lack of trust experienced throughout their life. The most common theme was reliance on substances and the misuse of those substances. Common themes of abandonment, mental health struggle, and substance misuse suggest that these are recurrent circumstances that led to individuals experiencing homelessness. Understanding the root causes of homelessness can help public health departments implement upstream interventions to prevent the perpetuation of homelessness.

Abstract Name: PERCEIVED AUDIENCE RESPONSES TO CHRISTIAN RHETORIC IN FILM

Film is a relatively new form of media in Western culture, and its impact on viewers' attitudes is still being researched. The purpose of this interdisciplinary study is to discover the impact on audiences watching films with varying degrees of Christian rhetoric in both the short- and long-term. This particular study focused on a general audience reception of films with Christian messages, whether subtle or overt, and whether Christian rhetoric provides a basis for cultivating moral growth or religious interest. First, evidence was provided from general psychology film studies to give an understanding of the psychological effects of watching a film. The study then categorized Christian film into three groups: "overt" (Christianity is key to the plot), "in-between" (strong Christian themes plus a secular plot), and "subtle" (secular plot with some understated Christian symbolism) to determine whether any of these types of films were effective in either teaching positive moral behavior, piquing religious interest, or shaping positive opinions about Christian values. The study presented three representative films (The Passion of the Christ, The Lion, the Witch, and the Wardrobe, and Gran Torino) and discussed their symbolism and placement into their respective categories. A survey instrument was developed to determine audience opinion about the effect of these films in their lives, and it was sent out as a snowball survey on social media. There were 222 total participants. Although most of the respondents came from Christian backgrounds, there were several respondents providing perspectives from other religious backgrounds. Findings indicated that there is a correlation between these films and moral growth or religious interest, especially in children who already had some Christian foundation.

Abstract Name: Distortion Product Otoacoustic Emissions in Ears with Hearing Instability

The pathophysiology of hearing instability (HI) remains undefined and may be related to a variety of genetic and environmental factors, including an enlarged endolymphatic duct5, congenital otologic abnormalities5, autoimmune dysfunction6, and several other comorbid conditions4,7. HI disorders include conditions characterized by sudden changes or fluctuations in hearing, including Meniere's disease.Meniere's disease (MD) is an inner ear disorder characterized by symptoms of fluctuating sensorineural hearing loss, tinnitus,

aural fullness, and episodic vertigo. Classically, it is associated with the histological hallmark of endolymphatic hydrops (EH), which is a buildup of endolymph in the cochlea resulting in excessive stiffness in sound-sensitive structures. We are investigating several measures to serve as biomarkers and diagnostic tools for MD, as current audiometric diagnosis requires a demonstrated fluctuation in hearing and lacks a measure amenable to diagnosis at a single time point. One of these measures is distortion production otoacoustic emissions (DPOAEs).DPOAEs are emissions generated by the outer hair cells of the cochlea in response to two stimuli tones: F1 (lower) and F2. (higher). Previous literature has identified that the phase of these emissions varies with body tilt as intracranial pressure (ICP) and intralabyrinthine pressure (ILP) fluctuate1,3. In MD patients, the manipulation of ICP and ILP, induced by body tilt, has a much larger effect on phase shift when compared to healthy patients2. Therefore, phase shift could assist in assessing the integrity of the cochlea and has the potential to be an efficient way to diagnose MD and other HI conditions.To better understand cochlear function in ears with HI, the relationship between body tilt and DPOAE phase shift was analyzed, over a series of visits, in a cohort of patients presenting with unilateral or bilateral HI.

Abstract Name: Fishy Behavior in Shrimp: Shelter Use and Predator Harassment in Grass Shrimp

This study examined how the presence of a predatory fish (mummichog, Fundulus heteroclitus) affected the habitat choice and group behavior of grass shrimp (Palaemon pugio). Although grass shrimp are abundant and ecologically important in salt marshes along the east coast of North America, their responses to predators have been minimally studied. The goal of this research was to determine how much the shrimp used the shelter with and without the presence of predators. Groups of shrimp were recorded before and after the introduction of the fish to quantify the amount of time spent in or near shelter, with fish shelter use recorded as well. We found that shrimp did not change their shelter use patterns in the presence of fish, indicating that shelter is probably not their primary means of avoiding fish predation. Shrimp also repeatedly attacked and harassed the predatory fish, in a novel antipredator behavior. These results shift our understanding of antipredator behavior in marine invertebrates, as we typically assume that small invertebrates will hide from or avoid predators, something these shrimp did not do.

Abstract Name: The Impact of External Factors on Urban Youth Behaviors

In what ways are urban youth behaviors in educational settings influenced by external community factors and experiences? It is important for educators to understand a student’s holistic experience such as their home dynamics, surrounding community, and the unique circumstances they endure. This is especially true for

children in urban communities that are exposed to systemic oppressions given that their experiences encompass higher levels of trauma, adversities, abuse, single-parent households, poverty, etc. It has been found in previous literature that students exposed to higher levels of adversities will externalize their experiences through, what is perceived as, “disruptive” behaviors in the classroom as their method of defense against their environment. Highly punished actions within academic spaces are often reflective of the many emotions a child feels in response to their triggering experiences but are unable to communicate. Researchers have noted that educators that label urban youth behaviors opposed to understanding their experience often re-trigger students and perpetuate the academic achievement gap found in urban communities. This study will build upon this body of research literature through identifying specific in-classroom behaviors and experiences to further the guide to understanding, predicting, and intervening with students’ behaviors properly. This will serve to support urban youth’s academic success and social interactions through adolescence and early adulthood. The methodology for this study consists of a qualitative approach that involves interviews and observations. There will be one focus group for educators/ staff at a local non-profit afterschool program followed by observations and interactions with the youth. Select youth will be invited to be interviewed based on the unique behaviors observed accompanied with an interview with their guardian to understand their personal home situation. It is expected that students who are reprehended more often than their peers will display unique behaviors that reflect their adverse experiences within their community.

Abstract Name: The effects of Lavendustin-A on peripheral nerve degeneration and skeletal development in hyperglycemic zebrafish (Danio rerio)

Previous work from the Clark lab has demonstrated that the induction of hyperglycemia in larval zebrafish (Danio rerio) causes peripheral nerves degeneration and bone defects. Preliminary data suggests that Lavendustin-A (LavA), an epidermal growth factor receptor (EGFR) inhibitor, promotes nerve regeneration in this model. Here, we were interested if skeletal defects would be corrected once nerves regenerate (following LavA treatment) and reinnervate the skeletal system, or if these defects were occurring independently. Larvae were incubated in 120mM glucose or egg water from 5-10dpf. At 10dpf, control larvae remained in egg water+1% DMSO (Cont). Glucose larvae were split into Glucose (120mM glucose+1% DMSO), GlucoseLav (Glucose+65.5µM LavA), Recovery (egg water+1% DMSO), or RecoveryLav (Recovery+65.5µM LavA). At 12dpf, lateral images of Alazarin red-stained vertebrae were collected and analyzed. No significant difference in skeletal development was observed following EGFR-inhibition in GlucoseLav compared to Glucose fish. Removal from hyperglycemic conditions improved bone development; the area of mineralized centra was significantly greater in Recovery (p<0.01) and RecoveryLav (p<0.0001) than GlucoseLav, and no difference was found between Recovery and RecoveryLav. The area of mineralized centra was greater in Cont fish compared to Recovery (p<0.0001) and RecoveryLav (p<0.0001), indicating that complete recovery was ongoing. Taken together, this suggests that EGFR activation is not directly responsible for the bone defects seen in this hyperglycemic zebrafish model. Furthermore, coupling this with preliminary data showing that EGFR plays a role in nerve degeneration (which is reversed by LavA), the current work suggests that nerve regeneration (and in turn, reinnervation) alone cannot reverse the bone deficits observed in this model. Moving forward, efforts will be focused on elucidating distinct molecular pathways for these two dynamic phenotypes.

Abstract Name: Intellectual Humility and Investigative Behaviors in Relation to Overclaiming of Knowledge

Fake news and other forms of misinformation are becoming increasingly prominent in today's world. Research has shown that people vary in their susceptibility to believing false information, but few studies have explored the factors that potentially aid individuals in avoiding misinformation. Intellectual humility (IH), or openness to recognizing the fallibility of one's opinions and beliefs, is related to discerning true from false information (Zmigrod et al., 2019). Research has also shown that IH is negatively related to one's tendency to overclaim one's knowledge and positively related to engagement in investigative behaviors such as fact-checking (Deffler et al., 2016; Krumrei-Mancuso et al., 2019, Koetke et al., 2022). This study examined investigative behaviors as a possible mechanism in the relationship between IH and the tendency to overclaim knowledge of false information. Participants (N = 120) completed the General Intellectual Humility Scale (Leary et al., 2017), an adapted measure of investigative tendencies, and the Overclaiming Questionnaire-150 (Paulhus, 2003), a questionnaire that asks participants to indicate their familiarity with existent (e.g., prejudice) and nonexistent topics (e.g., consumer apparatus). Correlational analyses showed that IH was not significantly related to claiming familiarity with either real or fake topics. However, high-IH participants (vs. low) were more willing than others to investigate all topics. Additionally, a negative correlation was found between overclaiming bias and investigative tendencies, showing that individuals who wanted to learn more about topics on the Overclaiming Questionnaire were less likely to overclaim their knowledge. These findings have implications for decreasing susceptibility to false information including fake news. People who are aware of the connections among these variables may be more likely to fact-check topics they encounter and avoid overclaiming knowledge.

Abstract Name: Worker-robot collaboration in hospitality tasks: Revealing robotic integration opportunities through image analytics

This research project explores a critical question at the intersection of technology and service: How can collaborative robots be optimally integrated within the hospitality industry to bolster the synergy between human and robot workers? The focus is to pinpoint specific areas and tasks in hospitality settings where robot-human collaboration can effectively reduce the workload of human staff. The study stands out for its attention to the hospitality industry, a sector still experimenting and exploring the full benefits of robotic assistance, particularly in contrast to manufacturing. Notably, while Asia has seen widespread adoption of robotics in this domain, North American and European markets are just beginning to explore these possibilities. This project aims to identify where robots can meaningfully contribute to the daily operations of hotels, restaurants, and similar venues, thus enhancing overall efficiency and customer experience. Our methodology is rooted in a data-driven approach. We plan to compile an extensive dataset of images

depicting robots in various hospitality environments. This dataset, sourced through targeted web scraping using specific keywords, will be systematically categorized into 'yes', 'no', and 'unsure' segments based on the relevance of robotic assistance in each image. Annotators then label these images to identify the specific roles. These labeled images assist in the development of a machine learning model that will provide deep insights into current trends and future potential for robotic deployment in hospitality. We aim to uncover patterns in robot utilization and effectiveness, offering strategic guidance for their integration. We anticipate that this study will yield significant insights into effective robotic integration in hospitality, paving the way for a more efficient and sustainable service industry. The findings will be crucial for industry professionals and policymakers, providing a roadmap for enhancing operational efficiency, worker well-being, and customer satisfaction through innovative human-robot collaboration.

Abstract Name: Using Music Therapy to Reduce Recidivism and Improve Post release Behavior in Solitary Confinement prisoners

Despite the research and studies completed on the effects of solitary confinement, restrictive housing, or administrative segregation, and supermax facilities, there have been few studies done on the aftereffects, such as recidivism, connected with solitary confinement and no studies done on how to reduce the recidivism rates among prisoners who have served time in solitary confinement. Studies completed in both the US and internationally on solitary confinement prisoners, the connection between solitary confinement and recidivism, and the use of music therapy on prisoners, cancer patients, and patients with schizophrenia, were analyzed to determine if music therapy could be a potential method to reduce recidivism among solitary confinement and supermax prisoners. Overall, prisoners who are serving time in solitary confinement or who have already done time in solitary confinement are oftentimes more violent and have been convicted of more serious crimes and have some pre-existing mental illnesses. By being extremely isolated for long periods, prisoners' behavior worsens as does their social or interpersonal skills causing them to reoffend at higher rates and with more violent offenses. Music therapy could provide a space, in both individual and group settings, where prisoners could learn how to control and cope with their emotions and mental illness symptoms as well as learn how to manage their anger, stress, and violent behavior, which could reduce recidivism and violent offenses after being released.

Abstract Name: Impact of Neglected Ecological Considerations in Economic Models on Societal Well-being.

Economic models are widely used as a foundational tool to analyze market behavior, but they glaringly ignore the complex interplay between the environment and economics. This is not just an academic error; it

has far-reaching consequences for the planet and society. This study explores the reasons behind economists' disregard for environmental factors, examines the effects of this disregard, and proposes a paradigm shift that includes ecological factors in economic models. This discussion highlights the need to incorporate environmental concerns into economic discourse to promote a sustainable and harmonious coexistence between ecological well-being and economic prosperity. It is a call to action, highlighting the necessity of an all-encompassing strategy that takes into account the demands of the environment and the economy before irreversible effects materialize.

Abstract Name: Oxidation of Ferrous Alloys

Oxidation is an important phenomenon that affects the performance of metallic alloys. In this study, ferrous alloys including carbon steels and cast irons, were exposed to a range of temperatures and times in air with the aim of characterizing the oxide films that form under these conditions. A number of methods were used to characterize the oxide films including macrophotography, optical microscopy and spectral reflectometry. Iso-chromatic conditions were explored for the different alloys. Results will be presented and discussed.

Abstract Name: Developing Antibodies to Block the Glyco-Immune Checkpoint Inhibitors, Siglecs

Current immunotherapy efforts focus on targeting proteins and are highly promising, but insufficient. We need to discover new immunological targets. Glyco-Immune Checkpoints are lectin (glycan-binding proteins) that transmit inhibitory signals to immune cells by binding to their glycan ligands on cancer cells. Siglecs are a family of inhibitory lectins expressed on immune cells, and they bind to Sialic acid on cancer cells. This binding allows cancer cells to evade immunosurveillance. We aim to develop blocking antibodies to a particular member of the Siglec family (Siglec-X). We will perform ELISA and Flow-based assays to validate the specificity of the produced antibodies to Siglec-X. We will examine the efficiency of these antibodies in enhancing immune-mediated clearance of cancer cells using in vitro cytotoxicity assays.

Abstract Name: Photoinduced Anti-Markovnikov Hydroxylation-Amination of Unactivated Olefins by HAT from Pyridine N-Oxide

The purpose of this research is to apply a visible-light photocatalytic alkene oxidation strategy to develop a simplistic synthesis for anti-Markovnikov hydroxylation-amination reactions. Anti-Markovnikov reactions are appealing due to how rare they are in chemistry because anti-Markovnikov compounds are made when a radical, when generated, moves to a less stable form than to the predicted more stable one. This is unusual for radicals to do since they naturally want to go to whatever structure makes them the most stable. The appeal of researching organic synthesis is the ability to increase efficiency and reduce the cost of synthesizing complex molecules. Even though organic synthesis, despite decades of ground-breaking research, is still underdeveloped in drug-discovery projects. Making projects allowing for innovative and cheaper reaction pathways for drug development very valuable, none more so than amination pathways. Many common drugs, such as antibiotics, blood pressure medications, and nausea/vomiting medications, contain nitrogen. Making novel amination pathways have a strong potential for drug discovery. This is a highly appealing synthetic process because current strategies use transitional metals and/or stoichiometry amounts of sacrificing chemical reagents. In contrast, our proposed pathway uses commercially available reagents that can initiate versatile radical cascade reactions for alkyl activation through amination and hydroxylation reactions. In addition, visible light is a much more sustainable and plentiful resource than precious transitional metals such as gold, palladium, cobalt, and more.

Abstract Name: 3D Optical Coherence Tomographic Imaging of Fibroblast-Populated Collagen Matrix

Fibroblast-populated collagen matrices (FPCMs) are tissue models that facilitate the investigation of fibrosis, wound healing, and cancer progression. The unique cellular and physical properties of fibroblasts play a crucial role in maintaining the structural and biomechanical homeostasis of the collagen extracellular matrix. Consequently, the study aims to image and quantify the cell-dependent morphological changes in developing FPCMs. Using optical coherence tomography (OCT), a noninvasive imaging technique, to capture detailed 3D structures of FPCMs under different conditions, it was reconstructed as 3D models of FPCMs using high-resolution cross-sectional OCT scans. A procedure was developed for the reconstruction using open-source Python software with assistance from ChatGPT. This software converts the 2D pictures from JPEG to NRRD, consolidating all the images into one file. After completing the file type conversion process, the file is imported into another open-source software, Slicer. In Slicer, the OTSU method is employed to find the

threshold and select all the pixels of the lattice, allowing the creation of a 3D model and calculation of the volume. These models are pivotal for unraveling the nuanced reactions of fibroblasts under various conditions. Currently, the main focus is reducing the noise to ensure that the results are not hindered when making the model and finding the structure and volume data. By studying the cell-dependent morphological changes of these 3D tissue models, we aim to uncover valuable insights into the dynamics of cell-collagen interactions, paving the way for novel treatment methods for various fibrotic disorders.

Abstract Name: Paralog Buffering in Genes TRA2A and TRA2B in Cancer Cell Lines

Alternative splicing allows for the creation of different RNA transcripts, and when abnormal, can lead to tumor formation. Alternative splicing is partially regulated by RNA binding proteins, including the paralogs tranformer2alpha (TRA2A) and transformer2beta (TRA2B). TRA2A and TRA2B have been implicated in cancer due to their regulation of the CHEK1 gene responsible for coding a DNA damage response protein. Double-gene CRISPR screens indicate that TRA2A and TRA2B are essential together, suggesting functional redundancy. However, we found that depletion of TRA2A only results in strong lethality in a subset of cancer cell lines. TRA2A dependency was validated in 2 sensitive cell lines (NCI-H23 and LN319) and 2 insensitive cell lines of the same tumor type (A549 and LN229, respectively). Re-expression of TRA2A or overexpression of TRA2B rescued lethality in sensitive cell lines, suggesting a dosage-dependent buffering mechanism between the TRA2 paralogs. Paralog buffering was tested by using a dual-guide CRISPR interference (CRISPRi) competition assay. Cell lines expressing ZIM3-KRAB-dCas9 were infected with a BFP-virus containing guides targeting TRA2A and TRA2B, only TRA2A, only TRA2B, or a control locus. Cell populations were tracked using flow cytometry to measure BFP-positive cells over time. We observed strong cell lethality only in all cell lines when TRA2A and TRA2B were both depleted compared to the control locus. A549 and LN229 cells displayed little to no sensitivity to loss of TRA2A or TRA2B alone. LN319 cells showed moderate lethality to TRA2A depletion. NCI-H23 cells exhibited varying lethality in all conditions. These results suggest that the loss of TRA2A and TRA2B display synthetic lethality, but some cancer cell lines display high dependency when just one paralog is lost. By determining the effects of targeting TRA2A and TRA2B in both sensitive and insensitive cell lines, we can further understand paralog buffering between these two genes.

Abstract Name: Leveraging AI for Potable Water Prediction: A Study of Drinking Water Quality in Developing Countries

The quality of drinking water stands as a pivotal public health concern, significantly affecting millions in developing nations. Given the substantial financial constraints faced by governments unable to invest in advanced water purification systems, this study endeavors to confront the challenge by harnessing the power of artificial intelligence (AI) to forecast water potability based on known impurities. Drawing upon U.N.O. guidelines on drinking water standards and an extensive dataset on water quality, we concentrate on ten key features, including pH value, to discern the health implications of water quality. Our hypothesis posits that AI and machine learning, specifically leveraging IBM Watson, can proficiently construct predictive models for water potability through novel analysis tests. Employing the IBM Watson platform, we formulated and assessed models using two advanced algorithms—the XGB Classifier and Extra Trees Classifier. The XGB Classifier yielded the highest accuracy (~69%) in model development, incorporating various enhancements such as HPO-1, FE, and HPO-2. The results substantiate the efficacy of these models through diverse metrics, including summary features, ROC curves, and confusion matrices. Several pivotal features were identified in constructing these models. For instance, in the case of Extra Trees, the percentage significance of sulfate, pH, hardness, chloramines, and solids was approximately 100%, 92%, 69%, 56%, and 46%, respectively. Correspondingly, in the case of the XGB classifier, these values were 78%, 100%, 43%, 31%, and 34%, respectively. A more in-depth discussion on ROC curves and confusion matrices will be presented. This study concludes by reflecting on the potential of AI to enhance water quality analysis in resource-limited settings and outlining avenues for future research and development in this crucial area. This innovative approach presents a cost-effective and accessible solution for governments and communities in developing countries, opening up new possibilities in the pursuit of safe drinking water.

Abstract Name: Risk Ontology: Safe Web Search Ontological Model for Children

As children use the Internet more frequently and freely, they are more likely to come across inappropriate content while searching for information. To prevent the younger generations from being exposed to inappropriate content, this research has explored the potential of an ontological modeling approach to create effective algorithms for future safe search engines. Other researchers have proposed different safe search approaches to deny inappropriate content to children. However, during our study of more than 225 research articles, no research has explored the properties and usages of ontological approaches in this particular domain, i.e., safe search for children. This work summarizes the state-of-the-art research findings and presents a novel ontological model called risk ontology. The continuation of this research has the potential to create more efficient, child-friendly, safe search engines.

Abstract Name: Examining the Effect of Art Therapy on University Students Psychological and Social Well-being

According to the National Center for Biotechnology Information, art therapy is a clinical intervention in which artmaking and interaction is used to improve physical, mental, and emotional well-being. It is often used in medicine to ease symptoms of various mental health issues. Art therapy can include complex strategies such as incorporating Cognitive Behavioral Therapy such as the use of positive reinforcement of something like listening to music or solving puzzles. It can also just incorporate one type of art into one's daily life, such as playing an instrument for a certain amount of time every day. Researchers have found that music specifically has a profound effect on anxiety and cognitive functioning. The aim of this study is to investigate if there is a correlation between art therapy and university student mental health through literature review. This study's purpose is to identify sustainable habits that improve mental health with students and encourage implementation of art within course syllabus. This topic will focus on music, art and literature looking into anxiety levels, overall wellbeing, and depression in undergraduate university students. Following this review, our team aims to produce an app to test our findings by integrating art into university student's lifestyle and assess their psychological and social wellbeing over time. We aim to use this application in a variety of course levels, majors, and honors distinction.

Abstract Name: Impact of various feeding diets on the action potential kinetics of preproglucagon

Understanding of the basic molecular mechanisms behind feeding behaviors has been a widely discussed phenomenon over the past few decades. This is due to the idea that properly understanding these mechanisms can lead to the development of therapies and treatments for diseases relating to eating behaviors, such as obesity which has been on the rise in recent years. Glucagon-like peptide 1 (GLP-1) is a hormone that is able to regulate the mechanisms of eating and has become the target for many weight-loss drugs on the market. GLP-1 works by activating GLP-1 receptors, which in the brain have been shown to decrease overall eating behavior. The endogenous GLP-1 system of eating and motivation is still being explored in the brain and is the focus of this study. This project focuses on the analysis of the action potentials of GCG cells, a precursor peptide that produces glucagon and GLP-1, in the nucleus of the solitary tract (NTS) of the brain. Previous studies have concluded that neuronal cell bodies encode information in the frequency patterns of their action potentials, and that the shape of action potentials is different depending on types of the neuron. These shapes can influence the frequency of the action potential. For example, more narrow spikes are correlated with fast-spiking behavior. We used a mouse model and fed three cohorts of mice different diets: ad lib, food deprived for 24 hours, or refeed on chow. Next live cell-clamp electrophysiology was performed to record action potential data; we then analyzed the data using Clampfit, which analyzes the varying kinetics of action potentials. Understanding the action potential kinetics of GCGNTS cells will be important in understanding

the impact they have on eating and motivation and exactly what roles they play in advancing current therapies of obesity related illness.

Abstract Name: Overexpression of Rad51KA results in increased rates of homology directed repair in zebrafish

Rad51 is a homolog of RecA protein from Escherichia coli. Here, we overexpressed rad51KA, a mutant in rad51 unable to hydrolyze ATP, to test its role in homology-directed repair at CRISPR/Cas9 double-strand breaks in zebrafish. We used a fluorescent reporter system in the noto gene of the zebrafish that can repair via engineered 48 bp repeats. Following generation of a double-strand break at this site, repair can utilize a variety of repair mechanisms, but only repair utilizing the homology will generate a RFP signal in the notochord. We divided the fish into two groups. One of the groups was injected with the CRISPR/Cas9 and ugRNA, while the other one had CRISPR/Cas9, ugRNA, and rad51KA. The individual zebrafish embryos were screened for RFP in the notochord to identify the individuals that showed a homology-based repair in their genome. We saw a higher percentage of embryos showing homology-directed DNA repair when rad51KA was overexpressed, suggesting an important role in homology-based repair.

Abstract Name: Socioeconomic Inequality and School Shootings

Background: The recent prevalence of school shootings in the United States has created increasing alarm throughout the nation. This study aims to examine the correlation, or lack thereof, between several aspects of shootings and their frequency. Few studies have been conducted on the relationship between economics and school shootings.Method: To study the economic factors that could possibly affect school shooting frequencies, we used data on school shootings in the USA throughout the past three decades, until April 2021, obtained from the Washington Post. Using data from the US Census Bureau on average household income and income inequality per geographic region from 2007-2021, as well as data on these statistics for the USA as a whole, we analyzed the relationships between the Gini index in different areas and the frequency of school shootings. We also observed the correlation between household income in these regions and shooting frequencies.Results: An analysis of 228 shooting statistics showed a correlation between

economic inequality and status with the frequency of these shootings. We also found that states with higher Gini coefficients, or higher income inequality, observed a higher number of school shootings through 2007-2021. We also observed that the number of shootings in the first 4 months of 2021 was 280% of the number in 2017. In analyzing the data on household income by county, a majority of shootings occurred in counties with an above-average household income. On average, household income in these counties was greater than the US average by 16700 USD. Conclusions: There's a positive correlation between average regional income and school shooting occurrences. There's also evidence of a positive correlation between income inequality and shooting frequency. However, further studies are necessary to conclude whether these economic factors have a role in increasing the likelihood of school shootings in the USA.

Abstract Name: Estimation of the Stochastic Gravitational Wave Background from Binary Mergers

The ground-based International Gravitational-Wave Observatory Network (IGWN), including LIGO, VIRGO, KAGRA, has detected gravitational waves (GWs) from Compact Binary Coalescence (CBC) sources in distant galaxies (8 Gigaparsecs) at a redshift >1. More distant sources are too faint to be detected as individual events, but are expected to be numerous to be detectable as Stochastic Gravitational Wave Background (SGWB). While stringent upper-limits on SGWB strength as a function of frequency in units of the cosmological closure density of the universe—ΩGW(f)—have been made via IGWN, there has been no observed SGWB detection. While this was overturned (June 2023 announcement on preliminary detection of SGWB from supermassive black hole mergers), the overall astrophysical background from all CBC sources is still to be detected. Early SGWB implications from the first observation of Binary Black Hole mergers, and recent LIGO-VIRGO advanced data-models have provided estimates of CBC merger rate, suggesting we are close to detecting SGWB. All estimated limits on SGWB aim at constraining energy density of the SGWB over frequency domain. We analyze all methods, reproduce current estimates, and study the degree to which they agree with each other and the extent to which the results depend on uncertainties in the merger rate as a function of mass and redshift distributions of the sources. The aim is to investigate the SGWB prediction-parameters and create novel constraints on its limits, thereby decoding how the background changes due to uncertainties in crucial variables to aid in the long-term goal of refining SGWB estimates.

Abstract Name: Comparative Study of Folin-Ciocalteu and Iron-Reactive Phenolics Assays for Phenolic Compound Concentrations in Wines

Phenolic compounds are essential in food and wine quality, as they are responsible for color, taste, texture, and flavor. Those compounds are antioxidants and are highly reactive with a variety of free radicals. Common methods used to quantify phenolic compounds in food and beverages include colorimetry and detection using spectrophotometry. Despite the rapidity, low cost and ease of the traditional methods, some of them are not specific to phenolic compounds, such as the Folin-Ciocalteu (FC) method. The FC method uses the reaction between hydroxyl groups with the FC reagent which often overestimates the concentrations of phenolics. In wines produced from non-Vitis vinifera grapes, the concentration of antioxidants tends to be higher than in Vitis vinifera wines. Given the high proteins and phenolics concentration in those red wines, it is expected to have a higher concentration of phenolics using FC method compared to other common methods. Phenolic compounds concentrations were quantified in red wines made from Marquette, Crimson Pearl, Frontenac, and Petite Pearl grape varieties of different vintages, using FC method and Iron-Reactive Phenolics method (Harbertson –Adams assay (HA)). After reactions, the absorbance values were recorded at 765 nm and 510 nm, respectively, using a UV-Vis Spectrophotometry. The concentrations were expressed as catechin or gallic acid equivalent using external calibration curves. The experiments were carried out in triplicate for each wine and standard. In all wines, the concentration of phenolics was two times higher using the HA assay than using FC method and the two methods were not correlated (r-square value lower than 0.4). These results were contradictory to the hypothesis and suggested that neither HA assay nor FC method were specific to phenolic compounds in wines. Subsequent experiments will focus on assessing phenolic concentration of standards, to evaluate the interference from compounds of the wine matrix.

Abstract Name: How Does odd-1 Affect Expression of Genes in Caenorhabditis elegans?

Odd-skipped genes are transcription factors, which control whether other genes are expressed. The human odd-skipped genes OSR1 and OSR2 are reported to be cancer suppressor genes. Research on these genes show that downregulated OSR1 can be a potential biomarker for gastric cancer and ovarian cancer. Caenorhabditis elegans is a model organism that has two related genes to the human odd-skipped genes, odd-1 and odd-2. In our experiment, we analyzed the effects of an odd-1 mutation. In C. elegans, odd-1 is expressed in the intestine. We developed a list of genes that contain possible binding sites for ODD-1 and that are expressed in the intestine. Using quantitative RT-PCR, we compared the expression of these candidate genes in normal worms (N2 strain) and worms that do not express odd-1 (ACG4 strain). Five genes have been shown in replicated experiments to be downregulated in the ACG4 mutant strain, indicating they are normally activated by odd-1 (dhs-3, ntl-2, and gly-5 (n =3) and K0911.1 and C24G6.61 (n =2)). In humans, one of the genes, dhs-3, works in response to oxidative stress. If dhs-3 is not expressed, oxidative stress can become uncontrollable and may be linked to cancer progression by increasing DNA mutations. As we continue to test other gene candidates, we also plan to analyze the expression of fluorescent reporters in the odd-1 mutant. Fluorescent reporter strains allow for the visualization of candidate gene expression in the worm. Confocal microscopy will be used to determine whether the fluorescence decreases when odd-1 is mutated.

Abstract Name: Culturing non-small cell lung carcinoma cell lines without carbon dioxide supplementation using carbon dioxide-independent medium.

A standard methodology of culturing human cell lines in vitro typically involves an incubator with carbon dioxide (CO2) supplementation. This gas next reacts with water to produce carbonic acid, which prevents a toxic alkalization of culture medium. However, such CO2 supplementation requires specialized equipment and continuous logistical effort. The purpose of this study was to test if CO2-independent culture media, recently introduced by one of the leading biotechnology companies, could serve as an alternative for small scale research projects utilizing such cultures. We selected two non-small cell lung carcinoma (NSCLC) cell lines which we plan to use for future functional studies, H1299 and H1975, to address this question. These cells were cultured in standard conditions of temperature and humidity, but without elevated CO2 concentration. Instead, CO2-independent medium from Life Technologies with added standard set of supplements (fetal bovine serum, L-glutamine) was used. Our data show that culturing H1299 and H1975 cells over the course of four weeks in such conditions is manifested by the same proliferation rates as those reported for CO2-supplemented incubators. Analysis of the culture medium metabolized by cells demonstrated that its pH remained neutral at all times it was tested. Lastly, no abnormal changes in morphology or increased cell mortality was found. Therefore, our results suggest that the use of CO2-independent media provides a viable alternative for external CO2 supplementation that can be utilized by research laboratories for small scale functional studies involving cancer cell in vitro models.

Abstract Name: Breaking Barriers to Learning: Empowering Nepalese Teachers with Knowledge and Understanding of Learning Disorders and ADHD in Children"

This awareness project targeted elementary school teachers in Nepal to educate them on mental health disorders in children, mainly ADHD and Learning Disorders. The project stems from personal experience and observation, emphasizing the need for knowledge, identification tools, and support for children with such challenges. Due to the nature of the disorder, it severely impacts children's academic success; hence, identification of the disorder by elementary school teachers at an early age could positively impact the lives of children. Awareness events were conducted across multiple schools across Nepal through seminars, presentations, discussions, and interactive activities to foster a deeper understanding of the disorder. Through collaboration with medical professionals and school authorities, the project helped elementary school teachers understand the biological and environmental interplay in the disorder, emphasizing the need for strong cooperation between parents, schools, and health to help children with the disorder. The project also gathered statistics on preexisting knowledge and prior understanding levels of elementary school teachers, which could be an excellent guide for future children's mental health initiative projects in Nepal. .

Abstract Name: Deficiency of ETB Receptor Results in Regional Differences in Renal Expression of the Inflammasome Component Pstp1 During Salt-Sensitive Hypertension

The vasoactive peptide endothelin-1 (ET-1) has an integral role in hypertension and the associated kidney inflammation. The inflammasome is a member of the innate immune response involved in hypertension. However, if the ET-1 system plays a role in activating the kidney inflammasome during hypertension is unclear. We hypothesized that the dysfunction of the ETB receptor leads to an exaggerated activation of the inflammasome in the kidney during hypertension. Male transgenic (TG) controls and ETB deficient (ETB def) rats (n=4-5/group) were placed on a 4% NaCl diet for three weeks to induce salt sensitive hypertension. RT-PCR was conducted on the cortex and outer medulla of the kidney (normally rich in the ETB receptor) to assess gene expression of different members of the inflammasome family. Results were normalized to the expression of the housekeeping gene Rpl18. Dysfunction of the ETB receptor resulted in a dramatic downregulation of the negative modulator of the inflammasome pathway, Pstpip1, in the cortex (TG Controls vs. ETB Def: 1.27±0.11 vs. 0.32±0.04, p=0.003), but not in the outer medulla. Interestingly, the rest of the inflammasome genes (Nlrp1, Nlrp3, Pycard, Il-1B) had a tendency of downward expression in the cortex and upwards expression in the outer medulla. Together our results demonstrate that expression of Pstpip1 gene is regulated by ETB receptor in the cortex but not in outer medulla during high-salt feeding. More studies are needed to fully understand how the downstream pathway of the inflammasome is affected by dysfunction of the ETB receptor, especially in regard to sex differences in the response. Funded by NIH K01HL145324 to CDM and NIH U54 DK137307 as O'Brien Scholar to BSM.

Abstract Name: Female Faithfulness Encouraged: Gendered Piety in Early American Baptist Publications

Following the American Revolution, membership in Baptist churches grew exponentially. As one of the fastest-growing Protestant denominations in early America, the interests of Baptists were often indicative of larger trends in religiosity. Conceptions of piety, including beliefs surrounding obedience, faithfulness, and duty, were central to the structure of Baptist congregations and their proximate communities. This paper explores the role of gender in the construction, presentation, and justification of Baptist notions of piety in their publications during the Early American Republic. It will further address questions of female autonomy and gender roles as illustrated in this discourse. Through a rhetorical analysis of denominational print publications, I will identify the places where ideas of gender permeated the values of these communities as well as examine the tools used to form and disseminate gendered notions of piety. The Massachusetts Baptist Missionary Magazine and its equivalents in surrounding spheres will serve as my main primary source base,

providing examples of published discourse that a large number of early American Baptists subscribed to. By analyzing the language used to set these standards, I will be able to highlight the congruence between Baptist values and male interests in 19th-century New England. The outcome of this was the deepening of ties between religiosity and gender structures in early America.

Abstract Name: Capitalizing on Engagement and Senses for Individuals with Dementia

The stigma against dementia persists while few dementia friendly programs currently exist. Montessori-based activities are designed to offer active and meaningful engagement and provide socialization and enjoyment for individuals with dementia despite their cognitive deficits (Hindt, Morris, Sohre, & Buchanan, 2018; Jarrot, Gozali, & Gigliotti, 2008). Research participants in this study comprised of eight college students who completed specialized dementia-friends training. Student participants conducted two 30-minute activities with a small group of residents with dementia twice a week for ten weeks. This study aims to examine meaningful engagement by comparing two Montessori-based activities addressing verbal modality vs. multiple senses. Two Montessori activities, Memory Bingo and a Sensory Station have been created to facilitate among individuals with dementia. The Sensory station allows individuals with dementia to explore a variety of theme-based objects (e.g., leaves, miniature pumpkins, harvest corn, and other fall theme related objects) along with a theme-based scent all incorporated in a slime mixture in a plastic container. This activity allows individuals with dementia to work alongside a student volunteer while capitalizing on their five senses promoting them to reminisce and engage in theme-based conversation without requiring demand on their impaired short-term memory. Memory Bingo is similar to Bingo but replaces the numbers on the bingo cards with theme-based sounds that may be familiar to the individual. This activity allows individuals with dementia to recognize sounds and relate the corresponding sound to a memory they may potentially have. Qualitative and quantitative measures prior to and after completing the program will be conducted to measure student perceptions on ageism, dementia and meaningful engagement. The expected outcome of this programming is for student volunteers to develop and facilitate purposeful engagement activities by maximizing the abilities of individuals with dementia.

Abstract Name: Enhancing Organic Contaminant Removal from Wool Scouring Wastewater Using Chemically Modified Biochars

In recent times, biochar has emerged as a promising and sustainable solution for COD reduction in wastewater treatment. This study explores the potential of chemically modified bio-chars as efficient adsorbents for the removal of organic contaminants, specifically oils, fats, and grease (OFG), from wool scouring wastewater. Proximate analysis revealed distinct properties among the biochars, with the KOH-treated biochar demonstrating the most promising characteris-tics, including lower volatile matter, higher fixed carbon content, and reduced ash content, indicat-ing a stable and carbon-rich structure. A meticulous examination of the KOH-treated biochar's sur-face characteristics revealed the presence of elevated carbon and nitrogen content, complemented by an expansive surface area measuring 724.4 m^2/g. This surface area was at least twice as extensive as that observed in the other post-treated biochar samples. The kinetic adsorption of COD and sol-uble COD was well-fitted by the pseudo-first-order model, with equilibrium achieved in approxi-mately 200 min. The KOH-treated biochar exhibited the highest equilibrium adsorption capacities for both COD and soluble COD in both Dorset and BFL wastewater, highlighting its efficacy in OFG removal. Despite these promising results, further research is needed to explore biochar's surface characteristics, pore structure, and performance under diverse conditions, as well as its integration with existing treatment processes and potential for regeneration and reuse. This study contributes to advancing sustainable wastewater treatment methods using chemically modified biochars.

Abstract Name: Does Consumerism Have an Effect on Relationships? The Influence of Consumeristic Tendencies and Empathy on Relationship Satisfaction.

Materialism and consumerism have been linked to higher levels of loneliness, an increased focus on extrinsic goals, various social challenges, and lower overall well-being of individuals. Previous research has linked people with higher levels of consumeristic/materialistic values to a lower frequency of intrinsic and pro-social pursuits. The area of discussion has primarily often looked at relationships and societal-level challenges separately and has a limited assessment of platonic personal relationships. This study adds to this discussion by addressing the gap in more friendship-oriented relationships, looking at how the same set of individuals are affected in both personal and societal connections, as well as seeing how various individual factors, such as religious affiliation and socio-economic class may impact these effects. This research will use mixed research methods, including surveys and in-depth interviews, to see how individual attitudes toward consumerism relate to their behavior and values toward their immediate social circle and larger communities. The samples were gathered from among the United States population and were collected at random through the use of online collection methods. The participants were contacted through the use of snowball sampling as well as the use of online platforms which include SurveySwap and SurveyCircle to acquire representative samples. The survey data will be examined through the use of multivariate analysis. The interview data will be reviewed through thematic analysis. The addition of this study will increase our understanding of not only how consumerism and materialism affect the individual’s well-being but also their capacity to meaningfully connect with their various communities.

Abstract Name: Education of Neonatal Intensive Care Unit (NICU) Nurses Regarding Evidence-Based Management of Feeding Tubes in Neonates

The aim of this evidence-based practice proposal is to educate Neonatal Intensive Care Unit (NICU) nurses on the most recent literature regarding best practice in management of feeding tubes in neonates. A comprehensive review of literature identified themes in three distinct domains: infection in feeding tubes, measurement for placement of feeding tubes, and verifying placement of feeding tubes. Despite conclusive evidence in these subjects, NICU nurses still use techniques that are less accurate or effective in their daily practice. Educational material created based on the review of literature will be dispersed to NICU nurses in a local hospital. This education will provide a new frame of reference and increase nursing knowledge, thereby changing the way nurses care for infants with feeding tubes. Nurses' understanding of the material will be assessed following the education to determine if the education was effective.

Abstract Name: The Value of Survivor Narratives in Social Justice Education

After World War II it was not uncommon for American Holocaust survivors to talk at schools to discuss their personal experiences through tragic events of the war. Fred Gross and his family spent years fleeing numerous countries across Europe in attempts to evade Hilter's grasp. They ran through war-torn trenches, stayed in hotels and castles, were held in Grus French internment camps, and hid in Switzerland. Fred Gross later wrote the book One Step Ahead of Hilter: A Jewish Child's Journey Through France which captures his family's experience through the Holocaust. In addition, Fred Gross toured and spoke at primary and secondary schools in Kentucky to talk about his experiences as a Holocaust survivor before his death in 2021. He did this to teach younger generations from his first-person perspective of history. Using the archival collection of Fred Gross Thank You Letters, 1997–2019, at the University of Kentucky Libraries Special Collections Research Center, research will investigate what students learned from his visits by analyzing their handwritten thank you letters sent to Gross after his visit. Research methods will quantify feelings identified by the students and what they learned from his visits. Further analysis will determine how effective survivor narratives are in genocide education and in invoking empathy in students. Today there are few Holocaust survivors left and statistics bear that Millennial and Gen Z generations know little about the event. As access to first-person Holocaust narratives disappears, it is vital to learn how to preserve their accounts and educate future generations.

Abstract Name: Investigation on the Effect of Photo Dose Parameters on Mechanical Properties of Photopolymer Resin

Digital Light Processing (DLP) has become a popular method for additive manufacturing due to its ability to cure a product layer by layer, decreasing production times. One important parameter of a DLP printer is the photo dose which is the product of the exposure time to light and the intensity of light. This project aims to see how varying the ratio of exposure time to intensity, while keeping the photo dose constant, affects the printed product's mechanical properties. This project also investigates how changing the photo dose itself effects these same properties. This was done by printing "dog bones" (ASTM D638 standard - Type I) from a DLP 3D printer, using a material by the alias Material X. Batches of dog bones were printed at 3 different ratios of light intensity to exposure time with each batch undergoing tensile strength tests to measure the tensile strength at break, elongation percentage at break and tensile modulus as well as hardness test. Similar tests were done on two more batches with varying photo doses. All batches were printed in the Z orientation. Tests showed that changing the ratio while keep the photo dose constant had no significant effect on the mechanical properties of the objects while changing the photo dose itself showed lower tensile strength and tensile modulus for products with a lower photo dose.

Abstract Name: Exploring the Legacy of Colonialism on Oklahoma Education: Using Historical Foundations of Education in Oklahoma to Understand Contemporary Education in Oklahoma and its Impacts on Native Youth.

As the sun sets on the plains of Oklahoma, it casts a long shadow that stretches far beyond the horizon—a shadow shaped by the intricate and often overlooked impact of colonialism on the state's educational foundation to what it is now. To understand Oklahoma's education system and how Western ideologies and European colonialism have impacted Native youth, you must trace back through Oklahoma's history to when the removal and genocide of Indigenous people across the U.S. by the federal government was a devastating reality. Therefore, how have Native communities been impacted by educational policies, especially Native communities in Oklahoma? Education became a tool for both assimilation and preservation, with the federal government implementing policies aimed at erasing Indigenous languages and traditional ways of life. One of the most pivotal moments in Oklahoma's history is the forced assimilation of Native children through the establishment of residential schools. These institutions were designed to eradicate Indigenous ways of life, with the aim of assimilating Native children into Euro-American society. The policy had devastating effects on Native communities, leading to cultural disconnection, loss of identity, and intergenerational trauma. Many Indigenous languages are now endangered, with only a handful of speakers remaining. Understanding this policy's impact is essential for acknowledging the historical trauma that continues to affect Native communities' social and educational experiences. Understanding how non-Natives used education as a form

of cultural erasure is significant to understanding Oklahoma's education system as we know it today. The purpose of this oral history is not to simply discuss Oklahoma's horrific Indian boarding school system, but rather to use historical foundations of education in Oklahoma, including the Indian boarding school system, to understand how colonialism had impacted and continues to impact Indigenous youth and their educational experiences in Oklahoma and all across the U.S.

Abstract Name: Imagery of Remembrance: Exploring Collective Memory and Political Trauma in Post-era Argentine University Students

From 1976 to 1983, the Argentine Republic was under the rule of the military dictator Jorge Rafael Videla. Historians have studied this dictatorship as a "dictadura de Estado" (dirty war). Student political activism and youth organizations played an important role in this era as they confronted the regime and were often victims of the state's systematic terror. Grounded in Maurice Halbwachs's collective memory theory, posthumously published in 1950, this paper aims to explore the impact of Argentina's military dictatorship on university students born post-era, emphasizing the role of modern visual representations on collective social memory and generational trauma. This study also aims to observe how literary artifacts of this era contribute to shaping and preserving such collective memory for university students. One of Halbwachs's statements is that the strength of collective memory derives itself from the individual memories of a cohesive social group, and that individual memories do not exist outside the influence of the collective memory. Additionally, the study of Natzmer (2002) on Post-Pinochet Chile will act as a parallel case to compare the political outcomes and findings of this study. Methodologically, the research is based on, first, qualitative analysis of original photographs of contemporary murals and visual displays at Universidad Nacional de Córdoba in Argentina. These photographs were collected during my study abroad within the span of several months—secondly, four semi-structured interviews of university students. I have registered and transcribed several hours of interviews for this study.This research highlights that Argentina's truth commission did not close any wounds. On the contrary, visual representations serve as a manifestation for strengthening the collective and individual memories of the trauma experienced by Argentine citizens under the military junta.

Abstract Name: Mental Healthcare Access In Military Service Members

Background: Mental healthcare (MHC) is important to the well-being of the men and women serving in the military. There are many stressors that are a part of serving in the military. These stressors may accumulate and increase the risk of mental illnesses developing or worsening in the service member (SM). Despite the

need for SM to have access to mental health care (MHC) and it being available to them, many do not seek MHC. Purpose: This study aims to assess whether the acceptance and commitment therapy (ACT) app or peer support networks are more effective to increase access to MHC. Method: Service members (SM) in the community will be invited to participate using convenience sampling. After receiving information about the two interventions being studied; the ACT app and peer support networks; they will be given the Department of Defense (DoD) Health Related Behaviors Survey (HRBS) with questions added assessing for preferences between the two interventions as well as any additional questions. Conclusion: There are many barriers to MHC among SM, with stigma being a key barrier. With fears of impacts to their careers, SM may refuse to seek MHC often worsening long-term outcomes. Two interventions; ACT app and peer support networks; are being studied to assess how effective they are at increasing access to MHC. With implementation of one or both of these interventions, it is hopeful that access to MHC will increase, as well as decreased stigma towards MHC and mental illness. Keywords: Mental health care, stigma, military service members, acceptance and commitment therapy (ACT) app, peer support networks

Abstract Name: COVID and Pollution: Evidence from Pandemic Lockdowns

Pollution has always been considered as one of the major environmental sources of detrimental health and deaths worldwide, due to which economies have always implemented policies to reduce pollution. According to World Health Organization (WHO), air pollution directly impacts the lung development, thus causing various respiratory diseases such as asthma, emphysema, and chronic obstructive pulmonary disease (COPD). Latest literature has shed light on how COVID-19 pandemic and lockdowns impacted the labor market, various outcomes of health and well-being of individuals, and time spent by people on various activities. But little research has been done on the impact of pandemic on pollution in the US. COVID-19 stay-at-home (SAH) orders create a natural experiment to investigate the effect of COVID-19 on air pollution, as SAH orders significantly impacted the individual mobility and economic activities in the US. In this paper, we exploit the differential timing of SAH orders in different states and utilize a staggered difference-in-difference (DID) econometric strategy/framework to compare the pollution levels of the counties with and without the SAH orders. We hypothesize that the pollution level in the counties with higher levels of SAH orders would reduce significantly as compared to the pollution level of counties with lower levels of SAH orders. As an extension, we also study its consequent impact on health outcomes due to reduced pollution. Since 2020, COVID-19 has hugely impacted the US and the whole world in various adverse ways. This project contributes directly to the literature of Environmental and Health Economics through the impact of COVID-19 on pollution and consequently on health of individuals. Also, it uses one of the widely used Econometric Models (Staggered DID) to achieve the main objective of the paper.

Abstract Name: The Impact of ESI on Reaction Time

Attention and memory are closely related, however the role that memory training plays in the interaction between attention and memory is not well understood. Episodic specificity induction (ESI), a memory training, is said to help individuals vividly recall past events, improving memory accuracy. Results from past ESI studies have highlighted its potential for application in individuals with overgeneralized memory, such as patients with anxiety. To explore attention concerning memory accuracy, it is necessary to assess the impact of ESI on reaction time variability – a behavioral correlate of sustained attention. Previous studies have associated less variable reaction times with sustained attention. Participants (n=147) underwent ESI which consisted of watching a brief video and recalling details of the surroundings, people, and actions in the video. After ESI (or control impressions), participants were shown pictures for which they made negative/neutral judgments. After a short delay, participants were given a memory test where they were asked to differentiate between the images they had seen before (targets), images they had not seen (foils), and similar images (lures). Using the collected data, a secondary analysis has been conducted examining the influence of ESI on reaction time variability during the encoding portion in the context of memory accuracy. We hypothesize that following ESI, people will exhibit sustained attention (i.e., less variable RT) during the encoding of the images and will exhibit higher accuracy in recalling the same images. This would suggest that ESI leads to better memory performance partly through sustained attention to the task.

Abstract Name: Faculty-student collaboration in the ECOLE

In this presentation we dive into the dynamics of faculty-student collaboration in the context of the Experimental and Computational Linguistics Ensemble (ECOLE) lab. The lab, housed in the English Department at San Francisco State University, serves as a hub for cross-disciplinary research on language. Students participating in the lab come from a variety of disciplines, from computer science and math to education and psychology. Diverse perspectives and backgrounds form a strong foundation for collaborative environment. Student-researchers have a complementary set of skills, from behavioral data science to qualitative research methodologies. Over the years, we have explored the topics that pertain to the nature of human-computer interaction, the cognitive foundations of language, and the role of language in society. The lab's most recent research project focuses on Large Language Models, such as ChatGPT. Using this project as an example, we discuss the dynamics of faculty-student collaboration and how the project evolves based on the unique contribution of lab members, who bring to the table expertise from diverse academic fields, curiosity, and passion for research.

Abstract Name: Enhancing Machine Learning with Tempered Fractional Gradient Descent

Fractional order gradient descent methods have grown in popularity on account of their practical applications in the training stage of machine learning. Compared to their well defined whole number (integer) counterparts, fractional gradient descent methods have been used to improve the speed of convergence in optimization algorithms. There is an interesting development in this area called tempered fractional calculus. Here, we add an exponential term to the fractional operations, making them a bit more complex but potentially more effective. In this paper, we will explore the addition of an exponential term to a fractional order gradient descent to see if this change can make algorithms reach their best performance more quickly. The exponential term creates a tempered fractional gradient descent, which will model the gradient descent function as a semi-heavy tailed function. To test this, we will conduct simulations on common machine learning training datasets to explore the effect of the tempered fractional gradient descent method on convergence speed and accuracy in comparison to older fractional order methods as well as the integer order methods. The study is expected to show that these new tempered models are better in several ways compared to the non-tempered fractional order method. One big plus is that our new model is more flexible. It has an extra 'tempering' parameter, which gives us more control over the method's memory. This could be a big step forward for optimizing how machines learn.

Abstract Name: Exploring Gender Differences in ADHD through Narrative Competency

Individuals affected by Attention-Deficit Hyperactivity Disorder (ADHD) often present with pragmatic language impairment. While not unanimous, existing literature on narrative language use generally provides evidence of a relationship between ADHD and narrative impairment. However, despite the large body of work studying ADHD and language, very little of it focuses on adults. Additionally, there is only a small (but increasing) data pool describing the effect of gender on ADHD symptomatology. The present study explores whether young adults with ADHD have less cohesive and coherent narratives than young adults without ADHD, and whether there is a gender component to narrative competence. Three prompt-driven narratives were collected from 4 groups of 5 people each: Clinical women (i.e. women with ADHD), clinical men, non-clinical women, and non-clinical men, and analyzed with regards to coherence and cohesion. Because these are largely mental organizational/executive functioning (EF) skills, study activities were designed to ensure participants were genuinely challenged in those areas. In the opinion of the investigators, activities used in prior research such as story retelling or other highly structured narrative tasks may mask deficits due to an insufficient EF load placed on the narrator. EF measures were also collected from participants using the Executive Skills Questionnaire (ESQ). It is expected that young adults with ADHD will have less cohesive and coherent narratives than young adults without ADHD and that gender will have a significant effect on the cohesion and coherence of narratives, with men having more difficulty than women. Understanding how ADHD affects narrative abilities may enhance understanding of ADHD's effect on areas such as executive function, social interaction, and language use for spoken discourse. Additionally, it may guide professionals' treatment of ADHD patients who struggle in any of those aspects.

Abstract Name: How Dark is the Dark Web? Examinations on the Purpose of TOR and Dark Web Usage

There have been hundreds, if not thousands, of studies conducted concerning the TOR Browser and Dark Web in general. However, many of these studies focus on the effects of the Dark Web rather than the issue of accessibility to the Dark Web and its harmful forums, blogs, and marketplaces. Harviainen, Haasio, and Hämäläinen conducted a study of similar nature in January 2020. This study scrubbed Dark Web forums to find users buying illicit drugs and find connections between their personal lives and lives online. Additionally, in June 2021, Davis and Arrigo detail the pitfalls and side effects of easy accessibility to the

Dark Web and find that they are wholly negative. To date, there is little research examining the use of the TOR browser and the Dark Web with a comprehensive approach. In this light, this paper examines the effects of unbridled access to the Dark Web through the TOR Browser and its effects on individuals' behaviors, specifically as it relates to extremist activities. Through the use of survey and browsing history collected via Wireshark, this research highlights the spectrum of TOR Browser and dark web usage. Studying this issue is beneficial for areas of cybersecurity and foreign and national policy and may assist in filling the gaps of data in these areas.

Abstract Name: Kintsugi 3D Viewer: User-Centric Design for Cultural Heritage Accessibility

This design project focuses on the creation of both 2D and 3D elements to develop and support the usage of the application Kintsugi 3D Viewer. The project aims to create appealing elements that simplify navigation and increase interaction while also representing the ethos of the application. Created to increase access to more accurate digital representations of cultural heritage objects, the application was designed to be used by a wide audience with varying levels of digital proficiency. With this information in mind the design approach rested heavily on the development of proto personas with a strong focus on accessibility. This approach along with concept testing, A/B testing, and surveying helps to guide the creation of minimalist iconography, logo, and UI that draw on commonly used practices and symbols. The design helped to define the image of Kintsugi 3D Viewer and enhance users' experience and usage of the application. This project illustrates the value of user-centric design and its positive impact on cultural heritage and computer sciences.

Abstract Name: Is asking about suicidality in a population with ASD and Social Anxiety a protective factor?

Suicidality is a major public health issue. A prevalent myth is that discussing or asking about suicidality can increase one risk of dying by suicide. This has been proven false, and that asking about suicidality can help mitigate it for the typical person. However, suicidality is a larger issue for those with ASD (O'Halloran et al., 2022) and social anxiety (Leigh et al., 2023). These groups have not been researched in the same way, and

there is no conclusive answer whether asking about suicide helps or hurts these populations. Thus, we pose the question: is asking about suicidality a protective factor for those with ASD and Social Anxiety? To answer this question, we recruited 95 individuals with 72 fitting into the clinical population. We sent out a survey over Metricwire every evening asking about suicidality. We then had participants come in every 6 weeks and we administered CSRSS to assess suicidality. We compared the CSRSS scores to the visit that the CSRSS was administered to get our results. Participants with autism decrease over a quarter of a point more each visit in their CSSRS scores (E=-0.28, SE=0.07, p<.001). We observed a similar decrease in the subjects with social anxiety (E=-0.35, SE=0.07, p<.001). This indicates that asking about suicidality can decrease suicidality in these populations. While the results from this study are promising, it still needs to be taken with a few limitations in mind. First, several participants dropped out of the study. Another limitation was that this was completed in a small group. Overall, this study is somewhat promising for potential treatments, however, this needs replication to further the investigation of whether talking about suicidality is a protective factor.

Abstract Name: Investigating Undergraduate Students' Persistence in Academic and Extracurricular Domains

We explored whether college students' coping strategies and intentions to persist differed between academic and extracurricular domains. Participants included 125 students from one Midwestern university. They were recruited from the athletics department, music and theater department, and the psychology department's online participant pool. Through one 10-minute online survey, students responded to two sets of items about their setback experiences: one in academic settings and the other with extracurriculars. In both domains, we measured active, avoidant, distraction, and support-seeking coping (support-seeking reflected venting in this study). Stakes captured the extent to which students felt that a particular domain was central to their long-term goals. Persistence measured the extent to which students would continue trying to complete tasks even after they encountered challenges. We addressed the following sets of questions: 1. Do students report different degrees of stakes and persistence across academic and extracurricular domains? 2. Do students differentially engage in coping strategies following setbacks in academic and extracurricular domains? 3. Do students' coping strategies and perceived stakes predict their persistence on tasks in academic and extracurricular domains? Students indicated that their performance on academic tasks was more central to their long-term goals than their performance on extracurricular tasks. However, students also reported greater persistence for extracurricular activities than for academic tasks. Active coping in academic settings predicted greater persistence in that domain, whereas more venting predicted lower persistence. Distraction coping (using humor) after extracurricular setbacks related to greater persistence in that domain. These results help us understand how undergraduate students value academics and extracurriculars. Different coping strategies may help support persistence among college students, especially when perceived stakes are higher. With this, we can develop methods to better support students through obstacles within the university system.

Abstract Name: An Exploration into Potential Function Conservation of the Kinesin 7 in Arabidopsis thaliana

This project examined the function of kinesin 7, a protein involved in mitosis (separation of duplicated chromosomes into daughter nuclei). Mitosis is a vital process conserved in all eukaryotes. While much research explored the role of kinesin 7 in animal mitosis, little is known about kinesin 7 function in plants. A comparative analysis of these protein across Plant and Animal kingdoms will provide insight into the differences between evolutionary lineages. To study kinesin 7 in plants, multiple SALK lines of the genetic model flowering plant Arabidopsis thaliana predicted to harbor an insertion allele at the kinesin-7 gene locus were used for genotyping. A PCR/gel electrophoresis genotyping protocol to genotype each plant to recover a homozygous recessive plant. Resulting genotypes will be linked to phenotypes of each plant, to reveal the plant kinesin protein's functionality and highlight differences in the protein across kingdoms. Possible homozygous recessive plant were found but have not yet been fully confirmed. Based upon a protein alignment of five kinesin 7 proteins among five different model organisms across both kingdoms, the results indicate a possible conservation within the motor domain of the protein. This conservation of the motor domain may indicate of function conservation, as similar protein domain structure often results with similar functionality.

Abstract Name: Money In Movement: A Cry For Federal Arts Advocacy

The starving artist is a stereotype used to describe how painters, musicians, and dancers who pursue their passion do so at the expense of their financial wellbeing. While not all artists find themselves in financial struggle, there is undeniable truth to the difficulties dancers face in their pursuit of a career in contemporary movement. While dancers in many developed countries in Europe and North America alike do not find themselves in the highest income bracket, dancers in the United States especially struggle to fiscally sustain themselves without making sacrifices to their health and lifestyle. Despite the struggles that artists face, some politicians in the United States actively try to defund the arts, thereby further increasing the difficulties dancers encounter. This study analyzes the current state of federal arts funding in the United States and its impact on the field of dance. The National Endowment for the Arts is an independent federal agency that provides grants to dance organizations. In addition to supporting specific dance companies, this funding positively impacts the surrounding community and economy as a whole. This paper compares the total number of federal grants and the total amount of money provided to dance organizations in the 1980s versus that of 2022, and also takes inflation into account. Using data from the US Bureau of Labor Statistics, and personal accounts of dancers in various countries, it compares arts funding in the United States to that of European countries and describes the wages and living experiences of dancers in these countries. Federal funding towards dance companies in the United States has not adjusted to account for inflation and has actually decreased significantly. Dance organizations and the entire United States economy would benefit if there was an increase in federal funding allocated to arts organizations.

Abstract Name: Impairments in Cerebral Autoregulation and Cerebrovascular Reactivity in Cancer Survivorship

Roughly 46% of cancer survivors report cognitive dysfunction across many types of cancer, which has been associated with anti-cancer therapy and often results in reduced quality of life. Pre-clinical studies have suggested that the underlying factors of cognitive decline likely involve cerebrovascular dysfunction. We aimed to characterize local cerebrovascular regulatory functions (cerebrovascular reactivity and cerebral autoregulation) and central large artery stiffness (aortic arch stiffness) in cancer survivors, within 1-5 years of completing treatment compared to age- and sex-matched healthy controls. Aortic arch pulse wave velocity (aaPWV) was determined using Doppler ultrasound scans of the aortic valve and the descending aortic arch. Cerebrovascular reactivity was assessed as the change in middle cerebral artery velocity relative to the change in end-tidal carbon dioxide during a modified rebreathing protocol. Cerebral autoregulation was determined using Mx, a moving correlation coefficient between finger plethysmography-derived arterial blood pressure and cerebral blood velocity of the middle cerebral artery. Higher Mx values indicate poorer cerebral autoregulation. 11 women were recruited (5 healthy controls and 6 cancer survivors who had received treatment). Mx values were higher in cancer survivors. Both cerebrovascular regulatory functions were impaired in cancer survivors compared to healthy controls and decreases in cerebral autoregulation were associated with increases in aortic stiffness. The present findings highlight the importance of monitoring cerebral and global vascular function in cancer survivors who are at high risk for cognitive decline.

Abstract Name: The Role of TIMP1 in Melanoma

Melanoma is the deadliest form of skin cancer due to its ability to metastasize to other organs, specifically the brain. A better understanding of the mechanisms of brain metastasis, the pathways, and genes that play a role in this mechanism can lead improved treatments. We are investigating genes in melanoma to study their influence on metastasis and identify possible therapeutic interventions. Differential gene expression analysis

between human melanoma brain metastases and extracranial metastases revealed differences in several genes, including higher expression of Tissue Metallopeptidase Inhibitor 1 (TIMP1) in melanoma brain metastases. TIMP1 is a multifunctional protein that has a primary role of inhibiting the activity of metalloproteinases (MMPs), which in turn inhibits the degradation of the extracellular matrices surrounding the cell. It has also been discovered that TIMP1 activates intracellular signaling pathways to promote cell growth and cell survival. In melanoma, TIMP1 was found to activate signaling pathways that have been previously found to promote metastasis and increase resistance to anoikis, which is a type of cell death that occurs following detachment from the extracellular matrix. In this study, we evaluated the effect of TIMP1 expression on melanoma progression and metastasis. We utilized in-vitro assays of melanoma cells expressing TIMP1 to study its effects on migration and invasion, as well as in vivo melanoma mouse model based on the well established RCAS/TVA avian retroviral system. The results of this study will have a profound impact on the understanding of melanoma metastasis and may identify TIMP1 as a possible target for future treatments in patients.

Abstract Name: A Pragmatic Framework for Inclusive Leadership Capabilities

The purpose of this research is to identify the capabilities (knowledge, skills, and mindsets) that enable leaders to be inclusive. We regard inclusive leadership as a set of leader behaviors and actions that facilitate group members contributions to process and outcomes by elevating their sense of belongingness and yet retain their sense of uniqueness. Inclusive Leadership is a rather new concept and needs significant more development. Through a thorough review of academic and practitioner's literature we first make the argument that earlier research on inclusive leadership has enriched definitions and grounded the concept in theory, but there lacks an understanding of how to pragmatically develop inclusive leadership capabilities. Capabilities fuel the identified inclusive behaviors grounded in literature; however suggested behaviors cannot be executed without developing inclusive leadership capabilities. We next propose a framework consisting of six dimensions namely, understanding oneself, creating connections, fostering collaboration, creating equity, motivating a diverse mindset, and conflict resolution to work with differences. These dimensions were selected by consolidating existing theories and definitions of inclusive leadership and building upon them to address the lack of focus on developing inclusive leadership capabilities. These capabilities can be built on for an individual leader rather than a framework for team or organizational growth. This model provides a practical framework to guide an inclusive leader's development and advances our conceptual understanding of how to become more inclusive. Our model can formatively influence organizations' leadership development programs and inclusive leadership education. It also provides direction for future research in developing measurement and evaluation tools for inclusive leadership competence and for identifying related developmental paths and experiences.

Abstract Name: The Impact of Organizational Restraints on the Accessibility of Educator Resources

Campfire has many educators who utilize the resources available to them. Although Campfire wants to help as many families as possible, there is a roadblock to assisting outside families not associated with the agency. Social work students are currently in the process of working with the Camp Fire agency within their community to develop a research outline leading to conducting community-based research which will lead to an intervention to address this accessibility concern.

Abstract Name: Prescribed burns: Is there an impact on small mammal diversity?

North American small mammals of the orders Rodentia (mice, voles, squirrels, etc.) and Eulipotyphla (shrews) hold important functions in many ecosystems. They act as prey for predators, consume vegetation, aerate the soil via digging, and disperse seeds. One notable habitat for small mammals is the prairie, an ecosystem whose area has declined by more than 90% due to habitat conversion (agriculture and development). Controlled burns are a common management tool in recovering and maintaining prairie ecosystems, but the link between the impact of burns and small mammal diversity is incomplete. To delve into this topic, we hypothesized that there would be a relationship between burn year and small mammal diversity. Our study was implemented during June – July of 2023. Small mammals were live-trapped and the following data collected, species, weight, gender, reproductive condition, and body length. Trap lines were distributed on three burn ages; year of burn (2023), burned in 2021, or burned more than three years ago. In our 594 trap nights, we captured 130 small mammals. Data analysis suggests a significant difference between the burn site age and species caught ($\chi 2 = 84.5$, df = 2, p < 0.001), which supported our hypothesis. These results contribute scientific information about the impact of controlled burns on the small mammal community in the prairie ecosystem.

Abstract Name: The Impact of Test-Optional Application Cycles on Institutional Diversity

The objective of my study is to analyze college admission requirements in light of increasing test-optional college applications, specifically, the rate of test score submissions in relation to student demographics. I will observe this over a period of four years (2019-2022) and look at various college categories (e.g., private selective). The primary perspective I have taken into consideration while designing this project is the widely held belief that standardized tests, specifically the SAT, are racially biased and exacerbate the systemic biases that exist within education. Many studies prove that there is racial bias embedded in standardized testing. If students were not required to submit test scores, would there be an uptake in the number of minority students enrolled in the more competitive institutions? That is the question that many parents, students, and university employees have asked in light of COVID and the push for test-optional applications, and that is the question I aim to answer with my study. My research began with an analysis of the common app data that reported on the demographics of students reporting test scores. I then moved to IPEDs data and selected 20 schools that fell into one of four categories: public selective, public non-selective, private selective, and private non-selective. I also conducted individual interviews with admissions representatives from 2-3 schools per category. These interviews addressed specific information on 2020 and 2021 first-year enrollment data. The primary conclusion, at this time, suggests that the move towards test-optional had a slight impact on the proportion of diverse students among the four different types of institutions, including the most competitive.

Abstract Name: "Is a Heathen Worth Educating?" Korean Student's Perspective on Race and Racism in the Jim Crow South

Yun Ch'i-ho, a Korean student at Vanderbilt University and Emory College in the late 19th-century, found himself in a society deeply invested in Jim Crow era racism and xenophobia, and kept records of his daily life in a diary he would maintain for 43 years. Despite being such a valuable source, there has been little scholarship connecting his experiences to the context of his time, as Yun is premierely remembered for being a pro-Japanese traitor, and is still relatively unknown to Western historians because of how quickly he had been shunned by the Korean people for the remarks he made during the Korean Independence Movement in 1919. However, as the only Korean in the American South, Yun Ch'i-Ho was placed in a unique position as a "foreign other" to observe and be observed by the white American population. This project is a deep read of the diary entries from 1889-1893, the years he spent as a student in America, that are then used to understand the relationship Yun personally has with racism in America. He was not only a victim of anti-Asian racism and discrimination, but this unique position also allowed him to observe the aggressions of anti-Black racism without expectations to interfere. As a result of his environment, Yun began to adapt pieces of that rhetoric into his own vocabulary and use it against other Asian students and Black Americans he met, contributing to the powerful role that language has in society.

Abstract Name: In Vitro Inhibition of Bacterial Plasmid Transfer by Dietary Zinc

Background: The emergence and spread of antimicrobial resistance (AR) in bacteria are a global concern as bacteria share large AR plasmids, allowing for novel resistance, virulence, and metabolic capabilities. This poses a threat to both human and animal health and productivity. The animal gastrointestinal tract serves as a reservoir for AR plasmid transfer. Unexpensive and safe strategies to reduce or eliminate AR in bacteria are needed. Both zinc and vitamin D3 are essential components of the human diet and have predicted antimicrobial properties. The objective of this study is to assess the role of dietary zinc on the transfer of AR plasmids between the bacteria strains E. coli APEC-02-211 and E. coli HS-4. Methods: Overnight cultures of APEC-O2-211 and HS-4 were prepared under appropriate antimicrobial selection. Cultures were standardized to OD600 nm of 1.0 and mixed 1:1. Water (control), zinc, or vitamin D3 were supplemented at a 1:10 ratio at varying final concentrations. Both over-the-counter zinc tablet homogenate and zinc gluconate were tested. The well plate was serially diluted and incubated overnight before being plated on selective and differential media. Colonies were counted and analyzed to validate the efficacy of the compounds of interest. Results: Conjugations supplemented with vitamin D3 did not have significant decrease in the rate of plasmid transfer ($p = 0.0873$). Conjugations supplemented with either zinc tablet homogenate or pure zinc gluconate resulted in significantly fewer transconjugants ($p < 0.0001$) and significantly less plasmid transfer ($p < 0.0001$). Overall, our data indicate that supplementation of diet with zinc may reduce the incidence and transfer of AR between bacteria in the gut.

Abstract Name: Modeling a Novel Detection Platform for Stage IV Breast Cancer using Murine PyMT+/- Models

The early detection of breast cancer is critical in improving patient outcomes; however, many patients lack access to effective methods of detection that are time-sensitive, affordable, and noninvasive. Here, I explore the dielectrophoretic-based separation of cells as a noninvasive point-of-care technique for the early detection of breast cancer. Cancer cells exhibit differences in morphology and cytoplasm contents compared to normal cells. Our hypothesis is based on the fact that changes in the cell membrane, cytoplasm, and ECM under breast cancer conditions lead to differences in their dielectric properties or bioelectric signatures, i.e., capacitance, permittivity, and conductivity of the membrane and cell interior compared to normal PBMCs which we have demonstrated in our previous study. In that study, we compared the dielectric properties of PBMCs obtained from PyMT tumor-bearing mice at age 14 weeks (stage IV breast cancer) and older with age-matched wild-type models, utilizing the dielectrophoretic crossover technique. My ultimate objective is to explore these dielectric differences to separate cells effectively by appropriately balancing hydrodynamic and dielectrophoretic forces within a microfluidics device. This has been demonstrated through simulations using COMSOL Multiphysics software version 6.1. The numerical results obtained by integrating the

creeping flow, electric current, and particle tracing modules in COMSOL v6.1 indicate that PBMCs from PyMT tumor-bearing mice can be maximally separated from age-matched wild-type models using a low voltage and frequency. This presentation also discusses the velocity profile, electrode potential distribution, and electric field streamline within the microchannel. This outcome represents an initial step towards developing a breast cancer sorting device utilizing PBMCs from mouse models. This outcome represents a crucial step towards a novel, non-invasive, rapid, and economical method for the early detection of breast cancer on a single microchip.

Abstract Name: Using a Quadrupole Electrodynamic Trap to Study the Equilibrium within Microdroplets

The physical environment of a microdroplet has the possibility of changing the equilibrium of certain reactions. Previous research has demonstrated that reaction kinetics show a distinct difference in microdroplets than in bulk solutions. And while it has been shown that microdroplets can be catalytic, little is known about the actual mechanism. And by using a different way to study the droplets by isolating single microdroplets in a controlled setting this research aimed to characterize the behavior of microdroplets. What is learned from this research could have particular applications in catalytic chemistry as a greener way of changing the equilibrium of stubborn reactions. This research studied the formation of an imine dye that was able to be studied through fluorescence. The reaction was characterized in bulk by measuring the equilibrium and kinetics with UV-vis and fluorescence. The conditions of the samples were tested with variations of pH, viscosity, and salt content as well as combinations of each. By using a trap to levitate the droplets their change in equilibrium was studied through their change in fluorescence as the equilibrium changed. It was found that the conditions of the microdroplet had no effect on the equilibrium of this imine formation showed through no change of fluorescence. Due to the negative result when compared to other research data, more needs to be done in order to fully discuss the conditions of a microdroplet and how they may work for certain reactions and not others.

Abstract Name: Higher depression is associated with lower self-reported adherence among patients with multiple myeloma taking oral anticancer medications (OAM)

Introduction: Patients with cancer, including patients with multiple myeloma (MM), are living longer in the

new OAM treatment paradigm. Depression correlates with reduced adherence in other chronic diseases, but little is known about these relationships in patients with cancer. We explored associations between depression and self-reported adherence among patients taking OAM for MM. Methods: Cross-sectional, secondary analysis of adherence study in patients taking OAMs for MM. The Patient Health Questionnaire (PHQ-9) assessed depression (0-27; higher=worse). Self-reported adherence was assessed by the PROMIS Medication Adherence Scale (PMAS) total score (9-45), a single item (“I took this medication as recommended;” 1-5), and subscales for medication beliefs and knowledge (MBK; 4-20) and medication-taking behaviors (MTB; 5-25); higher scores=better. Self-report and medical record review characterized sociodemographic and clinical variables. Spearman’s rank-order correlations summarized associations between depression and self-reported adherence. Results: Participants (n=73) averaged 63.9 (SD=10.3) years of age. Most (57.5%) were male; non-Hispanic white or Black (82.2% and 13.7%); and took lenalidomide (n=53) or pomalidomide (n=25) and an average of 9.4 (SD=5.0) concomitant medications. The median PHQ-9 score was 2.0 (IQR=1.0-5.0). Median (IQR) PMAS scores were: total=45 (43-45); single item=5 (5-5); MBK=20 (20-20); and MTB=25 (24-25). Moderate associations existed between depression and the PMAS total score and MBK subscale (r=-.364 and -.317, p<.01). Weak associations existed between depression and the MTB subscale and single item scores (r=-.253 and -.282, p<.05). Discussion: Self-reported adherence was high. Higher depression correlated with lower self-reported adherence (strongest relationships existing between depression and the PMAS total score and MBK subscale). Patients taking OAMs should be screened for depression. Future research should explore temporal relationships between depression and adherence and additional measures of medication adherence.

Abstract Name: Enhancing Literary Understanding in Secondary Education through Role-Playing Games

This project explores the idea of video games in secondary education. As part of our research in game-based learning, the classic epic poem "Beowulf," widely taught in higher secondary schools, has been adapted into a role-playing game (RPG). The core objective is to refresh literary education by offering an engaging and interactive platform for a deeper understanding and appreciation of this classic work. The Unity game engine has been used as the implementation platform. In the game, players navigate the legendary village of Heorot as described in the original poem, engage with non-player-controlled (NPC) characters who offer insights and narrative progression, and confront challenges that mirror the poem's key events. The gameplay is enriched with boss fights and cutscenes that bring Beowulf's story to life.The Beowulf story has been divided into four modules. Players take on Beowulf's role in defeating monsters. Central to the game's design is the integration of educational elements, such as quiz-based interactions at the end of each module, which test the players' comprehension of the text in an immersive manner. Players are encouraged to explore and interact with the game world, which feeds them more information about the story of Beowulf with dialogue and visual storytelling.This project stands at the intersection of literature, education, and gaming, offering a unique perspective on how traditional teaching of literary works can be reimagined for modern learning environments and better engagement. Preliminary observations suggest a positive influence on student engagement and comprehension of the poem, as commented by a local schoolteacher teaching “Beowulf.” The user study aims to evaluate the efficacy of game-based learning quantitatively and qualitatively in higher secondary education. This project not only represents a novel approach to teaching classic literature but also contributes to the broader scope for innovative educational styles in the digital age.

Abstract Name: Synthesis of Metallo-meso-tetraphenylporphyrin Derivative Using Zn(II) Metal

The study of metalloporphyrins has revealed enhanced reduction capabilities in porphyrins metallated with late first row transition metals, which in turn promises great potential as catalysts for different reduction reactions. These reactions include carbon dioxide reduction, oxygen reduction reactions, and hydrogen evolution reactions. Tetraphenylporphyrin was used in this experiment to determine if it could be metallated with zinc acetate and form metallo-meso-tetraphenylporphyrin. The procedure was changed over the course of multiple trials to result in the highest yield and ensure all of the porphyrin and zinc acetate were reacting. The resulting compound was analyzed using UV-Vis Spectroscopy, IR Spectroscopy, and thermogravimetric analysis. The compound was also sent to Georgia Southern in order to obtain a crystal structure. The structure revealed a slight trace of impurity but the main body of the crystal appeared to have successfully bonded with the zinc. Future work includes using other late period first row transition metals and determining if they can also react with the tetraphenylporphyrin and produce similar results. The experimental procedure as well as confirmation techniques used to determine the correct compound was made will be presented.

Abstract Name: Laboratory Life Cycle Maintenance of the Soft Tick Ornithodoros tartakovskyi

The soft tick genus Ornithodoros, of the family Argasidae, is associated with bacterial and viral diseases such as tickborne relapsing fever and the tickborne encephalitis virus complex. The purpose of this project was to generate life cycle history data for the laboratory maintenance of the soft tick Ornithodoros tartakovskyi. Ticks in this project were regularly blood-fed, and life cycle history events were quantified. Events included how many nymphal stages occur in this life cycle, how many days it takes each nymphal stages to molt to the next nymphal stage, how many minutes it takes different life cycle stages to engorge during blood feeding, how many minutes it takes for an engorged tick to detach during blood feeding, how many days it takes for female ticks to produce eggs, how many eggs are produced, and how many days it takes for eggs to hatch. This data, along with continued data collection, will be included in a manuscript entitled 'Laboratory Maintenance of Ornithodoros tartakovskyi,' which we will submit to the peer-reviewed journal Ticks and Tickborne Disease. Understanding the maintenance of this species in a laboratory setting is key to advancing research in the future. This project aims to outline approaches for continued community research.

Abstract Name: Preparative scale biosynthesis of muconic acids

Ring-cleaving dioxygenases (RCDs) are a class of enzymes responsible for breaking down aromatic compounds as a carbon source for cellular processes. These enzymes operate with chemo- and regioselectivity of their oxidation to generate ring-opened products. In particular, RCDs produce highly conjugated muconic acids and semi-aldehydes as the primary products of their reaction. These molecules have broad potential as building blocks for organic synthesis of valuable compounds, such as adipic acid. A wide variety of RCDs have been studied for their ability to metabolize aromatic compounds. However, few studies have been performed which utilize RCDs for organic synthesis. Our research aims to study the function and selectivity of a small library of RCDs on a diverse panel of substrates in order to classify the substrate scope of these enzymes. As a step toward reaching this goal, we leveraged the biocatalyst CatA for the milligram to gram-scale synthesis of several muconic acids with alkyl or halogen substituents at C2 or C3. Products were isolated and purified by trituration with cold acetonitrile in moderate to high yield. Product characterization via NMR spectrometry confirmed the stereochemistry of the resulting di-ene products.

Abstract Name: Increased School Absenteeism in Students with Attention/Hyperactivity Problems: A Scoping Review

Attention deficit hyperactivity disorder (ADHD) is a chronic neurodevelopmental disorder that, left undetected and untreated, can devastate and impede the life trajectory of thousands of children. Unfortunately, children and youth afflicted by this disorder often go unnoticed and unsupported within the Canadian and American education systems. Studies show that successful completion of education plays a critical role in equipping students with ADHD with the skills and resources to effectively manage their condition, leading to better overall life outcomes. Research has connected the lack of childhood skill development in managing ADHD symptoms with severe, interconnected psychosocial outcomes such as school failure, bleak employment outcomes, high crime and incarceration rates, and even premature death. Unfortunately, the COVID-19 pandemic has exacerbated children's educational outcomes, disproportionately impacting school attendance rates among children with ADHD. This scoping review aimed to investigate the relationship between attention and hyperactivity problems (AHP) among school-age children/youth and

school absenteeism in both pre-pandemic and post-onset-pandemic studies. The main objective was to investigate whether children with AHP were missing school at higher rates than their non-AHP peers. Through a systematic literature search across numerous databases, 1282 studies were assessed, identifying 37 studies focusing on the association between AHP and school absenteeism. Preliminary analyses revealed that students with AHP were more prone to experiencing increased school absenteeism, including cases of school refusal, avoidance, suspension and expulsion from school. Similar findings were noted between pre-pandemic and post-onset-pandemic articles. These findings are troubling, given that numerous studies have linked school absenteeism to adverse educational and psychosocial outcomes. In light of these findings, there is an urgent need for educational and policy reforms that prioritize supporting and accommodating children with attention and hyperactivity problems within the educational system.

Abstract Name: Investigating the Role of Concurrent NF1, BRAF, and NRAS Mutations in Melanoma

Melanoma is the deadliest form of skin cancer, largely due to its potential to metastasize. Utah has the highest incidence of melanoma per capita in the United States. Metastatic melanoma often has a poor prognosis, with a five-year survival rate estimated at 32%. Genetic alterations are major drivers of melanoma, and 91% of melanomas contain mutations that lead to hyperactivated MAPK/AKT pathway signaling. NF1 is the third most commonly dysregulated gene, behind BRAF and RAS, that can hyperactivate MAPK/AKT signaling. NF1 mutations are present in just under 20% of melanomas, and more than half of these are predicted to be loss of function mutations (NF1 LoF). Although previous research has established that NF1 LoF frequently co-occurs with mutations in the oncogenes BRAF and NRAS, as well as with mutations in tumor suppressors PTEN and CDKN2A, the cooperation of NF1 LoF, mutant BRAF, and mutant NRAS in the presence of altered PTEN and CDKN2A remains understudied. To address this, we used an established autochthonous in vivo mouse model of melanoma based on the RCAS/TVA avian retroviral system to assess the ability of NF1 LoF to cooperate with mutant BRAF and mutant NRAS in the presence of PTEN and CDKN2A loss to promote tumor progression and metastasis. These results demonstrated that mutant BRAF and NF1 LoF cooperate in the context of PTEN and CDKN2A loss to decrease survival from around 140 days (NF1 LoF alone) to 60 days (NF1 LoF and mutant BRAF). More research will be completed to evaluate cooperation in the presence of mutant NRAS. With 18% of melanomas exhibiting NF1 alterations, this research addresses a pressing clinical need and offers the potential to discover treatment options for a significant patient population.

Abstract Name: Comparative Analysis of Patient Satisfaction: Emergency Department Care for Self-Inflicted vs. Physical Concerns

The surge in emergency department visits for self-inflicted injuries in the United States, nearly doubling from 2018 to 2021 (CDC, 2023), raises significant public health concerns. Research indicates that patients with self-inflicted injuries often report lower satisfaction with emergency department care and staff compared to other units where they have received care (Hutchison et al., 2003). This dissatisfaction may contribute to an increased level of risk post-discharge (Geulayov et al., 2019). However, it remains unclear whether dissatisfaction with emergency department care is unique to admitted patients with suicide risk. This study aims to compare responses from the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) among patients (Male = 33.3%, Female= 66.7, % White=98.6%) presenting to the emergency department due to suicide risk (n = 27) versus those with other medical reasons (n=67) from January 2021 – December 2022. Anticipating lower satisfaction among patients with self-inflicted injuries, we conducted a one-way ANOVA revealing significant differences in staff responsiveness F (1,92) =26.62, p < .001, d=0.99 and ED wait time, F (1,92) =7.51, p < 0.01, d=0.57. Although the mean scores were lower in the suicide group for attitudes, courtesy, and supportive staff, the differences were not significant. Our hypothesis received partial support such that patients with suicide risk reported lower staff responsiveness and longer wait times, aligning with prior literature. However, other experiences appear to be similar to those experienced by those presenting with physical illnesses/injuries. These results can guide improvements in the quality of care for suicidal patients, recognizing the need for additional research to address the methodical limitations of the current study.

Abstract Name: The Role of Race and Gender on the Relationship Between Cancer and Quality of Life

As the population of cancer survivors in the United States increases, the implications of disease and treatment on quality of life (QOL) will become increasingly important. Numerous studies report lower physical QOL, but similar mental QOL and depression in cancer survivors compared to cancer-free individuals. However, few studies have assessed the role of race and gender with regard to mental QOL, physical QOL, and depression among those with cancer compared to those without cancer. Without such data, systemic interventions to address disparities in cancer survivorship cannot be implemented. Data for our study came from the Atherosclerosis Risk in Communities (ARIC) study, a longitudinal study of aging populations since 1987. We compared self-reported mental QOL, physical QOL, and depression in cancer survivors (1,019) versus cancer-free individuals (4,615) by gender and race in a population of white (75%) and Black (24.5%) men and women. Mental and physical QOL were measured using the SF-12 questionnaire, and depression scores by the CES-D questionnaire at ARIC visits 5 (2011-2013) and 6 (2016-2017). We compared outcomes by cancer status, stratifying results by gender and race and using mixed linear regression models adjusted for age, sex, and race. We found that regardless of cancer status, women and Black individuals reported worse mental and physical QOL and more depressive symptoms than men and white individuals, respectively.

There was no significant difference in mental QOL and depression scores by cancer status, except worse depression in male cancer survivors at visit 5. However, men, women, and White individuals who had cancer reported significantly worse physical QOL than their cancer-free counterparts; but the cancer versus non-cancer comparisons were not significant among Black individuals. Our findings suggest interaction between cancer status and race, as cancer was significantly associated with worse physical QOL in white but not Black participants.

Abstract Name: Breaking the Silence: Tackling Cultural Beliefs and Practices that Perpetuate Heteronormative Gender Roles and Gender-Based Violence in Vienna, Austria

Gender-based violence (GBV) is a global epidemic that is rooted in gender inequality and perpetuated through cultural norms and patriarchal values, with violence against women present within every country and culture. In Austria, 20% of women have reported experiencing physical or sexual violence within their lifetime, 15% have experienced stalking and over 100,000 people are registered as victims of human trafficking (European Union for Gender Equality, 2016). Despite the prevalence of this issue, the discussion of GBV is still considered a taboo topic and, due to the stigma surrounding it, there is severe underreporting amongst survivors, and the number of incidents of GBV is estimated to be significantly higher. This transdisciplinary qualitative case study explores how cultural norms and practices in Vienna, Austria, perpetuate the patriarchal devaluation of women and how that manifests itself within Viennese society. The research was conducted over a three-month period from September to November 2023 in Vienna, Austria, utilizing semi-structured interviews, participant observation and an anonymous survey of Viennese residents. Through the evaluation of the data collected from the survey responses, interviews and ethnographic field journal entries, the research highlights the patriarchal culture that exists within Vienna, the ways in which violence manifests, and the culture of silence surrounding it. The survey participants and interviewees overwhelmingly expressed the need for change within both culture and political systems, and gave insight into the effects GBV, street harassment and systems of oppression have had on their mental health, safety, and livelihoods. This study provides a better understanding of the lived experiences and enduring realities of Gender-Based Violence, especially in cities that appear, on the surface, to be safe and progressive.

Abstract Name: TIM/TAM Receptors: A Potential Biomarker for Predicting Sensitivity to Zika Virus-Induced Oncolysis in Non-Small Cell Lung Cancers

Zika virus presents a new oncolytic possibility for the treatment of non-small cell lung cancers (NSCLC). A marker predictive of cancer cell susceptibility to Zika-induced oncolysis has not been established. TIM/TAM proteins have been identified as the putative Zika virus receptors on human cells that mediate Zika virus entry. This project investigates the correlation between the expression of TIM/TAM receptors and Zika virus sensitivity in a panel of six diverse NSCLC cell lines.We hypothesize that the various TIM/TAM proteins on lung cancer cells act as activators or inhibitors of virus entry, and their expression predicts sensitivity to Zika virus-induced lysis. Based on preliminary studies, high AXL (TAM) expression correlates with cancer cell sensitivity to Zika virus-induced oncolysis. Conversely, high TIM-1 (TIM) expression correlates with decreased Zika virus-induced oncolysis.We will explore the effect of TIM/TAM receptors on Zika-induced oncolysis by siRNA knockdown of AXL or TIM-1 in each of the six lung cancer cell lines. In the cell lines sensitive to the virus, knockdown of AXL should result in reduced infection and a decrease in cytotoxicity. In the cell lines resistant to the virus, the knockdown of TIM-1 should result in enhanced infection and an increase in cytotoxicity. If siRNA-mediated silencing of AXL and TIM-1 affect cancer cell susceptibility to virus-induced lysis, then the expression of TIM/TAM receptors could be used as a predictive marker for cancer cell susceptibility.TIM/TAM expression, a predictor of cancer cell susceptibility to Zika virus-induced lysis, could be used to identify which tumors would be appropriate for Zika virus oncolytic therapy.

Abstract Name: Lightning Storm Detection on Saturn through Machine Learning Analysis of Cassini Dayside Images

From 2004 to 2017, Cassini captured high-resolution images including lightning flashes and also storm clouds on Saturn’s day side. We explore lightning storm clouds’ relationship with Saturn electrical discharges (SED) activity, and use machine learning for detecting lightning storm clouds. This paper introduces an advanced machine learning approach using the YOLOv5 algorithm for automated lightning detection and classification in previously unexplored Saturn images. The model was trained on 230 plus images of the 2010-2011 storm on Saturn’s day side, confirmed to have lightning. Furthermore, the model’s performance was evaluated on images without known lightning storms to assess its generalization capabilities. Another program, Google Cloud Vision API, successfully labeled 2010-2011 storm cloud images as lightning from its default settings without training. Our ongoing efforts aim to refine YOLOv5 algorithm’s performance for smaller lightning storm detection and improve its proficiency in analyzing storm-related phenomena on Saturn.

Abstract Name: Thermal Time Parameters for Milkweed Germination

It is unclear what the determining factors are for the successful growth of common milkweed (Asclepias syriaca) plants despite large efforts to restore milkweed in response to declining Danaus plexippus populations. This project analyzed previous experimental data to understand the effect of temperature and thermal cycling on the germination rate of milkweed plants collected from various latitudinal populations. In this study, seed pods were collected from 5 plants originating from 10 different geographical locations. These seeds were then divided into 4 incubation temperature groups of 10°, 16°, 22°, and 28° C. Seeds were further divided into three pre-incubation treatments, temperature cycling and cold stratification, cold stratification only, and a control group. These treatments mimic spring conditions that may trigger seed germination. To account for the hierarchical structure of the data, mixed-effects binomial regression models were used to determine the effects of temperature and pre-incubation treatments on milkweed germination rates across different latitudinal populations. Across all latitudes of origin, we found that temperature and exposure to cycling have a positive, significant effect on milkweed germination rates. Additionally, we found significant effects of latitude of origin on germination rates with high-latitude populations germinating at higher rates after controlling for temperature. Furthermore, high-latitude populations that are exposed to temperature cycling have higher germination rates and germinate across a wider range of incubation temperatures than low-latitude populations exposed to temperature cycling. As common milkweed plants are re-introduced to new locations in an effort to increase D. plexippus populations, these results help predict if a plant is going to succeed in its new home.

Abstract Name: The More the Unmerrier: The Impact of Ostracism, Group Size, and Self-Control on State Anger

Ostracism is the act of being excluded or ignored by either an individual or a group. Ostracism is associated with anger and other negative outcomes, and exclusion by a larger group exacerbates this effect. Self-control is defined as one's ability to consciously suppress impulsive, habitual, or automatic cognitions, emotions, and reactions in order to achieve a specific goal. Previous research indicates that individuals with reduced self-control were more likely to exhibit aggressive behavior. The current study is the first to assess the effect of ostracism, self-control, and group size on subsequent state anger. Participants first completed a measure of trait self-control and then were placed with either a group of 2 or 6 fictitious participants while they engaged in an online social media task where they were included by either all (viz. inclusion condition) or none (viz. ostracism condition) of the other participants. Finally, state anger was measured. A multiple regression

analysis revealed a significant three-way interaction between social condition (inclusion vs. ostracism), group size, and self-control on anger such that ostracism moderated the effect of self-control on anger in the context of the larger but not the smaller group size. Specifically, when ostracized by a larger group, simple slopes analyses indicate that self-control was negatively related to anger (i.e., lower self-control was associated with more anger) but there was no such relationship among participants in the inclusion condition. Implications for the impact of self-control and group size on the negative effects of ostracism such as aggression and violence will be discussed.

Abstract Name: Analysis of Mental Toughness in Backyard Ultra Marathon

An ultra-marathon is any race with a length greater than 26.2 miles. Over the past decade there has been a new type of ultra-marathon event that has become popular, the Backyard Ultra. In this type of event participants run a 4.1667 mile loop, called a yard, every hour on the hour. The participants can run the yard at any speed they wish provided they finish before the start of the next yard. A competitor is considered to have refused to continue (RTC) if they fail to start a yard. If the competitor fails to complete a yard before the next yard begins, they are considered a did not finish (DNF). The race format is followed until there is one runner left, if the last runner fails to complete their last loop in the one-hour time limit they are also considered a DNF and there is no winner of the race. In 2022 the Backyard Ultra Team World Championship continued for 4 days (each day = 100 miles), and no winner was declared as both of the remaining athletes refused to start the next loop. Previous research in our group has shown that RTC rates are greatest at milestone yard values (12 yards = 50 miles, 15 yards = 100km, etc). After 100 miles the predominant race withdrawals occurs via DNF. Since there are two ways a competitor can withdraw from the race, we hypothesized that there may be a difference in mental toughness for these competitors. At this time no research has been done on the mental toughness of the athletes as they race in a format that has no predetermined end. Our research is attempting to describe the mental toughness of backyard athletes and see if there is a quantifiable difference between the mental toughness of the two types of non-finishers.

Abstract Name: A Testing Framework for AI Linguistic Systems (testFAILS)

As artificial intelligence (AI) systems increasingly integrate into our daily lives, particularly in natural language processing (NLP), the need for comprehensive testing frameworks that ensure these systems

perform accurately and reasonably has become paramount. This paper introduces testFAILS (Framework for AI Linguistic Systems), a novel testing framework designed to evaluate AI linguistic systems on multiple performance dimensions, including accuracy, robustness, and bias detection. Developed by a multidisciplinary team of researchers, testFAILS aims to address the challenges of language-based AI systems, such as chatbots, virtual assistants, and translation services, by providing a structured methodology for systematic evaluation. The framework incorporates tests that simulate real-world scenarios, linguistic challenges, and diverse linguistic inputs to gauge the systems' responses and behaviors under varied conditions. We conducted comprehensive testing on several leading AI linguistic systems to demonstrate the efficacy of test fails. Our results revealed significant disparities in system performance, particularly in handling context-dependent queries, rare languages, and idiomatic expressions. We also discovered that some systems exhibited biases based on gender, ethnicity, and dialect, underscoring the need for bias mitigation strategies in AI development. The testFAILS framework is complemented by a set of metrics allowing quantifiable assessment and comparison of AI systems. These metrics facilitate the identification of specific areas where AI systems may require further refinement and development. Our research also offers insights into the ethical implications of deploying AI linguistic systems without adequate testing, highlighting the potential risks to inclusivity and fairness. In conclusion, testFAILS represents a significant step towards establishing standardized testing protocols for AI linguistic systems. Providing comprehensive testing methodology empowers developers, researchers, and policymakers to ensure these systems meet the high standards necessary for ethical and effective deployment. Our work encourages the AI community to prioritize transparency, accountability, and continuous improvement in developing linguistic AI technologies.

Abstract Name: Gut Microbiome Composition And Its Importance For Plastic-Degrading Process Of Waxworm Larvae

One of the primary challenges of modern society is plastic waste management. In particular, low-density polyethylene (LDPE) accounts for more than 30% of all plastic produced. Low quality of recycled products and associated energy costs make current plastic management strategies less feasible. There is an urgent need for fast, efficient, and energetically sustainable alternatives. Larvae of the waxworm Galleria mellonella have shown the ability to rapidly biodegrade LDPE at room temperature. Our laboratory has made similar observations in microgravity conditions on the International Space Station. Multiple studies suggest that microbes within the waxworm’s gut, together with its salivary enzymes, are responsible for biodegrading plastic. However, while some bacterial species have been identified, the literature lacks systematic assessment. We hypothesize that microbial composition and abundance in the waxworm’s gut will change according to diet, thus allowing us to identify key species important for plastic degradation. Before evaluating the microbiome from larvae exposed to microgravity stress, it is imperative to establish a microbial community under plastic diet conditions. Therefore, our current study evaluates the waxworm microbiome under a restricted beeswax diet (natural feed source) versus beeswax and plastic. Before the experiment, larvae were starved for 48 hours and exposed to these diets for 12 and 24 days. Sequencing was performed for a marker gene associated with bacteria (16S rRNA hypervariable region 4) to determine microbial community composition and differential abundance of bacterial species across different treatments. Initial results show that composition and species abundance are significantly different between pre and post-diet microbiomes, with no significant difference between dietary treatments. However, further research is

needed to confirm our findings. This study will help understand the microbial community in the waxworm's gut, which may give further insight into utilizing waxworms as a potential solution for managing plastic waste on Earth and in space.

Abstract Name: The cause of oppression of indigenous culture through dance

An art form that has unexpectedly considered a threat to authority throughout history is dance. There is a power behind the ability to organize a group of people that can create a shared experience. This is the foundation of what challenged the conquistadors of the new world.The essay dives into Spanish colonization of North America, from the Aztec Empire to the Tainos of Puerto Rico. The essay looks at oppression of dance through the indigenous people by, suppressing gender, culture and religious expression.Dance was a religious ritual and a tool to tell the history of the indigenous peoples. The ability to tell one's history from the body instead of written language made it hard for Spain to conquer.The expression of movement through the body connected the people to their higher power which simultaneously connected to their historical roots. A culturally significant event that will be discussed in this essay is the Dance of Death. This festival is an example of how the Spaniards felt threatened by the aggressive dance form. The organization of the people formed fear of revolt ending in a massacre.The European mentality was set in strict gender roles that using dance for gendered expression challenged the way of life and values that were outside of there.The journals of the conquistadors gave insight to their perception of the indigenous peoples dance. This example expresses the cultural mentality of the Spaniards which led to the destruction of indigenous culture.To conclude the essay we will look at movement and the connection to cultural transmission. As long as the body can move, the history and cultural information can still be shared. Something so simple as a movement of the arm could translate to ritualistic sacrifices, wars, and stories of love and loss.

Abstract Name: Limitations of Gender Privilege: Men's Masculine Ideologies and Mental Health

Despite experiencing male privilege, boys and men endure negative stereotypes and expectations, supporting the need for male health research (APA, 2018). Young men have been found to have higher rates of mental health disorders and lower rates of help-seeking behaviors (Slade et al., 2009). The present study investigates how self-identified men perceive societal constructs of masculinity and how well they feel they meet these standards. Masculine gender role discrepancy (GRD) results from the difference between men's individual ideas surrounding masculinity and how they perceive society's views of masculinity (McDonnell Mesler et al., 2022). At times, self-identified men feel they conform to traditional masculine norms, such as stereotypes emphasizing dominance, strength, and anti-femininity. The present study focuses on the adverse effects men

endure relating to gender role stereotypes. Self-identified men (N=227) were recruited via an online survey and asked to report their attitudes toward traditional masculinity. Participants were then instructed to identify the frequency of anxiety, depression, and avoidant coping mechanisms. Researchers found that participants experienced increased mental health concerns with increased gender role discrepancy. The results demonstrated a significant positive correlation between perceived social expectations and anxiety, depression, and avoidant coping mechanisms. In this sample, individual perceptions of masculinity were not significantly related to mental health, reinforcing that people's behaviors and emotions often reflect societal constructs. Little research demonstrates the correlation between individual and societal perceptions of masculinity and mental health, which speaks to the importance of the present study. More research must be conducted to understand these discrepancies since men's mental health is frequently overlooked. Additionally, destigmatizing men's mental health may aid in the overall objective of gender equality as people recognize that, regardless of identity, anyone is susceptible to cognitive discrepancies.

Abstract Name: Beyond Belief: Christian Nationalism and Xenophobia in U.S. Politics

As Christian nationalist beliefs have become increasingly mainstream, we have seen politicians blur the lines between church and state, as well as take positions reflecting the Christian nationalists' view of the United States. This paper explores how this worldview holds xenophobic beliefs, anti-immigrant sentiments, and an agreement with policies restricting immigration from Muslim countries, in addition to other factors outside of religion. Specifically, our hypotheses explore the relationship between Christian nationalist beliefs and xenophobia by examining whether those advocating government endorsement of Christian values are more likely to fear a shift in the majority demographic away from whites. We also investigate if individuals emphasizing the importance of Christianity to American identity are more inclined to support a cessation of immigration from Muslim countries, and finally, whether those advocating the declaration of the United States as a Christian nation are more prone to hold negative beliefs towards immigrants, such as the incorrect belief that immigration increases the crime rate. Relying on the Chapman Survey of American Fears, and the American National Election Survey (ANES), two representative national samples of U.S. adults, we found that holding Christian nationalist beliefs and simply identifying as a Christian makes an individual more likely to believe the falsity that immigration increases crime rates, hold xenophobic beliefs, anti-immigrant sentiments, and an agreement with restricting immigration from Muslim countries. These findings are important in a political system where the perpetuation of a Christian-nationalist, anti-immigrant agenda gains candidates votes. Seeing as this nation was founded on religious freedom and immigration, this research can be used to determine what has caused Americans to stray so far from the foundations of the United States.

Abstract Name: Importance of Translators and Wikipedia in Digital Language Hierarchies within Europe

The Internet serves many functions that help citizens be informed and participate in democracy and the economy in the digital age—the right to access the Internet links to the right to use your native language. The EU's language policy translates all documents into its official languages, and the resulting corpus makes translation and research within these languages easier. The paper attempts to identify whether the languages of the EU have greater utility on the Internet by comparing a broad measure of total contents and services in the languages of Europe. Economic and linguistic differences between member countries are possible explanations for the digital divide in Europe. EU official languages dovetail with high general internet utility. The study concluded that within Europe, EU language policy developed strong wikipedias in the EU languages, which was associated with gains in content overall in those languages.

Abstract Name: The Matrix: Seen through with Optical Coherence Tomography to Study Dupuytren's Contracture

The fibroblast-populated collagen matrix (FPCM) serves as an optimal model system for investigating cells associated with contractive diseases, exemplified by Dupuytren's Contracture (DC). This collagen matrix affords a structural and mechanical context conducive to replicating the conditions surrounding contractive diseases, facilitating the observation of cellular behavior. The objective of this project is to use this model to characterize the mechanobiology of fibroblasts from DC patients. Utilizing optical coherence tomographic (OCT) imaging, we captured cross-sectional structures of the FPCM during development or treatment. This not only enhanced image clarity, but also facilitated the longitudinal assessment of cell behavior. Prognosticate outcomes as substantiated by assessing the daily compaction of the collagen matrix, contrasting control and DC cells that are embedded into the collagen matrix. Notably, this data enables the estimation of cell-dependent tension generation in FPCM, offering comparative insights into cell characteristics.The correlation between cellular contraction and tissue compaction induced by DC cells was discerned. Our preliminary data showed that compared with normal dermal fibroblasts, DC fibroblasts can lead to faster and further compaction of the collagen matrix, which in turn resulted in more differentiation into myofibroblasts. The accrued data not only sheds light on the biophysical mechanisms underlying DC, but also paves the way for more effective identification of required treatments. Beyond contractive diseases, this study extends its relevance to wound healing and other fibrotic disorders.

Abstract Name: Effects of Leptin on Brown Adipose Tissue

Leptin is a hormone secreted by white adipose tissue that is extremely important in regulating metabolic processes. Expression of leptin in white adipose tissue is regulated by all-trans-retinoic acid (RA). However, we do not fully understand the connections between RA and leptin in brown adipose tissue (BAT). Brown adipose tissue (BAT); unlike white adipose tissue, is specialized in regulating body temperature through a process called thermogenesis, which is highly dependent on a protein proton carrier called uncoupling protein-1 (UCP1). Using brown adipose tissue cells in culture, we initially hypothesized that treatment with RA will decrease the level of leptin secretion into the media. To determine this, we performed enzyme-linked immunosorbent assay (ELISA) on media from cells treated with increasing concentrations of RA. However, upon analyzing our results, we observed a plateau, indicating an insignificant change in our samples. The results may be due to the lack of understanding of how leptin functions in BAT or there may be confounding variable affecting leptin and/or our analysis. To better understand this, we will determine the amount of leptin present in our cell samples and the cell media using Western blot. By using a different technique with the media, we will be able to determine how and if leptin secretion and expression are linked. In addition, we will evaluate leptin levels produced within the cells. We hypothesize that there will be a decrease in leptin expression in both the cells and cell media. Overall, this will begin to build a better understanding of leptin's function in BAT homeostasis which can be vital in developing possible treatments for obesity as cases are on the rise.

Abstract Name: Fatty Acid Composition of Spodoptera frugiperda to Investigate CPTII Deficiency

Fatty acid oxidation disorders are a complex set of metabolic deficiencies with a wide variety of causes. Carnitine palmitoyltransferase II deficiency is one such disorder which ranges in severity from a lethal neonatal form to a myopathic form. The CPT II protein is a transport protein located on the inner membrane of the mitochondria, so deficiency results in poor transport of fatty acids into the mitochondria for β-oxidation. Our lab is studying this deficiency in Spodoptera frugiperda by investigating how alterations in splicing and translation of the CPT II protein affects levels of various long chain fatty acids present in the whole organism. The Spodoptera frugiperda are homogenized then the lipids are saponified and converted to methyl esters using the method of Folch as modified by Bligh and Dyer. These samples are spiked with heptadecanoic acid methyl esters in order to determine absolute quantities of lipids. Gas chromatography-mass spectrometry (GC-MS) is used for separation and analysis of long chain fatty acids. Samples are compared by instar of the insect to investigate how fatty acid composition changes throughout the larval stages of the insects. Preliminary data suggests that relative abundance of the common lipids remains consistent throughout development. Continued work on this project will confirm or refute these initial findings in wild type Spodoptera frugiperda. We have also designed morpholinos to block splicing and translation of RNA for the CPT II protein. Future work will include introducing these morpholinos to the insects to discover how alterations in the CPT II protein effects metabolism of the fatty acids of interest.

Abstract Name: Continuous Positive Airway Pressure (CPAP) Adherence in Women: Associations with Pre-Treatment Stigma

Rationale: CPAP, the most widely used treatment for obstructive sleep apnea (OSA), uses masks for treatment, which may be a source of shame for users. Little is known about the associations of preconceived stigma on CPAP adherence in women. The purpose of this study was to assess if pre-treatment CPAP stigma is associated with 90-day adherence in women.Methods: In this prospective study of 89 women who were primarily middle aged (mean age 51+/-14) with clinically diagnosed OSA (apnea-hypopnea index [AHI] ≥5 events/hour) before initiating CPAP treatment. Women were dichotomized using Medicare criteria into adherent (≥4 hrs/night, 70% of the time) and nonadherent (< 4 hrs/night, 70% of the time). Stigma was measured using the Patient Reported Outcomes Measurement Information System (PROMIS) Neuro-QoL questionnaire for Stigma, which asked participants 8 questions about feelings of stigma towards their illness. Scores range from 8-40, with higher scores indicating higher stigma. Data were analyzed using t-tests and logistic regression. Results: A total of 43 women (48%) met Medicare criteria for CPAP adherence. Adherence to CPAP over 90-days was significantly greater in older women than younger women (Mean ± SD; 54.9±14.8 years vs 47.1±13.0 years, p= .01). Women who experienced greater stigma prior to CPAP initiation were significantly less adherent than women who experienced less stigma, (mean stigma =16.6 +/-4.2 vs. 13.3+/-5.3, p = .03). The odds of adherence do not depend on stigma after controlling for age. Conclusion: Stigma may be a barrier for many women with OSA to successful CPAP adherence in the first 90-days after treatment initiation. Clinicians may want to familiarize themselves with common feelings associated with the stigma surrounding CPAP treatment to better serve their patients. Research/Grant Support: Breathe PA

Abstract Name: Proliferating and Differentiation of Primary Airway Epithelial Cells in an Air Liquid Interface (ALI) Culture System

In respiratory diseases, epithelial cells that line airways are the first line of defense against bacteria, viral, and fungal infections. The airway epithelium is a pseudostratified columnar epithelium containing both ciliated in goblet cells. Studying this airway epithelium in vivo in these diseases is difficult to impossible. Utilizing an in vitro Air liquid interface (ALI) culture system in the laboratory, allows researchers to investigate the specific role of airway cells in their fully differentiated state into secretory and ciliated cells which reflect the mucociliary structure and function of differentiated epithelium as seen in vivo. The focus of this research project will be to successfully harvest, proliferate, and differentiate primary ferret and murine airway epithelial cells utilizing the ALI culture system. Specific aim #1 in this study will investigate the effects of passage of primary airway epithelial cells on transepithelial electrical resistance (TEER). Specific aim #2 will

investigate the effects of passage on cellular differentiation. Cellular differentiation will be determined histologically by the presence or absence of a pseudostratified columnar epithelium containing both goblet cells and cilia. In this study, primary cells harvested from laboratory animals will be expanded and passaged in T75 culture flasks for four passages (P2, P3, P4, P5). Each passage will be differentiated in transwell culture inserts utilizing the ALI culture system. TEER data will be collected using an EVOM3 Epithelial Volt/Ohm Meter (World Precision Instruments, Sarasota FL, USA) for each passage. To determine cellular differentiation, the passage sample will be fixed with 4% paraformaldehyde in phosphate-buffered saline (PBS). Immunofluorescence staining and confocal microscopy will determine the goblet and cilia cell populations.

Abstract Name: Art as Public Mourning: Changes in Expressions of Grief in Contemporary Artwork From AIDS to COVID-19

Death is an unavoidable fact of life. Though this is true, mourning is often done in private due to a cultural discomfort with death. Mourning itself is a culturally constructed set of behaviors expected of the bereaved as they grieve. As mourning is culturally constructed, it is subject to change. Such changes are at times manifest art. This is true of the three artists discussed here. Felix Gonzalez-Torres explores both the shared grief of gay artists during the AIDS crisis and his personal mourning for his lover in Untitled (Perfect Lovers) and Untitled (Portrait of Ross in LA). In both form and naming, Gonzalez-Torres makes his work both universal and immensely personal. Andrea Bowers's works about the AIDS Memorial Quilt, namely The Weight of Relevance, Continual Maintenance and Mending, and Still Life of The AIDS Memorial Quilt in Storage (Blocks 4336-4340) explore the grief of a cause being forgotten and the continuous and active mourning of those lost to the AIDS virus, regardless of public care. Finally, Vasileia Anaxagorou's works The Shelter and It Was Never Really About Care explore the suffocating isolation that the artist experienced as she was forced to mourn not only an immense loss of life due to COVID-19 but also the loss of normalcy in complete solitude. By examining the ways grief manifests and makes these pieces into acts of mourning, this paper will explore how the cultural construction of mourning and cultural attitudes toward death have shifted over the past five decades.

Abstract Name: Optimal t: Teaching R though Practical Demonstrations

Many students are reticent about taking their first introductory statistics course. Throw in requiring that they

learn R and they are downright terrified. This is unfortunate because mastery of statistics provides both a more complex way of thinking about research questions and a set of tools for testing hypotheses that emerge from those questions. It is thus imperative that we expose students to statistical analysis using R in order to position them to engage in meaningful undergraduate research.In this session, two undergraduate students and their research mentor introduce attendees to the concept of Optimal t, which is an R code that uses a multiple resampling strategy to determine the statistical power of the paired samples and independent samples t-tests in situations where data are collected from the same participants on two occasions. The code then applies the more powerful type of test (paired or independent) to the original data and provides the user with appropriate output.The presenters will then explain how simulaltion studies and accompanying graphical representations can be used to explain what makes each type of test appropriate in different conditions (e.g., degree of correlation between measurement points, proportion of missingess, etc.). The presentation will conclude with student narratives about how Optimal t has opened the door to using R for all types of analyses in introductory statistics, as well as motivated them to pursue research in quantitative methods. Examples of presentations at national conferences on education and psychology (e.g., Association for Psychological Science and the American Educational Research Association) will be provided to support their position that undergraduate students cannot only be brought into high-level discussion about statistics, but also produce research that is of sufficient quality as to earn acceptance by highly respected scholars.

Abstract Name: Synthesis and Characterization of Fe (II) Terpyridine Complexes that Show Temperature Dependent Spin Crossover

Gadolinium-based complexes are used to enhance the contrast in MRI imaging. However, once injected intravenously, gadolinium can be fatal if it accumulates too much within the body. Iron-based complexes are a possible alternative and exhibit an additional feature: temperature monitoring. Octahedral iron (II) spin crossover (SCO) complexes can exist in an ‘on’ or ‘off’ state within an MRI, depending on the local temperature of their physiological environment. This makes the complexes possible candidates for precision monitoring of high-temperature tumor ablation procedures. We aim to develop an iron (II) based contrast agent that undergoes SCO at temperatures between 60 – 80 °C (333 – 353 K), the range at which tissues begin to necrose, so it can become biologically applicable. In order to deliver these agents to specific cells and tissues, reducing their spread into non-relevant body parts, the goal is to bind the Fe (II) complexes to specific peptides through bioconjugation. Many Fe-based SCO complexes either undergo SCO at temperatures too high, too low, or do not achieve SCO at all in a biologically applicable range. Most terpyridine iron (II) complexes fall in the category of undergoing SCO at temperatures that are too high (>100 °C). However, placing strong electron donating groups on the terpyridine ligand can lower the temperature at which SCO occurs. Use of only dimethylamino group on each ring of the terpyridine results in terpyridine-iron complexes that are primarily high-spin at room temperature. Therefore, the donating groups on the terpyridine ligands have been modified to fine tune these iron complexes to achieve SCO at a biologically relevant temperature range. The synthesis and results of these endeavors will be presented.

Abstract Name: Outlawed: An Indigenous Way of Life After Colonization

How has the Walla Walla Treaty of 1855 with the Confederated Tribes of the Umatilla Indian Reservation supplemented the rhetorical strategies used to promote racist stereotypes against Indigenous people? Scholars (Koban, Johnson, and Hester) have examined the rhetorical strategies used to resist colonial attitudes in the Ojibwe, Cree, and the Umatilla tribes respectively. For the Umatilla, researchers examined the formation of the Confederacy of the Pacific Northwest tribes and the government's lack of respect for upholding the rights included in the Walla Walla treaty. What lacks from the aforementioned research is a synthesis of rhetorical analyses as it relates to the Umatilla tribe. As a member of the CTUIR, the history and formation of this confederacy was unknown; neither has this information been rhetorically analyzed and assessed through the means of arguments; the universal legality of racism unto Indigenous residents in Oregon territory has not been rhetorically examined, and the rhetorical aspects of the pedagogical method for tribal enculturation in the 19th and 20th centuries is also absent.This poster examines the Walla Walla treaty and senate reports throughout the 1890s. We see that while treaty rights were seldom upheld in favor of the Indians, other laws such as the Dawes Act of 1887 upheld the government's practice in overstepping Indigenous sovereignty under the treaty. For other documents, like the Indian Citizenship Act of 1924, the Indian Voting Rights Act of 1968, or the Indian Religious Freedom Act of 1978 rights were given to Indigenous people, for what purpose? This poster reviews The Oregonian newspaper historical archives that offer opinion pieces on Indigenous topics, among other political topics the paper would publish throughout the 19th and 20th centuries to be analyzed rhetorically. The conclusion is the government remains contemptuous towards Indians.

Abstract Name: Socio-behavioral Implications of Medical Waste Incineration in the US

This research contains both a review of the current literature and original analyses of demographic and violent crime data for the surrounding geographic area of the nine medical waste incineration facilities (MWIFs) in the country. MWIFs contain heavy metals that permeate the earth and atmosphere once released via incineration. Many of these, including mercury, cadmium, and lead, pose a known neurobiological risk to human health and are released at emission quantities graded by the EPA as unacceptable. Existing research along with the correlational study conducted in this paper will suggest that one's residential proximity to a medical waste incinerator predicts lower median household income as well as lower rates of grade school completion. While this study did not find statistical significance between proximity and violent crime at a confidence level of 0.95, the small sample size (N=9) may have led to a type II error resulting from an invalid p-value. A statistically significant negative correlation was observed for MWIFs and median household income. Additional research is needed to further reduce extraneous and confounding variables through a correlational design in which locations of similar demographic and environmental characteristics are measured and results are compared to those of the nine locations in which MWIFs were present. Results that yield statistically significant positive correlations between the presence of MWIF and poverty/criminality may suggest a history of systemic placements which have been a source of poor health and safety in these surrounding residential communities.

Abstract Name: Local Consumers, Small Businesses, and Healthy Economies: Creating a Self-Sustaining Community in Rural Western Wisconsin

The adoption of environmental initiatives is crucial for rural communities to mitigate the economic impacts of climate change. By focusing on the creation of a circular economy, local producers and consumers will benefit from economic transactions within their communities, thus a more resilient economy is established. Local purchasing habits in a rural community like Menomonie, Wisconsin, can be influenced by many variables such as affordability, quality, and convenience. Motivating local consumers to purchase from their neighbors, rather than from corporate conglomerates, is challenging, but necessary for the health of the regional economy. For example, local agricultural producers might have more sustainable agriculture practices. Therefore, purchasing from those in the community can minimize local environmental issues. To determine if individuals would be willing to adjust their consumption practices, business owners and company managers were interviewed about their consumption habits professionally, and personally. Overall, the participants expressed a greater desire to purchase locally and tended to feel more closely connected to their community when doing so. These individuals were more willing to adopt environmental initiatives, however, expressed concern over implementation and widespread support. Regenerative economies are becoming more prevalent, as communities recognize the socio-economic connections that they depend on. This change must be led by local initiatives, businesses, and consumers as this will lead to a localized approach to implementing a circular economy.

Abstract Name: Extent of Vascular Damage at Varying Degrees of Stretch of Hypoxic Neonatal Brachial Plexus

Neonatal brachial plexus palsy (NBPP) is an injury to brachial plexus (BP) nerves due to over-stretching during complex birthing scenarios. NBPP has an incidence of 1-4 cases per 1000 live births. Neonatal hypoxia can also occur as a result of obstetric complications, such as disrupted blood supply due to umbilical cord compression. Characterizing the extent of vascular damage of hypoxic neonatal BP at varying degrees of stretch can further the understanding of the injury thresholds of NBPP. All procedures were approved by the Institutional Animal Care and Use Committee. 15 neonatal piglets (3-5 days old) were anesthetized and

exposed to FiO2 of 7% for 1 hour to induce hypoxia and re-perfused to FiO2 of 21%. Immediately post hypoxia, the BP was exposed and stretched at a rate of 500 mm/min to predetermined low- (<15%) and high- (>15%) strains. BP nerves were harvested and OCT-embedded. Ten-µm-thick serial longitudinal sections were stained with Hematoxylin-Eosin (H&E). Using the Olympus BX53 microscope, stitched stained H&E images (10x) of the entire nerve were obtained. Using a custom MATLAB script, regions of interest (ROI) were identified for each nerve and scored for vascular damage on a scale of 0-2 (0-no damage, 1-torn vessel, 2-scattered blood cells) by an independent-blinded observer. Based on our modified scoring system, preliminary results show that vascular damage increased with increasing stretch injury such that no (n=30), low (n=33), and high (n=30) stretch ROIs reported average scores of 0.6±0.3, 1.0±0.3, and 1.1±0.3 respectively. Similar degrees of damage were observed in the central and peripheral regions of the stretched nerve. This ongoing study is the first to characterize vascular damage of hypoxic neonatal BP nerves with respect to varying degrees of stretch and helps further our understanding of NBPP.

Abstract Name: Roles of Asian Values and Acculturation on Mental Health Service Utilization and Attitudes Amongst Asian American College Students

Asian Americans have long been considered the “model minority,” the cultural expectation to remain diligent and self-sufficient, minimizing hardships they may face in everyday life. Asian Americans generally hold a negative perception of and underutilize mental health services. The limited use of mental health services has not been widely studied among Asian American college students, a population at risk of experiencing mental illnesses.To address this gap, this study aims to understand the roles of Asian values and acculturation on the attitudes towards and the actual use of mental health services amongst Asian American college students. A cross-sectional design will be utilized to collect data from a sizable sample of Asian American students in a university located in U.S. East Coast. Eligible participants include those who self-identify as Asian Americans, are university students, and age 18 and older. A total of approximately 300 Asian American college students will be recruited. Data will be collected using an anonymous online survey via Qualtrics to assess: participants’ sociodemographics, identity with Asian American cultural values, levels of acculturation, depression, anxiety, and mental health help-seeking attitude and service use. Data analysis will consist of 3 steps: 1) descriptive analyses for an overview of sample characteristics, 2) bivariate analyses (e.g., Chi-square and ANOVA tests) to compare mental health help-seeking attitude and service use among participants holding varied levels of Asian American values and acculturation, respectively, and 3) multivariate models (e.g., logistic regression) to estimate the impacts of Asian American values and acculturation levels on participants’ mental health help-seeking attitude and service use, controlling for covariates.Results are expected to inform future research and provide critical information to guide the development and delivery of culturally sensitive and appropriate mental health services to Asian American population, particularly the college student population, to better meet their mental health needs.

Abstract Name: Experimental Validation of Perception Metrics

Safe behavior in autonomous robotic systems relies on the robot's ability to accurately perceive its surroundings. Robot controllers with correctness guarantees often rely on the unrealistic assumption that perception is perfect. Specifically, predictions from object detection models allow greater flexibility but are error prone, and come with fundamental tradeoffs in performance metrics such as precision-recall. These traditional metrics incorrectly model the effects of perception uncertainties on system behavior and treat all misdetections equally. Previous research proposes leveraging confusion matrices to compute system-level probabilities for safety requirements, pioneering metrics such as distance-parameterized confusion matrices, and proposition-labeled confusion matrices. However, hardware validation is necessary to study the accuracy of the proposed theory. This work validates these findings through simulation and hardware experimentation on Duckietown - a miniature city-like autonomous vehicle platform. First, we compute confusion matrices from state-of-the-art pre-trained models on the nuScenes dataset and custom YOLOv5 models on a custom Duckietown dataset to test the evaluations on hardware. Ongoing work is implementing a perception, planning and control pipeline to implement a simple car-pedestrian experiment on Duckietown using Robot Operating System (ROS). The experiment then utilizes the confusion matrix to determine the probability of satisfying system specifications. Future work aims to develop more dynamic scenarios with multiple agents to test the robustness of the theoretical framework. The results from hardware validation will help guide future research to make this framework more correct, and generalizable.

Abstract Name: HALOTOLERANCE: AN INDICATOR OF ANTIBIOTIC PRODUCTION?

Fungi have adapted to survive in various habitats including marine and freshwater environments. Marine fungi have even developed mechanisms to tolerate freshwater conditions (Jones, 2022). Accordingly, the fungi in the Carlson Lab collection were classified based on their tolerance or requirement for marine conditions. This lead us to wonder if there was a correlation between halotolerance/salt-obligation and antibiotic production. The library contains 29 salt-obligate fungal species and 8 halotolerant fungal species - additional screening is underway. To determine if a fungal strain isolated in the lab is salt obligate, marine derived fungi are plated on Potato Dextrose Agarase (PDA) made with DI water, to observe the growth. If the

fungi exhibits significant growth impairment or inhibition the fungi is classified as salt obligate. Conversely, freshwater fungi grown on salt PDA that have no growth in media with salt are known as halotolerant fungi. To test for antibiotic production, fungi were cultured in liquid media and grown on a rotary shaker 110 rpm to form a hyphae layer. Fungal extracts were tested for antimicrobial activity by the disc diffusion method (Khan, 2019). Each fungal extract was screened for initial antibiotic activity against 5 human pathogens: Bacillus subtilis, Staphylococcus aureus, Salmonella, Escherichia coli, and Enterobacter cloacae. Zone of inhibition of greater than 1 cm will be screened for dose response. Our goal is to understand if testing our organisms for salt tolerance is a useful indicator of antibiotic production. Abstract Name: The Relationship Between Physical Health Behaviors and Mental Health Among Female Hispanic College Students

Background: Mental illness is a global public health concern and is particularly prevalent among young adult college students in the United States. Depression, anxiety, and stress disorders are the most commonly reported diagnoses and significantly impact academic persistence and success. Evidence suggests that gender and ethnic disparities exist. Physical activity and diet quality are two physical health behaviors that may be associated with mental health outcomes. Limited research explores these associations among Hispanic female college students. Purpose Statement: The primary aim of this study is to examine the relationship between physical health behaviors (i.e., physical activity and diet quality) and mental health outcomes (i.e., depression, anxiety, and stress) among a sample of Hispanic female college students.Methods: Cross-sectional data from female college students (n = 250) attending a public Hispanic-serving institution in the southeast was collected. Physical activity was measured using the International Physical Activity Questionnaire – Short Form (IPAQ-SF). Diet quality was measured using the Diet Quality Questionnaire (DQQ). Mental health outcomes were measured using the Depression, Anxiety, and Stress Scale - 21 items (DASS-21). Multiple linear regression analysis will be used to examine the relationship between variables.Anticipated Results: Descriptive statistics and odds ratios will be reported. We hypothesize that students who have higher levels of physical activity and better diet quality will report lower mental illness (e.g., depression, anxiety, and stress). For example, we expect that moderate or vigorous physical activity will have an inverse relationship with ill mental health. The results of this study will provide unique knowledge of mental health in a gender and ethnic minority group. Findings will provide insight into potential points of intervention for healthcare providers to improve mental health outcomes in this population.

Abstract Name: The last Five Years in Quantum Computing: A Literature Review

Quantum Computing, a field that has captivated science and media, is rapidly advancing with the realization of larger Quantum Computers. As we create larger and more complex Quantum Computers, it has become increasingly important to map the literature that has gotten the field to its current state. We used Litmaps and Semantic Scholar to compile and analyze some of the most cited papers in the past five years who have keywords “Quantum Computing”, “QC”, “NISQ”, or “Quantum Algorithm(s)”. Our analysis of these influential works offers insights into the current state of Quantum Computing and provides a roadmap for further research in this rapidly evolving field. A significant area of potential future research lies in the adoption of standards as a transition between Noisy Intermediate-Scale Quantum Computers and larger scale machines. While some papers such as Kannan B’s 2022 paper demonstrate the use directional microwave photon emission to communicate between interconnects of qubits, this field of research could be substantiated with realizations on other types of Quantum computers, or in a commercial setting. Furthermore, another observed result among these heavily cited papers is that much of the theoretical work in Quantum Computing has now yielded to experimental realization of Quantum Algorithms and communication protocols. This demonstrates the shifting attitude of the field of Quantum Algorithms towards adapting existing algorithms to fit into NISQ Machines rather than the theoretical capabilities of large-scale machines.

Abstract Name: The Power of the Pen: Understanding the Rise of Presidential Executive Actions on Immigration

Scholars have increasingly sounded the alarm on the expansion of presidential power in the United States. Yet, these arguments primarily focus on executive orders, failing to consider how the occurrence of executive actions varies across issue areas. In my honors thesis, I remedy this gap in the literature. First, I consider a wide variety of executive actions, not just executive orders—looking at proclamations and memorandums as well. Second, I examine the influence of executive power on immigration in the twenty-first century. As a case study, immigration illuminates how expansions of executive power influence the lives of millions of individuals, having enormous positive benefits or drastic dire consequences on their daily lives. It also carries consequences for broader questions of democratic governance. I argue that polarization in Congress on the issue of immigration, triggered by the terrorist attacks on September 11, 2001 and the differing conceptualizations of the threat and fear of immigration, has led to gridlock which has in turn incentivized presidents to exercise executive actions on immigration. To test my argument against competing hypotheses, I conduct historical research to compile and analyze an original dataset of all executive orders, proclamations, and memorandums from 1910 to 2022 across all issue areas, including immigration. I then compare trends in the use of executive action more broadly to those on immigration specifically. Here, I find that executive actions on immigration do indeed follow a unique pattern. Looking forward, my thesis will next test differing hypotheses as to why this expansion has occurred. I will look at conversations on the influence of presidential popularity, levels of support in Congress, divided government, time in term, presidential party, etc as factors for the use of presidential executive actions on immigration. Again, I will use original data to showcase these possible explanations.

Abstract Name: Synthesis of Platinum Complexes with Histone Deacetylase Inhibitors for Bifunctional Anticancer Agents

Histone Deacetylase (HDAC), an enzyme involved in the regulation of gene expression via chromatin conformation, is overexpressed in many types of cancer and is a popular target for cancer drugs. Cisplatin, an FDA approved anticancer drug, is an alkylating agent that binds to the DNA of cancer cells to induce cell death. By combining HDAC inhibitors (HDACi) and platinum-based alkylating agents into a single drug, the platinum complex with HDACi could have increased efficacy as a bifunctional anticancer agent.Panobinostat and chidamide, two HDACi, are composed of three groups: a protein-recognition cap domain, a hydrocarbon linker, and a zinc binding group. The cap domain fits into a groove at the exterior of the pocket, the linker reaches into the pocket, and the zinc binding group binds to the zinc cofactor of HDAC active site. Derivatives of these molecules were designed by modifying the cap and the linker to alter both length and flexibility of the molecule. Both hydroxamic acid and 2-aminobenzamide zinc binding groups are used in the derivatives. By additionally modifying the cap to have a platinum coordination site, the HDACi derivative could form a complex with platinum. The complex is composed of two chloride leaving- group ligands, a non-leaving ammonia ligand, and the HDACi derivative, coordinated similarly to the ammonia ligand.The HDACi derivatives will be synthesized via nucleophilic substitution to the cap domain, protection of the coordination site with Boc anhydride, a second nucleophilic substitution, and a condensation reaction to add the zinc binding domain. The Boc protection will then be removed and the HDACi will be coordinated to the platinum complex. The synthesized molecules will be characterized via NMR spectroscopy, mass spectrometry, and X-ray crystallography. The relative binding efficacy of the HDACi derivatives will be estimated via computational docking studies.

Abstract Name: Unveiling Mexican Minds: A Deep Dive into Gender Roles in Mexico

Over the last decade, Mexican feminist movements have gained momentum with protests and marches against the presence of machismo in Mexico. This paper aims to investigate how gender roles within Mexican households, workplaces, and social settings influence individuals' perspectives regarding the ongoing feminist movement in the nation. Given the rise of femicide in Mexico, researchers have examined the country's laws concerning gender-based violence. Researchers have also explored the influence of machismo on Mexican gender roles in family, career, and political contexts. The project will utilize

qualitative interviews with both Mexican men and women to compare responses concerning current gender roles within Mexican society. Thematic coding will categorize the key terms pulled from the interview responses, such as “machismo,” “marianismo,” patriarchy,” and “feminism,” to reveal each gender’s opinions. Predicted results may show how differing viewpoints on gender roles in Mexico help create an environment where women are consistently targets of gender-based violence. Understanding the results could educate the public about femicide and could contribute to future research aimed at discovering methods to prevent gender-based violence.

Abstract Name: Fostering Interdisciplinary Exchange Through Game Design: A Collaborative Effort

The APP FARM takes on projects that explore what education could look like in the future; by providing an opportunity for students to analyze data, explore the “world of the problem” and propose interactive solutions, students become producers of understanding, as opposed to consumers of content. By working with faculty researchers and community partners, students learn to understand that ideas are all around, embedded in everything. The student experience is more than “collecting information.” Through experiential learning, design + collaboration, students are exploring multiple perspectives, analyzing data, and creating “transformative experiences.” We make proofs of concept (PoCs) and minimum viable products (MVPs) designed to compete for grants to support undergraduate research. How can we educate and challenge our perspective as global citizens? How can we encourage reluctant students to engage with content? Games can contribute greatly to student learning. Based on the “Quest to Learn” program, we are endeavoring to build an, “ecology of learning that extends beyond the four walls of an institution and engages [students] in ways that are exciting, empowering and culturally relevant”. The students are balancing limitations that include pedagogical issues, what does this data mean?; technical issues, what can we figure out how to code? and gaming issues, what makes this fun? Instead of computerizing old teaching practices, we are radically re-envisioning the design of the learning experience in general. This presentation showcases successful interdisciplinary efforts, fostering deeper understanding among students, creating valuable educational games, facilitating meaningful interactions, and bridging theory with practical application. This initiative transforms education, fostering a common language for problem-solving that transcends disciplines. We look forward to sharing our outcomes through game play and inspiring others to embrace interdisciplinary collaboration.

Abstract Name: Effects of Environmental Enrichment on Enhanced Nicotine-Seeking Behavior Following Exposure to Chronic Variable Stress

Preclinical and clinical research indicates that individuals exposed to stress are more vulnerable to drug addiction (Koob, 2008; Ouimette et al., 2007). Chronic unpredictable stress increases the response to nicotine-rewarding properties in the CPP test (Biala et al., 2018). Contrary to the effects observed following exposure to variable stress, both running and environmental enrichment (EE) reduce CPP for cocaine (Mustroph et al., 2016). Based on the interactions observed between EE and chronic stress on learning and memory (Wright & Conrad, 2008), it is reasonable to postulate similar interactions on the rewarding properties of nicotine. Only one study (Biala et al., 2018) has assessed the effects of chronic stress on the rewarding effects of nicotine in the CPP model and none have measured the potential of EE in attenuating this effect. Therefore, this study will investigate and determine whether EE can reverse, or abolish, the enhancement in the rewarding properties of nicotine following exposure to chronic variable stress. One group of animals will be exposed to 20 days of randomized stressors either during adolescence or early adulthood. Another group of animals will be exposed to four weeks of EE. An additional group will be exposed to 20 days of randomized stressors followed by four weeks of EE. Control animals will not receive any exposure treatment. Following exposure treatment animals will undergo place preference conditioning to nicotine. Preliminary data indicate that animals exposed to EE exhibit lower place preference compared to animals exposed to variable stress. Data collection is continuing and comparisons between sex and adolescence versus early adulthood stress exposure proposed. In addition to providing evidence of the contributions of stress and environmental conditions to successful cessation of drug-seeking, the results obtained can have important implications for the use of environmental stimulation together with pharmacological and behavioral therapies in addiction treatment.

Abstract Name: Manipulation of Cocaine Preference on the Primrose Path of Addiction.

1.4 million people were diagnosed with cocaine use disorder (CUD) in 2021. CUD involves the use of cocaine at the expense of other alternatives, making it a decision-making pathology, driven by an increase in the relative value of the drug. Research focused on the underlying mechanisms behind decision-making and valuation processes are vital to develop effective treatment options for CUD. The goal of this study is to model CUD in rats via the primrose path–a model of decision-making that involves changes in the availability of reward based on previous choice behavior. The primrose path is said to follow the anecdotal experience of human CUD. As they continue to choose drug over alternatives, they begin to lose out on opportunities to engage with other alternatives, such as a job or other resources, leading to a continued preference for drugs and another “step” down the primrose path. This reduction in alternatives further drives the differences in relative value between the options, leading to a situation where the drug is chosen almost exclusively. To model this in rodents, the relative availability of drug and food will be contingent on previous choice hysteresis. For example, if the rats choose drug near exclusively, the next block of choices will be skewed such that more drug is available to earn. Thus simulating the feed forward loop seen in humans.

Secondly, we will alter the dose of cocaine (1 mg/kg to 0.1 mg/kg) to reduce the relative value of the drug. Given previous research, we expect rats to dose-dependently shift their preference from cocaine to food and that shift to be furthered by the alteration in reinforcer availability. The results from this study will help us better understand the path of addiction and how translational research can be conducted to better create effective CUD treatments.

Abstract Name: Efficient Simulations of Semiconductor Quantum Dots with Arbitrary Shapes and Materials

A semiconductor quantum dot, featuring a nano-scale core surrounded by a distinct material known as the matrix, essentially mimics a man-made atom. In this unique structure, electrons and holes are confined within the nano-scale dot, exhibiting atom-like properties. Unlike natural atoms, quantum dot materials can be tailored to achieve specific material properties by manipulating the compositions of the dot and matrix, along with their geometric shapes and sizes. As a result, semiconductor quantum dot materials have found widespread applications in innovative optoelectronic devices such as laser diodes, solar cells, and quantum computers. The comprehension and manipulation of the bound state energies and wavefunctions of quantum dots with diverse compositions and geometrical shapes are critical for optimizing the optical and electrical properties of these materials. Traditionally, supercomputers were used to conduct these complex calculations. To facilitate the research and design of semiconductor quantum dot materials, there is a great demand for an efficient yet accurate computer-aided engineering tool among semiconductor quantum dot researchers and engineers. With advancements in the k.p perturbation theory of bulk semiconductor materials, this research extends the four-band k.p model to simulate quantum dot materials. Through the utilization of COMSOL Multiphysics software, we have developed a user-friendly computer-aided engineering tool capable of calculating bound state energies and wavefunctions for quantum dots with various material compositions and geometric shapes. This simulator stands out for its robustness, efficiency, and accuracy, making it accessible for computations on standard laptops and desktop computers. We anticipate that this simulator will have widespread applications in both academic semiconductor research and industrial design, contributing to significant advancements in this interesting and challenging field.

Abstract Name: The Effect of Test-Optional Policies on Undergraduate Applications, Enrollment, and Student Composition

During the 2020 pandemic, many colleges decided to eliminate the requirement of standardized test results on college applications. Today, even after the end of the pandemic, many colleges still have this policy. According to research done in 2021, the vast majority of states required their public universities to become test-optional during the pandemic year of 2020, with the only exceptions being Idaho and Florida; most states have chosen to continue the policy into 2023 and beyond. These nationwide changes have led to numerous discussions of the ethics and actual importance of standardized testing in relation to college applications and enrollment. Standardized tests can create needless barriers to higher education because of test anxiety, learning disabilities, and socioeconomic disparities. We hypothesize that if colleges continue to eliminate entrance testing, then more students will be willing to apply. To test this, we conducted a literature review of past research. Then, we created a poll asking students if they would be more likely to apply to a college that did not require SAT or ACT scores and, if so, why they had that preference. We received answers from 54 students. The results revealed that 79.6% would be more willing to apply to a test-optional university, and most listed test anxiety as the reason. From these results and the literature review, we can conclude that more students would apply if universities did not require test scores. Additionally, the literature review revealed that the implementation of test-optional policies led to higher rates in the applications of underrepresented minority (URM) and first-time students. However, there is a discrepancy in numbers, seeing that while there is an increase in application rates, there has been a significant decrease in enrollment rates.

Abstract Name: Augmenting Hand and Arm Function for Persons with Hemiparesis

Background: Hand and arm dysfunction due to neural disorders significantly influences quality of life. Activity-based training has been found to improve function. These improvements could be augmented with transcutaneous spinal cord stimulation (tSCS) due to its modulatory effect on spinal and supraspinal networks. Objective: The primary aim is to determine if a 4-week training program will improve hand and arm function. The secondary aim is to determine if the addition of tSCS to a second 4-week training session will further enhance function. Design: This is a pre-posttest, controlled trial for persons 10-75 years of age, >6 months post-stroke, or with unilateral cerebral palsy. Methods: Participants will engage in two 4-week training periods, 3x/week for 2 hours/day. The first period will include unimanual and bimanual training alone. The second period will be augmented with low-frequency tSCS to the C5-T1 spinal region. Stimulation intensity will be based on individual muscle activation during three tasks: 1) grip dynamometry, 2) grip-lift, and 3) target pointing. Outcome measures are taken before, midway, and after training are Canadian Occupational Performance Measure (COPM), dexterity, daylong arm use, grip/pinch strength, sensibility, questionnaires, bilateral hand/arm surface electromyography, and Upper Extremity Fugl-Meyer (UEFM). Results: Six participants have completed the 1st 4-week training period without tSCS. Individual data reveals COPM, grip strength, dexterity, and UEFM improvements. Findings for other measures after the 1st period are mixed or in process. Conclusion: Preliminary results from this ongoing study reveal that participants improved most measures. The next phase of the study will determine if adding tSCS to training further augments hand and arm function.

Abstract Name: Rewarding Bioinformatics Research Experiences with Undergraduates from across STEM Disciplines

Since there are limited research funds awarded to predominantly undergraduate institutions, the Characterizing our DNA Exceptions (CODE) program was designed to bring research experiences to students who might not otherwise have the opportunity. This bioinformatics program allows small regional universities to partner with HudsonAlpha Institute for Biotechnology (HAIB). Working with HAIB as a facilitator trainer since 2018, my colleagues and I have trained over 85 university faculty to be CODE facilitators. In my lab I have supervised over 70 original student projects in bioinformatics, characterizing variants in proteins that have been associated with a disease or disorder through a clinical submission but have not yet been classified as pathogenic or benign. This means they cannot be used in patient genetic counseling sessions. Each student works to characterize variants associated with a disease or disorder of personal interest to them. They also work as a supporting team member in the larger multi-disciplinary group. This team of undergraduates from computer science, biology, mathematics and other STEM disciplines meet each week at a regularly scheduled time. Each class meeting begins with a 3 minute update from each student where they present what they accomplished that week and then receive feedback from the team. Previous students often come back to share how the program has helped them gain internships, graduate school acceptance, and paper publications. The importance of learning to communicate research findings to a general audience is emphasized and opportunities to share the results with introductory science classes, clubs, and other “town and gown” groups serve to develop these skills and spread the word about the accomplishments of the student research.Lastly, I will talk about invaluable partnerships with the Honors college, CUR (STR or Scholars Transforming through Research), and with HudsonAlpha Institute for Biotechnology.

Abstract Name: Medicaid Expansion and Lung Cancer Mortality in the US

Lung based cancers are historically and currently the most deadly cancers with predicted deaths in 2023, according to the American Cancer Society, being above 127,000 deaths with around 238,000 new cases estimated. Factors that damage lung tissues are significant as smoking tobacco is estimated to be responsible for 80 to 90 percent of lung cancer deaths. This study is centered around finding the impact of the medicaid expansion implemented in 2014 and its impact on access to prevent lung cancer deaths in the states that accepted the expansion versus those that declined. This state level policy study gathers data from federal sources to compile risk factors of lung cancer mortality rates across the states. The primary exposure variable that is focused on in this study is the states that expanded medicaid and those that did not expand it. The data is studied in a quasi experimental difference in difference format so the medicaid expansion policy exposure variable takes the form of an interaction term from the dummy variables for expansion states and policy periods. The results show that alongside risk factors like smoking and regions, the reduction of financial risks with the medicaid expansion by select states had no significant impact on reducing lung cancer mortality rates from the pre expansion period to the post expansion period. This implies that medicaid expansion policy

does not correlate to lower mortality rates suggesting that it failed in providing preventative measures to uninsured individuals. The significance of the smoking variable shows that perhaps policy should also target smoking prevention as this study provides further evidence to a correlation between smoking and cancer. The regional dummy variables shows that there may also be unequal healthcare availability in the southern states, further investigation should be taken to deliver equitable care in all regions.

Abstract Name: The Effect of spoT and badM Genes on EPS Expression and Motility in Paraburkholderia unamae

Paraburkholderia unamae is a plant-beneficial, non-pathogenic bacterium that lives in the rhiozosphere. It is a gram-negative diplobacilli with the ability to fix nitrogen to promote plant growth. Due to these characteristics, P. unamae could potentially reduce the need for synthetic fertilizers, which carry risks of eutrophication. The goal of this research is to identify genes in P. unamae that are involved in the development of the flagellum and the production of the exopolysaccharide (EPS) layer important for biofilm formation and root colonization. To determine the mutants, transposon mutagenesis was used with a highly efficient transposable element,Tn5-RL27. Mutants were screened for defects in motility and EPS production, and the disrupted region was identified using molecular techniques. In mutant LS13, motility was reduced by 67.1%, and the majority of the organisms slowly moved in a counterclockwise pattern. The transposon disrupted the badM gene, which codes for a transcriptional regulator. Mutant KT1.11 had a disruption in the spoT gene, which encodes a GTP pyrophosphokinase enzyme that facilitates bacteria to survive under stringent environmental conditions. Disruption of this gene resulted in a 55.4% reduction in motility and a visible overexpression of EPS. These genes are potentially responsible for diverse metabolic pathways in P. unamae. There is a lack of research on badM, and spoT's broad-ranging effects have yet to be fully mapped despite an abundance of research on the gene's function in E. coli. Further investigations into the mechanisms of these two genes are novel and of interest.

Abstract Name: Contemporary Rhetorical "Hype" in Clinical Trials for Psychedelic Medicine in Georgia

In a social media-driven society, "hype" or an exaggerated promotion surrounding drugs, specifically psychedelics, is ubiquitous, especially in the medical field. The anticipated findings of this research project will shed light on potential shifts in Georgia's clinical trial landscape concerning psychedelics. The analysis will consider the impact of ongoing hype, negative or positive, that surrounds decriminalization, and medical

applications on the formation of public opinion and policies. Contemporary “hype” will be drawn from multiple sources for analysis, to find multiple opinions. For insight into the medical field interviews with Dr. Emile Risby (Chief Medical Officer and Director, Division of Hospital Services of GA Departments of Behavioral Health), and Dr. Boadie Dunlop (Co-Director of the Emory Center for Psychedelics and Spirituality) will be cited. For historical, legal context information will be pulled from the Georgia Controlled Substances Act (Article 2. Regulation of Controlled Substances Part 1. Schedules, Offences, and penalties § 16-13-20- § 16-13-29.) The results of this analysis, given the historical and medical context, are to determine the current trajectory for hype surrounding clinical trials of psychedelics in Georgia, based on the contemporary hype.

Abstract Name: Mixed-Income, Mixed Motivations: Drivers of Socioeconomic Diversity in Rogers Park, Chicago & North Hollywood, Los Angeles

In Chicago and Los Angeles— and just about every pre-war American city— deep socioeconomic inequality often takes the form of residential income segregation. Yet, in these two deeply unequal cities, income-diverse areas exist reliably— large, contiguous, and stable neighborhoods where residents of all income brackets live amongst each other. Though their effects have been overstated in the past, research consistently shows that mixed-income neighborhoods offer consequential economic and social benefits for low-income residents. By comparing two long standing income-diverse neighborhoods— Chicago’s Rogers Park and Los Angeles’ North Hollywood— this paper seeks to better understand how neighborhood income diversity arises serendipitously. To make the comparison, I look at three potential spatial and demographic motivators of income diversity in the two neighborhoods (and their accompanying metropolises when possible): 1) housing diversity, 2) multi-ethnic enclavism, and 3) inner-ring connectivity to the central city. Using a mixed methods approach that includes data analysis, mapping, and questionnaire responses, this paper demonstrates that high housing diversity and inner-ring connectivity contribute to income diversity in North Hollywood and Rogers Park. Multi-ethnic enclavism positively influences income diversity in Chicago, but it shows no meaningful effect in Los Angeles. These results emphasize that while cities can lay bare striking inequality, they are also often optimal spaces for organic social cohesion. Chicago’s and Los Angeles’ distinct prescriptions for income diversity (see: multi-ethnic enclavism) suggest that policymakers need to go beyond a general understanding of fostering diverse neighborhoods in large cities and also consider the unique characteristics of the areas they are addressing.

Abstract Name: Welcome to the Club: How Georgian Democracy Reflects EU Candidacy Requirements

In November, the European Union (EU) recommended that the Republic of Georgia be granted candidate status after being denied less than two years earlier when they applied to join as part of the 27-nation bloc with Moldova and Ukraine. This was a monumental step in Georgia's path towards Euroatlantic integration, which is so ingrained into the country's ideology that it is included in their constitution and supported by 83 percent of the population. Despite this aspiration, EU candidate status rests on democratic reforms outlined in the nine conditions the EU set for Georgia in the November recommendation. The status of Georgian democracy has changed significantly over time and has recently been identified as potential democratic backsliding which poses a threat to successful integration. To understand the potential for democratic reforms and EU accession, this paper works to analyze the current state of Georgian democracy by assessing the existence of democratic backsliding and examining indicators of backsliding in mid-level democracies. Indicators this paper assess include suppression of media, perception of corruption, rise of populism, increased oligarchic influence, and lack of judicial independence. The insight from this paper is valuable because it is instructive of potential democratic backsliding of countries with aspirations of EU candidacy.

Abstract Name: Ecofeminism Will Save Us: Women and Their Impacts on Environmental Philosophy in Margaret Atwood's "MaddAddam" Series

Margaret Atwood's MaddAddam trilogy is often read as a warning about genetic engineering, but it also asserts that climate change impacts exacerbate already-existing forms of social oppression. Atwood illustrates this through the commodification of nature and women, both of which are exploited for financial profit. Atwood examines the breakdown of human-nature connections caused by greedy corporations that leads to devastating earthly consequences, but, at the same time, she proposes solutions for change through environmentalist philosophies. My paper focuses on how Atwood challenges the exploitation and commodification of nature and women in the MaddAddam series through the lens of ecofeminism. Ecofeminism believes nature and women experience similar domination by patriarchal society, resulting in strong connections between the two. I explore parallels between the exploitation of natural resources and female characters to ultimately determine Atwood's message: that the climate crisis is real and so is the domination over and oppression of nature and women. Most evidence is drawn from The Year of the Flood because it is set in the Pleeblands, where the effects of climate change are most prevalent, and because its protagonists are women. Examples include women who are forced to sell their bodies to survive in the Pleeblands or abandon their careers in science to escape their guilt. Attention is also paid to the God's Gardeners, an environmentalist group that seeks to repair human-nature relationships via unorthodox methods. Through countless examples, Atwood provides commentary on social oppression and exploitation and encourages ecofeminist solutions. She declares it is time to embrace the interconnectedness of all humans and nature, because to hurt one is to hurt us all. While Atwood addresses a seriously grave issue that presently impacts our world, she does so through a story of connections, love, and most importantly, hope.

Abstract Name: Ease the Sneeze: A Pilot Study Identifying the Impact of Social Determinants of Health on Allergic Disease Severity

This study aims to identify the specific social determinants of health (SDoH) associated with severe cases of comorbid asthma and allergic rhinitis (AR). Asthma and AR affect 40% or more of the US pediatric population. In preschool children, the diagnosis rate is 64.3% and increasing, with SDoH factors to blame. While both diseases can be well-controlled with medication, 50% of patients have uncontrolled asthma. Diagnosis of asthma and AR are strongly associated with sleep disturbances, irritability, fatigue, anxiety, and school absenteeism, causing over 200 million lost school days annually. Additionally, children with comorbid asthma and AR are significantly more likely to exhibit poor social functioning along with an increased prevalence of hyperactivity and learning disorders. These conditions lead to nearly twice as many visits to providers and double health-care related expenses — a significant burden on both child and caregiver. Furthermore, asthma and AR are diagnosed 2 to 3x more often in the African American community, where asthma mortality is 5x higher than that of their white peers. While SDoH factors are largely responsible for the increasing prevalence of asthma and AR disease disparity among the African American community, the SDoH identities most strongly associated with increased disease disparities remain unknown. This study administered a detailed survey via RedCap to patients scheduled for outpatient visits at multiple Nemours Children's Health pulmonology and allergy clinics in the Orlando area. We identified several SDoH factors associated with increased disease morbidity, including lack of internet access, transit challenges, and domestic violence. Interestingly, the most frequently identified SDoH vulnerabilities could be addressed by current government initiatives that aim to provide access to reliable internet and medical transportation. As such, the results from this study can improve patient care by bridging the gap between existing resources and families in need.

Abstract Name: Multiple-Choice Question Generator for an Equal Employment Opportunity Law Learning App

Question generators are an increasingly prevalent research interest in Artificial Intelligence, especially with the advent of large language models such as ChatGPT. A question generator is a model that, when given an answer and a context (usually a couple sentences of text surrounding the answer), generates a question. A fully-contained multiple-choice question generator, taking an article and generating questions and answers, has three main steps in the pipeline: keyword resolution, question generation, and alternative answer choice generation. Keyword resolution is a method to find informative words or phrases in a text that could be answers to multiple-choice questions. Key issues exist in prevalent question generator models, such as non-sensical questions, hallucinations creating misinformation, and questions lacking depth and quality. This research focuses on keyword resolution. We have been testing different methods in order to increase the quality of questions and answers. We have also been testing a novel method of training the generator model on subject-specific corpora. The subject is equal employment opportunity laws. The corpora are a raw text corpus and a question-and-answer corpus that have been developed in our previous research. The use of topic-specific corpora specifically is novel for generative models and may increase the model accuracy. Our

research may provide insightful information for utilizing and integrating topic-specific corpora in developing question generators. The research is conducted in Python, using Transformers for the question generator model.

Abstract Name: Evaluating Black Student Success at a Predominantly White University

In Spring 2023, the University of Wisconsin-Milwaukee (UWM) had a total of 16,091 students enrolled. Among this total population, only 1,238 students, 7.69% of the student population, identified as Black. There is a need to understand the curricular, programmatic, interpersonal, individual, and institutional factors that either support or impede their success to develop strategies that promote academic success and equal educational outcomes. Through this study, we gathered and analyzed faculty and student perspectives at UWM by analyzing a combination of past and current peer-reviewed studies on several factors, experiences and environments that impact the success of Black students. The aim is to gather a comprehensive understanding of the topic by drawing upon both historical contexts and current literature. According to UWM’s Office of Assessment and Institutional Research, the six-year graduation rate for Black students during the Fall 2023 semester is 31.6%. This project employs an exploratory sequential mixed methods design. Semi-structured interviews were used as a method of collecting data. A total of twenty interviews were conducted with current students, faculty members, and alumni of UWM. The coding process involve categorizing the responses and identifying recurring themes and suggestions for supporting the success of Black students at UWM. Based on the preliminary results, the study may uncover policies or practices that

inadvertently create barriers or perpetuate inequalities for Black students such as perceptions and stereotypes, White faculty discomfort, and peer rejection. These findings can inform discussions and recommendations for policy changes within the university. The anticipated outcomes of this research include providing students and faculty with academic strategies and resources that will promote success and foster better student-faculty relationships. Additionally, the research can lead to the creation of interactive workshops or training programs for faculty to increase their awareness and understanding of the experiences and needs of Black students.

Abstract Name: Exploring Pathways: Freshmen Perspectives on College Decisions & Readiness

Each year thousands of high school students make important post-graduation pathway decisions about attending college. While post-high school pathway decisions, specifically whether to attend college or not, are well-researched in education literature, individual student motivations remain elusive, even though several structural influences have been well-identified (Bransberger, 2020; EdChoice, 2022; National Student Clearinghouse, 2022; Tirado, 2022, and Yamamoto, 2023). It has been shown that those in low-income or rural communities lack the basic needs of educational opportunities through teaching methods, coursework offerings, and just basic "college knowledge" - knowing how to apply to college, etc (Morton et al., 2018; Oakes et al., 2021; Poynton et al., 2021; Romberger, 2021; Steiger et al., 2023, and Xing et al., 2019). Additionally, it has been that limited resources such as "college prep" courses adversely affect students' drive to attend college (Morton et al., 2018). Another factor is the common method of ability grouping and tracking students based on end-of-the-year exams, perceived abilities, and/or IQ. Research indicates this practice overwhelmingly negatively impacts students of color and has a downward effect on student, parent, and teacher expectations (Giersch, 2016). Therefore, this paper examines the factors involved in current college freshmen and their decision to attend college. Respondents will complete a self-administered instrument that focuses on their high school experience, relationship with their counselor, and their prior knowledge of college. A cluster sample will be used by selecting only freshman students at High Point University who are above the age of eighteen. This study has the potential to provide researchers and educators with data that could help reduce the college attendance gap between low-income and high-income students. By identifying "why" students make their post-high school decisions, it could find ways to bring "college readiness" to more students.

Abstract Name: Examining the Association Between Perceived Stress, Early Maladaptive Schemas, and Blood Pressure among Black Women

Background: Past studies have shown that perceived stress is associated with an increased risk of developing elevated blood pressure. However, few studies have examined how Early Maladaptive Schemas (EMS) can influence perceived stress and blood pressure among Black women. This study's purpose is to examine the relationship between EMS, perceived stress, and blood pressure in Black women.Method: Fifty self-identified Black women (Mage= 38 years) completed the Young Schema Questionnaire (YSQ) and the Perceived Stress Scale (PSS). The YSQ assesses EMS, providing insights into cognitive and emotional patterns that may contribute to psychological symptoms. The PSS measures individuals' stress levels by evaluating their perspectives. Additionally, two blood pressure readings for systolic (SBP) and diastolic (DBP) blood pressure were recorded and averaged for each participant. Linear regression models were used to determine whether participants' YSQ and PSS scores were significant predictors of blood pressure. EMS was used as a moderator to examine the relationship between perceived stress and blood pressure. Results: PSS did not predict blood pressure. A significant negative association between EMS and diastolic blood pressure was observed, explaining approximately 15% of the model variance as well as a negative association between EMS and systolic blood pressure explaining approximately 7% of the model variance. No significant moderation effect was observed.Conclusion: EMS significantly predicted blood pressure. This study provides preliminary evidence that Early Maladaptive Schemas may contribute to cardiovascular risk among Black women. This information can aid in the development of interventions addressing unique sociocognitive processes that Black women face.

Abstract Name: The Gretna State Fish Hatchery Digital Museum

This thesis describes the construction of a digital museum Story Map of the oldest fish hatchery in Nebraska and also presents this Story Map. This hatchery was established in 1879 within the community of Gretna, about 30 miles west from Omaha. I am currently distilling important elements of the history of the Gretna State Fish Hatchery to create an ArcGIS Story Maps website for the Nebraska Game and Parks Commission by digitizing the history of Schramm State Recreation Area. Analysis of over 90 reports of the Nebraska Reports of the Commission revealed the history for this facility and detailed the reasoning behind trying to keep the waters of Nebraska sufficiently stocked with game fish in the most economical way possible. I will also include the geologic history of the area to include the geologic outcrop at Schramm State Recreation Area which was donated by Eck Frank Schramm. I will draw a cross section, examine fossils, and create a stratigraphic column. I will include Native history to share traditional fish cultivation practices and land use by interviewing Omaha tribal members and use peer reviewed articles. The Gretna State Fish Hatchery seems to have cultivated mainly trout, German carp, and channel catfish. Geologic evidence presents that the area was covered by a shallow sea due to the presence of crinoids, brachiopods, and bivalves. Interviews with Omaha tribal members have not taken place as of 12/07/2023. The goal of this Story Map is to make this history publicly available to all Nebraska residents.

Abstract Name: The Effects of Chronic Self-Administration of Nicotine on Concentration and Attention

Nicotine, a highly addictive stimulant, negatively impacts the heart, blood vessels, respiratory system, and digestive system. It increases dopamine levels, affecting emotions of pleasure and satisfaction. Research shows that nicotine affects dopamine and attention, but the data on attention is contradictory, and studies are undertaken on nicotine subjects. This study aims to understand the impact of persistent nicotine use on attentiveness. The study aims to compare the neurological responses of smokers and non-smokers to auditory stimuli. Participants will be exposed to 300 brief tones, at an interval of 1.25 seconds, and their responses measured at 9 EEG recording sites (frontal, temporal, parietal, and occipital sites in the left and right hemispheres, along with area CZ). The reduction in neurological responses (as measured by auditory evoked potentials in the EEG) reflects habituation at the neurological level, resulting in a loss of attention. Three sets of data will be collected: (1) nicotine naïve individuals, (2) nicotine users while abstinent, and (3) nicotine users while using (2 & 3 are the same participants). The study will involve 20 participants half will be non-smokers and the other half regular smokers. The rate and degree of attenuation in the auditory evoked potentials (amplitude of the P300 and N400 waves) from these 9 cortical sites will be compared among these three sets of data. Smoking nicotine frequently may negatively impact neurological processes like attention. Students' academic performance in high school, college, and higher academic levels may be impacted by this. The results might also reveal additional information that could prompt further research.

Abstract Name: Can Practice Alter the Stress Response to a Stressor?

The human nervous system responds to stress through the fight or flight reaction, triggering changes in body temperature, heart rate, blood pressure, and sweating. Chronic stress has been linked to mental health issues and alterations in the brain's structure, affecting the hypothalamic pituitary adrenal axis, which regulates stress hormones and emotions (Sriram et al., 2012; Ramirez et al., 2013). Given the stress in college, adopting healthy coping strategies could benefit academic performance and overall well-being (Skowronek, 2014).Research indicates that music has therapeutic qualities, easing nervousness and positively impacting mental health, particularly among students (Chi, 2020). Music interventions have shown promise in reducing stress at physiological levels (de Witte et al., 2020). However, a preliminary study found no discernible impact on physiological responses (heart rate, skin response, body temperature) during a math task when different background music types were played (Kirschbaum et al., 1993). The current study aims to explore

how different music genres affect stress responses.The study will use a between-subject measures design, exposing participants to either relaxation/meditation music or fast-beat music after establishing baseline physiological measures without music. The goal is to compare the impact of calm meditation music versus techno music on stress response. Researchers hypothesize that calmer music might decrease stress, while faster music might increase it. By examining how music affects the human nervous system, the study seeks to provide additional stress management tools.

Abstract Name: Natural Disasters and State Cooperation

The importance of natural disasters and their impact on affected governments and neighboring states cannot be understated. Recognizing patterns between natural disasters and cooperation is necessary to determine how governments can best react and pre-empt the negative effects. Natural disasters cause some level of distress and panic within states due to the sudden decrease in available resources, the damage that the disaster caused, and other alternative factors. To combat this, states often expedite relief efforts and release public statements containing sympathetic messages and loose action plans to appease citizens. Our research aims to define the relationship between natural disasters and an increase in cooperation between states. We would like states to have the ability to predict how natural disasters will affect them because it would allow leaders and lawmakers to take preventative action against the potential negative effects

Abstract Name: The Impact of Life Course Community Belonging on Later-Life Cognitive Health Across Racial-Ethnic Groups

Prior studies reveal an association between elements of social relationships and cognitive health, but we examine whether the sense of community belonging at different ages is related to cognitive health during later life, guided by the life course perspective. This study also examines whether community belonging influences cognitive health among Black, White, and Hispanic adults. We used data from the 2016-2018 waves of the Health and Retirement Study, including unique data from the 2017 Life History Mail Survey, to analyze how feelings of local community belonging at multiple life stages may influence cognition scores and how this may vary across White, Black, and Hispanic respondents. In the full sample, respondents who experienced greater community belonging during early life and later life had better cognitive health. A

similar pattern emerged among Black respondents in analyses stratified by race-ethnicity. Among Hispanic respondents, community belonging was not significantly related to cognition. Among White respondents, community belonging in later life was associated with better cognitive health. The findings suggest community belonging over the life course is beneficial for later-life cognitive health, especially for Black adults. This study demonstrates the importance of incorporating the life course perspective to examine how the feeling of community belonging at various stages in life impacts later in life cognition.

Abstract Name: Not All Men: How Toxic Masculinity Varies by Sexual Orientation, Race, and Mental Illness Diagnosis

Societal standards encourage men to be rigid, show no emotion, behave aggressively, and not ask for help, along with many other avoidant coping strategies. However, this toxic masculinity is associated with poorer mental health and difficulty in relationships. Adhering closely to these societal standards has been shown to cause increased stress, while not feeling as though you meet these societal standards can also cause stress by way of feeling like an outcast. Because previous research has mostly focused on White, heterosexual men, it is unclear how social identities like race and sexual orientation correlate with perceived masculinity, so this study aimed to fill that gap in the literature. Participants (N=227) took an online survey on Prolific Academic. We examined gender role discrepancy (GRD), defined as a male's perception of themselves in comparison to traditional masculinity norms set by societal standards. Survey measures included participants' perceptions of their own individual masculinity and their perceptions of societal expectations of their masculinity, and then we calculated GRD by subtracting individual perceptions from societal expectations. The findings showed that both sexual minorities and heterosexuals have similar perceptions of societal perceptions of masculinity, but individually men who identify as heterosexuals felt more masculine than men who identify as a sexual minority, resulting in more GRD for sexual minorities. When investigating race, no significant relationship was shown between race and GRD. Confirming previous research, men with a diagnosis of mental illness had significantly higher GRD compared to men not diagnosed with a mental illness. This study takes a deeper dive into men and their masculinity by investigating how various demographics relate to how masculinity is perceived both individually and socially. Doing so helps us further understand how to tailor future aid and compassion towards men and their mental health.

Abstract Name: Determining Patterns of Mangrove Species Dominance in Different Life Stages Across

Differently-Aged Sites Post-Creation in Tampa Bay, FL

Despite mangrove's economic and ecological importance, successional patterns of mangrove forests are poorly studied. There is little support for white mangroves acting as pioneer species following habitat creation, with slower recruitment of black and red mangroves across the entire intertidal elevation. We assessed site development in three differently-aged-created mangrove habitats in Cockroach Bay Aquatic Preserve, Florida, USA, to meet this objective. Mangrove forests are a vital ecological system found along subtropical to tropical coastlines. They are essential blue carbon ecosystems and amongst the highest productivity of global ecosystems, including rainforests. Development threatens these forests, leaving coastlines vulnerable to storm surges and rising sea levels while reducing habitat for other organisms and facilitating biodiversity loss. Creating mangrove forests is essential in countering the loss of these forests, allowing mangroves to recruit facilitated by planting a sympatric salt marsh grass species.In our study, we determined mangrove density of different life stages for three species: white (Laguncularia racemosa), red (Rhizophora mangle), and black (Avicennia germinans). Three differently-aged (3-24 years old post-creation) created sites were sampled annually between 2015-2023. White mangrove seedlings recruitment consistently demonstrated a high dominance over red and black mangrove seedlings at sites across all ages and elevations. For juveniles, there is an increased representation of red and black, though white juveniles continue to dominate this life stage. Red and black continue to be better represented in the adult life stage but are not dominant after nearly a quarter of a century post-creation. This strongly indicates that white mangrove is the pioneer species and red and black recruit slowly in created mangrove sites. We show additional patterns of succession for mangrove life stages as well as critical comparisons of different created sites of the same age. This contributes to further knowledge in restoration ecology, supporting assessment policy for habitat creation.

Abstract Name: Unraveling Substance Use and Depression in Young Adults

Using data from the 2021 National Survey on Drug Use and Health, this study explored the role of substance use in exacerbating role impairment among young adults who experienced major depressive episodes. Role impairment refers to the difficulty in daily life functioning within domains of home management, work obligations, maintaining close relationships, and social interaction. Our analysis encompassed 2,366 individuals ages 18-25, examining the prevalence of alcohol, tobacco, and illicit drug use and their subsequent impact on daily functioning in the preceding year. Analyses of Variances (ANOVA) were conducted comparing impairment sum scores – a metric of role impairment severity – across groups differentiated by substance use, revealing pronounced differences in impairment related to tobacco [F(1, 2364)=7.53, p=.006, ηp2=.003] and illicit drug use [F(1, 2364)=11.32, p<.001, ηp2=.005], with users exhibiting significantly higher impairment scores than non-users. Conversely, alcohol consumption did not significantly impair participants [F(1, 2364)=.210, p=.647, ηp2<.001], highlighting the distinct pathways through which various substances may affect young adults with depressive symptoms. Notably, gender (p=.001 for tobacco, p=.004 for alcohol, p=.003 for illicit drugs) and family income (p=.002 for tobacco, p<.001 for alcohol, p=.001 for illicit drugs) consistently emerged as significant factors across all substances, emphasizing its influences on the relationship between substance use and impairment. The

observed effect sizes were modest, suggesting that substance use is one of several factors contributing to role impairment. This highlights the need for personalized interventions and further research into how substance use interacts with mental health challenges. The conclusions drawn from this study offer valuable insights for the development of targeted policies and educational programs aiming to mitigate the effects of substance use on mental health among young adults.

Abstract Name: The Magic of Mushrooms: Investigating the Effects of Psilocybin on the Depressed Amygdala

Building upon three key studies pertaining to Psilocybin's attenuation of top-down modulation from amygdala to visual cortex pathways, this project seeks to propose a Psilocybin-centric functional neuroimaging study over individuals suffering from major depressive disorder. First, the Kraehenmann et al. AMG to V1 processing model was selected to serve as the basis for the study proposal. According to this model, Psilocybin may reduce negative affect by altering emotional processing through relevant MDD pathways. Second, Barret et al. global connectivity maps implicate this shift in processing to result from a short-term spike in functional connectivity one-week following Psilocybin administration. This neuroplasticity may promote long-term reduction in negative affect through a bottom-up to top-down processing shift in AMG to V1 pathways. Third, a therapeutic study conducted by Gukasyan et al. on depressed individuals demonstrate the longevity of this processing shift through continual symptom reduction over the course of a year. Using these three studies, this project proposes that if individuals receive a single high 25mg dose of Psilocybin, then fMRI imaging will reveal increased amygdala attenuation for up to a year, because post-dose neuroplasticity will lower functional connectivity of amygdala to occipital pathways; Therefore, depression symptoms will be reduced through an AMG to V1 processing model. A preliminary double-blind placebo-controlled study will be conducted on screened-participants ranging from 25 to 65 years old. Participants will undergo fMRI emotional discrimination testing one-day, one-week, and one-month after receiving a high 25mg dose of Psilocybin, while follow-ups will be conducted at three-month intervals over the course of a year. Conducting fMRI emotional discrimination tasks along with mapping relevant pathways may clarify the length of varying functional connectivity levels after a single high dose of Psilocybin. Further research could explore Psilocybin's effect on the occipital lobe as a possible line of treatment for other mood disorders.

Abstract Name: Inhibiting the growth of Cutibacterium acnes with the Streptococcus salivarius M18 Probiotic

Acne Vulgaris (AV), typically referred to simply as acne, is a complex chronic skin disorder that affects millions of people in the U.S. One contributing factor of AV is the over-proliferation of a bacterium known as Cutibacterium acnes (C. acnes). Studies have shown that the commonly prescribed combination therapy for AV using anti-inflammatory drugs in conjunction with antibiotics has decreased the susceptibility of C. acnes to antibiotics and increased antibiotic resistance of C. acnes strains. Previous research has also demonstrated that C. acnes can transfer this resistance to other skin and gut microbiota. The study of alternative methods for AV treatment has shed light on the potential of probiotics like Streptococcus salivarius (S. salivarius) to combat the overgrowth of C. acnes through the production of bacteriocin-like inhibitory substances (BLIS) known as lantibiotics. Using the BLIS-producing S. salivarius M18 strain of probiotics, an in vitro deferred antagonism assay will be used to determine if the lantibiotics produced can inhibit the growth of C. acnes as well as other microbes, including Pseudomonas aeruginosa and Streptococcus mutans. Growth inhibition of C. acnes and other skin microbiota by S. salivarius M18 will provide valuable insight into alternative AV treatments that could increase compliance to topical therapies for AV patients worldwide.

Abstract Name: Limitations of Traditional Rhetoric Textbooks; An EDI Perspective

Rhetoric, as an applied disciplinary study, does not stray far from its own canon. Rhetoric textbooks, being the very foundation of how rhetoric is taught in academia, are indicative of this, as can be seen in the collegiate textbook: The Rhetorical Tradition: Readings from Classical Times to the Present. This text includes a wide array of classical works, such as that of Ancient Greek rhetoricians like Plato and Aristotle. While valuable in their own right, the textbook's readings from the present do not retain the same amount of depth as those from the canon do. Rhetoric is often overlooked as it applies to a contemporary society, being non-inclusive of relevant politics and identities of a vast percentage of people who aren't white, straight, and able-bodied. My research looks to further identify the limitations of rhetoric textbooks like The Rhetorical Tradition, and present solutions to how the rhetorical canon can be reconstructed around an Equitable, Diverse, and Inclusive (EDI) framework. The Rhetorical Tradition has already mapped out how the canon may be modified for a contemporary audience by including the works of rhetoricians Henry Louis Gates Jr. and Gloria Anzaldúa, leading me to further explore how the identities of marginalized groups are put in a constant state of rhetorical flux, such work only beginning to surface in texts like Critical Rhetorics of Race and Identity: A Reader For Writers, this work needing to be pushed further. My work explores the idea of what a contemporary rhetoric textbook would look like, retaining the values of canon rhetoricians, while also exploring how rhetoric plays into the daily lives of people of color, queer people, and disabled people. I aim to redefine rhetoric as an equitable, diverse discipline, being inclusive of people outside of a white, able-bodied, and cisheterosexual structure.

Abstract Name: Developing Cultural Competency and Empathy Through Archival Pedagogy

Archival pedagogy is the key to developing greater personal connections to history than can be found in a secondary source textbook. In the Learning Lab internship program at the University of Kentucky Libraries Special Collections Research Center, undergraduate student interns recently experienced a project that brought them in direct contact with records that heightened their awareness of historical injustices and created connections that spanned centuries. The director of the program coordinated with the archivist of the historic Lexington African American Cemetery #2 located near to the university. Students were each given two names of people buried at the cemetery, and they had a month to research everything they could find connected to the lives of the people they were given. Students learned primary source competency skills, such as how to scour local archival repositories, digitized newspaper platforms, and genealogy resources. They also quickly found records that were challenging to modern viewers, but that gave them a glimpse into the everyday difficulties of being Black in the American South in the early 20th century. Each student came to care deeply about the people they researched. The assignment culminated in a visit to the cemetery to talk about the findings with the cemetery's archivist, celebrate the lives of those researched, and physically clean and tend to the graves. The project created individual connections to history that are impossible to replicate from a book or lecture. Confronting everyday historic injustices deepened student empathy and raised their cultural competencies.

Abstract Name: “Scholarship as Conversation”: Successful Experiences of Mentor-Led Research at Franklin College

A common assumption is that academic historians conduct their scholarship in relative isolation. They research and write independently until they are ready to share their work at a professional conference or submit a manuscript to a journal. This idea of independent study is often replicated in capstone courses at the undergraduate level. Seniors work independently on their projects with dialogue limited to their research advisor until the time comes to present their scholarship at the end of the semester – likely to a small audience limited to the department and invited guests. While individual student research can be a solitary process, there are advantages to having undergraduates recognize how conversations throughout the process can make their work more meaningful.The History Department at Franklin College has implemented a new research initiative that aligns with current scholarship in teaching and learning that recognizes undergraduate research as a “high-impact practice.” The History Department’s framework of “Scholarship as Conversation” emerged from a department curricular redesign that focused on scaffolding as a way to develop skills and abilities. The framework begins with our majors recognizing that their scholarship is in conversation with fellow historians and that they are part of a larger academic community that cares about their research. The framework also builds upon the college’s existing Honors Symposium, where student panels present their findings to the entire campus community. All graduating history majors are required to participate in a new history symposium. The experience offers a sense of accomplishment and purpose to the seniors, while reinforcing the notion that historians are continually in conversation. This oral presentation celebrates the

spirit on undergraduate research and academic collaboration within a department and provides insights that could potentially help other humanities or social sciences departments that are navigating the challenges and joys of undergraduate research.

Abstract Name: Optimization of Casein Micelle Nanoparticle Formation using High-Pressure Homogenization

The casein micelle is highly stable against typical food processing procedures such as pasteurization, homogenization and drying. This stability along with the propensity to orient itself with a hydrophobic core makes casein an ideal compound to be used in the encapsulation of compounds (e.g., vitamins, polyphenols). Various techniques such as high-pressure homogenization (HPH), and the addition of emulsifying salts have been used to enhance casein dissociation and nanoparticle formation, but they have not been evaluated in combination. This research aims to evaluate the physical properties of dissociated casein proteins following emulsifying salt-based dissociation coupled with high pressure homogenization. Two emulsifying salts, sodium hexametaphosphate (SHMP) and sodium citrate (SC), were evaluated at different concentrations without high pressure homogenization and at varying high pressure homogenization treatments. The turbidity and hydrophobicity of the samples were then assessed using a spectrophometer and spectrofluorometer. Upon evaluation sodium hexametaphosphate, at the highest concentration without HPH, exhibited an absorbance of 0.111 ±0.010 and a fluorescence of 770.71 ±42 while sodium citrate exhibited 0.115 ±0.033 and 910.04 ±55.3. At the highest level of high-pressure homogenization (300 MPa) sodium hexametaphosphate produced an absorbance value of 0.069 ±0.006 and fluorescence of 768.03 ±43 and sodium citrate produced 0.075 ± 0.015 and 917.16 ±38. Encapsulation potential of the SHMP and 300 MPa HPH treated sample was evaluated by comparing fluorescence data between samples with and without caffeine. Samples including caffeine exhibited a lower fluorescence than those without caffeine, indicating an interaction with the protein. The impact on the physical properties exhibits that while higher concentrations of emulsifying salts are efficient at dissociating the casein micelle, dissociation can be further optimized using high pressure homogenization.

Abstract Name: Reversing Neuronal Cell Damage through Mitophagy Induction

Familial Dysautonomia (FD) is caused by the single point mutation of the major signaling scaffolding elongator protein IKAP/ELP1. This disease disrupts the autonomic nervous system leading to decreased sensory perception, poor reflexes, inhibition of vascular and cardiac functions, orthostatic hypotension, and recurrent severe autonomic crises. Patients with FD experience increased incidence of severe adverse reaction and increased neuropathy after anesthesia. Neuropathy is associated with mitochondrial damage and increased cellular reactive oxidative species (ROS). Mitophagy is a cellular process that recycles damaged or dysfunctional mitochondria. We hypothesize that increasing mitophagy or reducing ROS levels will lead to greater neuronal cell viability. We will employ the dopaminergic LUHMES cell line and apply a mitophagy stimulator known as CCCP. We expect the cellular viability to be increased because CCCP will cull the defective mitochondrial pool as measured by MTT assay and Western blot for mitophagy markers (PINK1) and apoptosis markers (Caspase-3). Future directions of this experimental plan will include the addition of the anesthetic Ketamine. We hypothesize that a greater level of neuronal cell death will occur after Ketamine application. To counter this death, pre-treatment with CCCP or a ROS inhibitor will delay or prevent Ketamine induced cellular apoptosis. We envision patient pre-treatment with a ROS inhibitor or mitophagy stimulator may counteract anesthetic neuronal damage. Implications of this study could elucidate new methods in preventing anesthesia-associated nerve damage in FD patients as well as diabetic- and cancer-induced neuropathic conditions.

Abstract Name: The Institutionalization Of Disabilities- Why WIllowbrook Made A Difference

Before the Americans with Disabilities Act (ADA) was passed, Americans with disabilities were rarely allowed to work, access public places, or even be included in public schools. Instead, institutionalization was the way the American Government decided to “deal with” those who had disabilities. These institutions were supposed to offer individuals with disabilities a safe place where they could get their needs met without the judgment of the outside world. When looking at cases of institutions, specifically Willowbrook, it isn’t hard to argue that institutionalizing individuals with disabilities was not the solution. Many disability institutions can be very closely comparable to American Prisons. It is argued by many historians that with the treatment of those with disabilities being so similar to prisoners, there was a heavy disregard for individuals with disabilities, especially in Willowbrook. Willowbrook State institution in Staten Island first opened in October 1947, with only 20 students, who were transferred from mental institutions. The original goal was to give these patients a 1 on 1 opportunity to gain skills, but because of the success of these 20 students, admission for the school greatly increased to over capacity with 4,000 students by 1955. This institution was incredibly understaffed, overcrowded and underfunded. This case set important precedents for the humane and ethical treatment of people with developmental disabilities living in institutions. The findings of Willowbrook, was a turning point for individuals with disabilities, and a large reason behind the inclusion of those with developmental disabilities, the expansion of community services, and the establishment of the rights for children with disabilities to receive a public education.

Abstract Name: "Revealing Microbiome-Driven Indicators for Assessing Kelp Health through Extracellular Enzyme Analysis and Nutrient Profiling"

Giant sea kelp (Macrocystis pyrifera) plays a vital ecological role, yet the impact of changing environmental conditions on its physiology remains poorly understood. This study investigates the correlation between kelp's microbiome, nutritional value, and chemical composition. Recent experiments have revealed a declining organic matter gradient from distal to proximal locations on the frond, accompanied by an inverse relationship in enzyme activity. Therefore, we hypothesize that the associated microbiome influences variations in enzyme activity and nutrient profiles across the frond and different ages. Using extracellular enzyme analysis and nutrient profiling techniques, we analyze nutrient and enzyme concentrations in various kelp frond samples. We aim to uncover phenotypic expressions influenced by the kelp's microbiome and understand how enzyme activity and nutrient concentrations vary based on age, location, and collection sample. Anticipated results include identifying the declining organic matter gradient along the frond, accompanied by an inverse relationship in enzyme activity. These findings will offer valuable insights into the influence of microbial activity on giant kelp physiology and reveal the complex dynamics between the kelp and its associated microbiome. This research has practical implications, including optimizing kelp collection strategies, understanding kelp-microbe dynamics, and supporting the sustainable management of kelp ecosystems. By identifying microbiome-driven indicators, we can mitigate the impacts of changing environmental conditions on kelp health. Ultimately, this study contributes to preserving and managing kelp forests, benefiting ecological systems and other economic uses.

Abstract Name: Dual Analysis of Biomass and Carbon Sequestration in Secondary Successional Forests in the Piedmont of North Carolina Utilizing Geographic Information Systems and Field Truthing Methods

As levels of atmospheric carbon continue to rise, so does public concern about climate change; however, not enough is being done to prevent further damage to our planet. While the scientific community turns its attention toward high-tech solutions, many local conservation options are being overlooked, such as the carbon mitigation opportunities offered by local parks. This research looks at carbon sequestration, the process of trees absorbing and holding onto atmospheric carbon, in Cedarock Park in Alamance County, North Carolina to help better understand the capabilities of county parks to mitigate climate change. During the summer of 2023, prism cruising was employed to collect diameter data from trees <10 cm diameter at breast height (DBH) from 87 randomly selected plots. Precise geographic coordinates were recorded using Google Maps. Subsequent analysis involved calculating tree density, species richness, and Shannon's H' diversity index for each plot. Geographic information systems technology was used to obtain elevation (in meters), slope (in degrees), and aspect (in degrees). Our results demonstrate that Cedarock Park stores between 163-181.1 MG/ha CO2e, a significant contribution to local carbon sequestration efforts. This figure aligns favorably with other forests in Alamance County, such as Elon University Forest (88.6-98.5 Mg/ha), Cane Creek Mountains Natural Area (190.7-211.9 Mg/ha), and US Forest Service estimates of carbon storage in Piedmont forests. No significant correlations were found between carbon storage and elevation, slope, aspect, tree species richness, or diversity. Cedarock Park, due to its classification as a secondary successional

forest, is likely to possess even greater carbon sequestration potential than currently estimated. This study underscores the overlooked role of local parks, exemplified by Cedarock Park, in mitigating climate change.

Abstract Name: Effect of High-Low Training on Well-Being after Chronic Spinal Cord Injury

Introduction: Athletes utilize high-low training (H-L) to maximize performance by exercising under normoxic conditions paired with hypoxic exposure when resting. Exercise and hypoxia are beneficial in treating spinal cord injury (SCI) in rodent models. Exercise after SCI increases neurotrophins whose decreased levels are associated with anxiety-like behavior. In humans with SCI, decreased well-being is attributed to increased rates of mental disorders and suicide. Post-SCI inflammation is common and linked to anxiety-like behavior. One aspect of this project was to test the hypothesis that H-L training doesn't induce anxiety when implemented chronically after SCI. H-L training was executed in rats with chronic SCI by combining voluntary overnight exercise with repetitive, sustained hypoxia 5 days a week for 8 weeks. Methods: Starting with n=62, and final n=49, Sprague Dawley female rats underwent baseline training before receiving a left C2 hemisection (LC2Hx). Subjects were randomly assigned to 4 groups: sedentary control, H-L, exercise-only, or hypoxia-only. At 6-7 weeks post-injury (WPI) treatment was initiated. Voluntary exercise was performed via exercise wheel access and sustained repetitive hypoxia was administered in 4-hour bouts of 11% oxygen. Activity Boxes were used to measure anxiety-like behavior. Results: Monitored exercise wheels showed that H-L subjects tend to increase voluntary exercise distance and speed over time. Activity Box data showed that after 4 weeks of treatment, H-L rats had increased ($p = 0.0126$) rearing activity compared to sedentary rats. Sedentary rats increased time spent in the perimeter (open field assay) at each timepoint ($p=0.0024$), while H-L rats experienced an insignificant negative trend in time spent in perimeter. Weekly weight checks showed an expected decrease in all subjects, but both groups gained weight as the experiment progressed.Conclusions: H-L was tolerated by rats with chronic SCI and shows potential as a treatment for humans with SCI without unnecessarily increasing post-SCI anxiety.

Abstract Name: Pixels to Pillars: AI's Role in Architectural Design

In the field of architectural design, the invention of artificial Intelligence or (AI) has sparked incredible

amounts of curiosity and debate in regard to its potential impact on classical design principles. For this Project I will dive into the relationship between AI and classical Architecture and aim to determine whether AI can Measure up to the educated experts of classical architecture and how we can use AI as a tool for design. The project will unravel in three separate phases (1-3). Phase 1 will explore the interior and exterior images provided by AI when describing a building akin to the Pantheon because it is considered to be the pinnacle of beauty. The incremental process of refining the text prompt is essential to obtain quality images to continue into the subsequent phases. In phase 2, the VAS by 3M, will be used to assess which of the AI images are the most captivating for both the exterior images and the interior images. The winning interior image and the winning exterior image will then move on to phase 3. Phase 3 will take these AI images and compare them to photographs of the Pantheon VAS 3M. This phase will evaluate the extent that AI can pull attention and will offer insights into the potential utility for architects or designers to use in the design process during the conceptual phase. In conclusion, I expect findings will show VAS attention percentages are slightly skewed in favor of human design and, while AI can enhance the efficiency in the design process, it cannot replace years of classical training. Architects would be wise to, instead of resisting change, fully embrace AI as a tool for design enhancement. This study emphasizes the importance of collaboration between “man and machine” in shaping the future for architecture.

Abstract Name: The Remediation of Ocean Acidification Using the Bio-adsorbent: Ludwigia Peploides

Carbon emissions do not just drive climate change; CO2, when absorbed by the ocean, forms carbonic acid, which ultimately results in reduced pH, a phenomenon known as ocean acidification. A lower pH disrupts development of calcifying organisms and degrades overall aquatic health. Our research aims to investigate the potential of Ludwigia peploides, an invasive and resilient plant, to mitigate CO2. We collected water and Ludwigia peploides samples from the San Joaquin River at Big Break Regional Shoreline. One plant sample was dried and mixed in a sample of water from Big Break and another in a solution made from a combination of hydrochloric acid and the same water. We then measured the pH of each solution every 10 minutes for 1 hour. In our experimentation, we found a pH dependent trend on L. peploides acidity adsorption. A pH of 3 demonstrated strong adsorption, averaging 94%. As we decreased the pH, the average percent of adsorption also decreased. With a pH of 2, adsorption was at 80%, while a pH of 1 displayed a noticeable decline with only 15% acidity adsorption. Though results vary based on the pH, Ludwigia peploides has shown to be a viable tool in the process of reducing the acidity of water. We plan to perform additional trials for data collection, aiming to enhance our gathered evidence and reinforce the significance shown through our current analysis . Our research holds significance being that it explores the potential of an invasive species to mitigate the effects of carbon emissions.

Abstract Name: Early Interventions in STEM Education: Examining Spectrums of Youth Interest in Engineering

This research proposal seeks to investigate the impact of early engagement opportunities in engineering concepts on computational and systems thinking, as well as the subsequent influence on interest in STEM majors and careers among underserved and underrepresented youth. Utilizing the innovative approach of Project-Based Learning (PBL) and Design-Based Learning (DBL) within the context of the CIEE Summer Engineering Camps, this study aims to provide insights into effective strategies for promoting inclusivity and sustained interest in STEM. The curriculum design focuses on situating learning in culturally relevant contexts to enhance the development of computational thinking and systems understanding. By immersing K-12 students from Dallas and Fort Worth area schools in hands-on, real-world problem-solving experiences, we aim to bridge the gap between abstract concepts and practical applications. Diverse cultural perspectives will be incorporated to create an inclusive learning environment that engages students from underrepresented backgrounds.A key component of this research is the development of a qualitative research tool in the form of a rubric for coding academic discourse in STEM contexts. This rubric will facilitate the analysis of student notebooks, differentiating between high, medium, and low-quality work. Conformational factor analysis will complement this qualitative approach by evaluating relationships between student demographics and markers of scientific learning.The research findings will contribute valuable insights into the success of early interventions in STEM education and the factors influencing academic and career interests among students of different demographics. The presentation and paper resulting from this study will not only inform the academic community but also provide actionable recommendations for educators, policymakers, and program developers aiming to enhance STEM engagement and inclusivity. Ultimately, this research strives to foster a diverse and enthusiastic pipeline of future leaders in STEM fields.

Abstract Name: Analyzing the Role of PCSK9 in Cholesterol Uptake in Pancreatic Ductal Adenocarcinoma

Pancreatic Ductal Adenocarcinoma (PDAC) is a highly aggressive form of cancer known for its tumor heterogeneity and resistance to traditional chemotherapy. It poses a significant threat worldwide, with a 5-year survival rate of approximately 12% following diagnosis, primarily due to its invasive nature and propensity to metastasize to the liver and lungs. Past research has shown that PDAC can be classified into two distinct subtypes termed basal and classical based on their differential gene expression. Basal PDAC cells tend to have higher levels of LDL (low density lipoprotein) uptake and lower levels of cholesterol

biosynthesis while classical PDAC cells tend to have the opposite. Interestingly, patients with basal PDAC tended to have a lower life expectancy than those with classical PDAC. In this study, we investigated the metabolic differences between basal and classical PDAC cells. We find that a protein known as proprotein convertase subtilisin/kexin type 9 (PCSK9), an LDL-receptor inhibitor that inhibits LDL-uptake by the cell is highly expressed in classical PDAC and absent in basal PDAC. Thus, we aimed to knock out PCSK9 in a classical PDAC cell line to see if a more basal phenotype could be observed. By employing CRISPR gene editing, we have successfully knocked out the PCSK9 gene in two classical PDAC cell lines. Through immunofluorescence imaging, we were able to observe increased uptake of LDL, reminiscent of a basal-like phenotype in the classical cell lines. Reintroducing the PCSK9 gene in the classical PDAC cells through viral transfection was able to rescue the classical phenotype, characterized by decreased LDL uptake and increased cholesterol biosynthesis. These findings highlight a potential important role of differential cholesterol uptake as a determinant distinguishing classical and basal PDAC cells. This sheds light on the underlying mechanisms driving PDAC progression in patients and provides potential targets for therapeutic interventions.

Abstract Name: The Egyptian Identity: The Disillusionment of Pan-Arabism

In the 1950’s Gamal Abel Nasser created a national identity that would redefine Egypt and its people. With the cementation of Egypt’s Pharaonic past as a national identity, Egypt fore fronted the Pan-Arab and Arab nationalist movements that many Egyptians who have lived through the 70s and the 80s look back with fondness. The unified struggle of Arab states from Western imperial power and a promise of a prosperous future were the core factors that drove the Pan-Arabist movement. But since the early 2000’s a decline in the belief in united Arab struggle was seen across many Arab countries. Egyptians on social media refuse to identify with “Arab-ness” and instead identify as African or Egyptian. I focus on the disillusionment of the Pan-Arab identity in younger Egyptians who have only lived through Hosni Mubarak’s reign. I examine the Egyptian identity through time from the 1950's to the present to understand the shifts away from Nasser’s Pan- Arab political identity. I examine social media, historical events primary and secondary as a means to explain why the national identity of Egypt is shifting into what it is today.

Abstract Name: Distribution of Healthcare in Puerto Rico: Supply and Demand of Physician Specialties

In the past several decades, Puerto Rico has undergone numerous cycles of healthcare change, as well as continuous challenges in providing adequate medical care for the number of people on the island. There have

been major trends of physician migration from Puerto Rico, worsening healthcare disparities through a lack of physicians remaining on the island to care for the population. These disparities disproportionately affect rural and suburban areas most, with the majority of physicians located in more densely populated urban areas. In order to quantify this issue, the supply of physicians of 25 different specialties was compared to their projected demand by municipality, region, and as a whole for Puerto Rico. Data regarding the availability of physicians across the island was obtained through a partnership with the Health Industry Information Platform of Puerto Rico, the largest database of physicians on the island. The resulting data has shown that only 36% of the investigated specialties have an adequate supply of physicians in Puerto Rico. However, these physicians are predominantly located in the Metro region of the island, leaving the majority of Puerto Rico without proper healthcare to rely on. Moreover, when accounting for rural and suburban populations as a whole, not a single specialty has an adequate supply of doctors. The specialties analyzed include some of the fields that require the most attention in Puerto Rico based on the prevalence of certain chronic diseases and medical causes of death, such as cardiology, endocrinology, and oncology. The supply and demand projections emphasize the need for healthcare reform as the system in place is unable to ensure the medical safety of its people. The resulting data can be used to aid in the training and placement of physicians in the most pressing areas of need to help address this problem.

Abstract Name: Feeling Our Way Through the Climate Crisis: Reading Dark Affects in Thoreau's "Cape Cod"

Henry David Thoreau’s Walden is often a starting point for environmentalism, but compared to the natural world in the Anthropocene, Walden’s depiction of the natural world suggests an unattainable relationship with pastoral nature. The purpose of this project was to find a Thoreau text that is accessible to readers existing during the climate crisis. In 1849, Thoreau made his first visit to Cape Cod. During his visits he observed horrific shipwrecks that had no visible emotional impact on the inhabitants. Not only did he witness physical wrecks, he also saw wrecks within the landscape as he came face to face with a deforested Cape Cod. The emotions Thoreau experienced during his visits mirror the unsettling existential feelings occurring during the climate crisis. Beyond the mutilated landscapes, Thoreau found that the natural world was still controlling Cape Cod through the force of the Atlantic ocean. Some scholars either misread the book as promoting an unsettling view of nature, or just as a “cheery” travelogue. Through the lens of affective ecocriticism and the ecogothic, Cape Cod may be seen as an environmental narrative that suggests a way of accepting an “unsettling” natural world. This paper aims to explore Thoreau’s anti-sentimental and dark affects in Cape Cod. Thoreau’s observations ultimately provide readers with ways to navigate the existential dread they face in the climate crisis.

Abstract Name: Models of health and disease among Sidama agropastoralists

Cross-cultural differences in perception around disease transmission, disease treatments, and models of health have direct relevance to efforts intended to prevent spread of infections. This study investigates models of health and disease via semi-structured group (n=5) and individual interviews (n=20) among Sidama agropastoralists living in Loqqe, a peri-urban village near Hawassa, Ethiopia. Adult and adolescent participants were asked:1) to define a healthy person; 2) the factors that positively or negatively affect health; 3) to identify which diseases are present in the area; and 4) how these illnesses are spread. On average, participants mentioned 5.7 diseases present in the area (range 2-16). Results indicate that there is salience among diseases of concern and their routes of transmission. Biomedical explanations were frequently (but not always) provided for malaria and the common cold whereas greater variation (e.g., hunger, malnutrition, and weather) was associated with transmission routes for diseases such as typhoid and typhus. Absence of disease and cleanliness were associated with healthy individuals as was living a comfortable life; poverty is explicitly linked with ill health. The associations noted between poverty, malnutrition, and disease suggest that our participants have identified a locally relevant syndemic which, in turn, provides insight into possible areas for address by public health specialists.

Abstract Name: Mejo[r] o mejo[ɹ]: Variación entre los acentos de hispanohablantes dependiendo del trasfondo lingüístico

The sounds of the Spanish language vary incredibly, from the “th” of Spain to the infamous “sh” sounds of Argentina. Given the linguistic diversity present in the United States, an “American Spanish” accent is especially variable, being simultaneously influenced by immigration from an array of Spanish-speaking countries as well as the dominant English language. Thus, the present study seeks to quantify said variation, connecting various sociolinguistic factors (time spent in the United States vs. time spent in Spanish-dominant countries, the age at which Spanish was acquired, contact with Spanish at and after that age, and self-rated proficiency in Spanish speaking) to the varied phonetic realizations of different phonological sound classes (/s/, /r/, /p/, etc.). To do so, groups of Spanish speakers with varying linguistic backgrounds (native speakers, bilinguals, heritage speakers, and L2/Spanish-as-second-language speakers) were asked to complete a survey examining said sociolinguistic factors. Each participant was recorded speaking freely in Spanish as well as reading off 5 investigator-constructed Spanish sentences, to assess accent under both informal and formal conditions. Each realization of a phoneme (e.g., /s/) was then scored, being categorized into its most appropriate allophone (e.g., [s] as in “super” or [z] as in “zipper”). Patterns of realizations were then assessed under the various sociolinguistic factors. Expected results are that native speakers will have allophonic realizations most in-line with Spanish and with their native dialect (being most influenced by time spent in the United States), bilingual and heritage speakers will have great variation in pronunciation (most influenced by age at which they started learning Spanish as well as level of contact with Spanish at younger ages/during the “critical period”), and L2 speakers will have realizations most in-line with English (highly influenced by self-rated level of proficiency and time spent in Spanish-dominant countries). Note that this presentation will be given in Spanish.

Abstract Name: False appearances a modern epidemic

La Casa de Bernarda Alba is a representation of the dilemma that has impacted the lives of many. Today technology has given us the ability to connect on an even grander scale than ever before. However, instead of using it to share our lives with others, it tends to be used in a way to distort and paint a different picture of our lives. Many mediums for communication, content creation, and news outlets intentionally focus their content to promote the views that they want others to follow. La Casa de Bernarda Alba shows this through the control that the mother has over the daughters and her house. To put on the image of a family unified and put together when that couldn't be farther from the truth. This video put together by Tate Jensen, Grace Gunn, and Robert Summerhays uses the family of Bernarda Alba and their intrafamily struggle to highlight the importance of being true to who you are and confronting the difficulties that we experience.

Abstract Name: Developing countries attract foreign direct investment in a politically unstable environment

Our study explores the challenges and strategies used by developing countries like Brazil, Palestine, and Egypt to secure foreign direct investment (FDI) during periods of political turmoil. Drawing on five years of data drawn from the World Bank, the International Monetary Fund, and the International Country Risk Guide (ICRG), we found some strategies developing countries can use to enhance their appeal to foreign investors, even during a time of political instability.Specifically, our research highlights the importance of maintaining stable economic policies, offering incentives for investment, and actively engaging in diplomatic efforts to mitigate the perceived risks associated with political instability. We also delve into the role of international organizations in providing support and assurance to potential investors. Our findings suggest that a combination of these approaches can significantly improve the attractiveness of developing countries to foreign investors. This study contributes to the existing literature by providing empirical evidence on the effectiveness of these strategies in diverse geopolitical contexts. Furthermore, it offers practical insights for policymakers in developing nations seeking to attract and retain foreign direct investment during challenging political periods

Abstract Name: Identities, Intercession, and Resistance: Comparative Perspectives on Still Life and A City of Sadness

This research delves into the connections between East Asian filmmakers Jia Zhangke and Hou Hsiao-Hsien. Despite Jia's involvement in the Sixth Generation of contemporary mainland Chinese Cinema and Hou's active engagement in Taiwanese New Wave Cinema, their films Still Life (centered around the construction of the Three Gorges Dam in the 1980s) and A City of Sadness (depicting the February 28 incident in Taiwan) respectively, both directors share a common cinematic approach characterized by restraint and intermediation. Despite their distinct historical and cultural contexts, Jia and Hou employ similar cinematic techniques to highlight the struggles of marginalized individuals and emphasize the power of individualized, displaced, and fragmented identities and experiences. Jia navigates the border between history and memory, documentary and fiction in Still Life, while Hou utilizes long takes with deliberate interruptions to evoke insecurity and bewilderment, transforming vulnerability into a departure from the pace of one's own fate in A City of Sadness. In Still Life, symbols of destruction and ruins serve as alarms against both governmental propaganda and the fanatical pursuit of progress and prosperity, and a moral nihilism concealed beneath the veneer of compromise and transcendence of reality. Similarly, A City of Sadness subverts the dominant discourse of bureaucrats by introducing fragmented, individualized experiences akin to collages. Both Jia and Hou start from a reflection of collective memory, display a conscientious approach to the marginalized and underrepresented individuals affected by traumatic politics. Their filmic gestures navigate and supports individual lives by resisting a distinct choice and intercessing between truth and belief, achieved through a dialectical, non-linear representation of history that juxtaposes past and present.

Abstract Name: Health Disparities Among Rural Indian Women: Colonial Legacy, Current Realities, and Resilient Practices

This presentation explores the enduring healthcare challenges faced by rural Indian women, delving into the historical and contemporary contexts that shape these disparities. Colonialism's legacy of disruption to indigenous health practices is examined alongside the present-day struggles of limited access to quality healthcare services, information, and reliable medical professionals. This lack of accessibility further exacerbates existing health disparities and fosters mistrust in formal healthcare systems. However, rural communities exhibit remarkable resilience, utilizing traditional healthcare systems like Ayurveda and homeopathy to address their health needs. While these practices offer invaluable support, they often fall short

in addressing complex medical issues. Recognizing this limitation, the presentation proposes solutions that focus on empowering communities through education, including health literacy initiatives and increased awareness of available resources. Additionally, strengthening the supply chain of essential medications and medical products in rural areas is crucial to ensure equitable access to vital healthcare components. Technology presents another promising avenue for bridging the gap in healthcare access. By leveraging advancements in telemedicine and information dissemination platforms, rural communities can receive health-related information and connect with medical professionals remotely. This integrated approach, encompassing education, resource accessibility, and technological advancement, underscores the need for a multi-pronged strategy towards achieving healthcare equity for rural Indian women. The journey towards equity, however, extends beyond simply acknowledging disparities. It necessitates implementing solutions that respect the rich cultural fabric of these communities, recognizing the value of traditional practices while simultaneously bridging the gap with modern healthcare advancements. By embracing this holistic perspective, the presentation aims to inspire action towards creating a more just and equitable healthcare landscape for all rural Indian women.

Abstract Name: Dopaminergic organization of mating motivation over days

Changes in the dopaminergic circuitry underlying mating drive and motivational states can be long lasting. We investigated how the brain organizes these long time scales over days in the context of the male mating drive. These findings may help explain the mechanisms that control the transition between motivational states. Brief investigation of females elevates a male mouse's interest in mating for several minutes. However, a successful mating leads to satiety and decrease of mating behaviors that gradually recover over days. The anteroventral and preoptic periventricular(AVPV/PVpo) dopamine neurons in the hypothalamus regulate the male mating drive and are responsible for endogenous dopamine release in the medial preoptic area(MPOA) - a critical region involved in mating behaviors. We hypothesized an increase in absolute dopamine levels that parallels the return of mating behaviors. Using 2-photon fluorescence lifetime imaging (2p-FLIM) to track absolute dopamine levels, we show that recovery of absolute dopamine levels is correlated with the recovery of mating behaviors post-satiation. Through patch clamp recordings, we found that changes in the firing rate of AVPV/PVpo neurons post-satiation alone does not explain the time course of recovery. There is an initial drop in firing rate, but returns to baseline on a faster time scale than dopamine levels and mating behaviors. With Tyrosine hydroxylase(TH) being the rate-limiting enzyme of the dopamine synthesis pathway and observing a decrease in TH cells in the AVPV/PVpo region post-satiation, we predict neurotransmitter switching to play a role in mating behavior recovery. To causally show this, we overexpressed TH and observed an accelerated recovery of mating behaviors post-satiation. Therefore, the decrease in spontaneous firing rate of these hypothalamic dopamine neurons and neurotransmitter switching both underlie the time course of motivational recovery and, hence, may explain how the brain is able to organize mating behavior recovery across days.

Abstract Name: Exploring the use of the Hierarchical Taxonomy of Psychopathology (HiTOP) to understand Temporality of Psychological Distress in Lower Extremity Trauma Surgery Patients

Orthopedic and lower extremity trauma injuries are a significant health burden and accounted for more than 7 million diagnoses and 1,100,000 emergency surgical procedures between 2013 and 2014. Interventions for serious traumatic injuries also can include amputation, resulting in limb loss, which is projected to affect 3.6 million people by 2050. There remains a lack of research about how emotional distress manifests in trauma patients following intervention. An understanding of how psychological outcomes and timelines of recovery or development of trauma-induced psychological disorders are integral to designing and providing optimal mental health care for trauma patients. This study investigates the progression and temporality of emotional distress over 24 months among a cohort of orthopedic trauma surgery patients (N= 601) participating in the Lower Extremity Assessment Project (LEAP). The Brief Symptom Inventory 53 (BSI-53) was used to measure emotional distress. The paper investigates the psychometric properties of the original BSI-53 compared to a factor structure that follows the Hierarchical Taxonomy of Psychopathology (HiTOP) which uses a broader theory organizational structure compared to the BSI. Items were organized into new domains following HiTOP and each model was evaluated using confirmatory factor analysis (CFA). Results show that the HiTOP model fit is comparable, if not slightly better, than the BSI model fit, and can be used as a model for emotional distress following acute orthopedic trauma. Both models reinforce the idea that distress organizes itself within 3 months following trauma and generally remains consistent in its organization over two years following trauma.

Abstract Name: Acoustically modulated bond activation for vesicoureteral reflux imaging

Vesicoureteral reflux (VUR) is a disorder affecting young children in which urine flows backwards from the bladder to the kidneys. This can have serious health consequences, such as causing urinary tract infections, and thus it is important to diagnose VUR reliably. Current diagnostic tests involve physically and emotionally traumatizing catheterization of children to inject radiographically detectable contrast agents. We propose an ultrasound-based technique in which a CO2-loaded polymer, polyethyleneimine, is injected intravenously and targeted by ultrasound in the bladder to produce CO2 microbubbles. These bubbles can then be visualized

with ultrasound imaging to determine flow direction, and thus detect VUR. Visualization was successful with a 37 mm thick layer of pork belly interposed between the ultrasound and balloon containing polymer. Following this proof-of-concept, current testing attempts to optimize CO2 loading by varying CO2 gas pressure, buffering using sodium phosphate as a proton acceptor, and testing polymers of different sizes. Ultrasound videos are analyzed using a MATLAB code that binarizes the brightness of the produced bubbles to generate a quantifiable comparator. We find that smaller polymers, ca. 1.8 kDa, enable superior effervescence than larger polymers through a swine tripe layer. In both swine and humans, the polymer is expected to be excreted by the kidneys. If successful, this strategy is remarkable in that it would eliminate the need for catheterization and radiation exposure; this technique can also be adapted to various other clinical needs, to potentially take bladder pressure measurements in older adults. This is the first documented decarboxylation of a polymer using ultrasound and a novel use for acoustical chemical modulation in vivo.

Abstract Name: Ultra-sensitive characterization of TP53 mutations in non-cancerous tissue of individuals at high risk of ovarian cancer.

High-grade serous carcinoma (HGSC), the most common subtype of ovarian cancer, originates in the fallopian tube epithelium from precursor lesions carrying somatic TP53 mutations. Individuals with germline mutations in DNA repair genes are at high risk of HGSC but the reason is unknown. We hypothesize that individuals at high risk of HGSC carry an excess of pathogenic TP53 mutations in fallopian tube epithelium, which predisposes them to cancer. Preliminary data suggests that individuals with germline mutations in BRCA1 and BRCA2 (lifetime risk of HGSC 45% and 21%, respectively) have more TP53 mutations in fallopian tube than individuals without germline mutations, supporting our hypothesis. However, TP53 mutations have not yet been characterized in individuals with germline mutations in RAD51C/RAD51D, BRIP1 and PALB (lifetime risks of HGSC 10%, 6% and 5%, respectively). Our goal is to conduct an ultra-sensitive characterization of TP53 mutations in patients with germline mutations in RAD51C/RAD51D, BRIP1, and PALB2, and compare their mutational profile with those of individuals without germline mutations in HGSC risk genes and those with BRCA1/2 germline mutations. Fallopian tube was collected, frozen, and macrodissected using a 1mm biopsy punch. DNA was extracted and sequenced for TP53 using ultra-deep (15,000x) duplex sequencing. We have sequenced 6 patients and observed varying degrees of pathogenic mutations in individuals with germline mutations. BRIP1 and PALB2 patients showed low and moderate levels of TP53 pathogenic mutations (11% and 41%, respectively), while RAD51C patients showed the highest percentage of pathogenic mutations (67%), matching their higher HGSC risk. We plan to sequence 6 additional patients to get more comprehensive data. By showing the differences in TP53 mutation patterns among these distinct populations, our research seeks to enhance our understanding of the underlying mechanisms of ovarian cancer development and design better tools for early cancer detection, prediction, and risk assessment.

Abstract Name: Aging Gracefully: Exploring the Impact of Aging on the Quantitative and Qualitative Characteristics of Pu'erh Tea

While tea has had extensive quantitative chemical analysis under a myriad of conditions within both living and processed tea leaves, these same researchers often neglect to incorporate qualitative analyses which would allow them to effectively investigate tea quality. This is especially problematic considering the vast cultural and economic importance of tea that is heavily affected by its quality. Additionally, an aspect of certain teas that has been overlooked by the scholarship is the substantial aging (>10 years) that post-fermented teas, notably pu’erh teas, often undergo. Consequently, my research paper will seek to determine if and how long-term aging significantly changes the quantitative chemotypes as well as the qualitative flavor profile in pu’erh tea. I will seek to determine the relationship between these quantitative and qualitative profiles and discuss the potential applications these findings have on the methods used to create, process, and value pu’erh tea. Two data streams will be collected on a sample set of five pu’erh teas of variable age and standard terroirs, cultivars, and fermentation processes. For the quantitative data surrounding the tea chemotype, an assay of total polyphenols will be carried out via the Folin-Ciocalteu method with three replicates per sample. For the qualitative data surrounding tea flavor profile, a group of subjects in the tea industry will be surveyed in a blind tasting of the sample set teas and asked to judge the teas on their taste, aroma, astringency, mouthfeel, and overall quality. In order to achieve this, I will be using survey questions crafted by myself in tandem with insights from tea industry veteran Philip Parda and using the tasting standards of the International Tea Masters Association.

Abstract Name: Assessing the Impact of Women’s Educational Attainment on Political Empowerment in Latin America and the Caribbean

This project aims to explore the relationship between women’s educational attainment and political empowerment in Latin America and the Caribbean (LAC). A large body of literature supports the idea that increasing women’s education can facilitate political empowerment. However, few studies have been done to determine the mechanisms at work behind this dynamic. Using Lieberman’s Nested Analysis (LNA), this project employs mixed methods to uncover the contextual nuances between the two variables. The quantitative analysis draws data from the “Educational Attainment” and “Political Empowerment” subindices of the World Economic Forum’s Global Gender Gap Index (GGGI) across the thirty-three countries of LAC over a period of ten years. The combination of regression analysis with a qualitative inductive process-tracing method works to determine country-specific factors that influence the effectiveness of women’s empowerment efforts. This study seeks to reveal the complex nature of combating the gender gap, especially within the diverse context of LAC.

Abstract Name: Renal Cell Carcinoma patients with obesity exhibit gene expression changes in the tumor microenvironment

Obesity has been associated with worse immunotherapy outcomes and a decreased survival rate in renal cell carcinoma (RCC) patients, as compared to those without obesity. The reason for this observation is unknown. Determining the reason for this difference could enhance survival for patients with obesity by improving the efficacy of immunotherapies. To investigate if immune cell populations in the blood are affected by obesity, peripheral blood leukocyte composition was compared between RCC patients who were lean (n=27; Body Mass Index “BMI” 18-24.9 kg/m2) or who had obesity (n=40; BMI >30kg/m2). Because RCC is more common in men, samples were also evaluated for sex-related differences. We found no significant differences between males and females for any leukocyte population examined, indicating that biological sex of the patient does not have to be considered when assessing results. To evaluate possible differences in tumor microenvironment (TME) gene expression, 24 RCC tumor biospecimens (n = 12 with obesity [BMI >35 kg/m2] and 12 lean [BMI 18-24.9 kg/m2]) were analyzed using nanoString with the Rosalind platform. In total, 36 genes of the 730 analyzed were differentially expressed in the obesity cohort. The five most upregulated genes were found, when upregulated, to be a negative prognosis marker in RCC patients (The Human Protein Atlas). There were three genes that were seriously down regulated, all of which are positively associated with the function of T cells. Notably, tumors in RCC patients with obesity were found to downregulate CCL21, a gene that encodes a chemokine involved in the chemotaxis of activated T cells. If the chemotaxis of T cells is impaired, their ability to infiltrate tumors and neutralize malignant cancer cells decreases. Immunotherapy treatments that overcome this weakened chemotaxis response may be beneficial to RCC patients with obesity.

Abstract Name: Engineering HeLa Cells to Better Support Rhinovirus C Infection In Vitro

Human rhinoviruses (RVs) are non-enveloped, positive-sense, single-stranded RNA viruses that target the respiratory tract for infection, leading to common cold-like symptoms, bronchiolitis, or, in some cases, pneumonia. RVs are classified into three phylogenetically distinct groups: RV-A, RV-B, and RV-C, with RV-C being identified most recently, in 2006. However, while RV-A and RV-B viruses have been studied for decades in HeLa cells, RV-C does not naturally infect conventional cell lines and thus, it has been difficult to propagate and study in the lab. Further, no assay currently exists to quantify infectious RV-C particles, such as a plaque assay or limiting dilution assay. It has been demonstrated that cadherin-related family member 3 (CDHR3) is a critical cellular entry receptor for RV-C, and further, that RV-C may depend on the stimulator of interferon genes (STING) for viral genome replication. To investigate the roles of these proteins in RV-C infectivity, inducible human STING (hSTING) was transfected into HeLa cells that stably express CDHR3. Elevated STING expression was then confirmed in these cells after induction with Doxycycline (Dox).

Ongoing studies seek to further explore how the expression of additional ciliated cell-specific host factors - such as Prominin-1 (PROM1) - in HeLa cells impact virus infection in this cell line. We hypothesize that combined expression of CDHR3, PROM1, and STING in HeLa cells will enhance viral entry and replication, facilitating amplification of RV-C in the laboratory and aiding detection of infection via antibody-mediated staining or enhanced cytopathic effects. These engineered HeLa cells would thereby constitute a novel cell line that is more amenable to the establishment of a plaque assay or limiting dilution assay to quantify infectious virus.

Abstract Name: Graphic Slave Artisans

The history of African-American design is extensive, with its roots immersed in America's intensive story. Narratives of the origins of black design are consistently being researched in the discussions in BIPOC design communities. Graphic communications permanently intend to correspond to audiences through visual forms. The definitive history of African Americans begins in Africa, with the beginning of the Trans-Atlantic slave trade. Through the establishment of slavery, millions of enslaved Africans involuntarily objected to forced labor, cruel and unjustified punishments, and mental and systematic oppression, with some historical accounts being undiscovered and unknown. The acquisition of slaves reflects a new economic society being constructed on the backs of disadvantaged enslaved people for enforced labor. Through these horrors, some slaves were able to achieve success through multiple skill sets in artistry and craftsmanship. This is where graphic design history and black history combine, perhaps the beginning of black visual arts history. Here lies the stories graphic communications history books skip and overlook. This is the history of the first graphic designers in this country who were black and how their skills were neglected. It shows their significance not only to this country but also to visual design pedagogy.

Abstract Name: Exploring the Unknown Information About Preparing for Death and Dying

Holistic planning for end of life regardless of age, expectancy, health and agency is lacking across the United States. Covid, along with the aging of the largest generation have shown that preparation is needed. The purpose of this study is to gather baseline information to broadly determine existing knowledge of end-of-life planning, to create a framework for a foundational structure to address the information and knowledge gaps that exist across the board. Utilizing an online survey, over 2,000 responses were collected. The survey consisted of multiple-choice and long and short answer questions focusing on financial, emotional, legal, and planning. This is the beginning step in the process of building the full scope of the model that will be a free

source of information available to anyone in need. Early results indicate a broad lack of knowledge, and general misconceptions regarding what is and is not available. Initial findings will be presented.

Abstract Name: Marketing Strategies To Increase Sales & Revenue For Small Business In Middle Georgia

This project explores the marketing strategies employed by small businesses around Middle Georgia to maximize sales revenue. Since the incidence of Covid 19 in 2020 and the subsequent economic downturn and reduction in face-to-face activities, consumers and businesses have adopted new ways of buying and selling. Small businesses need to attract customers to increase sales and profit. This research uses a survey of retail businesses in middle Georgia to determine the strategies used to market their business and to examine if the use of social media is dependent on the sex of a manager. Secondary data is obtained from relevant academic literature and online sources. The survey result indicates that 90% of the businesses surveyed use social media for marketing while the use of social media does not depend on the gender of a manager. 80% of companies increase sales and revenue by selling and re-targeting to existing customers within the business, 90% of companies keep up with market research, and 70% of small companies give incentives to former customers who refer new customers to the business.

Abstract Name: Understanding College Students' Perceptions of Alzheimer's Disease

The purpose of the study is to gain insight into younger adults' worries surrounding Alzheimer's disease and other dementias to create a support group curriculum and/or educational presentation to aid young adults with education about the disease and coping mechanisms to live life to the fullest before possibly acquiring the disease in the future. There isn't much research looking into how Alzheimer's disease affects this age cohort, as most of the research is geared towards caregivers and Alzheimer's patients. Yet, dementia affects the whole family unit. Currently, 6.7 million Americans are living with Alzheimer's (Alzheimer's Association, 2023). With the population rate of people 65+ years of age growing, this number is expected to increase significantly in the next few decades. This research study is interviewing college students who have had Alzheimer's or dementia experience in their families. Then, the qualitative interview transcripts will be analyzed with thematic analysis. Interviews conducted in January through March 2024 will examine the mental health effects of the disease and the participants' understanding of the disease. This will grasp both a psychological and public health lens by asking questions regarding participants' mental health surrounding their experience with the disease and attempt to understand their medical knowledge of dementia. It is expected that younger adults will desire more resources to cope with their Alzheimer's experiences. The

studies findings will be presented back to the Alzheimer's Association so they can better understand how to help the younger population of family members affected by Alzheimer's disease.

Abstract Name: Women's Writing is Risky! Risk and Forecasting Dangers in A Room of One's Own

This is an analysis that uses contemporary risk theory and the concept of safe spaces to lend a greater close reading of Virginia Woolf's essay, A Room of One's Own. The traditional reading of Woolf's essay is that a room of one's own produces great literature. However, when you add the lenses of safe spaces and risk theory it reveals this feminist gesture of needing a room of one's own is not just a space of creativity, but of security and safety. Using Maslow's Hierarchy of Needs and Kathleen Woodwards Statistical Panic creates a model of potential risks to consider that was unavailable to Woolf during her era. Applying this model to Woolf's writing reveals that this literature is speculating about her own safety. This speech will focus on Woolf's thematic depiction of the speculative risk and prevention of harm women writers must consider when delving the world of authorship. It is difficult to be a creator of academic or artistic writing when an author is worried for their personal safety and survival. She speculates the possible outcomes women writers have when they choose the risky path with a juxtaposition of William Shakespeare to his fictional sister Judith. She also speculates based on fact and fiction the liberation women writers could experience when the risk is removed through economic means. Overall, viewing A Room of One's Own through the lens of risk theory and safe spaces reveals that women writers must calculate risk to have the security needed for writing.

Abstract Name: Using Contrast, Shape, And Texture to Create a Comfortable Home That Is Easy to Navigate for A Client with Diabetic Retinopathy

This project aims to design a residence for a middle-aged couple where the wife has grade 1 diabetic retinopathy. The wife has her own pottery business, and the husband is a radiologist. Their needs for the space are individual offices, space for a home gym, and a sunroom for relaxing and creating pottery. Diabetic retinopathy is a disease where new blood vessels aren't growing. Some symptoms are spots or strings floating in vision, arterial narrowing, limited peripheral vision, and dark or empty areas in vision. Since the client currently has grade 1, the condition is not severe, so colors were incorporated into the design for her to enjoy. A case study called the home for the blind by So & So Studio was referenced to provide an evidence-based design. This case study inspired a design that incorporates subtle elements to assist the clients with their daily tasks. Other studies indicated that highly contrasting colors, different textured flooring for each room transition, obvious walking paths, and warm-colored furniture are essential for inclusive house design. These are all important design features for the user because as her disease progresses, she will have

difficulties distinguishing different surfaces and rooms in her home. Warm colors like shades of brown, red, and gold create an inviting ambience to the home and throughout all the spaces. The different flooring textures include wood for the living room and hallway, various tile patterns in many rooms, and different textures of carpet in the bedrooms. Walking paths are created using furniture placement as well as the floor plan layout. Contrast is applied to surfaces the user will need to distinguish such as door handles and the door. Overall, this residence implements contrasting colors, textures, and various space planning tactics to accommodate for the development of this client's visual impairment.

Abstract Name: Adaptadesk: The Automated Desk Design for Someone Living with Multiple Sclerosis

Multiple Sclerosis (MS) is a disease where communication issues happen between the brain and the body, which can cause permanent damage or deterioration of the nerve fibers. This research aimed to define the specific needs of individuals with MS and apply functional solutions to a workspace desk design to allow individuals to continue to work comfortably for as long as possible. Research methods included studying articles about MS and interviewing a target user to determine design directions. Some people with MS may lose the ability to walk independently, as well as the loss of mobility in their arms. "Adaptadesk" is designed for individuals with MS who are losing mobility or require a wheelchair. The desk assists the user as their MS progresses. Powered with voice controls and a remote, work surface height and knee space adjustments are seamless. Cupholders for drinks, pencils, and paintbrushes remain upright as the desk tilts to accommodate the user's needs. Interviews conducted with a target user help capture specific design functions and features that reflect the client's interests. A Mid-century modern style is incorporated into the design of the desk, utilizing elegant lines and warm wood tones. The desk's form is inspired by the shape of a painter's palette, including incorporating a cutout to mimic the thumb hole, creating a space for a planter. There is a silicon strip where a laptop or canvas can sit to prevent it from slipping downward when tilting the desk. There is a smaller silicon strip on the lower right side of the desk to provide a place for a notepad. While function is a top priority, the research behind the development of Adaptadesk creates a design that fits elegantly into residential settings while enabling individuals with MS to remain active and productive.

Abstract Name: Exploration of DNA Variants Associated with Chronic Lymphocytic Leukemia

Chronic Lymphocytic Leukemia (CLL) is the most common form of leukemia in adults with more than 18,000 new cases every year. DNA variants that occur in the body overtime contribute to CLL as well as

other forms of cancer. One of the top ten genes associated with CLL is the FBXW7 gene. FBXW7 is a critical tumor suppressor gene that codes for an F-Box protein. Variants of FBXW7 are known to contribute to CLL as well as other forms of cancer by causing the build up of oncoproteins. This research focuses on a missense variant of uncertain significance (VUS) of FBXW7 at amino acid position 505 in which arginine is swapped with histidine.The goal of this research aims to contribute to the classification of this variant as benign or pathogenic and determine the likelihood that this variant will contribute to the development of CLL. Using data from DNA databases such as ClinVar, Uniprot, PolyPhen, Meta LR, and Mutation Assessor, a variant impact chart was designed that shows the relative CADD score of R505H compared to known pathogenic variants of FBXW7. YASARA was used to model the structure of the protein that is encoded by FBXW7 and visualize the differences between the wild type and the variant of this protein. Molecular dynamics simulations (mds) and evolutionary analysis were used to determine the impact of the R505H variant on the FBXW7 wild type protein. MDS revealed that R505H had significant deviation from the wild-type and another pathogenic variant. This along with evolutionary analysis concludes that R505H is likely to be pathogenic and could contribute to the development of CLL as well as other forms of cancer.

Abstract Name: Gender Performance and Heteronormativity in Fried Green Tomatoes

Jon Avnet's 1991 film Fried Green Tomatoes follows the sexually ambiguous relationship between characters Idgie Threadgoode and Ruth Jamison, who find themselves unknowingly navigating gender performativity and heteronormativity in the Depression-era South. Viewed through a 21st-century lens, Fried Green Tomatoes tells a love story, labeled "special friendship," between two women who fall victim to heterosexual normativity through marriage and expected ideas of what it means to "settle down." Through their strong characters, Ruth and Idgie share a complex relationship that breaks from "the norm," pushing the boundaries of their upbringing, breaking away from society's standards, and subverting expectations regarding gender expression, partnership, and learned behaviors, creating identities separate from what is expected in 1930s Alabama. Referencing scenes and dialogue from the film, this paper applies secondary sources to illustrate how the film depicts heterosexual normativity and gender performance. This includes Judith Butler's Gender Trouble, where Butler coined the term "gender performativity" in 1990, and "Performativity" by Tavia Nyong'o, from Keywords for Gender and Sexuality Studies, which describes how gender is defined not by sex but by learned behavior, illustrating how Idgie Threadgoode creates a strong sense of self-identity, constantly subverting gender expectations in refusing to "do" her gender correctly. I also cite Brenda Cooper's work on female masculinity and heteronormativity, which helps explain heterosexuality as a privilege and define heteronormativity. Viewed through these lenses, Fried Green Tomatoes illustrates expectations of women in the 20th century and creates a strong sense of rebellion against gender norms that resonates with third-wave feminism's views of heterosexual normativity and gender performance, influencing representations of women in film in the decades that follow.

Abstract Name: Sex-Related Differences In PACAP Expression In The PVT Of Rats

Both the paraventricular nucleus of the thalamus (PVT) and the neuropeptide, pituitary adenylate cyclase activating polypeptide (PACAP), are associated with motivated and affective behaviors, including alcohol drinking and binge eating, and sex-related differences in neuronal activity have been identified in the PVT. While PACAP has been found to be densely expressed in the PVT of male rodents, with the isoform PACAP-27 being more prevalent than PACAP-38, this remains to be characterized in females. The purpose of this research was to examine PACAP in the PVT of female rats and to determine if there are sex-related differences in this expression. We performed fluorescent immunohistochemistry for PACAP-27 and PACAP-38 on tissue containing the PVT from adult, male and female Sprague-Dawley rats (n = 5/sex), followed by confocal microscopy and ImageJ analysis. The percentage of DAPI cells that co-labeled with PACAP-27 was greater in female rats than in male rats (52% vs. 44%) and increased from anterior to middle to posterior PVT, displaying a significant main effect of sex [$F(1, 8) = 13.867$, $p = 0.006$] and subregion [$F(1.23, 9.84) = 7.758$, $p = 0.016$]. Analysis of the percentage of DAPI cells co-labeling with PACAP-38 also revealed a significant main effect of sex [$F(1, 8) = 19.866$, $p= 0.002$], but showed no significant effect of subregion [$F(2, 16) = 2.465$, ns], and female rats exhibited a higher percentage of DAPI cells co-labeling with PACAP-38 than male rats (17% vs. 11%). These results indicate that both PACAP isoforms were more highly expressed in the PVT of female rats, and that PACAP-27 is expressed in greater quantities in the more posterior regions of the PVT. These findings highlight sex-related differences in PVT PACAP and suggest that PACAP may underlie some established sex-related differences in motivated and affective behavior.

Abstract Name: A Mathematical and Statistical Approach for the Obesity Epidemic

The global obesity epidemic poses a significant public health challenge, that overall demands innovative strategies for effective intervention. Due to the growth of social media in our society, processed food companies use online sites to successfully market their products, such products are portrayed to be healthier than they are and seem to be a cheaper and safer alternative to natural products. Many Americans bear the false assumption that they are saving money by buying processed food when the cost of medical attention for obesity, is extremely more expensive. Research has shown that if American families do not change their food habits and exercise patterns, between 50%-60% of the population will be obese in the year 2030. This presentation explores a mathematical approach to comprehensively address this crisis while also highlighting the magnitude of the obesity problem, emphasizing its adverse health and economic consequences. In correlation to obesity, there are other factors that need to be looked at being that obesity can lead to other chronic diseases. Many of these chronic illnesses pose a bigger problem to society being that individuals will be stuck with the obesity issue as well as other health issues.

Abstract Name: False Memories: The Fear Factor

Purpose How does mood affect susceptibility to false memories? People are less likely to form false memories when sad, ostensibly because sadness encourages memory encoding of item-level information, while neutral moods encourage holistic processing, in favor of the gist (Storbeck, 2013). Though the protective benefit of sadness in avoiding false memories has been demonstrated, we investigate how both sadness and fear–another important negative emotion– affect susceptibility to false memories. This is significant to investigate because when a negative event is experienced, people often remember vivid and specific details of the incident. In these traumatic scenarios, fear is likely the strongest emotion. From our work, we will be able to demonstrate whether fear, like sadness, protects against false memories.Procedure Participants view movie clips validated to reliably elicit the desired emotions: neutral, sadness, fear (Gross & Levenson, 1995; Hewig et al., 2005) and rate their mood using the positive and negative affective schedule (PANAS). False memory susceptibility is evaluated with the Deese–Roediger–McDermott (DRM) paradigm in which participants study lists of words that are each related to a critical, unpresented lure, then take memory tests on the words. If a participant misremembers a critical lure as being presented, a false memory has occurred (Roediger & McDermott, 1995). The mean number of falsely recognized critical lures across the three mood conditions will be analyzed using ANOVA. This project has received IRB approval and data collection has begun. Expected Results and Implications If fear, like sadness, confers a protective benefit against forming false memories as we hypothesize, participants in neutral moods will have significantly more false memories than sad or fearful participants. Of theoretical significance, we will determine if fear, like sadness, encourages detail over gist processing. Of applied significance, this study may add to our understanding of memory formation in traumatic situations.

Abstract Name: A Geochemical Investigation of the Chemical Weathering Characteristics of Old Glacial Tills

Glaciers periodically advance over North America from 2.58 million years ago to 11,000 years ago during the Pleistocene epoch. An enigmatic increase in the length of glacial cycles and coincident increase in ice volumes occurred in the middle of this time interval and is known as the middle Pleistocene transition (MPT). This transition remains poorly understood and is motivation for further studies. Samples for this study were sourced from two different locations (Missouri and Indiana). Missouri tills are sourced from the western sector of the Pleistocene Laurentide Ice Sheet (LIS), while tills from Indiana are influenced by the eastern (Labrador) sector of the LIS. The geochemical characteristics of these samples were determined by X-ray Fluorescence (XRF) on the <63 um of the tills. A comparison of the chemical index of alternation (CIA) and major element geochemistry of tills derived from these sources confirmed the geochemical characteristics from both sample locations are different. The CIA is calculated from major element concentrations determined by XRF, and an independent measure of the carbonate content of the sample. The geochemical characteristics of early- and middle-Pleistocene tills were influenced by both changes in

evolving rock weathering characteristics, and changes in glacier flow direction which incorporate contrasting rock sources.

Abstract Name: “I Simply Am Not There”: Post-Truth Politics and Gentrification in Mary Harron’s American Psycho

Mary Harron’s American Psycho has been lauded as a commentary on American identity and how it’s been stripped and replaced with empty representations through the materialistic values of capitalism. Beyond this common analysis is a more significant interpretation of how this emptiness doesn’t merely affect individuals, but also American politics. The film toys with ideas of Baudrillard’s explorations of simulacra and how they intertwine with identity, television as a reproducer of reality, and representations of gentrification and the effects of the upper class on the poor. This paper opens with a crucial scene of Patrick Bateman’s introspective monologue about his missing individuality: “There is an idea of a Patrick Bateman; some kind of abstraction. I simply am not there.” Using Jean Baudrillard’s exploration of simulation and the hyperreal, and Marshall McLuhan’s analyses of the power of media (or television), I argue that Bateman moves beyond his superficial representation of vacant identity. Indeed, Bateman is a robust illustration of how the hyperreal expands past an individual level and into a widespread political sphere. This paper concludes gentrification and contemporary U.S. representatives are a symptom of American society’s progression into the hyperreal. In the modern epoch, Donald Trump, who reflects Patrick Bateman, is a representative of the hyperreal because of his employed post-truth political strategies in his presidency. In addition, Trump is a model of 80s capitalist values. He has always been concerned with monetary gain and established himself as an apotheosis of greed; he’s constructed a hollow image of a successful businessman that promotes the nostalgic ideologies of the 80s. Trump has introduced his alluring image of the capitalistic hero into US politics, profiting from post-truth strategies. Like Patrick Bateman, Trump basks in the hyperreal to manipulate others and the film can influence audiences to recognize it for the betterment of society.

Abstract Name: Enhancing Spatial Awareness of Robotic Dog: Integration of LiDAR and Depth Data

The development of robotic systems has expanded across various sectors, including industry, security, and user assistance. For these systems to be effective, they must possess the capability to be aware of their surroundings. This awareness is typically achieved through the use of sensors. Enhancing these primary sensors with supplementary sensing methods and fusion, such as RGB-D via stereoscopic or other

techniques, increases accuracy and yields more detailed results. To address the inherent limitations of 2D LiDAR (Light Detection and Ranging) and RGB-D cameras, a complementary approach is adopted. LiDAR sensors allow a robot to scan and map its environment enabling it to plan a path and accurately avoid obstacles. However, thin or metallic objects can cause noise in the LiDAR scan that appear as irregularities on the map. By cross-referencing data from a depth camera (RGB-D) a three-dimensional perspective is introduced, equipping the robot with a holistic field of view by giving context to the mapping irregularities. Using ROS simulation tools such as Gazebo and RVIZ, LIDAR, and RGB-D data will be collected and tested to understand how it can subsequently be fused into a single dataset. Previous studies for LiDAR and RGB-D cameras have been used for indoor applications, in contrast, our research focuses on both indoors and outdoors resulting in a more optimized algorithm for environment scanning and navigation. Utilizing the GoAir 1 robot dog, testing and data capture can be generated in uneven outdoor terrains where trees, roots, and bushes can limit the navigation of traditional wheeled mobile robots. By using generative mapping techniques such as Simultaneous Localization and Mapping (SLAM) and Generative Adversarial Networks, autonomous path planning, and obstacle avoidance in various environments can become more efficient.

Abstract Name: “The Nation and Sub-Nation: Ethnic Federalism, Nation Building, and Ethnic Political Economy in Ethiopia.”

The early emergence of the Tigray People's Liberation Front (TPLF), which dominated the Ethiopian People's Revolutionary Democratic Front (EPRDF), brought with it relative stability, which helped promote Ethiopia as a peacekeeper and a model to look up to for the Horn of Africa, as it had a phenomenal record of economic growth and, compared to neighboring nations such as Somalia, Sudan, and Eritrea, was relatively stable and more democratic. However, the political system that it operates under has made its growth and stability vulnerable to several shocks. Ethiopia is identified as a multi-ethnic federalist democracy where political power is distributed among self-governing regions that are home to homogenous ethnic groups or coalitions of minority ethnic groups. The ethnic federalist approach was used to combat, on paper, the historically ethnically marginalized and fractionalized Ethiopian communities in hopes that it would promote political representation, further fostering a stable democracy. This has created a challenging political environment, as reflected by the surge of “ethnic attacks,” division, and conflict over the past decade. As such, this system has sparked several debates among several scholars who examine its pros and cons. This paper explores the short- and long-run effects of the ethnic federalist model in Ethiopia, where Ethiopia went wrong, and why it was successful in the early years of the ethno-federalist model in sustaining some level of stability and development.

Abstract Name: Effects of Blue Light on Various Vaginal Microbiota

Candida albicans is a fungus that serves as the major cause of vulvovaginal candidiasis (VVC), affecting 75% of women at least once in life. Conventional antifungal treatments, including oral or topical medications, can be inadequate for treatment and cause detrimental effects including high recurrence episodes. Antimicrobial blue light (ABL), ranging between 400-470 nm, is an alternative approach to combat microbial infections, as ABL inhibits microbial growth by causing oxidative stress and DNA damage to the affected microorganisms. So far, limited research has investigated its potency against fungal infections. This study aimed to evaluate ABL's effectiveness in inhibiting C. albicans growth and establishes ideal parameters for VVC treatment. In this study we compared the viability of blue light-treated C. albicans with Gardnerella vaginalis, a common bacterial pathogen that induces bacterial vaginosis, and Lactobacillus crispatus, a vital bacterium for maintaining vaginal homeostasis. Microorganisms in log-phase growth were exposed to 400-450 nm blue light at various durations and energy levels. This study displayed 405 nm blue light as efficacious for inhibiting C. albicans growth and revealed C. albicans exhibits higher resistance to ABL than G. vaginalis. A ninety percent reduction in C. albicans viability required 400 J/cm2 of blue light, compared to 200 J/cm2 for G. vaginalis. Additionally, the energy level used for C. albicans did not influence Lactobacillus viability, suggesting ABL can serve as a selective treatment targeting vaginal pathogens while preserving advantageous microbes. This study showcases the promise of ABL as a safe and effective treatment for vaginal infections that prevents vaginal dysbiosis.

Abstract Name: Local Refugees

Local Refugees The US-Dakota War in 1862 was one of the most catastrophic events for both the Dakota people and European settlers in Minnesota. The war resulted in condemnation and death sentences for 303 Dakota warriors. Eventually, 38 were executed by order of President Abraham Lincoln. For more than 50 years, there have been efforts to bridge the knowledge gap and build reconciliation between descendants of the Dakota Nation and European settlers. The Mahkato Wacipi (Mankato Pow Wow) is one of the more significant opportunities for reconciliation. This project researched and documented the stories of some of the Native American individuals and descendants of European settlers in Greater Mankato and Southern Minnesota. The investigation results will be presented in the form of a documentary video. This film presents storytelling about reconciliation among individuals and communities. This is a partial response to the dilemma: 'now what' do we learn from history so we can move together into our common future? The production may be valuable in terms of community storytelling, which impacts the social presence of Native American history and raises the understanding of the whole context of the US-Dakota War and Southern Minnesota's history. The project also generates new reflections and understandings about the history of the US-Dakota War and the relationships between descendants of Dakota people and European settlers.

Abstract Name: Clarify the Relationship between Japanese TV Dramas and Social Conditions: Focusing on Entrepreneurs

While "entrepreneurship" is gaining attention as a future option, the image of the "entrepreneur" in society is not well established. In this context, I have focused on changes in the way entrepreneurs are represented in TV dramas compared to TV dramas in my field of interest. Since I was able to conclude from my previous research that the image of "entrepreneurs" has changed from a negative to a positive image over a period of 10 years, I decided to deepen this study. The purpose of this study is to clarify how Japanese social conditions are related to and quoted in TV dramas. The uniqueness and significance of this study lies in the novelty of the subject matter. By limiting the representation and purpose of entrepreneurs in TV dramas, a clear comparison can be made even when the subjects of analysis are represented in different ways. In addition, to our knowledge, no study has attempted to analyze media representations as a starting point. This study will take dramas in which entrepreneurs are the main characters and analyze them individually to deepen detailed research from a broad perspective. This study not only reveals changes in entrepreneurs as seen by society, but also changes in the way TV dramas are structured, making it meaningful as a study of the media field.

Abstract Name: Empowering Innovation: Analyzing the Impact of Entrepreneurship Education on Student Growth at Musashino University

This paper presents a study conducted at Musashino University's Entrepreneurship Department, Japan's first academic institution specializing in entrepreneurship. The department's innovative curriculum, focusing on 'Mindset,' 'Business Advancement,' and 'Practice,' aims to cultivate students' creative thinking, PDCA skills, and management abilities, empowering them to generate new societal values. The growth trajectory of Musashino EMC students, who have been applying their learning in diverse social contexts, is particularly noteworthy. This study seeks to elucidate the factors underlying this growth, which remains challenging to articulate concretely.We conducted a comprehensive survey targeting all students in the department, followed by semi-structured interviews. The study specifically zeroes in on the shifts in mindset, a fundamental aspect of entrepreneurship education. By analyzing the responses, we aim to uncover insights into how the educational framework influences student development and practical application in real-world scenarios.The findings of this research are significant for understanding the impact of entrepreneurship education on student growth, particularly in fostering a mindset conducive to innovation and practical implementation. This study contributes to the broader discourse on educational methodologies in entrepreneurship and their effectiveness in preparing students for real-world challenges, offering valuable insights for educators and policymakers in shaping future curricula.

Abstract Name: Bioengineering Heparan Sulfate to Create a Safe and Effective Heparin Alternative

Heparin is one of the most widely utilized drugs in the world and is a potent anticoagulant that is routinely prescribed for treating deep vein thrombosis and pulmonary embolism during surgery and in the acute care setting. Currently, therapeutic heparin is a fractionated form of heparan sulfate derived from animal sources, predominantly from connective tissue mast cells in pig mucosa sourced from China. Heparin's anticoagulant activity is based on its ability to bind to and enhance the inhibitory activity of the plasma protein antithrombin III (AT) in the coagulation cascade. Unfortunately, 2-5% of patients on heparin therapy develop a life-threatening side effect known as heparin-induced thrombocytopenia (HIT), which results from the formation of heparin-platelet factor 4 (PF4) immunoreactive complexes. Thus, there is an urgent need for safer, alternative sources of heparin. Since PF4 binding to heparin depends on distinct binding sites compared to AT, we hypothesized that cells could be engineered to produce anticoagulant heparan sulfate with decreased PF4 affinity. In this project, we utilized genome-wide CRISPR/Cas9 screens to search for regulatory factors that could be harnessed to bioengineer an anticoagulant form of HS with enhanced affinity to AT and lower PF4 binding. From these screens, we uncovered novel regulatory factors and distinct HS proteoglycan proteins as modulators of both HS expression and AT binding. Future studies include validation of top hits using flow cytometry, mass spectrometry, and bio-layer interferometry to investigate site-specific glycosylation of proteoglycans and identify novel regulatory mechanisms of heparin biosynthesis in cells.

Abstract Name: Testing Novel Brain-Permeable ACSS2 Inhibitors to Block Breast Cancer Brain Metastatic Growth In Vivo

Triple negative breast cancer is the most aggressive subtype of breast cancer commonly resulting in metastasis to the brain. This diagnosis is terminal with a median survival of 6 months and no forms of targeted therapies, thus there is an urgent need to develop novel treatments against breast cancer brain metastasis (BCBM). BCBM have been shown to adapt their metabolic needs in the stressful low lipid environment of the brain becoming heavily dependent on acetate as a fuel to generate lipids. Acetate can be converted to acetyl-CoA, the backbone of de novo lipid synthesis, via the enzyme Acetyl-CoA synthase 2 (ACSS2). ACSS2 is elevated and required for breast cancer growth in the brain and not in the mammary

gland making ACSS2 a BCBM-specific target. Using a computational pharmacophore-based shape screen, we identified novel compounds that bind to ACSS2 at high affinity and are predicted to be stable and cross the blood brain barrier (BBB). Here, we show that novel ACSS2 inhibitors 5584 and 8007 can block BCBM cell lipid stores and growth in vitro. Importantly, we show that these inhibitors cross the blood brain barrier and reduce tumor burden in vivo with no observable toxicities. Taken together, these results identify novel brain permeable ACSS2 inhibitors that show promise as therapeutics to block breast cancer brain metastatic growth in vivo and may serve as candidates for further drug development as agents for treating patients with breast cancer brain metastasis.

Abstract Name: Transcription and Digital Accessability in Primary Source Documents

The Lyell Project, in association with the University of Cambridge, Edinburgh University, and the American Philosophical Society compiles primary source documents to be published digitally alongside transcriptions. This project is a case study of 100 letters from Charles Lyell, with transcriptions and high-resolution images uploaded to the host domains of these organizations. This case study shows both the increase in engagement, ease of use, and potential for scale of digital archives and the lowering of multiple barriers through digital archiving. Digital archiving of this kind allows researchers internationally to access these documents, without the fiscal barrier of traveling to the host library. In the same regard, it enables information sharing between institutions, alongside promoting collaboration. Additionally, the project allows international researchers to access the primary source documents through transcriptions, as the use of digital translators opens information to those who cannot read English in its primary source form, instead allowing for accessible translations.

Abstract Name: THE EFFECT OF KETONE BODIES AND AICAR ON HUMAN NEURONAL CELLS WITH MPP+ INDUCED PARKINSON'S PATHOLOGY

Parkinson’s Disease (PD) is the second most common form of neurodegenerative disease, resulting from the death of neuronal cells in the substantia nigra. Evidence suggests both genetic and environmental factors play a role in PD development. This study focuses on determining the effects of two potential environmental factors, diet and exercise, in order to develop future therapeutic methods for treating PD. Specifically, this study tested how the ketone body **β**-hydroxybutyrate (BHB) and the exercise mimetic AICAR affect the protein expression of MPP+ treated cells. Oxidative stress provoked by a surge of reactive oxygen species (ROS) due to mitochondrial injuries is a significant hallmark of PD. Given that BHB and exercise improve

antioxidative capacity and mitochondrial biogenesis, this experiment investigated the cellular and molecular protective mechanisms of BHB and a combination of BHB and AICAR. The concentrations of antioxidants and protein markers of mitochondrial biogenesis, autophagy, and proliferation were compared between groups using the Western Blot procedure. Only one protein, mTOR, showed a significant difference between the control and MPP+ treated cells. However, the proteins p-mTOR, p-AMPK, and PGC-1 showed some differences between AICAR and non-AICAR treated cells. While there were few significant differences between groups, there were many nonsignificant trends, indicating the potential for differences between groups given a larger sample size.

Abstract Name: Characterizing Metabolic Remodeling Induced by Tonic Signaling of Chimeric Antigen Receptors

T cells expressing tumor-targeting chimeric antigen receptors (CARs) have shown remarkable response rates in treating patients with hematologic malignancies. Prior work has demonstrated that modulation of the costimulatory domain and scFv linker can confer enhanced CAR-T cell cytotoxicity, persistence, and stem cell-memory phenotype, but the impacts on CAR-T cell metabolism remain unclear. In particular, prior clinical trials of short-linker and long-linker CD22-targeting CAR constructs demonstrated that only the short-linker CAR exhibited high antigen-independent tonic signaling, resulting in a significant level of complete remission. In this study, we performed metabolic and functional assays to characterize the metabolic profiles conferred by various CD19 and CD22 CAR constructs. Tonic signaling levels of the CAR-T cells were quantified via immunoblot analysis of the phosphorylated CD3ζ chain, with metabolic profiling conducted via Seahorse Extracellular Flux Analyzer and flow cytometry-based translation inhibition profiling (SCENITH). To interrogate cytotoxicity, the CAR-T cells were cocultured with NALM6 leukemia cells at 1:1, 1:2, and 1:5 effector:target ratios, with multiple tumor restimulations. We observed that the glycolytic activity of all CAR-T cells was higher than that of the mock-transduced T cells, and that despite similar levels of glycolytic and mitochondrial metabolic activity, the CD22 long-linker CAR exhibited greater cytotoxicity than the short-linker CAR at low effector:target ratios. These results suggest that tonic signaling by both CD19- and CD22-targeting CARs induces metabolic remodeling of the T cell, promoting the engineering of metabolically distinct CARs for greater efficacy in treating patients with relapsed/refractory cancers.

Abstract Name: Understanding Salivary pH vs Life Satisfaction Through Perceived Stress and Sleep Quality

Life satisfaction significantly influences various life aspects, such as motivation, purpose, resilience, and overall well-being. Defined by Anataramian (2017) as a cognitive assessment of life quality, it forms an integral part of subjective well-being. Notably, Halkos and Bousingakis (2010) identified a positive relationship between life satisfaction and academic performance. Complementing this, Palmore and Luikart (1972) discovered a correlation between life satisfaction, organizational activity, internal control orientation, and perceived health. Recognizing the critical role of life satisfaction, this research further investigates its association with sleep quality and perceived stress. Lee et al. (2016) uncovered an indirect correlation between perceived stress and life satisfaction, while Shin and Kim (2018) affirmed a direct connection between sleep quality and life satisfaction. Moreover, existing literature, including findings by Dickman et al. (2007) and Cohen and Kaliha, indicates a correlation between salivary pH, sleep quality, and perceived stress. Given these insights, the study aims to examine salivary pH as a viable, economical biomarker for life satisfaction, particularly considering the potential influences of sleep quality and perceived stress. The study focused on the student population to establish a foundational correlation between salivary pH and life satisfaction. Participants answered screening questions, completed the Perceived Stress Scale-10 and Pittsburgh Sleep Quality Index, and provided saliva samples as per researcher guidelines. Data analysis will encompass various statistical methods, including correlation analysis, regression models, and t-tests, supplemented by descriptive statistics to characterize the sample. The anticipated results are hypothesised to substantiate the indirect correlation between salivary pH and life satisfaction. This finding could pave the way for utilizing salivary pH as an accessible and cost-effective means to evaluate life satisfaction. If confirmed, this correlation suggests the potential of salivary pH as an indicative biomarker for life satisfaction, offering valuable insights into student health and well-being.

Abstract Name: Building bridged nucleosomes to evaluate sterically-hindered linker histone folding

This project aims to examine H1 CTD condensation across varying linker DNA distances through the use of DNA origami. Nucleosome cores are connected by 20-70bp of linker DNA, allowing for the formation of higher-order chromatin structures. Upon binding to the nucleosome, the linker histone (H1) CTD is thought to “collapse” into an undefined structure, while the two linker DNAs are brought closer together. Fang et al. showed that CTD condensation appears impacted by steric interactions with adjacent complexes. To examine the effects of steric hindrance on H1 folding, a base of 167bp was synthesized from plamsid DNA using tailed PCR. THe base was then digested to yield sticky ends at which assymmetric 60bp oligonucleotide duplexes could ligate. A ssDNA linking "bridge" could then be inserted between the duplexes, transforming linker DNA into a steric boundary. Bridges of different length allowed for the study of the effects of varying degrees steric hindrance on H1 folding, which will be evaluated with FRET spectroscopy.

Abstract Name: Human Activity Recognition

Human Activity recognition (HAR) is the interpretation of human motion using machine and computer vision. Human activity recognition refers to physical detection of various human activity. Human activity is different from one to another due to their purpose, for example, behavioral analysis, health monitoring, fitness tracking and others. Before going out to the real world this device learns about what they have to detect and consider. The detection of these activities is made possible through the integration of video cameras, wearable physiology and motion sensors. For detection of meaningful information sensors use machine learning and data mining to provide information, even though it faces its own difficulties. An illustrative example is especially figuring out the transition of when the activity is started and ended to the actions that have similar natures for instance distinguishing when a person starts jogging after they have been walking. We could work on that problem to find a better solution. Regardless of solving problems like sensor motion, sensor placement, cluttered background, and inherent variability in HAR, they are commonly employed sensing technologies in HAR system with their computational models. Computational models powered by machine learning and data mining continue to be at the forefront, offering valuable insights into human activities while paving the way for more refined and accurate HAR solutions. The ongoing exploration of innovative methodologies is essential to overcome the problems we have encountered.

Abstract Name: Development of an Assay to Assess Target Site Resistance in Organophosphates in Culex quinquefasciatus

Insecticide resistance in Culex quinquefasciatus may be a major factor in the continued transmission of vector-borne diseases such as West Nile Virus, other encephalitides, and filariasis. In Miami-Dade County, where 20% of vector-borne diseases are transmitted by Culex mosquitoes, effective vector control is a primary concern and recent surveillance efforts have shown widespread insecticide resistance to the pyrethroids. Notably, these same studies found that insecticide resistance to organophosphates, like malathion, was much more variable from population to population, thus inviting the need for a tool to rapidly assess OP resistance. To determine possible mechanisms that may explain these differences in organophosphate resistance, we colonized five populations and determined resistance intensity by topical application of malathion. Following the bioassay, we then conducted acetylcholinesterase long-read transcript sequencing via Nanopore from susceptible and organophosphate resistant Miami-Dade Culex quinquefasciatus populations, which revealed the presence of a single nucleotide polymorphism in the most resistant strains -- this may confer target site resistance to organophosphates. This mutation, which results in a glycine to serine change (G --> S) in the acetylcholinesterase protein, may have significant operational implications. We subsequently developed a competitive melt curve assay, using unpurified mosquito homogenate, to rapidly identify this mutation. We found a strong correlation between the frequency of this single nucleotide polymorphism and malathion resistance intensity. This study provides a toxicogenomic marker of organophosphate resistance in Florida Culex quinquefasciatus and provides an additional

integrated vector management tool that can be used to rapidly identify populations likely to be poorly controlled by organophosphates.

Abstract Name: Global Food Insecurity and Agricultural Sustainability: A Comparative Analysis of Selected Developed and Developing Countries

Amid escalating global food insecurity, the SURF Development Award 2022 facilitated an in-depth exploration of the interplay between declining agricultural labor and advancements in precision agriculture, focusing on the United States, Wisconsin, and its neighboring states. While technological progress has augmented farm efficiency, it has concurrently reduced the need for human labor in farming. An alarming 65.7% decline in farms was noted from 1920 to 2019. Data spanning 1995-2018, sourced from federal and state levels, confirmed these findings. Building on this, the intended application for the SURF Fellowship Award 2023 aims to enhance the study by incorporating key socioeconomic variables, such as access to broadband internet and financial loans for advanced agricultural tools, in both high and low-middle-income countries. This endeavor will not only provide a comparative analysis between nations but will also delve deeper into the scenario in Northwest Wisconsin counties. The objective remains to discern if initial observations persist when juxtaposed with broader, diverse datasets.This study employs data analysis utilizing Stata, and the data was collected from the World Bank Data. Results from the regressions indicate that fertilizer applied, and agricultural land positively influence the food production index. While the Hausman Test suggests fixed effect model works better with the project, both fixed effect and random effect models suggested a similar result. The result of the project suggests that investment in technologies is likely to increase the country's food security.

Abstract Name: The Most Common Challenges of Teaching Literatures in Myanmar

This study explores the challenges encountered by English literature teachers in Myanmar universities during the first semester of the academic year 2022-2023. The research, conducted through a questionnaire and semi-structured interview distributed to 10 female and 12 male instructors, identifies key impediments to teaching literature. Results indicate that instructors perceive students' language proficiency, the linguistic and stylistic complexity of texts, and the degree of cultural familiarity as pivotal factors affecting the teaching-learning process. Noteworthy strategies employed by instructors to address these challenges include bridging the gap between students and literary texts by relating themes and characters to personal experiences and promoting independent reading. The findings contribute to a better understanding of the obstacles faced by

English literature teachers in Myanmar, offering insights for the improvement of teaching practices in this context. Keywords: challenges, teaching literature, English literature teachers, Myanmar

Abstract Name: Gender and Social Media: Delving into Young Adults' Daily Participation on Facebook How Does the Social Construction of Gender Affect and is Affected by Social Media?

With the prevalence of social networking platforms, it is crucial to study the role that gender plays in its use, for gender, which is continuously shaped by society, plays a critical role in our identities and daily lives. This paper explores how the social construction of gender affects and is affected by social media through discussing the usage of Facebook by young adults, especially Middle Eastern males and females, and women's limited freedom on this social networking site in the Arab countries. It is argued that social media gives space for one to choose who they want to be and represent themselves away from the social constructs, acting as a tool for beautification, while at the same time maintaining the restrictions women face by the society on their online behaviour. The main focus of this paper is on young adults since they are the dominant age group of users and on the use of Facebook due to its popularity and multi-functionality that allows an offering of tailored user experience. It is concluded that gender differences play a significant role in how social media is used since women tend to use social media for emotional interpersonal purposes while men use them in task-oriented individual manners alongside multiple other dissimilarities. Additionally, users tend to present an edited version of themselves online due to societal pressures and norms, and particularly women in the middle-east struggle to have complete liberty in their online behaviour.

Abstract Name: Analysis tool for Mapping and characterization of Climate, Chemistry, and Clouds of Exoplanets (including promising Terrestrial planets) using MIRI (Mid-Infrared Instrument) Phase Curve Program of James Webb Space Telescope(JWST).

In this project we are utilizing data gathered by the JWST(James Webb Space Telescope) to understand the atmosphere of transiting exoplanets. The purpose is to create a framework to analyze atmosphere of exoplanets by using datasets derived from the observations of exoplanets' atmosphere from recently launched JWST(James Webb Space Telescope). I will also present findings based on the investigations of the star spots of transiting exoplanets with the ground based telescopes. I will be using simulated data to attain the necessary skills and techniques over the course of an academic year . These techniques are utilizing data from JWST. Data are in the process of being more and more available.MIRI (Mid Infrared Instrument) onboard JWST helps to study very high redshifted entities for example galaxies in the distant universe. MIRI can pierce through dust to study and take images to study chemistry of the planet formation regions and take images of planets' atmosphere including our own Earth.In addition, on a larger grand scheme of scientific applications, it is important to study the high redshifted objects, because the signature of metals in the the universe moves to the wavelength of the Infrared which MIRI will be able to study. MIRI is operating over a wavelength range of 5 to 28 microns. This instrument onboard JWST has a camera as well as a mid-infrared

spectrograph. A spectrograph is an instrument for dispersing radiation (electromagnetic radiation or sound waves) into a spectrum and recording the detected light into a multichannel detector Main goal is to showcase scientific findings by proposing processes of an open source software framework which will leverage interdisciplinary segments of astrophysics that consist of physics of optics, data analysis, instrumentation (MIRI) onboard JWST, infrared spectrography, planetary atmosphere of a transiting exoplanet, and software development in open source python-jupyter notebook.

Abstract Name: Changes in Bone Growth and Mineralization Rates following Brachial Plexus Birth Injury

Brachial plexus birth injury (BPBI), a neuromuscular injury occurring during a difficult birth when the neck is excessively stretched, damages the brachial plexus nerve bundle leading to shoulder and elbow impairment. Resulting musculoskeletal deformity occurs around the glenohumeral joint, which facilitates functional shoulder range of motion and movement. While previous studies assessed specific impairments including mineralization rates and bone deformities caused by BPBI, they only examined one time point post-injury when deformity was already established. Our objective is to create a timeline over which these deformities develop and understand their impact on shoulder growth and function.Sprague Dawley rats (n=9-60 per timepoint) were divided into 4 surgical groups (postganglionic or preganglionic neurectomy, forelimb disarticulation, or sham) and received surgery on one forelimb at postnatal days 3-6, followed by sacrifice at 2, 3, 4, 8, or 16 weeks after surgery. Calcein and alizarin fluorochrome labels for bone were injected in the rats prior to sacrifice. The humeri were dissected, sectioned into transverse and longitudinal sections with a cryotome, imaged, and analyzed using standard dynamic histomorphometry. Metrics were compared across groups with ANOVA and Tukey posthoc tests (GraphPad Prism, α<0.05).Preliminary results for the postganglionic group indicate that bone volume per total volume ratio was greater at 8 weeks than at 4 weeks, while bone tissue cross-sectional area and cortical bone area were lower at 8 weeks than at 4 weeks (p<0.05). Endosteal and periosteal mineral apposition rate and bone formation in the postganglionic group were also greater at 4 weeks than at 8 weeks for both injured and uninjured limbs. These results suggest that BPBI reduces bone growth and mineralization over time during early postnatal development. Understanding when bone trabecular architecture is altered following BPBI is critical for developing more targeted and timelier treatment strategies.

Abstract Name: How do cultural ideologies affect children with special needs and how they are raised?

Our lives are greatly influenced by culture since it shapes so many aspects of our lives. For instance, the way we approach and interpret life's circumstances. My topic focuses on The impact of culture on children with special needs. Especially their mental health. I chose this topic because parents find it challenging to accept this and provide their children with the best care possible, and this topic is not discussed enough. A lot of parents have children with special needs, but they don't know how to take care of them and are not educated on their condition. While some parents can accept reality and make an effort to educate themselves on their child's condition, the majority of parents refuse to acknowledge that their child has special needs and will live in denial for a very long time. Raising a child with special needs is undoubtedly challenging; some families become closer as a result, while other families grow apart and experience many conflicts. It's critical to understand that children with special needs will gain a lot by receiving the assistance they require and that parents who downplay their child's special needs are not benefiting their child. Due to the stigma associated with having a child with special needs in most countries, parents often choose to hide their child’s condition, even when it is apparent to others. This is not right, and by refusing to accept that their child has special needs, parents are making the situation worse. Children with special needs require more love, care, and support from their families. I hope that this research will help parents understand the value of supporting their children and how to find resources to do so.

Abstract Name: Hero, Villain, Victim, or Fool: The Evolution of Disability Representation in Children's Visual Media

It is every human being's right to seek understanding and seek to be understood. Under the American government, this protected freedom of expression is never more prevalent than in American contemporary media. However, assuring this right is upheld for all facets of human diversity in American media is a complex and ongoing process. This research examines the representation of disability in children's media to demonstrate how archetypal representation leads to a generalized and incomplete understanding of disability. In response to this examination, this research proposes the concept of Productive Representation: representation that seeks to culturally integrate abled and disabled individuals through humanizing, naturalizing, and giving voice and equal participation in culture to disabled people. This new criterion for the representation of disability encourages expression that is purposeful and goal-oriented. Through examining archetypes currently existing in media through the lens of the medical, social, and cultural models of disability, this research will demonstrate the stereotyped perception of disabled people as a minority culture in America. Second, the comparison of both nonproductive and productive character examples will be provided to advance the notion of Productive Representations. Third, this examination will briefly discuss how Productive Representation can be used by educators to further the goal of cultural integration within the classroom setting.

Abstract Name: Effects of Different Drying Methods on the Nutritional Properties of Powdered Beetroot (Beta vulgaris)

Beetroot is a biennial highly perishable root crop whose cultivation has gained popularity among farmers in Kenya. It’s abundant health properties is a fundamental reason why it is included in specialty diets. Obtaining a dried product from beetroot would be a solution addressing the perishability of the crop and extending its shelf life. The objective of this project is to investigate the the effects of different drying methods (ie. oven, sun, and solar) on the nutritional properties of the dry powder of the crop. The use of biochemical and spectrometry analytical techniques specifically, the study employed the titrimetric method, and the atomic absorption spectrophotometric method to determine the levels of vitamin C, total phenolic content, and mineral (iron, zinc, potassium), respectively. The obtained results showed that oven drying retained the highest amount of vitamin C, whereas, sun drying retained the least. Additionally, solar drying retained the highest total phenolic content, while oven drying retained the lowest total phenolic content. Lastly, solar and oven drying retained the highest average mineral concentration.

Abstract Name: Herculaneum Spectral Enhancement

In the pursuit of deciphering the text concealed within opened Herculaneum scrolls, the inherent challenge lies in the often imperceptible contrast between ink and papyrus. This research project aims to enhance the readability of such ink through spectral imaging using infrared photography. The approach involves capturing 16 raw images of each Herculaneum tray under unique wavelengths (420-1050 nm), revealing a wide dynamic range that lacks inherent contrast. To address material variations across trays, four different enhancements are applied. The primary goal is to develop a method for generating a singular "best contrast" image for each tray, deviating from the traditional practice of providing multiple enhancements to scholars. The proposed solution integrates a convolutional autoencoder with a clustering algorithm, clustering scrolls into groups to determine the most effective image enhancement for each cluster. Through this innovative approach, we aim to optimize the selection and application of enhancements, offering a promising solution to the challenge of interpreting opened Herculaneum scrolls.

Abstract Name: Flexible Energy Sources Using Embedded PVDF Films

Power is required for wearable devices. In this research, we have focused on self-powered energy sources that can harvest both mechanical from motion as well as magnetic field. Due to high piezoelectric coefficient, outstanding stability, and excellent flexibility. b-phase polyvinylidene fluoride (PVDF) is the most well investigated piezoelectric polymer material. Because PVDF lacks magnetic characteristics we use Iron (III) Oxide magnetic nanoparticles to introduce magnetic properties. This summer I investigated the embedding of Iron (III) Oxide nanoparticles (magnetic) in PVDF films with two distinct Iron (III) Oxide mass fractions, (1) 20%,(2) 40% and one without any magnetic property (added 40% Iron (III) Oxide , alphas phase) as a control, as well as their applications.

Abstract Name: Anthropogenic Ocean Acidification Mitigation: Potential for the Expansion of an Interactive Multi-Tropic Bioremediation System in the Chesapeake Bay

Zostera marina is a species of marine macrophyte that has been largely prioritized in past submerged aquatic vegetation (SAV) restoration initiatives within the Chesapeake Bay because of its 1) previous abundance, 2) demonstrated carbon burial abilities, and 3) observed ability for meadows of Z. marina to ameliorate low pH conditions. Due to the temperature variability and poor water quality associated with anthropogenic disturbances in the Chesapeake Bay, Z. Marina beds have experienced several die-off events with limited capacity for regrowth. This meta-analysis explored the possible benefits of focusing future SAV recovery initiatives on ensuring a diverse variety of SAV species with varying environmental stressors so that SAV coverage may be maintained. Ruppia maritima, an opportunistic species with a tolerance to environmental shifts within the bay, may have the potential to maintain SAV coverage in areas experiencing Z. marina die-off. The potential benefits of calcium carbonate production via calcifying organisms such as Thalassia testudinum and Crassostrea virginica are also investigated. If the location of SAV and bivalve restoration efforts take the environmental needs of each organism into account, each species may be able to observe an increase in productivity and an increased ability to carry out biological functions, such as photosynthesis and calcification, with the support of the other organisms present in the Bay's ecosystem. Given the recent shifts in environmental qualities of the bay, this meta-analysis may have implications that could assist the formation of a more effective ocean acidification management strategy with a potential for increased longevity. Evidence from this study suggested that future SAV research initiatives in the Chesapeake Bay could investigate how biodiverse and traditional Z. marina beds compare in terms of pH modulation abilities, as well as how the strategic placement of calcifying organisms nearby restored SAV beds may impact the beds ecosystem services.

Abstract Name: From Pods to Profit: Designing a Game across Disciplines

Drawing on interdisciplinary expertise from farmers, biologists, computer scientists, and economists, “From Pods to Profit” addresses the pivotal question: Can sustainable agriculture be profitable? By navigating the complexities of farming decisions, the game serves not only as a valuable educational tool but also fosters collaboration in game development across diverse fields, highlighting the importance of effective communication in translating information into a cohesive gaming experience. This project emerged from the transformation of the card game "Can You Farm?" initially conceived by agriculture students under Dr. Kimberly Gwinn. Evolving into a web-based experience, the game immerses players in soybean farming, challenging them to make decisions impacting individual, local, and global scales. Navigating seasons fraught with real-world challenges like droughts, floods, diseases, and insects, players must balance financial considerations with organic and sustainable farming practices. To create the appropriate design values, inspiration was drawn from tycoon and economic simulation games while staying rooted in biopesticide research, mimicking authentic farming challenges.The project emphasizes the vital role of effective communication in translating complex agricultural concepts into an engaging game format. As noted by Erickson (2000), the challenge lies in the diverse perspectives of designers, engineers, managers, marketers, researchers, and users. The game's development underscores the necessity for a shared language and collaboration between disciplines, fostering a common ground for the effective design of an educational game tailored to a diverse audience. "From Pods to Profit" not only stands as a testament to the potential profitability of sustainable agriculture but also exemplifies the power of collaboration in creating an immersive, educational, and entertaining experience.

Abstract Name: Effects of Autism and Gender Diversity on Identity Formation During Adolescence

Autism Spectrum Disorder (ASD) is one of the quickest growing diagnoses in the country, with the number of children who are diagnosed doubling in the last decade (CDC, 2020). These children are more likely to struggle with intense emotion and prosocial behaviors, which limits their adherence to social norms (Oerlemans et al., 2018, p. 1043). Additionally, they are more likely to possess deviations from common gender schemes, creating feelings of dysphoria or gender incongruence (George & Stokes, 2018, p. 977). Due to the nature of ASD, autistic individuals typically experience gender differently from binary masculine and feminine identities, using labels which fall under “gender diverse.”This study aims to analyze the identity formation experiences of gender-diverse and autistic individuals in order to discover intersections that may exist among these identities. James Marcia’s (2012) identity status theory will be used to analyze how ASD and gender diversity may affect the formation of identity in adolescence. This study will utilize a phenomenological, qualitative method. Data analysis will include coding to determine common themes among responses (Miles et al., 2014). Data will be collected via semi-structured interviews with individuals over 18 years of age and who have a diagnosis of ASD and consider themselves to have a gender diverse identity. Findings from this study will increase understanding of individuals with these identities and allow medical professionals to offer more effective resources and support. Common themes researchers may find include: fear or shame due to gender identity, gender incongruence at a young age, dismissal of typical gender schemes, and personal associations of ASD with gender identity. It is also expected to be concluded that both ASD and gender diversity play a defining role in identity formation during adolescence, and as a result, the individual’s perception of themselves and others' perceptions of the individuals are altered.

Abstract Name: Why does the carry trade exist work, and how effective can it be?

The carry trade is when a person borrows a currency with a low-interest rate to invest in a higher interest rate currency to make the spread. According to interest rate parity theory, this investment strategy should be irrational, since the difference in two countries' interest rates should equal the depreciation or appreciation of the currencies. Therefore, any spread you make on the trade should be lost to inflation. In practice, however, this doesn’t hold. It is common for people to profit from carry trading in times of low volatility. This study investigates why this market imperfection exists and if carry trading is a sustainable long-term strategy. I examine the G10 currency's inflation and interest rates over the last ten years to see what extent interest rate parity holds. I also study external factors to explain why some currencies appreciate and depreciate more than expected. I factor in the bid-ask spread and inflation rates to see how the strategy compares to the market and risk-free rates to determine if the strategy is viable. I show that interest rate parity does exist, and risk helps explain market imperfections. The potential for capital gains with G10 currencies is low, and thus, a carry trading strategy is only viable as a low percentage of a consumer's portfolio. This research is valuable as it can help investors inform their trading practices. After reading this thesis, investors will know why carry trading isn’t a favorable investment method and is unlikely to produce significant returns.

Abstract Name: Improving Undergraduate Research Experiences Through Graduate Mentor Training: A Transformative Model Across STEM and Beyond

The Entering Mentoring (EM) mentor training curriculum has been well-studied and shown to promote positive outcomes for research faculty mentors. However, evidence related to the impact of mentor training for graduate students who are mentoring undergraduate researchers is limited. The Future Mentors (FM) program was launched at the John Martinson Honors College at Purdue University in 2021 to increase student access to high-quality mentored research experiences in STEM. Adapted from the EM curriculum, the FM program employs a comprehensive model offering a structured training course as well as a guided community of practice with the goal of equipping graduate students with evidence-based tools and strategies for the effective mentoring of undergraduate researchers across racial, ethnic, and gender differences. In addition, mentors gain practical experience by working concurrently with matched undergraduates from the Honors College. Positive feedback has emerged consistently from both the graduate mentors and the undergraduate mentees across all three iterations of the program. This presentation will highlight 1) the structure of the model, 2) key assessment outcomes for mentors and mentees from the third iteration of the program, and 3) reflections on the successes as well as the practical challenges of implementing a graduate mentor training program in undergraduate research programs. Dissemination of the FM model and experiences may offer valuable resources for institutions, faculty and staff who seek to initiate similar programs or courses to enhance the mentorship culture for undergraduate student research experiences within their academic communities.

Abstract Name: EFFECTIVENESS OF VR-BASED STRESS REDUCTION ON PEOPLE WITH ACUTE INDUCED STRESS.

Stress is a biological response shared by all organisms, yet the manner which organisms experience it is vastly different. There is no direct sensor which can measure stress but there are a variety of physiological markers that are impacted by stress and can be measured. Such markers include increased galvanic skin response (GSR), heart rate, and blood pressure. There are numerous ways to manage stress but modern technologies like virtual reality (VR) can offer new ways to manage stress. In this study, the effect of VR on stress levels was assessed in situations with and without acute stress. Participants were asked to either sit quietly or they were placed into a VR naturescape after either an induction of acute stress or remaining seated quietly. In situations after acute stress was present, those who were placed into VR showed a statistically significant 5.89 mmHg decrease in mean arterial blood pressure (MAP) ($p=0.000149$). No significant difference in MAP was found in those that were not placed into VR after an induced acute stress situation

(p=0.7928). A drop of 0.199 volts in GSR (p=0.0172) was seen by those using VR after an induced acute stress event as well as those that were not using VR after the stress event. This indicated that VR is as effective as sitting quietly at lowering GSR. Self-reported results indicated that participants felt 22% greater stress reduction after using VR than if they were just sitting (p=0.02029); however, this was only found in groups that had not been exposed to an acute stress event. No significant changes were observed in heart rates when using VR. Our findings suggest that VR can lower GSR and MAP; however, additional testing is needed to make a general conclusion about its effectiveness.

Abstract Name: High-Accuracy Machine Learning Approach for Medical-Imaging Cataract Classification

Thesis/Objective: Cataracts, a leading cause of visual impairment and blindness worldwide, can be effectively managed and treated with early diagnosis. In an attempt to reduce misdiagnosis and increase the efficiency of the process, machine learning has emerged as a promising tool for automated cataract detection by analyzing medical-grade images. This research paper outlines a comparative study of various machine learning models for the purpose of cataract detection, eventually utilizing an InceptionV3 architecture to predict cataracts with 91.02% accuracy. Methods: Our study parsed ~6300 binary labeled optical coherence tomography (OCT) eye scans in order to build an effective dataset. From this dataset, we tested a variety of machine learning modes in the range of convolutional neural networks (CNNs) such as InceptionV3, VGG16, DenseNet121, ResNet50, and MobileNet. Each model was also evaluated with a variety of flat/dense layers to most optimally predict the cataract. Results/Findings: The most optimal model at the end predicted the correct cataract from the image 91.67% of the time with a 0.92 ROC-AUC score. This model used an InceptionV3 architecture along with a flatten/dense layer to work the best. Conclusion/Impact: In conclusion, this research paper underscores the potential of machine learning, particularly the usage of the InceptionV3 model, as a valuable tool in cataract diagnosis. Our work contributes to the growing body of knowledge in the field of medical imaging analysis and paves the way for more accurate and efficient cataract detection systems, ultimately benefiting patients and healthcare providers.

Abstract Name: Exploring Life and Loss Through Oil Paintings

This project aimed to create a series of eight to ten large-scale artworks on handcrafted canvases. These

artworks explored themes of grief, self-image, love, and the delicate nature of life, using an expressive and abstract style. The main goals included improving technical skills, strengthening the portfolio for better opportunities in getting a graduate degree or finding jobs, and raising funds for a semester abroad in Florence, Italy. Taking from painting courses and reflections on abstract art seen in museums, the project focused on understanding the balance between technical precision and intuitive creativity needed for outstanding art. Aspects like using harmonious colors, carefully placing subjects, technique, and design played crucial roles in creating these paintings The project aimed to blend personal perspectives with acquired skills, injecting fresh ideas into the art world. Taking notes, sketching extensively, and painting prolifically helped to develop skills further, and learning from celebrated artists' techniques added to this growth. Embracing the "neo-expressionism" style, characterized by intense themes and bold medium use, the project was inspired by artists like Jean-Michel Basquiat,and Keith Haring. The resulting artworks were vibrant and immersive, briefly offering viewers a glimpse into the artist's view. The themes in the paintings acted as channels to convey emotions and thoughts, fostering the artist's growth and connecting with others. While each canvas had different content, the distinctive artistic style remained consistent. Using larger canvases allowed for exploring diverse subjects and evoking deep feelings on a larger scale. This interaction required viewers to step back and understand the artwork's size, creating a sense of intimacy and connection. It allowed for broader brushstrokes, thicker layers of paint, and vibrant colors to evoke dynamic motion that is hard to achieve on a smaller scale.

Abstract Name: Examining the Effect of State-Level Paid Family Leave on Mental and Physical Health Outcomes: Evidence from Seven States and the District of Columbia

The United States is one of two countries without a paid maternity leave policy. Although there is no federal paid leave, many states have passed their own paid family leave policies, starting with California in 2004. While much of the early research is limited to data from California, the available literature demonstrates that paid leave can benefit child and maternal health. As more states implement paid leave policies and advocacy for a federal paid leave program grows, understanding how paid leave potentially impacts parents' wellbeing is critical to informing the policy debate. This is especially important in the context of the care crisis exacerbated by the pandemic. In this research, I use data from the CDC's Behavioral Risk Factor Surveillance System for the years 2000-2022 to investigate the effect of having state-level paid parental leave on the mental and physical health outcomes of women and men of childbearing age who have a child under age 18 in the household. I contribute to the literature by considering all states with mandatory leave policies implemented before 2022. Using a difference-in-difference model, the health outcomes of women and men ages 20-35 years old living in the seven states and the District of Columbia are compared to those of women and men living in states that don't have paid leave. These comparisons are made both before and after the implementation of paid leave policies. I hypothesize that paid leave policies alleviate stress and therefore will improve health outcomes for women. As men's leave take-up is significantly lower, I predict that there will be little or no effect on men's health outcomes.

Abstract Name: Updating the Patas Monkey Fact Sheet

As new studies and observations are conducted on primates, it is important to compile these research findings into one accessible and easily understandable fact sheet so that people of all ages are able to read about different primates that are not as well-known like gorillas, orangutans, and chimpanzees. The Wisconsin National Primate Research Center not only conducts medically-related and ecological research but also manages their “Primate Info Net” as a large hub of research and conservation on non-human primates. The Primate Info net organizes the fact sheets of 50+ different primate species, each with its own unique fact sheet. The purpose of this research paper was to help the “Primate Info Net” update its fact sheets on, specifically the fact sheet of the Erythrocebus Patas (Patas Monkey). Since the initial creation of the fact sheet for the Patas Monkey on December 18, 2006, many new studies have been conducted as well as the addition of information that was left out of the first fact sheet. The importance of this fact sheet was to help spread awareness of the situation of the Patas Monkey. Currently the International Union for Conservation of Nature (IUCN) labels the Patas Monkey as “Near Threatened” as they are being driven out of their habitat due to deforestation and bush killings due to farming. With the help of the Wisconsin National Primate Research Center (WNPRC) and Dr. Graham L Banes, this research was able to compile a meta-analysis like paper on new and updated information regarding the Patas Monkey. This new info was then written into a research paper where it discussed their Evolution and Ecology as well as Behavior and Sociality. It would then replace the old fact sheet on the Primate Info Net.

Abstract Name: CRY-Based Optogenetic Tools for Drug Discovery

The circadian clock involves input signals, an oscillator, and output functions that regulate circadian rhythms. Clock protein disturbances can cause sleep, immune, and mood disorders. In the mammalian circadian clock, the suprachiasmatic nucleus relies on transcription-translation feedback loops with activators CLOCK and BMAL1, and repressors period (PER) and cryptochrome (CRY). CRY, a negative regulator, inhibits its own expression. Small-molecule modulators alter the circadian period by targeting pathways or clock protein pockets, working as selective drugs that bind to CRY or have therapeutic properties for various disorders. To study CRY's role, we developed an optogenetic tool to examine its interactions with nuclear receptors (NRs).As presented during NCUR 2023, we used a mammalian two-hybrid assay to examine interactions between mouse cryptochrome 2 (mCRY2) and NRs: androgen receptor (AR), glucocorticoid receptor (GR), and pregnane receptor (PXR). Prior to the assays, mCRY2 was cloned into the pACT vector, containing the VP16 transcriptional activation domain, while the NRs were cloned into the pBIND vector, containing the GAL4 DNA-binding domain and the renilla luciferase reporter gene. Our optogenetic tool revealed mCRY2 and NR interaction, proving it to be an accurate indicator for interaction between clock components and receptors. Since then, we have tested interactions between mCRY2, NRs, and small-molecule modulators in

transfected mammalian cells. We ran titrations of KL001, which targets CRY's ability to bind with other proteins, and dexamethasone, which functions as a GR agonist. Our data revealed that KL001 reduces mCRY2's binding ability to GR, while dexamethasone enhances it.For future work, we are cloning mCRY2 into the pBIND vector and GR into the pACT vector to determine KL001 and dexamethasone's effects on the mCRY2 and GR interaction. Overall, our study sheds light on the connections between circadian clock components and key regulators, providing valuable insights for potential therapeutic interventions in circadian-related disorders.

Abstract Name: Precision Treatment in Non-Small-Cell Lung Cancer through Advanced Machine Learning Approaches.

Non-small-cell lung cancer (NSCLC) is a prevalent and impactful disease affecting over 200,000 Americans annually and constituting 85% of lung cancer cases. The two treatment options for patients with NSCLC are Adjuvant Cisplatin-based Chemotherapy (ACT) and curative surgery, a surgical procedure aimed at completely removing the cancer. With NSCLC affecting a substantial amount of the population and being a leading cause of lung cancer, this research explores the potential of genomic biomarkers to optimize individualized patient treatment in the context of chemotherapy, which aims for maximum efficacy. Implementing advanced statistical methods and learning algorithms such as Cox proportional model and Random Survival Forest, we comprehensively analyze genomic data from two independent clinical trial datasets (GSE14814 and GSE68465) found in the National Institutes of Health Gene Expression Omnibus (NCBI GEO) of patients with non-small-cell lung cancer (NSCLC). The findings underscore the importance of genomic biomarkers for optimizing and tailoring treatments for patients with non-small-cell lung cancer (NSCLC), showcasing significantly higher survival times for patients who cohere to the recommended treatment strategies, and emphasizing the clinical impact of genomic-guided interventions. Our findings also illustrated actionable insights into the identification of treatment-associated genes. Importantly, the Random Survival Forest model scores a .925 on the concordance index in predicting the best treatment outcomes, which creates a strong basis for personalized medicine in treating non-small-cell lung cancer (NSCLC). In conclusion, our study reinforces not only the significance of genomic markers in enhancing treatment but also is a stepping stone for precision medicine in cancer care with the help of advanced machine learning approaches.

Abstract Name: Arachidonic acid content in human milk is negatively related to neurodevelopment through early childhood

Omega-3 and omega-6 polyunsaturated fatty acids (PUFAs) are crucial for brain accretion and central nervous system development, and a source of docosahexaenoic acid (DHA; 22:6n-3) and arachidonic acid (AA; 20:4n-6) or their essential fatty acid precursors need to be consumed in diet. Clinical studies suggest that milk PUFAs are related to developmental outcomes in infancy, but whether these relations persist is not known. This study investigated whether milk DHA and AA content is related to neurodevelopment through early childhood. Human milk was collected between two and eight weeks (n=80) postpartum and fatty acids were analyzed by liquid chromatography-coupled mass spectrometry. The Bayley Scales of Infant Development (BSID-III) was administered at 12 months and the NIH Toolbox was used to assess Picture Sequence Memory (PSMT) at 36 and 54 months of age. Multiple regression determined associations between relative DHA and AA content in milk and developmental outcomes. Milk DHA content was not related to BSID or PSMT performance. Relative milk AA content was a predictor of infant cognitive (r = -0.28; p < 0.02), language (r = -0.28; p < 0.02), and motor (r = -0.27; p < 0.02) composite development. Relative milk AA content was inversely related to the PSMT scores at 36 (r = -0.35; p < 0.03) and 54 months of age (r = -0.32; p < 0.03). All associations persisted after adjusting for infant sex and age as well as maternal education level. Exposures to higher levels of milk AA content is associated with less optimal neurodevelopment at least through 5 years of age, indicating the importance of optimizing fatty acid nutrition in early life. The study was funded by NIH grant (MH096889).

Abstract Name: Advancing Minority Representation: Evaluating Cumulative Voting in a U.S. Context

Alternative voting systems in the United States should be seriously considered, as it allows minority representation to prosper. The current winner-take-all system does not effectively translate the minority community's vote into their preferred representation. Cumulative voting (CV) has primarily been used in local and state governments across the United States, most notably in Texas and New Mexico. A prominent and most extensive use has been in the Illinois state legislature in the 20th century. An analysis of past use of cumulative voting (CV) in the United States and predicting potential situations in which it could be used, including congressional elections, is necessary to create a foundational background. Qualitative comparative analysis and situational analysis are proven methods for answering these questions. The findings show that CV has been successful in increasing minority representation. It is more impactful in areas where minority groups are a significantly low percentage of the population and coalition building has a strong foundation. CV, in conjunction with multi-member districts, will allow congressional representation to have an increase in minority officials. While it has proven successful, most Americans are unaware of cumulative voting and other methods, so a coordinated voter education effort is necessary. Public officials and politicians should also put aside their partisan goals and unite to create a more just electoral system that works for all Americans, not just a privileged few. Especially when the country's democracy is at risk, establishing other voting methods is crucial now more than ever. The longstanding Voting Rights Act of 1965 has been slowly whittled down; its protections won't be enough to allow minority communities to elect their preferred representation equitably. Cumulative voting is essential for advancing minority representation.

Abstract Name: One Man's Terrorist: The Kurdistan Workers' Party's Use of Political Violence and Terrorism for Democratic Autonomy

The Kurdistan Workers' Party (PKK) is commonly identified generously as an insurgency, and less generously as a terrorist group. The exact nature of the PKK's function and intentions has fundamentally changed from its origins as a communist, ethnonationalist, guerilla group to a self-described anarchic, libertarian political force within Türkiye and broader Kurdish communities. This case study approaches an analysis on the cause-and-effect relationship of the PKK's goals and strategies as a Kurdish nationalist group with a chronological case study. The strategy undertaken by the PKK at any given period in history will be broadly categorized as violent or nonviolent; the cause, therefore, is the goal from which the PKK calculates its stratagem. This research seeks to elucidate the relationship between and pattern of the category of goals (causes) and nature of tactics (effects) used by the PKK. This research will then analyze the efficacy of different tactics used by the PKK in pursuit of political recognition, secession, and security. The methodology of this research will include a case study that analyzes the four phases of the PKK's history for the PKK's stated goals, tactics, and the degree of success achieved by different violent and nonviolent tactics.

Abstract Name: Transdifferentiating Muscle Stem Cells into Brown Fat to Treat Metabolic Disorders

Metabolic disorders, such as obesity and diabetes, pose increasing global health challenges with limited long-term success from existing treatments, leading to high worldwide morbidity and mortality. Our project explored a novel approach to treat obesity by transdifferentiating muscle stem cells (MuSCs) into brown adipose tissue (BAT), which expends energy as heat, in contrast to white adipose tissue which stores energy as fat. The objective was to identify a specific MuSC subpopulation with an enhanced capacity to develop into BAT. The methods involved isolating MuSCs from mouse hindlimb muscles, sorting them into subpopulations based on Sca1 expression levels with fluorescence-activated cell sorting (FACS), and growing them in a pro-adipogenic medium to induce brown adipocyte differentiation. We analyzed the efficiency of BAT transdifferentiation through morphological changes, immunostaining for brown adipocyte markers, and quantification of lipid droplets. Preliminary analysis from the first two experiments revealed no significant expression of BAT derived from MuSC in either the Sca1- or Sca1+ subpopulations, suggesting the need to modify the methods of future experiments to obtain more meaningful results.

Abstract Name: Save COVID-19 Scapegoats: The Time Is Now for an Accurate Report on Anti-Asian Hate Crimes

This secondary research examines the topic of why anti-Asian hate crimes are not addressed adequately and perceived as an immediate threat. Criminology scholars have examined anti-Asian hate crimes' growth. Still, none have addressed the effect of underreporting and low statistics in hate crime records. This study analyzes FBI 2020 anti-Asian hate crime statistics with local crime reports. The FBI reported a 77% spike in anti-Asian hate crimes in 2020, while the Center for the Study of Hate & Extremism reported 145%. Although, it is well-established that many, if not most, anti-Asian hate crimes are still underreported, unlike the case for other bias-motivated crimes (Lantz and Wenger). Statistics on anti-Asian hate crimes are not reliable due to two underlying factors; a fraction of law enforcement agencies are not reporting and poorly investigating Asian hate crimes and the victims themselves are not reporting. Two underlying factors overlap; victims' reluctance to report crimes intensified tracking challenges for agencies. In many Asian cultures, being a victim of a hate crime has a shameful stigma and humiliation for the victim's family, which is one of the factors that prevent Asian American victims from coming forward (Pezzella and Fetzer). Additionally, hate-biased crimes are typically psychologically driven, creating challenges for law enforcement agencies to identify murderers' animosity without racist remarks. "#Chinese Virus" tweet by President Trump condemned Asian Americans as scapegoats for the pandemic (Lloret-Pineda et al.). Agencies have been extensively indoctrinated by Trump's denial claim that "This is not Racism," leading them to examine anti-Asian hate crimes as typical crimes. Though several legislations and solutions have been proposed to combat anti-Asian hate crimes, only a few focus on the reporting issue yet still cannot be tackled. Therefore, it is crucial to address this issue for the actual accurate figures to appeal action and forestall anti-Asian hate crimes.

Abstract Name: Interpreting Constructs: A Phenomenology of Race

This is an analysis into the phenomenology of race and racism. This research hopes to act as a genealogy of the current circumstance of race and white supremacy (as it exist in a black/white binary). By inspecting different philosophers, historians, and political theorist ideas on racialization, assimilation, and indoctrination, I investigated and critiqued the condition into which we are socialized in a racist society. It explores the effects of racism on those socialized into it, and considers whether we are able to recover from racism. This research includes an analysis of the phenomenology of race, what different philosophers have interpreted from this condition, and finally, my thoughts and additions to this dialogue.A phenomenology is the examination of a phenomena, an inquiry into the way of things as we experience them. A phenomenology of race, then, would be an inquiry into how the subjective person consciously experiences race. We live in a racialized world. From racism, to colorism, to caste- race and color have been a topic of discussion, specifically in the Americas, (but throughout the world) since the rise of colonialism. The hierarchy of culture, and thus people, and thus races emerge persistently into modernity, but begins especially when the

Americas transitioned from an indentured slavery system to a racialized slavery system. Slavery itself is not the system that is being investigated in this research. Slavery has been a human practice since the Ancient Greek, the difference and effects of racialized slavery, and conditions of the subsequent caste system that still exists, is what we will be producing an ontological critique of. This ontological interpretation of race will observe of the most general features of racism, and how racism relates to black and white people alike in the metaphysically most general ways.

Abstract Name: A triplet loss model using transportation metrics to identify income disparity in Dallas, TX

Addressing income disparity in the United States is crucial for fostering economic stability, social mobility, and ensuring equal access to opportunities for all citizens. Consequently, remedying income disparity stands as a top priority, exerting a substantial influence on policymaking. However, effective intervention necessitates a comprehensive understanding of income disparity. In this study, we adopt a unique perspective by employing a transportation lens to identify and analyze this multifaceted issue. Through an examination of variables such as travel time to work, transportation mode, and household income, we employ a triplet loss model to explore potential connections between transportation metrics and income disparity in Dallas, TX. Our research aims to uncover nuanced insights that can aid policymakers in crafting targeted interventions. Notably, we demonstrate how an increase in transportation infrastructure funding serves as a viable means of addressing income disparity systematically.

Abstract Name: Metaverse-based Platform for Enhanced Active Shooter Preparedness and Response in Developing Countries

Global increases in disasters are rising threats worldwide. Innovative safety training methods are thus required to improve disaster preparedness and response. The emergence of metaverse presents unprecedented potential to address this need. However, despite extensive existing studies, there is still a lack of effort focusing on training for man-made disasters like mass shootings, terrorism, and gang violence. The few studies tailored for these events are usually meant to train law enforcement personnel, not civilians. To address these knowledge gaps, this paper proposes a metaverse-based virtual game platform designed to train civilians on active shooting events. The proposed platform features a user-controlled design, which allow the

users to customize their training environment to familiar settings (e.g., home, office, or school). This approach aims to simulate the real-world situation of the users, thus significantly enhancing their spatial awareness and improving their training performance. The platform is developed using the Unity game engine and is implemented and tested using Haiti as a case study. Preliminary results indicate substantial promise in employing the metaverse to enhance disaster preparedness and response in developing countries with limited resources. Keywords: Gamified safety training; Disaster preparedness and response; Developing countries.

Abstract Name: Enhancing Knowledge in Clinical Ethics: An Evaluation of MSK's Bioethics Ambassador Program

Statement of the Problem: At Memorial Sloan Kettering Cancer Center (MSK), the Ethics Committee developed the Bioethics Ambassador Program (BAP) for an annual cohort of 25-30 multidisciplinary staff. The primary goals of BAP were to provide the analytic tools necessary to identify common ethical challenges, inform about useful ethical frameworks, and create a safe space for thoughtful/transparent discussions about ethical issues. Our study aims to evaluate the change in students' knowledge of bioethics after BAP.Methods: A Bioethics Core Competency survey, comprising 20 multiple choice questions, was administered through REDCap to every BAP participant before and after program completion. 50 (89%) of 56 participants completed the pre and post BAP surveys. We compared pre and post survey scores for these 50 participants, and we analyzed which questions and related topics were associated with the highest percent increase and lowest proportion of correct answers. Results: Among 50 BAP participants who completed pre and post surveys, 37 (74%) scored higher in the post survey than the pre survey. Scores improved most in questions on patient decision-making (Question 1, pre=56%, post=80%) and clinical ethics consultations (Question 2, pre=54%, post=74%). These topics were addressed in multiple sessions. Scores were lowest in pediatrics (Question 11, pre=24%, post=32%). Pediatrics, a topic in which none of the participants had prior expertise, was addressed in only one session.Conclusion: We found substantive improvement in BAP participants' bioethics knowledge as demonstrated by higher scores in their post BAP Bioethics Core Competencies surveys. This improvement in knowledge indicates the potential impact of BAP on multidisciplinary participants at a large cancer center like MSK. In the complex area of bioethics, we hypothesize that addressing a topic in multiple sessions over time enhances learning. Our findings may allow evidence-based recommendations to improve future bioethics trainings.

Abstract Name: Designing for Controlled Chaos: Stefan Sagmeister's profound impact on the graphic design community

Stefan Sagmeister has played a considerable role in graphic design for decades and has a habit of pushing the envelope and experimenting in ways no one before him ever had. Using recurring themes of human emotion, disturbance, humor, and sexuality, he has had a hand in reshaping the way that designers think and feel about their work. Sagmeister is a well-educated and highly decorated designer who is often thought to be responsible for the resurgence of handwritten and handmade typography. As well as being a two-time-Grammy-award-winning album designer, he has dipped his toes into many different aspects of design and inspires countless others to broaden their horizons as well. As an outspoken, odd-ball designer he has worked hard to make a name for himself in the community, consistently challenging the status quo about what institutes "good design." While it is clear that he has made a substantial impact in this field, his work, along with his contentious attitude is oftentimes met with controversy. Due to Sagmeister's ability to think so far outside of the box and idiosyncratic personality, he has found himself at the center of extremely unfavorable discussions. Despite the pushback, Sagmeister prevailed to become one of the most influential designers in the career field, and his legacy will live on for several generations to come. He has had a long career full of highs and lows, but his ability to change the monotonous way things were being done at the time solidified his place in graphic design history. While not necessarily a design hero, Sagmeister changed the direction of graphic design forever.

Abstract Name: Responsible Design: Designing with Purpose for the World Around Us

In a world where graphic design's influence is profound, but often overlooked, this paper delves into the importance of practicing responsible design. Responsible design lends itself to many different aspects, including acknowledging the impact designers have on society, and using sustainable design practices. Using historical examples such as the French Revolution and more recent ones such as the ongoing conflict in Palestine and Isreal, this paper gives historical context and examples of times when the power of design has been both used and abused, from protest design to propoganda. With work by Stephen Kroningeer and Michael Lebron being used as an example, this paper highlights examples of past designers who were able to make waves by using their voices and their platforms. It is through these historical examples that the paper is able to call attention to the overwhelming impact that graphic design can have on society. Along with this, it looks into the impact that graphic design, and more specifically the printer, has on the environment. The environmental impact that is caused by certain materials used in the printing process is examined and scrutinized, and more sustainable alternatives, such as algae ink, are presented. Realizing that responsible design is necessary for the profession to stay legitimate and stable as a career. Overall, this paper covers a variety of topics under the umbrella term of "responsible design" and challenges readers to make a conscious change for the betterment of the world.

Abstract Name: Anti-Abortion Extremism Post-Dobbs

Protesters harassing those seeking abortions, glue in the locks of clinic doors, the doxxing of healthcare professionals – all of which have been part of the long history of anti-abortion violence, before and after the overturning of Roe v. Wade with the Dobbs v. Jackson decision in 2022. This paper aims to establish connections between anti-abortion extremism and extremist actors pre and post Dobbs, focusing on groups working together with additional attention on lone wolf actors. Additionally, this paper hopes to track anti-abortion rhetoric inside other political movements, including a new and expanding left-wing anti-abortion movement. Scholarship on anti-abortion extremism can be traced back to before Roe v. Wade, but in the post-Dobbs v. Jackson era, it's critical to expand knowledge of the new and continuing extremism and violence that persists in its wake.

Abstract Name: Mapping the Time Development of Hydrogel Inhomogeneities using Laser Interference

Hydrogels are materials composed of inhomogeneously crosslinked polymer chains. When exposed to an aqueous solution, hydrogel samples can expand up to ten thousand times their dehydrated size. The intense swelling of these materials, along with their naturally inhomogeneous structure, results in widely varying polymer chain densities in hydrated states. This unique property has made hydrogels a material of interest in many fields, such as biochemistry and Health care; hydrogels are used as contact lenses, tissue reinforcers, and distributors of medicine throughout the body. However, the nonuniform swelling of hydrogels is still widely unexplored. To better understand the time evolution of the material's polymer chain structure, our team is using two laser interference techniques (Bragg scattering and coherent interference) to develop a three dimensional mapping of polymer chains within hydrogel samples. In each method, a light source is shone into a hydrogel sample, where it interacts with the polymer chains and scatters accordingly. The resulting interference pattern can then be analyzed to gain information about internal spacing between polymer chains. By employing these techniques at different sizes in the swelling process, we can quantify a sample's time evolution. Preliminary results suggest that our set of experiments produce valuable information on the polymer chain density/sample structure and we have since focused on fine tuning our data collection process. The ability to accurately characterize the internal configuration of hydrogels will allow us to study the time development of our samples at an in depth level. Better understanding these materials may help advance their current uses and uncover new applications/relevance.

Abstract Name: THE LIFE OF CIPE PINELES

ABSTRACT Cipe Pineles historically helped women transition into a male-dominated industry at a time when women began needing to step up and take jobs outside of the home; she was an example of how to reach high and work hard in everything, encouraging women to do the same in everything they do. Cipe Pineles was a kind woman who cared about others and took the time to educate and help others improve their work. She collaborated with her coworkers to design and create very successful magazines and in turn reached teens and working women through her designs, helping women transition from at-home moms to women in the working world and influencing young women to make their dreams come true. She made history by becoming the first woman accepted into the Art Directors Club, this was not her first attempt but she did not give up. She was a woman who made steps in history to help women become accepted into a once male-dominated workplace.

Abstract Name: Modeling The Influence Of Collective Music-making On Group Formation

It is well-established in the fields of social neuroscience and ethnomusicology that engaging in collective music activities promotes prosocial behavior—that is to say, they make us more cooperative with one another. However, the way this relationship between music and prosocial behavior has evolved has not been elucidated. Thus, we explored the evolutionary dynamics of group formation via music-making. To do this, we turned to game theory and mathematical modeling.We devised a multi-stage model to simulate the process of making music in a group followed by an opportunity to make a social decision. In this model, players first choose whether or not to make music and then play either a Hawk-Dove (HD) or Stag Hunt (SH) game, simulating a competitive and cooperative situation respectively. To imitate the prosocial behavior caused by group music-making, musicians are always friendly to one another. Non-musicians and musicians playing against non-musicians play individual strategies in both games. By imposing these rules, music acts as a way to make team membership (and therefore, likelihood of cooperation) known, following Bacharach's teamplay schemata.We found that none of the pure strategies are evolutionarily stable, meaning that none are perfectly better than any other. However, there are two musician strategies that are stable against non-musicians. Applying mixed group analysis, we found that musicians have quite large benefits in the SH game and smaller, conditional benefits in the HD game. These results indicate that being a musician and cooperating with other musicians is beneficial not only in settings where cooperation is favored, but also in competitive settings. Even with these positive results, we have work left to do. Future work will incorporate the more unique aspects of group musical activity. It will also involve the creation of an agent-based simulation to analyze individual behavior and N-player games.

Abstract Name: NASA needs more funding before our return to the Moon.

We are going to the Moon before 2030 and NASA's Artemis program aims to put the first African American and Woman on the Lunar surface and pave the way for future scientific discovery. NASA's ambitions face financial hurdles as the Lunar program is projected to cost $93 billion, and NASA currently has a budget of $30.92 billion in 2024. However, this budget lacks the financial sustainability needed. Leadership within NASA, particularly Administrator Bill Nelson, expressed concerns that if NASA were to receive less funding than requested, many programs would be forced to shut down. Programs such as the Cancer research done onboard the ISS will create challenges for scientists currently exploiting the microgravity environment to construct more efficient protein structures to combat cancerous cells. Such program cancellations would mean loss of scientific opportunities where technological innovations would revolutionize the world we live in. Neglecting budget constraints and their effect on space flight can lead to disaster. The Rogers Commission report clearly underlined that financial pressure led to mismanagement with construction of Space Shuttle Challenger. Moreover, NASA economically benefits the US both internationally and domestically. Our partners in space, such as the CSA and ESA, foster international cooperation and provide economic commerce through research and development. Additionally, the private sector helps NASA generate an economic output of $21 billion annually as well as collect $7.1 billion in tax revenue as we prepare for Lunar exploration through the M2M campaign. To ensure NASA's additional funding, reconsidering expenditures in the Department of Defense is vital. Emphasis on benefits of redirecting resources towards NASA's innovation, particularly the medical and scientific industries. Highlighting NASA's role in driving progress and improving lives would garner support for increased funding, ensuring a better future for scientific exploration and technological advancement.

Abstract Name: The Currency of Medieval Friendship: The Portable Altar of Bishop Nitker and Emperor King Henry III

The objects we make are fragile and transitory; some pieces have managed to persist with only minor scars from the vicissitudes of time, yet others have disappeared completely and mysteriously from the historical record. The portable altar-turned-reliquary of La Trinité is one such example of an object that remains only in the fragmentary traces of written and visual sources. However, from these sources stems an intricate and unpredictable narrative concerning a friendship between Holy Roman Emperor Henry III (1016-1056) and a lesser-known bishop of 11th-century Germany, Nitker of Freising (r. 1039-1052). Weaving clues from the drawings of an 18th-century publication, scholars have predominantly explored the object in its final form as a reliquary for the Holy Tear of Jesus in the abbey of Vendôme, France. However, an intriguing inscription incised in gold and nailed upon the chest suggests there is more to the story. Written unassumingly on the edge of the lid, the inscription reads: HEINRICO NITKERUS DAT (Nitker gives [this] to Henry). These three Latin words indicate a previous life of medieval societal practice and ecclesiastical opulence. This paper focuses on the object's prequel as a portable altar. Originally crafted in 11th-century Germany, I demonstrate that the portable altar signified the complex political-ecclesiastical reality of the Middle Ages and affirmed the relationship between HRE King Henry III and Bishop Nitker of Freising. Likely given as a gift to Henry

on Nitker's episcopal installment, my research shows that as an object of exchange between the two men, the portable altar negotiated the physical and conceptual space between ecclesiastical and royal power. This paper specifies how the altar was a symbol of affirmation in a time when gift-giving was the very foundation of society, solidifying roles of power, esteem, and of the church and state respectively.

Abstract Name: Quantifying RF Radiation of common items

Electromagnetic fields (EMF) AM-11 equip you to make quick and informed judgements regarding radiofrequency (EMFs) in your environment. This study measures and catalogs common item radiation levels. After extensive testing and measurement, the study tries to comprehend these electronic objects' radiation emission. These data will raise awareness of radiation exposure from everyday objects. This study illuminates the radiation spectrum of ordinary products and emphasizes the need for educated usage decisions. In this study, the purpose is to validate that EMF decreases when increasing the distance and to determine if older models of electronics emit more radiation than newer models.

Abstract Name: Quantifying Caloric Consumption through PhyPhox

Phyphox is a Cartesian-coordinate-based mobile application useful for conducting physical phone experiments. It houses a repository of tools with raw sensors, which can be used to measure various kinematic variables. We are interested to see if a mobile application like Phyphox is sufficient in computing such variables for broader relevant use. In this project, we want to determine if a mobile application like Phyphox can accurately frame our caloric consumption from derived values. We used Phyphox's raw sensor, GPS Location, to simulate twelve walking trials and determine the accuracy of a subject's average movement. We utilize this data to quantify caloric consumption. However, preliminary experimentation only provided a few useful trials, as Phyphox was often unreliable. The initial data obtained did demonstrate an accurate measurement of work done and calories expended; but, further study is necessary to find significant data points for conclusion.

Abstract Name: Investigation of High-Frequency mode activity in the HBT-EP Tokamak

High-frequency transient mode activity in tokamaks, like the High Beta Tokamak - Extended Pulse (HBT-EP), can be excited by instabilities and are often associated with minor and major disruption events. Previous HBT-EP observations have focused on lower-frequency modes by applying digital low-pass filters to multiple plasma diagnostics, including magnetic sensor arrays, X-ray detector arrays, and scrape-off-layer (SOL) tiles. In this presentation, we instead use high-frequency filters to separate the high-frequency activity from the lower-frequency modes. We find the most intense high-frequency magnetic activities occur in brief mode bursts associated with strong plasma perturbations caused by large amplitude low-frequency modes. We present a correlation analysis for characterizing these high-frequency mode bursts from multiple diagnostics and determine the spatial, as well as temporal, dynamics for these bursts in the HBT-EP. This work was made possible by funding from the Department of Energy for the Plasma and Fusion Undergraduate Research Opportunity (PFURO) program. This work is supported by the US DOE Contract No. DE-AC02-09CH11466 and DE-FG02-86ER53222

Abstract Name: Female Rappers, Sexuality, and Intersectionality: Empowerment or Objectification?

Hip Hop, a musical genre that was once dominated by male rappers, has slowly embraced and celebrated the presence of a plethora of female artists. Some of the most popular ones use sexuality regularly to attract fans and followers, to the tune of millions of listens, views, and dollars. This research focuses on female rappers' sexuality and intersectionality as possible agents of empowerment and/or objectification with a look at specific lyrics, videos, and social media posts. Artists such as Sexyy Red, Megan The Stallion, Nikki Minaj, and Lil Kim are highlighted. Aspects of rhetorical studies and critical feminist theory are used to contexualize the lyrical and visual rhetoric of these female rappers as they communicate and display their sexuality.

Abstract Name: Mechanical Characterization of Amorphous Silicon Carbide as a Neural Interfaces Device

Intracortical microelectrode arrays (MEAs) are implantable devices used for neural recording and stimulation. Following MEA implantation into cortex, the neural recording performance decreases over time by glial scarring. The use of ultra-thin microelectrode arrays (UMEA) has been proposed to minimize the glial scar as UMEAs have a small cross-sectional area which is expected to minimize persistent foreign body response associated with implantation. However, unaided implantation of UMEAs can be challenging because they tend to buckle prior to penetration into the brain. Therefore, this study investigates amorphous silicon carbide (a-SiC) UMEA designs with various cross-sectional areas and lengths, used to determine those geometries that facilitate unaided implantation into the cortex of rat, pig, and macaque.First, we evaluated the critical buckling force (Fc) of UMEAs as a function of geometry. We measured UMEAs with 200, and 300 μm2 cross-sectional area and lengths of 1.3, 1.5, and 1.7 mm We then characterized the penetration force (Fp) into the cortex of rat (n = 3), pig (n = 4), and macaque (n = 1) after exposing the brain through surgical craniotomy and durotomy procedures. Subsequently, the UMEAs were inserted cortex at a controlled speed of 100 μm s−1.As expected, increasing the length, and decreasing the cross-sectional area of the UMEAs decreased Fc. The UMEA design with a length of 1.7 mm and cross-sectional area of 200 μm² required the least Fp (0.55 ± 0.304 mN) in macaque brain. However, in pig and rat brains, the UMEA design with a length of 1.5 mm and cross-sectional area of 200 μm² (Fp = 0.7 ± 0.25 mN and, Fp = 0.13 ± 0.14 mN, respectively).By measuring the Fc, the study determined an insertion-depth-dependent critical buckling force that could predict whether insertion would occur without buckling based on the UMEA geometry.

Abstract Name: Empowering female students in higher education: An In-Depth Exploration of Needs, Expectations, and Challenges, with a focus on learning disabilities

This research will cover the topic of Empowering female students in higher education: An In-Depth Exploration of Needs, Expectations, and Challenges, with a focus on learning disabilities. The research questions that will be discussed are, what are the specific needs and expected support of female students in higher education settings, what are the main challenges and pain points that female students encounter inside

and outside of the classroom, what factors influence female students academic performance, career aspirations, mental health, and overall well-being, what strategies and institutional support to empower female students effectively? The methodology used in this research will be survey (quantitative) and interview (qualitative). Women have faced barriers throughout history on many topics, including education. Though some barriers have been remedied, women still face some hardships in higher education. In this research, the author will explore the barrier to learning disabilities in higher education. Most learning disabilities present differently in women than in men. Previous research on learning disabilities has only been done with men. To create a better learning environment for women they must be understood just as much as men are. This research hopes to scratch the surface of understanding learning disabilities in higher education and how teachers and institutions can best support these women. In this research women in higher education will be asked questions to understand their pain points in and outside of school, their aspirations in higher education and careers, their overall mental health and well-being, and how their learning disabilities affect these variables.

Abstract Name: Preamble-based RF-DNA Fingerprinting Under Varying Temperatures

A total of 30.9 billion Internet of Things (IoT) deployments are expected by 2025 with most employing weak or no encryption at all, which raises concerns about IoT security. This concern is exacerbated by IoT-connected critical infrastructure and the successful exploitation of this security vulnerability. This led researchers to propose a physical layer-based IoT security solution coined Specific Emitter Identification (SEI). However, SEI has been shown to be sensitive to temperature changes. This sensitivity is important when considering IoT deploymentsin highly variable temperature environments. The presented ap- proach shows the temperature sensitivity of SEI is mitigated whenthe classifier is trained using RF-DNA fingerprints drawn from waveforms collected at two temperatures. In fact, SEI performance improves the most when the two temperatures are at or near the extremes of the operating temperature range. Specifically, our work shows that training SEI classifiers using the extremes of the collected temperatures improves overall classification performance across temperature ranges. The work in this paper also shows that emitters operating in a sub-ambient, exothermic state have a more consistent fingerprint than those operating in a high-temperature, endothermic state.

Abstract Name: Pig Taste-Cell Derived Organoids Synthesize Insulin

Insulin is a hormone responsible for the uptake of glucose into myocytes and adipocytes, where it can be turned into usable energy. Insulin is essential to life. Recent findings suggest that insulin exists in taste receptor cells on the mammalian tongue, and these cells' high rate of proliferation from taste stem cells makes taste stem cells a promising source of insulin-producing cells. This project aimed to obtain mature taste cell organoids from taste stem cell organoids and increase insulin gene expression in these organoids. Porcine tongue stem cells were plated in a matrix structured to encourage organoid formation, and these initial cultures were grown in an Lgr-6 promoting control condition. Immunofluorescent staining revealed that some stem cell organoids spontaneously differentiated into mature taste cell organoids in this control condition. To encourage cell differentiation, new taste stem cell organoids were exposed to the control media and a condition named "C5," which was designed to downregulate developmental pathways via the removal of exogenous growth factors from the media. After 16 days in culture, the experimental organoids appeared to contain mature cells and had an increased expression of mature cell markers, a decreased expression of stem cell markers, and an increased expression of insulin transcription factors and insulin gene itself. To achieve this project's second goal, more stem cell organoids were exposed to the control condition, the C5 condition, and a new condition named "CQ," which actively inhibited growth pathways via small molecule inhibitors. These new cells showed a 4000-fold increase in insulin expression compared to the control. This project establishes a proof of principle for taste-derived organoids as an accessible and potentially renewable source of insulin- producing cells. Although the primary presenter is affiliated with the University of California, this project was conducted at the NIH's National Institute on Aging.

Abstract Name: Evaluating notum interaction with glypican-3 in hepatocellular carcinoma

Hepatocellular carcinoma (HCC) is the third most common cause of cancer related death. Typically, HCC arises in patients having a previous liver condition such as cirrhosis or inflammation. There are few treatment options that exist for HCC but they are only curative if the HCC diagnosis occurs in the early stages. Therefore, current therapy explorations involve identifying molecular targets for a personalized medicine approach. Uniquely, Glypican-3 is only overexpressed HCC tumor cells making it an attractive target for potential therapies. Glypican-3 on the surface of the cells has been known to play a role in growth factor signaling to aid in tumor progression. Like glypican-3, notum is overexpressed in HCC cells and minimally expressed in normal healthy tissues. Here, we investigate notum interaction with glypican-3 using an ELISA

assay by comparing CRISPR-edited notum knockout HCC cells with wild-type HCC cells. We propose further exploration on notum and glypican-3 relationship for developing HCC-targeted therapy approaches.

Abstract Name: The Neuroscience of Vocal Flexibility: Mapping Auditory-Motor Dynamics in Songbirds

Few species have developed the ability to adaptively change elements of a learned vocal signal to communicate information. Vocal flexibility – the ability to modify, combine, and learn new vocal expressions – has been theorized to depend on interactions between auditory and motor brain regions. Humans and European starlings both display this ability in speech and in song, respectively. In songbirds, natural variations in vocal flexibility between species offer an opportunity to explore the neural connections underlying this ability. Zebra finches are closed-ended vocal learners; they learn their song from older birds during their juvenile developmental window, after which they lose all vocal flexibility. Preliminary investigations have found an auditory-motor projection from avian auditory center NCM to pre-motor nucleus HVC in zebra finches that is present during the developmental phase, but fades once this period has ended. The disappearance of this auditory-motor projection coincides with the loss of vocal flexibility. European starlings, however, are open-ended learners, possessing lifelong vocal flexibility in their communication. We hypothesized that starlings possess a persistent auditory-motor projection between NCM and HVC that allows them to maintain vocal flexibility throughout adulthood. To determine if projections exist between these two areas, we injected a fluorescent retrograde tracer (Dextran Alexa Fluor 488) into neurons in both NCM and HVC of adult European starlings. If this projection exists bidirectionally, the fluorescent tracer will appear in NCM neurons in the HVC-injected birds, and in HVC neurons in the NCM-injected birds. The existence of information transfer between auditory and motor brain regions in adult starlings may explain how some species maintain vocal flexibility, while others do not. This study aims to contribute valuable insights into the neural mechanisms that arise from functional connectivity between auditory and motor brain areas to govern vocal flexibility, ultimately providing insight into human speech and language.

Abstract Name: The Effect of Cerium and Cooling Rates on the Cast Microstructure of Aluminum-Cerium

Alloys – Wedge Mold and Melt Spun Castings

Aluminum Cerium alloys are receiving increasing attention given their excellent high temperature properties. A series of nine Al-Ce alloys of compositions ranging from 2 – 18 wt% Ce were cast in steel wedge molds, and the changes in microstructures, including primary α-Al (in hypoeutectic alloys) or primary Al11Ce3 (in hypereutectic alloys) phases and the lamellar eutectic phase (of α-Al and Al11Ce3), were studied. The Al-12wt% Ce sample was recast in a water-cooled copper wedge mold and also melt-spun on a copper drum. The cooling rate in the copper mold was estimated to be 23.36 oC/s and 10.93 oC/s at 1" and 2" from the base of the wedge. The secondary dendrite spacing in Al –12 Ce alloy in copper wedge mold increased from 14.5 μm at 1" from the base to 18.5 μm at 2" from the base. The secondary dendrite arm spacing was 2.6 μm in the melt-spun sample. The microstructures in Al-Ce alloys have been compared with the microstructures in Al-Si alloys.

Abstract Name: Examination of Trace Metal Content in Sparklers and Effect on Lungs Utilizing Synthetic Lung Fluid

Sparklers are designed for use by burning metallic particles, a process that produces a variety of colored flames and releases metal oxides as a result. Respiratory exposure to subsequent fumes and pollutants can induce oxidative stress and increase the risk of developing health issues such as lung irritation and cancer. While previous research has examined particulate matter emission from fireworks and related health consequences, little research has been done regarding handheld sparkler use. This study examined handheld sparklers that produce red, blue, green, and gold flames to determine the quantity of trace metals left in lung fluid after combustion. Filter papers with particulate matter were submerged in Artificial Lung Fluid (ALF) and Gamble's Solution (GS) and analyzed to determine metal content via ICP-OES. Results revealed high levels of aluminum in sparklers compared to other metals (i.e., arsenic and chromium). Future research will indicate the associated health risk of sparkler use by inhalation.

Abstract Name: A Study of Deviance: Why Might a Person Join a Gang

My research involves watching and analyzing multiple youtube videos from the Soft White Underbelly channel run by Mark Laita. This channel is dedicated to interviewing different deviant individuals and others who are often ignored by society. In his interviews he talks about their experiences and lives. At first I was assigned to watch just one video for a deviant behavior course I was enrolled in, but after that I decided to do more research and look into multiple indidvuals experiences and how they compare to each other. For my research I selected multiple videos interviewing deviant individuals such as Mohawk Matt, Johnny, Spooky, and El Gordo. These individuals were/are all deviant in different ways, but the common theme for all of them is that they have all been involved in gangs. While analyzing these videos I applied multiple sociological concepts such as theories surrounding culture and subculture, both formal and informal sanctions, and stigma management. After analyzing all of the videos, I was able to draw comparisons between all of the individuals about things such as what got them into gang subculture and why they stayed involved. These results can help to better understand why a person would get involved in this type of deviant lifestyle, and also what society could do to prevent harmful deviant behaviors, such as this one, from continuing to occur.

Abstract Name: Where have all the Females Gone? Examining Causes of Male-Biased Sex Ratios in the Eastern Painted Turtle

Biased sex ratios in animal populations can significantly reduce reproductive rates and contribute to population decline. Here, we examine the potential causes of male-biased sex ratios in eastern painted turtles (Chrysemmys picta picta) captured in wetlands in the Patuxent Research Refuge and nearby Bowie State University campus. Using two years' of capture data, we tested two hypotheses and their predictions: 1) females are killed by vehicles while traveling to lay eggs, and therefore sites closest to roads will experience the most male-biased sex ratios, and 2) females are active in earlier months of the year compared with males, and the timing of our trapping efforts bias study-wide sex ratios in favor of males. We ranked ten sites based on their relative proximity to roads and relative vehicle traffic. However, we did not find a significant relationship between sex ratio and road proximity. Instead, we found differences in sex ratio based on season, with spring sample dates showing a slightly female-biased sex ratio, on average, and fall sample dates showing a strong male-bias. We conclude that male-biased sex ratios in our study are mainly driven by our history of fall sampling. The study-average bias in sex ratio could also be influenced by higher depredation rates of females during nesting. While we cannot conclude that traffic causes biased sex ratios in our eastern

painted turtle population, we note that turtles are regularly killed on local roads and we therefore urge the community to consider tunnels or similar means of preventing turtle road mortality.

Abstract Name: Plastic nesting material and its potential impact on predation

Rising levels of plastic pollution in the environment continue to impact aquatic and terrestrial organisms, including birds when they incorporate it into their nests. Whether the use of plastic as nesting material is entirely helpful or harmful is largely unknown. Potential detrimental effects of incorporating non-anthropogenic matter as nesting material include entanglement, ingestion, alteration of thermal properties, and increase in predation risk. The proportion of plastic used in robin (Turdus migratorius) nests was determined in 3 types of locations in Northwest Indiana. These sites included shopping area parking lots, Valparaiso University campus, and local parks. Post-breeding season robin nests (n=44, f=4.51, p<.025) were collected and dissected. Overall, 89% of the nests contained plastic. The nests with the most plastic originated from shopping areas. The effects plastic material had on nest predation rate were examined by placing artificial and natural nests around campus with model clay eggs. Half of the trials had white polyethylene plastic incorporated into their nests, and half contained no plastic. Time to nest disturbance or the presence of animal markings on the eggs were used to measure predation. In 2022, 74% of the nests were attacked with more predation from bird species than mammals. The time until predation was significantly longer for nests with plastic (n=11, t=2.3, p<.050). In 2023, the experiment was replicated, and results indicated that the time until predation was significantly longer for nests without plastic. Findings also suggested there are seasonal differences between the rate of predation for nests with and without plastic. Plastic might be making the nest more visible to predators, the sound of the plastic moving could attract predators, or the plastic might deter predators by scaring them away. Future research is required to understand the comprehensive impacts plastic has on bird nest quality and breeding success.

Abstract Name: The Relationship Between Mexican Informal Labor and Poverty

By looking at the relationship between historical Labor Market Regulations and the growth of Informal Labor in Mexico, this research studies poverty as a spillover effect of informality growth. This study will test if a reduction in the size of the informal economy in Mexico leads to a decrease in poverty levels. Moreover, this

research will also confirm if past policies that lead to labor market rigidities increased informal employment in Mexico, hoping to clarify a causal relationship between labor market rigidities and informal labor growth.

Abstract Name: Advancement of Autonomous Animal Burrow Detection at the Vernal Pools and Grassland Reserve: A Deep Learning Approach Using Drones

The Merced Vernal Pools and Grassland Reserve situated behind UC Merced constitutes a vital ecosystem, hosting delicate vernal pools with unique biodiversity and hydrological significances. Traditional vernal pool counting and tracking methods often fall short due to the dynamic nature of these pools. In this study, we propose a continued exploration of an innovative approach combining drone technology and deep learning to accurately count and track vernal pools in real time. By deploying drones equipped with high-resolution cameras, we capture detailed aerial imagery of the reserve's landscape. Using deep learning, we use models that can find and track the ground mammal burrows by themselves, even in the complex grassy surroundings. This research not only introduces a state-of-the-art methodology for vernal pool monitoring but also contributes to the broader goals of the Natural Reserve System by facilitating precise ecosystem assessments. The outcomes will empower conservationists, researchers, and policymakers with timely, accurate data to inform decisions and safeguard the delicate balance of the Vernal Pools and Grassland Reserve. Identifying certain land characteristics that determine the range of burrow abundance. This would allow species to thrive and also ensure future land management to safeguard this natural reserve for many more years.

Abstract Name: Substance Coping Mechanisms and Startle Responses Related to Trauma History in Post-9/11 Veterans

In post-9/11 combat-exposed US veterans, rates of alcohol and other substance use are notably high and suggest their use as often problematic coping mechanisms. Evidence of significantly heightened fear responses in these veterans may be a result of enduring previous traumatic experiences and/or subsequent post-traumatic stress disorder (PTSD). Previous literature suggests that fear responses operate differently in trauma-exposed brains, thus this research aims to further investigate the startle responses of this population and its association with PTSD and alcohol use disorder (AUD). Those with increased startle response may be at a greater risk for substance use coping over time. Identification of this risk is important given that problematic alcohol and other substance use amongst veterans are associated with significant negative impacts including physical health consequences, functional impacts, and even increased mortality.This research will examine startle responses as they relate to trauma history, PTSD status, and AUD status as a

potential driver of substance coping. Our sample consists of post-9/11, combat trauma-exposed, white, male veterans (n=27) who completed self-report measures, a clinical interview, and a laboratory task assessing fear potentiated startle. In this sample, 46.2% had PTSD and 38.5% had AUD. This research will present descriptive information and run association tests between startle responses and numerous trauma and alcohol-related variables: trauma load, drinking motives, PTSD status, AUD status, and binge drinking. Preliminary findings indicated that shocked-associated startle response ($p = 0.031$) correlated with trauma load ($M = 7.8$, $SD = 4.2$). Further, there was a trend-level difference in baseline startle response ($p = 0.067$) such that individuals with PTSD ($M = 50.4$, $SD = 2.3$) demonstrated greater baseline startle compared to those without ($M = 47.8$, $SD = 4.0$). There was no significant difference in AUD diagnosis ($p = 0.408$) with baseline startle response. Additional findings will be reported and implications and next steps discussed.

Abstract Name: Identifying Mechanisms Underlying Cardiovascular Health in Black Adults: Investigating the Role of miR-122-5p on Glutamine Production through Regulation of Glutamine Synthetase Expression.

Cardiovascular disease (CVD) is the leading cause of mortality and morbidity in the United States of America, and there are marked disparities in CVD prevalence and outcomes between Black Americans and other racial groups. Previously, the Morehouse-Emory Cardiovascular (MECA) Center for Health Equity examined the microRNA (miRNA) and metabolomic profiles underlying cardiovascular health (CVH) in a cohort of Black Americans living in Atlanta, GA. They found that plasma levels of microRNA-122-5p (miR-122-5p) and glutamine correlated with CVH. While much is known about the benefits of glutamine, nothing is known about the mechanisms that connect miRNA 122-5p to glutamine. The goal of this study was to further examine the relationship between expression of miRNA-122-5p and glutamine. We hypothesized that miR-122-5p can suppress glutamine production in endothelial cells by targeting glutamine synthetase, the enzyme responsible for converting glutamate to glutamine. In silico analysis revealed that the 3' untranslated region (3' UTR) of glutamine synthetase mRNA contains a target sequence for miR-122-5p. Subsequently, human aortic endothelial cells (HAECs) were cultured in glutamine supplemented media or in glutamine free media. To overexpress miR-122-5p, HAECs were transfected with miR-122-5p mimic or scrambled mimic control. Real Time polymerase chain reaction (RT-PCR) was performed to measure expression of glutamine synthetase mRNA. Overexpression of miR-122-5p did not suppress glutamine synthease mRNA levels in cells grown with glutamine-free or glutamine supplemented media. Although these results indicate that miR-122-5p did not suppress the expression of glutamine synthetase through mRNA degradation, miRNA can also modulate target expression through translational repression. In future studies, protein expression of glutamine synthestase will be investigated through western blot analysis. This work provides insight into the connections between the miRNA and metabolomics pathways underlying cardiovascular health. Understanding the role of miRNA in regulating metabolite levels will also help identify therapeutic targets.

Abstract Name: Direct Human Impact on Whitewater Mammal Species

Human activity and disturbance have a very large effect on the diversity and survival of mammal species. The purpose of this study is to see if direct human presence could have an effect on the makeup of species in different parts of a habitat, and potentially affect the times they are active in these areas. In this experiment, 10 motion-sensing cameras were deployed for two months in areas of the Whitewater Nature Preserve. Six of the cameras were facing trails, with direct, consistent human contact throughout their deployment. The other four faced more off-trail, forested areas that saw no human activity. Our results showed that there was a greater diversity in the mammals that were captured off the trails. In addition, mammals like the coyote (Canis latrans) and the red fox (Vulpes vulpes) were captured only during the early morning and late night on the cameras facing the trails, times where there is little to no human activity. Mammals are very important factors in our ecosystems. Our impact on these species could affect our environment and how it functions. Understanding how we affect mammal species, directly or indirectly, could help to prevent the loss of biodiversity and endangerment of key species in our environments.

Abstract Name: Parental Ethnic-Racial Socialization and its Influence on Asian American Adolescents' Psychological Well-Being

Despite the increasing demand for more minority representation, Asian American research continues to be an underrepresented demographic. Current research on Asian Americans delves into socialization effects on Asian American adolescents. The term parental Ethnic-Racial Socialization (ERS) entails the types of messages and conversations Asian parents have with their children pertaining to race, ethnicity, and identity. While parental ERS significantly influences the development of racially and ethnically minority youth, there is a scarcity of research specifically addressing Asian American youth (Juang et al., 2016). ERS may benefit or harm Asian American adolescents' psychological well-being depending on the level of significance Asian parents imply with concepts of race and ethnicity. Adverse effects were shown in Asian American adolescents doubting the validity of belonging in a minority demographic as a result of the lack of racial conversations with their parents (Young et al., 2020). This paper aimed to expand the current literature about the effects of ERS on Asian American adolescents' psychological well-being. We administered a questionnaire and collected 554 samples who identified within the age range of 18-24 years old, including both first and second Asian American immigrant generations. Subsequently, we employed t-tests to examine the impact of parental ERS on Asian American adolescents' psychological well-being. Preliminary findings reported that parents' minimization of race significantly reduced Asian American adolescents' self-esteem. In other words, Asian American youth were more likely to exhibit increased self-esteem if their parents advocated diversity and emphasized the significance of race. Our findings emphasized the significance of parental ERS research for Asian American adolescents and highlighted protective and risk factors regarding their psychological well-being.

Abstract Name: Evaluation of Behavior and Welfare in Laboratory-Housed Beagles (Canis lupus familiaris) When Provided a Raised Surface

In 2022, USDA-registered laboratories contained approximately 48,000 dogs; thus, providing proper enrichment to them and assessing its quality is an important topic of study for ethical and scientific reasons. Laboratories are recommended to provide dogs with environmental enrichment in the form of furniture, such as raised platforms and ramps, but the welfare benefits provided by such interventions have not been thoroughly researched. This study examined the behavior and welfare of four pair-housed beagles (Canis lupus familiaris) when raised platforms were added to their enclosures. We hypothesized the beagles would prefer resting on the platform over the ground floor when provided the choice, and that the platform's presence would enhance their welfare, which would be demonstrated by lower activity rates and better sleep efficiency scores. Two pairs of beagles were observed in their enclosures through surveillance cameras over four 1-week long phases, following an A-B-A-B study pattern (A=baseline: no platform; B=intervention: platform provided), to compare the beagles' behavior with and without the platform. One pair of beagles had collar-mounted accelerometers that collected data concerning their activity patterns, and the quality and duration of their sleep. On average, the beagles chose to rest on the platform half the time the platform was present, and the amount of time they spent in the platform's segment of the enclosure increased during the B phases. We conclude that the platform affected the beagles' behavior and potentially positively impacted their welfare, and therefore recommend the implementation of platforms in dog enclosures.

Abstract Name: Rethinking Bilingual Advantage: Examining the Interaction of Language Experience and Executive Function

As the demand for bilingualism increases in our culturally diverse society, various issues related to bilingualism have garnered considerable attention. One such area of focus is the cognitive benefits associated with being bilingual. Over the past decade, numerous studies have explored the concept of bilingual advantage, particularly its impact on executive functions. However, the findings in this regard have been inconsistent. While a substantial body of literature supports the idea that bilingual individuals possess cognitive advantages over their monolingual counterparts in specific cognitive tasks, there are also scholarly works that have failed to demonstrate such enhanced cognitive benefits. This discrepancy in research findings

may be attributed, in part, to the multifaceted nature of bilingualism, which includes factors of language experience, such as language proficiency and daily language usage. Many experimental studies on bilingual advantage have overlooked the necessity of controlling these variables in their participants, contributing to the inconsistency in results. Recognizing the complex nature of bilingualism and its potential influence on executive functions, this study aims to identify the language experiences that impact executive function. Through a systematic review, we aim to scrutinize the methodologies employed in previous research, specifically focusing on how these studies controlled for variables, in order to identify the influential factors of language experiences on executive function. We expect to find a strong correlation between language experience and the cognitive advantage of bilingual individuals. The finding will provide clear direction for future bilingual research and will ultimately be a valuable reference in the cognitive enhancement of bilingual individuals in the field of Speech-Language Pathology.

Abstract Name: Factors That Can Affect the Accuracy of Some Non-neural Machine Learning Models Applied to Numerical and Categorical Data

My research investigates what factors affect the accuracy level of various machine learning models when applied to different attributes of the same database. I'll test the dataset "Data Science Salaries 2023" and experiment with key data fields. My hypothesis is: will providing more data points and outcomes for various models to work on lead to better results, and will all the models produce the same level of accuracy? My method uses six non-neural network models to predict accuracy: Linear Regression, Logistic Regression, K-nearest Neighbor Classifier, Decision Tree Classifier, Random Forest Classification, and Naive Bayes Classifier. After seeing the result, my first conclusion is that too many outcomes to predict will lead to less accuracy. Second, the accuracy will increase if there is a big gap (one factor takes the majority). This research can help identify the optimal model for specific data types.

Abstract Name: Assessment of Antibiotic Resistance and Water Quality in Urban and Rural Watersheds:

Ballona Creek to Playa Del Rey Beach and Topanga Creek to Topanga Beach

Water quality includes the assessment of total coliform bacteria, specifically Escherichia coli (E. coli). The Environmental Protection Agency (EPA) has a limit for E. coli of 125 CFU/100 mL for high-contact water activities and 576 CFU/100 mL for low-contact activities. Besides bacteria's direct role as potential human pathogens, they are a source of antibiotic-resistant (AR) genes, a growing public health concern, and there is a lack of research on their role in the environment. We studied two watersheds in the spring and summer of 2023: urban (Ballona Creek (BC) and Playa Del Rey Beach (PDR)) and rural (Topanga Creek (TC) and Topanga Beach (TB)) to look at the connectivity between the streams and the ocean. Water quality was evaluated with onsite environmental sensors, IDEXX Colilert-18, and a modified IDEXX method using antibiotics (tetracycline and erythromycin). We hypothesized that the urban watershed would contain higher levels of coliforms and AR compared to the rural watershed and that within each watershed, the streams would have higher levels of coliforms and AR than the beaches, which could serve as inputs into the ocean. BC consistently had high levels of AR (35% were resistant to erythromycin), and the E. coli count was above EPA limits. Meanwhile, its connected beach PDR contained low levels of coliforms and AR. In contrast, TC had low levels of E. coli and AR, while the beach had higher levels. TB is a popular surfing spot and could be a source of AR in the environment.

Abstract Name: Inequalities Between Intrinsic and Extrinsic Quantities for Three Dimensional Smooth Hypersurfaces

By J.F. Nash's Theorem, any Riemannian manifold can be embedded into a Euclidean ambientspace with dimension sufficiently large. S.-S. Chern pointed out in 1968 that a key technicalelement in applying Nash's Theorem effectively is finding useful relationships between intrinsicand extrinsic elements that are characterizing immersions. After 1993, when a groundbreakingwork written by B.-Y.Chen on this theme was published, many explorations pursued thisimportant avenue. Bearing in mind this historical context, in our present project we obtainnew relationships involving intrinsic and extrinsic curvature invariants, under natural geometricconditions.

Abstract Name: Mapping Accessibility to Health Care Using Public Transportation

Can people get to healthcare facilities promptly using public transportation? Public transit offers various advantages for both communities and individuals in terms of mobility and has the potential to serve as a

practical alternative to private, motorized transportation. Public transportation improves the population's health and provides reliable general accessibility to care. Meanwhile, timely and convenient public transit becomes a lifeline for people who cannot access other types of transportation, especially when it comes to emergency care. We will analyze the spatial accessibility to care via public transit by building a private network analysis within ArcGIS Pro. Data layers include: (1) coordinate data of hospital and stand-alone emergency rooms as designated by the North American Industrial Classification System (NAICS), (2) public transit route and stop data for Orlando, Florida, and (3) demographic data by ZIP code. We will compute and visualize the public-transit accessible areas within the benchmark accessible time of 30 minutes, determining inaccessible regions (i.e., healthcare deserts via public transit) as a separate layer. We will overlay the map generated with demographic data to determine the relation between the population characteristics and access to healthcare facilities via public transit. Based on the literature review, we expect to find an overlap between areas with high poverty levels, vulnerable populations, and healthcare deserts via public transit. Future implications of this research include establishing GIS analytical methods to address disparities in access to healthcare facilities (i.e., primary care, specialists, or labs) via public transit.

Abstract Name: Reactivity of N-heterocyclic carbene nickel(0) complexes for CO2 reduction

Greenhouse gas emissions contribute to a concerning increase in the global temperature, with CO2 being of significant concern. CO2 activation with transition metal catalysts can be an effective method for greenhouse gas reutilization. This work aims to probe CO2 activation with bidentate N-heterocyclic carbene (NHC) Ni(0) complexes and captured CO2 sources. Bis(imidazolium) salts as ligand precursors can be synthesized from substituted imidazoles reacted with dihaloalkanes. This work created a new bis(imidazolium) salt using bifonazole (BIF) and dibromomethane to form [BIFNHC2Me][Br]2. The NHC ligand was formed by deprotonating a bis(imidazolium) salt, [tBuNHC2Me][Br]2 or [BIFNHC2Me][Br]2, using two equivalents of KHMDS. The NHC2 was then reacted with Ni(COD)2 to form (tBuNHC2Me)Ni(COD) or (BIFNHC2Me)Ni(COD). These NHC2Ni(COD) complexes were tested with captured CO2 sources in the form of imidazolium carboxylates and under electrochemical conditions.

Abstract Name: A Reinforcement Learning Method for the Inverse Acoustic Scattering Problem for a Sound-Soft Obstacle

The mathematics of scattering theory has contributed to the fields of computational wave phenomena, ocean

acoustics, geophysics, remote sensing, and medical imaging by creating technology such as radar, sonar, and MRI. Recent advancements in Artificial Intelligence have catalyzed research into improving image reconstruction using methods such as reinforcement learning. Finding a cost-effective method could improve accuracy and reduce costs of imaging technology. My research focuses on expanding upon a reinforcement learning method that optimizes sensor placement for image reconstruction. Prior research efforts have yielded a reinforcement learning program to optimize sensor placement if waves pass through the target object unchanged. My research will attempt to expand this model for sound-soft objects, which reflect some of the incoming waves. Preparatory steps include first testing star-shaped objects, which have a finite dimensional representation due to the number of coefficients in the Fourier series representing the radius. This aspect makes star-shape more complex than geometric to construct. After testing star-shaped objects, I will move forward with implementing the sound-soft boundary conditions into the model. Expanding the current reinforcement learning model or creating a new model able to efficiently reconstruct sound-soft objects will enable this program to be a cost-efficient solution in settings where a high-definition image of a sound-soft object is necessary. Many situations in the medical field such as the process of tumor analysis require high resolution reconstruction of domains. Cancer is the second leading cause of death in the United States, with over 600,000 deaths in 2022 (CDC). I hope to find a reinforcement learning algorithm that will enable faster generation of high-definition images with accuracy similar or better than current methods therefore reducing the cost of MRI scans for patients. Lower costs will help potential cancer victims identify tumor growth at an early stage and receive life-saving treatment.

Abstract Name: Expandable Music Recommendation using a Joint Embedding Space

Current music recommendation algorithms use user data to recommend similar songs to other users. This method is prone to cold start, where the model requires initially gathering ample user data. In addition, updating the model requires a training process that grows exponentially with each new song in the database. My research will create a model for music recommendation borrowing methods used in music generation. The premise is for an input paragraph of text detailing aspects of the desired song to produce an existing song with the desired elements. To enable learning of audio given text, the model will utilize a lookup space where points in the space are vectors representing a single song. These song vectors are created by joining a text vector and audio vector, hence the term “joint embedding space”. The distance between two points in the joint embedding space represent the similarity between those songs, with the closest point to the input text point being the recommended song. A music recommendation model created with the proposed method cuts costs for updating, since adding a point to the space is all that is needed. The proposed method also standardizes the recommendation process for other high-quality, specialized media such as videos. Any media that can be represented by text can utilize this method. Therefore, the method of using text data as an intermediate is versatile with promise towards creating a multi-media recommendation system. For example, a music piece can be recommended for an art piece with a caption, for a movie given a summary, or for a book through reviews. A multi-media recommendation system would combine all creative platforms including music, art, and video to allow users to discover new varieties of media and increase exposure for lesser-known artists.

Abstract Name: A Glance into the Origin of Life through the Lens of the DNA Repair Enzyme MutY from the Lost City Metagenomes

I have been studying the DNA repair enzyme MutY found at the Lost City thermal field 3000 feet deep in the Atlantic Ocean with conditions similar to those that may have shaped the origin of life. With no sunlight and very little oxygen, life at the Lost City is driven by chemical transformations in rocks at extremely high levels of pH and temperature. DNA in all organisms strictly follows base pairing rules in which A pairs with T and G pairs with C. We all think of oxygen as beneficial, but it can cause damage to DNA. Oxidized guanine (OG) violates the base pairing rules and pairs with A. This causes mutations, which can lead to changes in the genetic information. The mutagenic potential of OG was a challenge that had to be solved early in the emergence of DNA-encoded life. The enzyme MutY functions in suppressing mutations and therefore protects us from developing cancer by finding and removing A from OG:A mispairs. In my effort to replicate conditions at the Lost City so as to explore how the DNA repair enzyme MutY evolved to function in this strange environment I need to purify the enzyme. I used DNA cloning to attach the MutY-encoding genes to a soluble bacterial protein called GST that hopefully will make it easier to purify the MutY proteins. Encouragingly, these fusion proteins expressed well in bacteria and appeared to be soluble. I am now exploring different conditions looking for optimal enzyme activity, which I predict to be different from what familiar bacteria can tolerate. Basic science research on how DNA repair enzymes adapted to the strange environment at the Lost City may inform future translational applications to treat and cure cancer and thus ensure a healthy society.

Abstract Name: A Preliminary Study: Harvesting and Storing Electromagnetic Radiation using Animal Blood and Micromagnetic Beads

Electromagnetic (EM) radiation, omnipresent in our surroundings, serves diverse purposes from simple cellular communication to advanced medical treatments and space exploration! Our research explores a preliminary study utilizing laser-trapping, micromagnetic beads, and animal blood for potentially revolutionizing EM energy harvesting and storage. The livestock industry annually generates an excessive 1.4 billion pounds of waste, primarily animal blood, representing a significant environmental concern. By utilizing blood samples from key livestock animals, including sheep, goat, chicken, bovine, turkey, horse, and porcine, our study produces enduring, self-sustaining EM radiation. The experiment involves a 3:1 mixture of animal blood and micromagnetic beads on a depression slide within an infrared laser trap, progressing through two phases: Plasma formation and Star-like radiation. In Plasma formation, exposure to the laser trap induces electric breakdown, ionizing blood cells and micromagnets, forming a dense plasma. The subsequent Star-like radiation phase accelerates the dense plasma, generating intense black-body radiation. The study attains 90-95% radiation energy absorption over 1.5 to 7.5 hours, marking a micro-level advancement in EM harvesting with animal blood. We envision this as a foundational step for macro-level applications like solar

energy harvesting, offering potential benefits for the environment through waste reduction and enhanced safety in the livestock industry.

Abstract Name: Construction of Antibody-Antifungal Protein Hybrids as a potential Drug Against Candida albicans

Candida albicans is a yeast-like fungus commonly found in human bodies in a commensal symbiotic state. It may cause localized superficial infections but it can also cause systemic candidiasis through the bloodstream. Systemic candidiasis is life-threatening and is associated with an extremely high mortality rate, in part due to a lack of effective anti-Candida drugs. With the emergence of drug resistance, there is an urgent need for the development of new drugs. This project proposes to generate anti-Candida antibody-antifungal protein hybrids as a potential drug for candidiasis. The anti-Candida antibody is M1g1, a human recombinant IgG1 antibody previously developed in our lab. The antifungal protein is human chitotriosidase, an enzyme that directly hydrolyzes the fungal chitin. We hypothesize that when M1g1 and chitotriosidase are combined in a hybrid form, the antibody should direct chitotriosidase specifically to C. albicans cells for killing. The gene for M1g1 will be linked to the gene of chitotriosidase, and the gene construct will be verified by DNA sequencing. The gene construct for M1g1-chitotriosidase will be introduced into Chinese hamster ovary cells for expression. M1g1-chitortisisidase hybrid proteins will be subsequently purified and their antifungal properties will be analyzed through a series of tests, such as germ tube inhibition and fungicidal assays. The antifungal hybrid proteins may be a potential alternative to conventional anti-Candida medications.

Abstract Name: Effect of low poly-unsaturated fatty acid diet on Drosophila melanogaster larval development and motility

Fatty acids play a significant role in an animal’s developmental biology and the nervous system. Unsaturated

fatty acids, including monounsaturated fatty acids (MUFA) and polyunsaturated fatty acids (PUFA), have been pivotal in dietary enhancing Drosophila melanogaster behaviors. The omega-3 alpha-linolenic acid (ALA), one example of PUFA, is an essential fat only obtained from diets. In contrast, MUFAs, such as oleic acid (a MUFA), are synthesized by most animals and considered non-essential. Previous unpublished studies in the Dorsten lab have shown that Drosophila melanogaster larvae on diets where the source of PUFA is removed (low PUFA diet) display slower crawling speeds than those raised in diets with sufficient PUFA (high PUFA diet). Hence, we continued to confirm the Drosophila melanogaster crawling defects by conducting crawling assay experiments, measuring larval body weight, and calculating percent pupal recovery. In assaying the crawling experiments, we recorded the distance the larvae in various diets had crossed and the frequency of pause-turns during larvae crawling traces, which were then analyzed manually or through Python coding. Although the final results illustrated no significant defects in Drosophila melanogaster larvae crawling behaviors between low PUFA diets and high PUFA diets, we were able to demonstrate the mechanism of adding more MUFA or Omega-3 would benefit Drosophila melanogaster larvae from crawling faster. Further conclusions for no crawling defects could be reduced straight-line crawling speed, developmental delays resulting in smaller larvae, or alternations in other crawling behaviors. Our future work should include applying tracking software to measure and calculate animal traveled distance and speed precisely. We want to investigate the Drosophila melanogaster eclosion rate and percentage of pupal lethality for data authority in larval developmental delays.

Abstract Name: Visual Perception of the Classical Orders: Eye-tracking Simulations on the Orders

I am studying architectural column orders and how they are interpreted by the average person. I chose this because I want to learn how people are drawn to the orders when looking at them so I may better understand the orders themselves, and how the world perceives them without an in-depth knowledge or understanding of their composition. I will be doing a comparison of three column orders via eye-tracking software. These consist of the doric, ionic, and corinthian orders. First, I will use the eye-tracking software over an image of each column capital on its own, afterwards I will run it again with all three images side-by-side. This process will help us discover which column order is preferred by the human eye, and why. I believe by doing these two comparisons we will learn which column order will draw the eye of its viewers, and how in-depth someone might look at the detailing of the capitals. I anticipate that the corinthian order may draw the most attention due to the higher level of detailing this capital contains. As a designer it is important to learn and understand what the human experience and interaction is with a building's design. To understand what your viewers prefer and how it makes them feel is important in the world of architecture. An architect doesn’t design for themselves, they design for others of the world, and thus, it is important to understand why people enjoy a certain amount of detailing, or proportionality. Although I’ve sampled at a small scale, it shows that there’s room for expansion into other aspects of design. I hope that through this research we can better understand why the classical orders are important to have in the world of design today and how they impact design in our world today.

Abstract Name: Talking About Death: Exploring How Attitudes Towards Death Influence Our Openness and Honesty in Discussing Mortality

This study aims to expand our knowledge of death attitudes as they correlate with willingness to be open and honest about death. We have recognized that the topic of death and dying is taboo in America, which often leads to people avoiding these important end-of-life discussions. We hypothesize that individuals who have more fear and avoidance of the subject of death would demonstrate lower levels of openness and honesty in discussing it. In total 243 respondents with an average age of 30.54 completed the anonymous online survey. We also assessed their gender, religion, and religious level, the latter of which was measured on a five-point scale with an average of 2.91. Included in the survey was the already established Death Attitudes Profile-Revised questionnaire, which measured levels of fear, avoidance, and acceptance. We also created a Willingness to Lie About Death scale of our own for this study. With the information collected, we wanted to determine if individuals with more negative attitudes toward death would be willing to lie about it, and for what reasons. This research aims to contribute to understanding the barriers to discussing death and the impact of insufficient education.

Abstract Name: Determining the Labeling Accuracy of Nicotine Content Across U.S. E-Cigarette Manufacturers Using HPLC and GCMS

The popularity of nicotine usage, especially among adolescents, is increasing. However, studies have shown that the labeling of nicotine content on e-cigarette products is often inaccurate. Some products contain higher levels of nicotine than stated on the label, while others have lower levels. Due to the lack of FDA regulation on e-cigarette products, manufacturers in the U.S. are not held accountable for accurately disclosing nicotine content. This project aims to investigate whether the nicotine levels reported on e-cigarette labels align with experimental findings. Implementing regulation in this area can ensure trust between e-cigarette users and U.S. manufacturers.

Abstract Name: Examining Felony Disenfranchisement: A Tripartite Ethical Analysis through Consequentialism, Deontology, and Ethics of Care

This paper considers the ethical implications of felony disenfranchisement through several ethical lenses, including consequentialism, deontology, and the ethics of care. After reviewing literature on criminal law and philosophy, I contend that felony disenfranchisement is morally impermissible and serves as a punitive mechanism. A critical analysis reveals that consequentialist frameworks often fail to justify the burdens imposed on offenders, neglecting their autonomy. Similarly, deontological perspectives find felony disenfranchisement to be unethical, deeming it a degrading treatment of the guilty and a tool for the benefit of the privileged. This study extends its focus to care ethics, critically evaluating the United States' prison system. Proposing a care-centered approach to justice, I advocate for an alternative to the prevailing retributive system in the US. Throughout the paper, race-related issues associated with felony disenfranchisement will be closely explored, and a nuanced examination of the intricate intersectionality within this complex ethical dilemma will be provided.

Abstract Name: Development of Novel Camera Trap System to Monitor Hymenoptera

Monitoring of native bees has significant importance as populations continue to decline, primarily as the result of exposure to pesticides, habitat fragmentation, climate change, and the introduction of non-native plant and bee species. Pan trapping is one of the most commonly used methods for monitoring in the field because it requires little labor, collects samples passively, and is cost effective. However, biases impose important limitations on pan trapping data. Pollinators captured by pan traps are often smaller which could skew statistical analyses and interpretation. In the present study, camera monitoring was done in direct comparison to pan traps to determine the viability of a non-destructive and potentially less-biased form of collection in the field. Initially, no significant difference was noted in the collection of Hymenoptera. As testing continues with improved trap designs deployed into the field, a continued trend of comparable Hymenoptera catch between methods and insight into genera richness may be seen.

Abstract Name: Navigating the Mediterranean: A Comprehensive Analysis of Refugee Health

Objective: This research explores the complex challenges affecting the health of refugees in the Mediterranean region. Background: To grasp the nexus between refugees and health, it is crucial to examine the roots of these issues. Refugees often grapple with trauma, leading to mental health issues, while language

barriers and financial constraints impede healthcare access. Crowded living conditions elevate the risk of infectious diseases, reproductive health challenges, and potential worsening of chronic diseases. Issues related to vaccination and preventive care further compound health concerns. Legal frameworks, cultural competence, and collaborative efforts by governments, NGOs, and international agencies are vital in addressing refugee health challenges. The study investigates the adverse impacts of migration, congested camps, and trauma on refugees' physical and mental well-being. Methods: Utilizing a comprehensive causal theory model, the research includes a literature review, network analysis, and synthesis of key factors affecting refugee well-being. Results: Examining migration routes, the study analyzes health risks during perilous sea and land journeys, considering the impact on fatigue, malnutrition, and exposure to harsh conditions. Host country factors, such as healthcare access and social integration, are explored, along with the role of humanitarian aid and health policies. Emphasizing healthcare infrastructure's significance, including capacity, resources, and cultural competence, the research delves into individual and community resilience, exploring coping mechanisms and support networks to mitigate trauma and enhance mental well-being. By synthesizing these elements, the research aims to comprehensively understand factors influencing refugee health around the Mediterranean. Discussion: The literature review and network analysis provide nuanced insights into the challenges faced by refugees, contributing valuable information for policymakers, healthcare professionals, and humanitarian organizations working to improve the health of displaced populations in the region.

Abstract Name: "Harmony in Radiance: Designing an Accessible Home Inspired by the Northern Lights"

This project addresses challenges unique to individuals with retinitis pigmentosa, a degenerative visual impairment. The symptoms of retinitis pigmentosa, which include night blindness, tunnel vision, and light sensitivity, can be reduced by custom-made solutions, including tactile pathways, non-glare surfaces, and smart home systems. Accessibility, ease of travel, and sensory pleasure are enhanced by creating an indoor garden and clearly marked pathways. Inspired by the northern lights, the project merges accessibility features with sensory design elements, aiming to contribute to the inclusive house design. Understanding how individuals with retinitis pigmentosa interact with their environment, the study seeks to create solutions tailored to their unique visual needs, potentially involving lighting, sound, and other design elements to enhance navigation.This project's relevance stems from the increasing awareness of inclusive design practices and understanding of the built environment on the well-being of individuals with vision impairment. Expert insights from meeting with a specialist of the non-profit organization that provides vision services to people who are blind or have low vision, Sandy Wright, enriched this project's outcomes. This project aims to design a single-detached family home, adopting a qualitative approach emphasizing a user-centric perspective and analyzing observed phenomena in accessible housing projects.Anticipated outcomes encompass design principles and recommendations specifically tailored to the needs of individuals with retinitis pigmentosa. Through design solutions inspired by the Northern Lights, this inclusive home environment addresses a family's needs while prioritizing accessibility, safety, and sensory experiences, especially for a family with a member's visual impairment, leading to an improved quality of life and a serene retreat in Anchorage that reflects their diverse travels. In summary, this research project aims to contribute actionable insights for developing accessible and sensory-rich homes for individuals with retinitis pigmentosa.

Abstract Name: Negative Implications in Meaningful Work. A Latent Profile Analysis of Meaning and Well-Being Among Nurses.

Meaningful work is key to improving and maintaining well-being among workers. However, a small but supportive amount of research has shown that meaningful work may not always result in positive outcomes, suggesting potential negative implications by acting as a “double-edged sword” to well-being. In this study, we propose to identify distinct profiles based on the perceived meaningful work, work engagement, subjective well-being, and emotional exhaustion among nurses. We sampled 380 nursing staff from the US and collected the data using a Qualtrics Panel. Most of the participants were women (77.6%) and were working primarily in a hospital (55.3%) in the private sector (47.4%). We employed Latent Profile Analysis (LPA) as the methodological framework to identify distinct profiles within our sample based on selected continuous variables. In our analysis, we consider participants' responses to meaningful work, work engagement, subjective well-being, and emotional exhaustion. The LPA showed four profiles, of which two presented a distinct pattern of emotional exhaustion regardless of their well-being scores. Profile 1 showed workers with high meaningful work, work engagement and subjective well-being, and low levels of emotional exhaustion. Profile 2 shows workers with above-average meaningful work, work engagement, subjective well-being, and higher levels of emotional exhaustion. One-way analysis of variance (ANOVA) post hoc test showed non-significant differences in meaning, work engagement, and subjective well-being between both profiles; however, Profile 1 showed significantly lower emotional exhaustion ($M = 2.20$, $SD = .814$) compared to Profile 2 ($M = 5.50$, $SD = .769$). These findings indicate that workers with highly meaningful work can experience emotional exhaustion and suggest that meaningful work can bring forth a series of consequences to the individual’s well-being. Additional research to understand the mechanisms that explain this pattern is needed.

Abstract Name: Domain-Specific Transfer Learning for Diabetic Retinopathy Classification in Resource-Constrained Settings

Background. Diabetic Retinopathy (DR) is a leading cause of vision impairment and blindness among diabetic individuals worldwide. DR diagnosis still relies heavily on the manual examination of retinal images by ophthalmologists and can be prone to observer bias; hence, automation is highly desirable. With the success of deep learning methodologies in various medical imaging tasks, data availability remains a key issue, especially in resource-constrained settings. Therefore, we propose a domain-specific transfer learning technique for limited datasets used for robust and accurate DR classification.Methods. Utilized the EyePACS database (n=5,000) of retinal images split between 4 classes (Normal, Mild, Moderate, and Severe). Applied advanced data augmentation techniques like rotations, random scaling, cropping, and random noise addition. Three DenseNet121 architecture variants were trained and adapted for multi-class classification: a baseline

model without pre-training, a model pre-trained on the ImageNet database, and another pre-trained on a chest X-ray (CXR) dataset. Rigorous hyperparameter tuning and 5-fold cross-validation were conducted to optimize the model's performance. Results. The performance of each model variant was evaluated using Area Under the Curve (AUC) metrics. Preliminary findings suggest that the model pre-trained on CXR data demonstrated superior performance, achieving an AUC of 92%, which indicates the viability of domain-specific transfer learning in scenarios with limited medical image data. The model pre-trained on Imagenet, and the model with no pre-training had an AUC of 84% and 72%, respectively. In comparison, state-of-the-art (SOTA) models trained with 30,000 images achieved an average AUC of 94%. Conclusions. Our results confirm the efficacy of domain-specific transfer learning in the robust classification of DR, especially when limited by data. Taking a significant step towards automated and reliable DR diagnosis in resource-constrained settings and setting the stage for broader applications of domain-specific transfer learning in medical imaging.

Abstract Name: Deep Learning-Based Natural Language Processing for Classification of Renal Surgical Pathology Outcomes in a Multi-Site Dataset

Background Accurate classification of pathology is essential for guiding clinical care and measuring patient outcomes. Natural language processing (NLP) can automate the analysis of medical data, including pathology reports. In this study, we developed and evaluated a deep learning-based NLP framework on a multi-site database to accurately classify renal surgical pathology outcomes as benign, indeterminate, or malignant. Methods We utilized a multi-channel convolutional neural network (CNN) model for the classification task. The model was trained on 688 renal surgical pathology reports from three different health systems in the state. The reports were labeled by two radiologists with 10 and 14 years of experience, respectively. The four labels used were: “malignant,” “indeterminate,” “benign,” and “ignore” (n = 140, 51, 192, and 305, respectively). “Ignore” was used to indicate cytopathology, urinalysis/urine cultures, or any other pathology not specifically from a mass lesion in the kidney. Only the summary text from each pathology report was used and tokenized. The model was validated using a 20% holdout validation sample using 10-fold cross-validation and evaluated using cross-entropy loss. Results We achieved an average validation accuracy of 83.67% across all the folds. The model was also evaluated on precision, recall, and F1 score. The model is generalized and robust over all three sites and does not exhibit any site bias. The model performance was best in the "ignore" class while suffering in the "indeterminate" class due to class imbalances in the dataset. Performance in the classification of “malignant” and “benign” classes remained consistent through each fold. Conclusion The proposed framework will not only improve the efficiency and consistency of renal pathology assessment but also have the potential to uncover novel insights and correlations within the dataset. Also, automated pathology data can be correlated with radiology reports in order to map imaging features with patient outcomes.

Abstract Name: Estimating Virus-Host Encounter Rates Using Mass Action vs Agent Based Modeling

Viral lysis of microbes is a leading cause of microbial death. Lysis is commonly modeled using the Mass Action term, where encounters are proportional to the products of host and viral densities, despite it not being validated empirically or theoretically. To assess the validity of Mass Action in modeling virus-host encounter rates, we implemented dynamical models using ODEs and agent based models to determine if it accurately estimates virus and host encounters. Doing so, we found that Mass Action overestimates encounters between virus and host populations by nine orders of magnitude (i.e.1,000,000,000 fold). Further, we found that implementing models without the Mass Action term leads to stability of both hosts and viral populations while including Mass Action leads to oscillations and collapses within the populations. Altogether, this suggests that the Mass Action term is logically problematic and may not reflect findings in the empirical world.

Abstract Name: The Effect of Social Media on Interpersonal Communication

The purpose of this project was to provide insight into the effect of the internet and social media on the interpersonal skills of Generation Z. The work is a digital artifact that replaces an essay and is a digital rhetorical argument that was created using Monroe's Motivated Sequence as its organizational structure. Research was acquired through several mediums, including videos, journal articles and scholarly internet articles. These secondary sources all provide context that substantiates the negative effect of an overreliance on social media. For instance, an article written by New York Behavior Health provides statistics that support the claim that increased screen time has eroded the social skills of younger generations. A brief clip from a TedTalk used as the introduction to the project simplifies this claim with the bold statement that "social media is making us unsocial." Finally, an article by Martech Zone provides a brief description of how each generation utilizes technology. The author states that Generation Z primarily uses handheld devices with the goal of making communication more efficient, rather than substantial. These materials are discussed in a creative video format with the purpose of informing a variety of demographics on how increased screen time can result in a decreased desire to communicate in person and can potentially diminish one's mental health. Although it is not the primary focus of the project, the work also encourages mindfulness of the danger of isolation and dependency on external validation. As the developed world becomes increasingly reliant on technology, it is imperative that research be conducted and shared to spread awareness of its effects.

Abstract Name: Alexey Brodovitch and His Influential Career

For this research paper, I was researching Alexey Brodovitch and whether or not he was inflectional as a graphic designer. In the process I learned about his life, how he grew up, what influenced him from a young age, and his journeys. I also was able to gain knowledge on his teaching styles while teaching at the Pennsylvania Museum School of Institutional Art. He pushed students to do their best and wanted them to succeed. He wanted to truly teach them visually instead of just speaking the words into their heads. He would try to be more of a student to them instead of a teacher. Then after that, I went on to learn and write about how he got his job at BAZAAR and how he changed the game. Brodovitch pushed boundaries that were not yet fully pushed in the United States. He brought Eastern art from places like Paris to BAZAAR and even America. He used fun energetic photography and paired it with experimental layouts and type. In doing this he was able to make a visually interesting magazine that people wanted to read. Not only did I learn that he was a teacher and an art director, but he was also a photographer. Most well-known for his Ballet book, he took pictures that were not ordinary stand and shoot. He would purposely make them blurry or high contrast to make them more visually interesting. In my research process one of my main sources that I found helpful was the book by Kerry William Purcell titled “Alexey Brodovitch”. This is a book that provided the most information about his life from start to finish.

Abstract Name: Exploring GdTe1.8 Through Raman Spectroscopy Under High Pressure

Gadolinium Telluride1.8 (GdTe1.8), a type of Rare Earth Chalcogenide, presents intriguing properties under ambient conditions. The non-integer number found for Te atoms signifies the occurrence of some structure defects, which leads to attractive properties. Due to the presence of special f orbital characteristics in Rare Earth Tellurides (RETe), the lanthanide-based compounds are able to display interesting magnetic and optical properties. GdTe1.8, possesses an exclusive 2-D shape that leads to paramagnetic properties at low temperatures while retaining high electrical resistivity. Rare Earth Chalcogenides can undergo pressure-induced changes of the structure which may enhance its properties.The objective of this project is to investigate the behavior of GdTe1.8 at high pressure using a diamond anvil cell (DAC). In a DAC, the sample GdTe1.8 is placed between two opposing diamonds and compressed up to the desired pressure while performing in situ measurements. DAC can be used to generate pressures up to 1,000 Gigapascals (GPa), surpassing Earth's core pressure of 360 GPa. In situ measurements such as Raman spectroscopy can be used due to the transparency of diamonds and the wide range of electromagnetic radiation. By using software T-Rax, Fityk, and Origin, we analyzed the Raman spectra taken during compression of GdTe1.8, identifying peak positions and assessing pressure dependence. GdTe1.8 was compressed up to 53 GPa with a step of 6 GPa. Upon compression, the position of Raman peaks shifts. We detected those movements of 6 Stokes and 5 anti-Stokes peaks. The appearance or disappearance of the peaks indicates the phase change. Our study uncovered two phase transitions below 14 GPa.

Abstract Name: Determining Potential Oxygen Transport Membranes with Hexagonal Perovskites BaFeO3 and BaCoO3

The increase in global warming causing greenhouse emissions caused by the dependence on fossil fuels has led to the demand for cleaner energy. Oxygen Transport Membranes are solid-state membranes that can separate oxygen from complex gas mixtures and an in the process synthesize H2 from the partial oxidation of methane or water splitting. Many different oxides can be OTMs, but the perovskite structure has been shown to be a strong OTM candidate due to its ability to adopt a wide range of chemical compositions. To develop new OTMs, the perovskites, BaFeO3, BaCoO3, and oxygen deficient derivatives will be studied. Through computation of the columbic repulsions throughout the structure, several compounds in these families were determined to support oxygen diffusion. The samples have been synthesized via sol-gel synthesis. The H2 production from the partial oxidation of methane will be measured using a Gasboard 3100 and the oxygen content will be determined via iodimetric titration. In the future the structural changes in these materials as a function of gas atmospheres will be explored via in situ diffraction.

Abstract Name: Structural Studies of Yeast Prion Mot3 using Electron Paramagnetic Resonance Spectroscopy

Prions disrupt normal neural structure, causing a set of neurodegenerative diseases collectively called transmissible spongiform encephalopathies (TSEs) which are characterized by their spongy appearance. TSEs occur in humans, cows, deer, cats, and more, causing diseases such as Creutzfeldt-Jakob Disease (CJD) in humans and Bovine Spongiform Encephalopathy (BSE) in cattle. In our lab, we are using yeast prions as a trackable system due to very similar features to mammalian prions including protein only hypothesis, species barrier, and strain phenomenon. Recent studies have revealed that other amyloid proteins involved in neurodegenerative diseases, such as Aβ in Alzheimer's disease, form a parallel in-register β-sheets. The purpose of this research is to investigate if the Mot3 prion structure also adopts the parallel in-register β-sheet structure via the use of spin labeling and electron paramagnetic resonance (EPR).Using the preliminary data from previous work in the lab, we will use site-directed mutagenesis to introduce cysteine mutations every 20th residue position from 1-295. By attaching spin-label to the residues with cysteine mutations, EPR spectra revealing the strength of intermolecular forces can be generated. The residue is presumably located closer to the amyloid core and is in a region of high order when there is stronger interaction. This process is

repeated for multiple residues across the Mot3 sequence, defining the boundaries of the amyloid core. After obtaining the EPR scans of fibrils at various residues, we will quantitatively compare scans via simulation and the single line ratio, which determines the strength of spin interaction. Stretches with high spin interaction and a periodicity of 2 are consistent with beta sheets, while stretches with low spin interaction are consistent with turns or loops. Current qualitative data suggests high interaction near the 120th residue. Through this method of analysis, Mot3 structure and mode propagation can be proposed.

Abstract Name: Implantable Artificial Kidney Model

The pursuit of an artificial kidney arises from challenges in treating end-stage renal disease (ESRD), where transplantation and dialysis have limitations. The quest aims to offer a sustainable solution, improving patient outcomes and transforming renal replacement therapy. The development process involves breaking down the kidney into components, such as the bioreactor, hemofiltration unit, sensory technology, and biocompatibility. The team focuses on replicating a single nephron initially, which forms the basis for a nephron bundle and, ultimately, the entire artificial kidney. The hemofiltration unit becomes a key component, integrating tangential flow, osmotic pressure, and hydrostatic pressure principles to mimic the natural kidney's filtration mechanism. The team employs CREO Parametric 7.0 for modeling and A/B testing to optimize pore sizes and shapes, simulating blood plasma and waste. The results showcase promising advancements in mimicking the selective filtration process of the human kidney. While facing software and manufacturing limitations, the iterative design process enhances understanding and lays the groundwork for an efficient kidney filtration unit. The project's outlook involves optimizing tangential flow and pressure, evaluating efficiency, and scaling up the model for potential incorporation into a complete artificial kidney design, contributing to the broader goal of curing kidney disease.

Abstract Name: Fabrication of a Composite Polymeric Membrane Made with Green Solvents for Water Filtration

Water filtration via polymeric membranes is one of the most efficient ways to assure access to clean water security. However, most membranes are made with petroleum-derived solvents which can be toxic to work with during fabrication and also have a negative impact on the environment. In the interest of sustainability, research on alternative materials has shown that green solvents such as Rhodiasolv® PolarClean and gamma-valerolactone (GVL) can be used in conjunction with the polymers polysulfone (PSF) and polyvinylidene fluoride (PVDF) to make membranes with high permeability associated with PSF and selectivity of PVDF. The objective of this research is to make a composite membrane using both polymers so that the filter can have the benefits of both. A composite membrane like this has not been made before, as it is difficult to cast the two layers simultaneously due to different viscosities, repulsive charges, and delamination. By characterizing PVDF and PSF membranes separately and then using different casting methods to combine them, a solution to this challenge can be found to cast a composite membrane. PSF and PVDF membranes were characterized by observing the phase inversion rate, diffusivity, water contact angle, pore structure, and permeability. Then, different casting methods were examined, first in lab scale casting with a doctor blade extrusion and then in scale up casting with a slot die coater. It was found that having a similar viscosity and rate of phase inversion aided in making a stable composite membrane. A sustainable composite membrane made of both PVDF and PSF will not sacrifice strength or functionality and will provide the benefits of both a higher flux and selectivity to ensure our future water security.

Abstract Name: The kinematics of Social Distancing

This experimental study aimed to simulate and analyze potential transmission patterns of COVID-19 by utilizing spray bottles filled with liquids of various consistencies. Students of various heights conducted trials by spraying these mixtures onto a sheet of poster paper, emulating potential scenarios of respiratory droplet dispersion. The primary goal was to investigate how the viscosity and consistency of the liquid might influence the spread and dispersion patterns, resembling the potential transmission mechanisms of COVID-19. The study sought to provide valuable insights into how different fluid consistencies could affect the dispersion and surface deposition of respiratory droplets, contributing crucial information to our understanding of viral transmission dynamics.

Abstract Name: The Price of Submission: Exploring Gender Roles and the Violation of Women's Boundaries in "The Husband Stitch"

Sacrificing your liver to satisfy your husband's hunger, allowing the one you love to remove the ribbon that

ties your head to your body, ignoring a madman lurking outside the car as you continue to please your boyfriend; these are some of the elements of horror that Carmen Maria Machado uses in her short story, “The Husband Stitch,” from Her Body and Other Parties to creatively illustrate the ways in which traditional marriage and gender roles pressure women to surrender all boundaries in relationships, resulting in the destruction of their individuality and autonomy. Machado’s “The Husband Stitch” shows the effects of these toxic gender roles by recounting a woman’s life and her relationship with her husband. The woman in the story establishes two rules with her husband, reflecting her bodily and mental autonomy, but as she becomes more intimate with the man he begins to repeatedly challenge and strip away her boundaries. Unable to battle against both the pressure her husband has placed on her and traditional society’s expectations of women, the woman relinquishes her control, which results in her metaphorical death. Machado presents this as a bold retelling of “The Green Ribbon,” while also alluding to other horror stories, such as “Just Delicious” and “The Hook” to unmask the barriers that women face as they attempt to protect their bodies and identities against men while also revealing the toxic culture that allows this behavior. The stories ultimately combine grotesque imagery with everyday events to depict the adverse effects that traditional marriage and gender roles have on women, who, as a result of the pressure placed on them by men, allow their boundaries to be violated and become a shell of their old selves, living in a state of submission comparable to death.

Abstract Name: Susan Kare: Her “Iconic” Accomplishments and Impact on the World of UI/UX

Susan Kare was an early pioneer of 1980s desktop user-interface design through her creative formation of elements, such as icons and typefaces, for the early Macintosh computer. The desktop user interface was a newly developed advancement of the time, where fresh designs were needed for new functions. It is Kare’s designs for these functions that she is best known for. This was due to her talent in both visualizing aspects of function and emotional conveyance, all while keeping her designs simple and comprehensive to the user. She often employed ideas of symbolism or metaphor to achieve this. There were challenges in early icon design and other desktop element design, including the medium itself, pixel-based bitmap format, and how to represent a wide array of functions. In addition, visual accessibility through analysis of elements of design, such as the use of line, had to be prioritized by Kare to ensure that her designs, particularly typefaces in this respect, remained comprehendible. In addition, she had to consider the attitudes of the users she was designing for, which comprised a public where most had little familiarity with the new concept of computers. This led to her prioritization of keeping her designs visually friendly with a welcoming appeal to users. Her designs were a success of the time in conveying this. Her impact is still felt as many of these designs are in continued use in operating systems, such as the modern-day MacOS. In addition, her sense of giving designs a human feel is a concept that has stuck in the UI/UX industry. Therefore, Kare’s wide-reaching work has been and is successful because of the innate creativity she possesses, and her careful consideration of how visual conveyance can reach a wide audience through UI/UX.

Abstract Name: Plasma Temperature Measurements in Argon and Helium Plasma with Nitrogen Addition

Plasma, an ionized gas, manifests in two primary forms: thermal plasma, where electrons and ions coexist at equivalent temperatures, and non-thermal plasma, distinguished by elevated electron temperatures and lower ion temperatures. Specifically, Dielectric Barrier Discharge (DBD) plasma, a subset of non-thermal plasma, arises between two electrodes separated by an insulator, creating charge within the gas particles which results in a plasma plume. Dielectric Barrier Discharge (DBD) plasma has applications in the medical field for healing and sterilization of wounds, through Reactive Oxygen and Nitrogen Species (RONS) reacting with the water in blood to produce Hydrogen Peroxide, which allows for growth factor production. Through the generation of RONS, hydrogen peroxide is formed, allowing for wounds to clot. Since RONS produced from DBD plasma allows for medical wound healing and sterilization, studying the optimum rotational and excitational temperatures of the DBD plasma will maximize wound healing. The addition of Nitrogen addition to Argon plasma and Helium plasma impacts the produced RONS concentration. Analyzing the rotational and vibrational temperatures influenced by Nitrogen's inclusion provides crucial insights into specific emission line variations within the spectra. Employing an Ocean Optics Spectrometer (HR4000CG-UV-NIR) for emission spectra measurement and SpecAir for plasma characterization, this study examines the differences in the behavior of Argon with Nitrogen plasma and Helium with Nitrogen plasma's behavior.The obtained results show notable alterations in temperatures of Nitrogen’s addition to Argon and Helium Plasma at similar operating conditions (13 kV, 40kHz, 16slpm, 0.01%-1% Nitrogen by volume). This presentation aims to expand upon the acquired results and analyze the emission spectra to look at the impact of Nitrogen addition on the two plasma's behavior and emission characteristics. These findings will assist us to understand RONS production in DBD plasmas.

Abstract Name: Absence of Brain Angiogenesis Inhibitor (BAI3) Improves Energy Expenditure in Skeletal Muscle

The Brain angiogenesis inhibitors (BAI1-3) constitute a poorly studied subgroup of the adhesion G-protein coupled receptors (aGPCR) and are implicated in various neuronal and metabolic disorders. Previously, our research revealed that the deletion of BAI3 reduced body weight gain while enhancing whole-body energy expenditure. Additionally, we demonstrated elevated mRNA expression and protein levels of genes associated with energy expenditure in brown adipose tissues. Although muscle significantly contributes to energy expenditure, the impact of BAI3 on the expression of these genes in muscle under obese and lean conditions remains unknown. To investigate this, we utilized tissues isolated from BAI3 whole-body knockout mice fed normal and high fat diet to assess the effect of BAI3 deletion on the mRNA expression of genes—Cpt1a, PPARγ1, PGC1a, Tfam, Ampka1, and HSL—in muscle. This study is ongoing, and our hypothesis posits that the data will indicate an upregulation of genes promoting energy expenditure through increased fatty acid oxidation due to the absence of BAI3. Augmented energy expenditure might contribute in reducing weight gain and lowering susceptibility to metabolic diseases such as obesity and type 2 diabetes.

Abstract Name: Social Media Algorithm Development

This research explores the worrisome side of social media algorithms and how the technical uses of them can both help and hurt us. Concerns about algorithmic influence on public opinion and decision making are discussed, emphasizing the importance of understanding and transparency. Reciprocal relationships between online news consumption, political knowledge, and behavior are examined, highlighting the need to comprehend the interplay between algorithms and news dissemination. The benefits of algorithms are presented, challenging fears and discussing their role in content curation and personalization. The potential impact of algorithms on political speech and news recommendations is explored, raising concerns about filter bubbles and lack of normative standards. The importance of researching algorithms is underscored, focusing on combating fake news through social norms and addressing advertising standards. This paper will emphasize the need for understanding, transparency and further research into how these algorithms are influenced.

Abstract Name: Analysis of Crocin, Picrocrocin, and Safranal Content in Crocus Sativus L. Samples from Iran, Spain, and Morocco

Crocus sativus, a small perennial plant with a height of about 20-30 cm, is native to the Mediterranean and Central Asia regions. Iran, India, Greece, and Morocco are the leading producers of saffron, followed by Spain and Italy. It is primarily cultivated for its highly prized spice called saffron, which is obtained from the dried stigmas of its flowers. The stigmas are carefully handpicked and dried to obtain saffron, which is used as a seasoning and coloring agent in many cuisines worldwide. Extensive studies and ongoing research on the chemistry of C. sativus aim to further explore the plant's chemical composition and potential therapeutic applications. However, due to the high cost and labor-intensive nature of saffron production, research into alternative sources and methods for obtaining saffron's bioactive compounds is also being pursued.The principal components of C. sativus are crocin, picrocrocin, and safranal. In addition to these compounds, C. sativus contains other bioactive compounds such as flavonoids, terpenes, and phenolic acids, contributing to its medicinal properties.Eleven samples of C. sativus flowers from Iran, Morocco, and Spain were examined for the relative composition of saffron's principal components from the stamens of the sample. The dried

petals were extracted with aqueous methanol (70%) and the extracts were subjected to reverse-phase HPLC. The relative composition of the three main compounds was determined for each sample with crocin being the major constituent. Significantly the stamens contained very little of crocin, picrocrocin, and saffranal. The comparative composition will be presented. In addition, the samples are being tested against ESKAPE pathogens to test for antibacterial and antifungal activity. The research is important because it enables the standardization and grading of the C. sativus samples on the market and also explains differences in biological activities.

Abstract Name: Risk Affinity and the Willingness to Forgo Civil Liberties

Civil liberties are the bedrock of Western political culture; so if the factors that lead to the preservation of civil liberty can be determined, it will be a victory for Western democracy. Nevertheless, some people are willing to give up their civil liberties in the name of national security and public safety. Why are some individuals willing to forgo their civil liberties in times of crisis whereas other individuals are not? Forgoing one’s civil liberties in the name of security is a large gamble due to the uncertainty of these liberties being regained. This paper argues that risk affinity is a significant factor that determines individuals' willingness to forgo their civil liberties. Furthermore, risk-acceptant individuals are more willing to wager that their civil liberties will be returned once they are renounced, and risk-averse individuals are less willing to commit to this gamble. To test this hypothesis, I surveyed undergraduate students at a U.S. liberal arts college in 2022 on their willingness to gamble in order to gauge risk affinity and their position on COVID-19 lockdowns, which many view as an infringement upon civil liberties, in order to gauge their willingness to forgo their civil liberties. Then, I compared the results of the survey to see if risk-acceptant individuals were more willing to forgo their civil liberties. I demonstrate that risk-averse individuals are less likely to support COVID-19 lockdowns than risk-neutral or risk-acceptant respondents. These findings suggest that if risk aversion promotes protection of civil liberties, global campaigns can be implemented to educate individuals on the risks of renouncing civil liberties in order to ensure that individuals’ natural rights are not infringed upon and the state does not become too powerful. This paper also details avenues for future research pertaining to individual attitudes toward state measures that curtail civil liberties.

Abstract Name: Developing a Conservation Program Plan for the University of West Florida

The University of West Florida Campus Master Plan 2021-2031 designates over one thousand acres of

undeveloped natural landscape for long-term conservation and sets forth a policy to “establish an environmental stewardship program for the University to follow.” This land is part of the UWF Main Campus in Pensacola, Florida, and home to valuable longleaf pine habitat, a Great Florida Birding Trail, and the largest vascular plant flora of any southeastern university campus. Ongoing activities in these natural areas include academic research, course-related field learning, interdisciplinary events, and recreation. To effectively implement conservation on the UWF Main Campus, it is vital to devise a conservation plan that specifies program goals, management, values, strategies, and projects. This research project addressed the above need by developing a proposed UWF Conservation Program Plan. Diverse research methods were followed to inform the Plan and included reviewing literature, investigating other successful conservation programs, assessing the UWF community’s current relationship with its natural spaces, and consulting experts across multiple relevant disciplines. Major program goals, values, strategies, and projects drew from a synthesis of the Campus Master Plan, best practice found in research, and assessed community needs. The culminating proposal was a written document that considered possibilities such as establishing a formal entity tasked with Program management, development of specific conservation projects, strategies for maintaining community investment, and collaboration with other entities and agencies.

Abstract Name: Probing the Active Site of Guanylurea Hydrolase to Investigate Catalysis and Substrate Specificity

Metformin is one of the most regularly prescribed Type II Diabetes drugs in the world, and its use is likely to expand as diabetes diagnoses rise globally. This drug and its main degradation byproduct, guanylurea, are not fully metabolized by humans and cannot be removed through conventional water treatment processes. These compounds have been detected in coastal waters around the world and are currently considered emerging pollutants. The goal of this research was to examine the catalytic mechanism and substrate specificity of Guanylurea Hydrolase (GuuH), a recently discovered enzyme that converts guanylurea to ammonia and guanidine. Bioinformatic analyses were conducted to predict the active site and three-dimensional structure of GuuH. Site-directed mutagenesis was performed to construct mutants in amino acids predicted to be part of the enzyme’s catalytic triad and substrate binding site. The mutants created were K138R, E211D, and E211N. The wild type and mutant enzymes were purified using His-tag affinity chromatography. Enzyme activity was assessed by measuring ammonia released using Berthelot assays. The results showed that the K138R mutant had similar specific activity compared to the wild type GuuH when reacting with guanylurea, while E211N and E221D showed a low specific activity under the same conditions. All of the enzymes had no detectable activity when reacting with biuret, which suggests they have low affinity for this substrate. Future work will focus on kinetics analyses of the wild type and K138R enzymes and additional mutagenesis to identify the amino acids that determine the substrate specificity to the enzyme. Understanding GuuH's catalytic activity and substrate specificity is essential to use this enzyme in the development of biotechnological applications for water treatment.

Abstract Name: Implications of Hypothyroidism on Reproductive Development in Xenopus laevis

Exposure to propylthiouracil (PTU) is known to induce hypothyroidism in Xenopus laevis, which in turn causes the inhibition of larval to juvenile metamorphosis. The aims of this project, using Xenopus laevis as the model organism—a well-developed model for a variety of systems, processes, and structures—are to determine how PTU exposure affects the gross anatomy of male and female gonads in tadpoles arrested at metamorphosis stage 54 and whether these animals produce sterile or fertile gametes. Xenopus laevis tadpoles at varying stages of metamorphosis (stages 40-45) will be randomly separated into groups: control (no treatment) with replications and treatment (PTU) with replications. The collected data from histology will be analyzed using the one-way ANOVA—similarities of specific male and female structures and gamete development stages—and any possible significant differences will be analyzed with the Tukey test to determine which values differ from each other. The methodology described should yield expected results of structurally underdeveloped and non-functional female gonads and gametes—inhibiting gamete maturation and fertilization. Male gonads are expected to have some functionality, permitting the reproduction and transport of gametes; the male gametes are expected to be slightly developed, specifically with limited sperm motility and general sperm structure.The level of function and ability to successfully reproduce has not yet been studied in these animals. Both normal gonadal development and inhibited gonadal development have been studied, but neither has been compared to the other to determine the exact maturity and level of development in experimental tadpoles. This is the aim of the research project.

Abstract Name: Comparative Analysis of Synthetic Deaminated Kynurenine versus Kynurenine Deaminated via Collision-Induced Dissociation

Kynurenine, a ketone and amino acid derivative, is an important compound to many metabolic processes. As an intermediate compound of the tryptophan catabolic pathway it participates in immune regulation, inflammatory action, and possesses a structure capable of crossing the blood brain barrier leading to important roles in nervous system pathology. It is also an essential compound in the synthesis of photo pigments in many different species. Kynurenine's collision-induced dissociation (CID) fragmentation patterns might serve to characterize other compounds that are synthesized from kynurenine. CID in multiple successive rounds of fragmentation – referred to as MSn – can yield robust structural information. The most abundant CID fragment of kynurenine is deaminated kynurenine. MSn of synthetically deaminated kynurenine showed differences in fragmentation compared to the MSn patterns of kynurenine that had been

deaminated within the mass spectrometer via CID. This study postulates structural dissimilarities based on these fragmentation differences. Additionally, should our syntheses provide sufficient xanthommatin (a chemical synthesized from kynurenine) to effectively deaminate it, CID will be employed to explore both xanthommatin's fragmentation patterns, and its deaminated product - a compound whose structure remains uncharacterized.

Abstract Name: Synthesis of Heterocyclic Biaryl Catechols for the Characterization of Ring-Cleaving Dioxygenase Activity

Non-heme iron (NHI) ring cleaving dioxygenases (RCDs) are important enzymes for the bioremediation of aromatic chemical waste products in the environment. Benzene-derived aromatic molecules are widely used for industrial applications, such as in the synthesis of pharmaceuticals. The enzymes can break open oxidized aromatic substrates to detoxify and break down the materials. However, to achieve broad scale bioremediation, these enzymes must process structurally diverse catechols. We seek to probe the substrate scope of a library of RCDs, aiming to discover and characterize enzymes capable of oxidizing complex heterocyclic biaryl catechols. We have synthesized a variety of diverse biaryl catechols to quantify NHI enzyme activity against these potential substrates. Several biaryl catechols were shown to have activity with enzymes in the library, enabling broader characterization of the substrate scope of these catalysts. We envision that these results will inform future efforts in genome mining or evolution of improved catalysts for bioremediation of aromatic compounds.

Abstract Name: A Systemic Functional Linguistic Analysis of Remote Real Estate Listings

In the aftermath of the Covid-19 pandemic, Canada’s rural population increased faster than in any other G7 country. The province of Newfoundland was a distinct outlier, seeing a 6.4% decrease during the same period, the most drastic drop of all rural Canadian regions. This is no surprise to Newfoundland communities: since the 1992 Cod Moratorium, these populations have faced a continuing period of socioeconomic hardship and decline. While Lynch (2007) traces decades of outmigration from Newfoundland’s rural communities to urban centres, current research does not account for this post-pandemic phenomenon. Newfoundland’s population decline has been analyzed from a linguistic viewpoint, noting a redirection of regional discourse towards a perpetuation of tourism development (Stoddart, 2016). While tourist discourse represents one

apparent strategy for combating population decline, the linguistic implications upon the genre of real estate listings have not been investigated.In an era of increased global mobility and urbanism, this project strives to investigate the linguistic implications of such changes on real estate listings. Drawing upon the theoretical framework of Systemic Functional Linguistics (SFL), this project analyzes the Interpersonal, Experiential, and Textual metafunctions of a 2022 real estate listing from the remote town of Harbour Breton, Newfoundland. As the 2023 Linguistics Global Winner selected by the Global Undergraduate Awards Committee, this project not only strives to demonstrate the analytical value of SFL, but systematically reveals persuasive linguistic choices made by an author as they attempt to attract buyers to a declining rural region. Findings include the frequent use of declarative mood structures, a prevalence of relational attributive processes, and a majority of topical themes relating to the home. These features demonstrate a deliberate saturation of favourable details, and a foregrounding of the home's features above other notable factors (e.g. location, proximity).

Abstract Name: Optimizing BodyPix for the Measure of Body Fat Percentage Readings

Obesity related disease is a leading cause of preventable death not only in the United States, but in other countries where healthcare is less available or affordable. Traditional methods of measuring body fat require professional understanding or expensive equipment. If body fat percentage could be estimated quickly and in a cost-effective manner, users impacted by obesity could more quickly monitor their own health independently of their country's health care systems. Building on other research, which uses deep learning to quickly estimate body fat percentage through pictures, the current research will improve on these methods to create more reliable results. The Navy Body Fat Formula uses the circumferences of a user's neck and waist to calculate BMI, which compared to other methods of BMI calculation, such as bio-electrical impedance scales, is cost effective and accurate. Through AI image segmentation, users will take a picture of their front and side from which a neck and waist circumference can be attained, leading to an accurate BMI calculation. The error will then be based on the estimated BMI and a user's known BMI measured by their general practitioner. The choice was made to use TensorFlow's MobileNet as our body segmentation model since it is efficient enough to run on a user's mobile device, despite being less accurate compared to TensorFlow's ResNet. In order to improve on the work of previous research, optimizations will be made on the image segmentation model used in previous research to continue performance on mobile devices, but allow more accurate predictions. By improving the efficiency and accuracy of BMI calculation, a user's obesity related health information can be obtained almost anywhere with internet and a smartphone making health awareness more accessible.

Abstract Name: Correlation between Instagram Use and Political Apathy Among 2020 Young Adult U.S. Voters

Voter turnout among young adults, aged 18 to 29, have consistently been lower than their older counterparts in the United States. Despite this lack of voting, the engagement over social media through online movements such as Black Lives Matter and Me Too paint a different picture. In order to create a more representative democracy, engagement among young adults should match the engagement of older generations. While the correlation between social media and political apathy - or the distaste for participating in politics - has been previously researched, the impact of certain social media sites like Instagram on U.S. young adults has been overlooked. The current research studied the use of Instagram, and its correlation with political efficacy, apathy, and voter turnout in the 2020 U.S. election. Data was collected through a survey open between January through March of 2021 and asking Likert-scale questions for Instagram use, political engagement, and voting behavior. Through the use of Chi-squared Pearson tests, the correlation between voting, political efficacy, and political apathy was found. To find the correlation between Instagram use and voting rate a sample T-test was also used. The study found no significant correlation between Instagram use and political engagement among young adults. Although the study did not find a significant correlation, it is possible that this was influenced by the insufficient sample of data. In order to fully investigate the impact of social media, a new type of media, on young people's political participation, we believe that there is an urgent need for further research on a wider range of people. This suggests that factors influencing political apathy and voter turnout are more complex and extend beyond social media use.

Abstract Name: Visualizing Star Clusters That Form Within Giant Molecular Clouds

Stars are born in open star clusters when large regions of cold molecular gas and dust in space, giant molecular clouds (GMCs), meet a density threshold for star formation. By looking at simulations of GMCs, the relationship between these clouds and open star clusters can be determined. We used both the Friends-Of-Friends (FOF) Python code and developed our own visualization package to easily and clearly see individual GMCs and the star clusters that form inside of them. In this work, we present our analysis run on FIRE-2 (Feedback In Realistic Environments) galaxy simulations from the Latte suite of Milky Way-like galaxies. We started with one galaxy and focused on visualizing one GMC at one particular moment in time. Then we generated multiple images of the same GMC over time to track the full evolution of the gas and the star cluster that formed within it. We hope to make this code accessible and available for the astrophysics community to use in the future. With this data, we can form a deeper understanding of the influence of Galactic structure and its environment on the formation of star clusters.

Abstract Name: Mapping Affordable Housing: Advancing Lafayette's Housing Stability through Automated Data Integration and Analysis

Since 2010, the city of Lafayette, Indiana has identified higher than average levels of homelessness, eviction rates, and transiency among the six neighborhoods: Lincoln, Hanna, Vinton, Monon, St. Lawrence McAllister, and Historic Jefferson. One of the largest causes attributed to these city detriments is a lack of affordable housing. The U.S. Department of Housing and Urban Development defines affordable housing as necessitating occupants to allocate no more than 30 percent of their gross monthly income towards housing costs, including utilities (1). In an earlier phase of this ongoing research initiative, another group of Purdue undergraduate researchers developed processes to identify unaffordability in the aforementioned neighborhoods. However, the frameworks developed in these studies lacked the ability to provide continuous and accurate data to the city, highlighting the clear need for a regularly updated system. The future stability of these neighborhoods now hangs in question, with permanent residency retention reaching an unprecedented low. Without regularly updated housing information, the city risks prolonged economic instability. As a community partner responding to the City of Lafayette's need for an automated solution, the team proposed the development of an interactive heatmap. Affordability metrics are to be collected by comparing HMDA mortgage data against the Polk Directory's income data for each identified neighborhood. Data storage and manipulation are to be streamlined between a SQLite database and Python's extensive data analysis libraries like Pandas and Seaborn. Map creation will be facilitated through the GoogleAPI, allowing granular geographic visuals for Lafayette community leaders. By leveraging the heatmap alongside additional resources, our research initiative provides Lafayette with powerful tools for informed decision-making on affordable housing efforts. With the affordability threshold at 30%, our methodology offers a strategic framework for Lafayette to identify and create more accessible housing solutions for the citizens of these neighborhoods.

Abstract Name: Investigation of Cytosine and Isocytosine Analogs as DNA Binding Agents

During ordinary biological processes such as DNA transcription or DNA replication, double-stranded DNA must unravel into its single strand. During this unraveling processes, these single strands undergo supercoiling and can form secondary structures. Regions that are primarily guanine rich can self-associate to form a secondary structure called the G-quadruplex, and its complementary cytosine rich strand can self-

associate to form another secondary structure known as the i-Motif. The targeting of these secondary structures have drawn great interest over the recent years due to their presence in oncogenes. More reserach have been dedicated to the G-quadruplex with the i-motif recently gaining more recognition. Small organic compounds have been synthesized and act as binding agents to stabilizes the i-motif, but none utilize compounds with cytosine or isocytosine as its base core. Herein, the syntheses, characterizations, and calculated binding energies of bisguanidynlated 1-methylcytosine and guanidynlated 6-hydroxyisocytosine with all nucleobases are presented. Density functional theory (DFT) calculations were utilized to calculate and predict stable protonation sites and binding orientations of bisguanidynlated 1-methylcytosine and guanidynlated 6-hydroxyisocytosine with DNA nucleobases. These compounds have been shown to significantly increase in DNA melting temperatures of both telomeric and hypoxia-inducible factor 1 (HIF-1α) DNA sequences.

Abstract Name: Examining the Role of Familial and Social Factors in Promoting Resilience Among Children, Parents, and Adult Migrants

The process of migration and subsequent events following immigration influence the mental health and overall well-being of migrants. Migration, as a social determinant of health, can expose migrants to a diverse range of factors that can influence their health outcomes. Previous research has primarily relied on cross-sectional studies that compare the rural-to-urban migrant experience or the mental health of migrant children to their peers, highlighting a detrimental impact on migrant health. Contrary to what can often be assumed, the migration experience can also provide multiple protective factors for children and adult migrants. However, there is a lack of evidence on what factors may promote mental health and resilience among migrants. Using community-based participatory research methods, this qualitative study investigated experiences of migration, mental health, and resilience. Semi-structured focus groups and interviews were carried out with a purposive sample of migrant children, their parents, and adult migrants. Recordings were transcribed and analyzed using thematic analysis and an ecological framework. Individual-level themes, including social and familial connection, emerged as promoters of resilience among migrants. Specifically, participants detailed how connections with friends and relatives enabled them to persevere through several challenges. Key findings across 24 participants highlight the pivotal role of familial relationships in fostering resilience among children and parents navigating the complexities of migration. The significance of support networks, cultural adaptation, and adaptive coping mechanisms promote resilience across generations. Additionally, this study identifies nuances in the experiences of different family members, shedding light on how varying sociocultural contexts impact individual resilience within the family unit.

Abstract Name: The Relationship between Hyperglycemia Following Traumatic Brain Injury and Depression

Traumatic brain injury (TBI) may result in mortality as well as long-term mental and physical changes. Such changes may include depression, one of the most prevalent psychological disorders, and hyperglycemia. Hyperglycemia, or high blood sugar, is a common occurrence following a stressful or traumatic event. Additionally, prolonged episodes of hyperglycemia may lead to diabetes. Part of the treatment process following TBI includes lowering glucose levels to a normally accepted range. However, previous studies regarding optimal glucose levels and health outcomes following TBI have been contradicting, with some associating hyperglycemia with poor outcomes, while others indicate that some level of controlled hyperglycemia may pose benefits. The current study is utilizing the TBIMS National Database to examine the relationship between hyperglycemia, measured through diabetes onset following moderate or severe TBI, and depression. Participants (n = 275, White = 68.36%, African American = 18.91% Hispanic = 11.27%, Asian = 4.00%, Native American = 1.82%, Pacific Islander or Native Hawaiian = 1.09%, 69.5% Male) were diagnosed with diabetes (Type 1 or Type 2) either before, same time as, or 1 year, 5 years, or 10 years post-TBI. Depression scores were assessed using the Patient Health Questionnaire-9 (PHQ-9). Additionally, all participants were above the age of 16. A one-way between-SS ANOVA was conducted to assess if there is a difference in PHQ9 scores across time of diabetes diagnosis in participants. Results showed no significant difference in PHQ9 scores across time of diagnosis, $F(4, 270) = 0.33$, $p = .860$, $\eta 2 = .01$. Depression may not show immediately after diagnosis, therefore future studies should examine depression over time. Additionally, future studies should explore differences in glucose levels, as the database did not have a glucose measure. Furthermore, the database does not have data on mild TBI, but all participants received TBIs severe enough to require hospitalization and physical rehabilitation.

Abstract Name: Detecting Elusive Exosomes in Various Bacterial Strains

Exosomes are emerging as promising candidates for future diagnostic tools in disease detection due to their ability to carry disease-specific cargo. By isolating exosomes from various bacterial strains, researchers can explore the unique cargo carried by these vesicles, which may contain biomarkers indicative of the presence of specific diseases. This innovative approach could offer a non-invasive and highly sensitive method for early disease detection. This study aimed to isolate exosomes from various bacterial strains using diverse methodologies. The research involved multiple techniques, including the use of bacterial growth media such as terrific broth to enhance exosome production, concentration of media, and affinity/size exclusion chromatography techniques. Manual and automatic chromatography processes were conducted to isolate exosomes effectively. To confirm the presence of exosomes and their cargo, the study utilized protein

analysis and nano particle tracking analysis (NTA). These analyses helped validate the isolation process and provided insights into the characteristics of the exosomes. It was confirmed through the aforementioned techniques that bacterial exosomes are present in culture mediums, as well as in raw bovine milk. Confirmation was done through SDS-Page where exosome signals were found to be clear on milk, while signals for the concentrated bacterial mediums were found to be low to none. In conclusion, this study investigates diverse methods for isolating exosomes from different bacterial strains and verifies their presence and cargo through protein analysis and NTA. The findings hold promise for the future development of diagnostic tools that rely on exosome-based biomarkers, potentially revolutionizing disease detection and monitoring.

Abstract Name: Contributing Factors to Natural Human Mummification

Natural mummification is known to occur in a diverse range of global locations throughout time, including in temperate climates. This stage of decomposition can have important impacts on determining the post-mortem interval (PMI) of a set of remains by forensic specialists. However, the factors that contribute to natural mummification remain poorly understood in current literature. This lack of understanding has reflected itself in such instances, as reported in Volume 206 of the Forensic Science International Journal (Schotsmans et al. 2011), where a man's partially mummified remains were found in a shallow grave in Belgium during spring. The PMI was unable to be determined by forensic experts due to the lack of typical evidence such as the body itself or entomological specimens on or surrounding the deceased. Cases such as this prove the need for additional research into the study of natural mummification. This study will review previous literature to assess what variables appear to contribute to natural mummification in relation to the decomposition process. It will examine where reported rates of natural mummification are known to occur and hypothesize what factors may lead to natural mummification. Once identified, these variables will be evaluated to see if they can be subjected to further experimentation to help answer how and why mummification occurs in such a wide variety of climates, including, specifically, the temperate climate of western North Carolina. This research will provide new information to the field of human taphonomy concerning mummification patterns. It will serve as an important step in better understanding the factors that contribute to the widely observed phenomenon of natural mummification, which may one day lead to more refined methods for estimating PMI when mummification is observed.

Abstract Name: Correlation Between Composition and Mechanical Properties of Dental Filling Materials

Objective: Tooth colored dental filling materials (resin composites) are composed of filler particles and a resin matrix to bind it together. The filler particles are claimed to increase strength and decrease its shrinkage (an undesirable property). This study aimed to test that correlation.Methodology: Nineteen commercially available dental composites were included in the study. Filler percentage by weight (n=5) was determined by burning the resin and weighing the residual filler particle (800°C for 15 minutes). Three-point bend flexural strength and modulus (n=10) were measured by making 2x2x25mm bars of composite in a ISO specified mold. The bars were fractured in a Universal Testing Machine. Shrinkage stress (n=8) was evaluated using a testing machine in which composite was bonded to and light polymerized through two transparent acrylic rods (diameter = 6.45mm). The maximum force applied to the acrylic rods was measured (following 500 seconds) and divided by the surface area of the rod to determine shrinkage stress. Linear correlation between mean filler weight percentage, flexural strength, modulus, and shrinkage stress were measured by Pearson's correlation coefficient using statistical analysis software.Results: The Pearson's correlation coefficient determined that there is a positive linear correlation between filler weight percentage and both flexural strength (r=0.70 p<.01) and modulus (r=0.85 p<0.01) but not shrinkage stress (r=-0.14 p=0.54).Conclusion: Filler weight percentage is a good indicator of the stiffness (modulus) and flexural strength of a resin composite. Shrinkage stress may not be determined solely based on filler weight percentage.

Abstract Name: Translanguaging in the classroom: Unveiling the power of multilingualism

Using a sociocultural lens, this paper examines the practice and use of second languages in pedagogy. Due to the increasing diversity in the world, we will look at multilingual learning education, more specifically translanguaging behaviors in pedagogy. Literature suggests that translanguaging is not just beneficial, but also fundamental for rich learning outcomes. As well as the sustainability of cultural identity. Although Dual Language (DL) has shown good results, English Learners (EL) are the less likely to graduate college and receive unequal instruction in areas of study in Science, Technology, Engineering and Mathematics (STEM). Literature propose that educators should not make the focus on language as a deficit but build on their funds of knowledge to make multilingual education an asset for learning and creativity. During this investigation, we observed video recordings of Texas students in dual classroom settings, Bilingual Teacher Candidates (BTC), and mentor Teachers. We also look at how the adaptation of this multilingual pedagogy, could leverage these inequalities in minority students in higher education, more specifically STEM disciplines. We observed classroom instruction and interaction between students and teachers, transcribed these videos, and analyzed the instances in which students, and teachers, engaged in translanguaging behaviors. To analyze the discourse, we applied thematic analysis to identify patterns and themes. Based on the data, we identified three main themes: student reciprocity, recall of learned concepts, and group collaboration. Hence, this paper focused on the behavior of translanguaging in a real classroom setting, investigating when and how students use translanguaging.

Abstract Name: Development of an in-vitro Model with Controlled Stiffness to Study Adipogenesis

The extracellular matrix (ECM) is a three-dimensional, multicellular network composed of proteins such as collagen that characterizes cells' fundamental properties and behavior. One of these properties is stiffness, which has been proven to play a role in stimulating stem cell differentiation and tumorigenesis. In obesity, research has shown that ECM stiffness increases drastically, however, there is minimal information on how this change affects adipogenesis. This study works on optimizing the characteristics of polyacrylamide (PA) gels to create an in vitro model of controlled stiffness to understand its effects on mouse adipose-derived stem cell (mADSC) culturing.For this, a mixture of acrylamide and bis-acrylamide is made using varying concentrations to make the hydrogels. The gels are then coated with collagen in preparation for cell attachment. Human and mouse adipose-derived stem cells were seeded in the different stiffness PA gels, to observe attachment on coated gels. The cells are then cultured for two weeks with media changes every other day to ensure cellular adaptation.The Young Modulus was measured using the compression tester: Mach-1TM Mechanical Testing System. Analysis of the gels showed a consistent range of young modulus with the flexible gels having an average of 3.58 kPa and 7.29 kPa, and stiffer gels having an average of 76.03 kPa. Microscopic images showed human and mouse ADSC were able to attach and grow on top of the coated gels of different stiffness. Preliminary findings show a higher expression of integrins adiponectin, UCP1, and PPRG by hADSC seeded in 7 kPa range gels. Further analysis must be performed to elucidate the effects on the differentiation of brown and white adipocytes with varying stiffness.

Abstract Name: Latinos in Education. Bridging the Gap: A comprehensive Exploration of Educational Inequity faced by Latinos in the United States from Historical Struggles to Current Challenges

Latinos, the largest and fastest-growing minority group in the United States, face a striking disparity in college completion rates, with only 15% attaining a bachelor's degree or higher. The perplexing question arises: why is this the case? Latinos encounter unique challenges in the educational landscape, struggling more than their English-speaking counterparts. A primary hurdle lies in the lack of resources tailored to non-English-speaking students and their families, compounded by barriers related to immigration status, economic factors, and other obstacles hindering their pursuit of higher education. Latinos, representing diverse Latin American origins, including Mexico, South and Central America, and Brazil, grapple with systemic issues spanning the pre-20th century to the 21st century. This research seeks to explore essential changes needed in the current school curriculum to bolster Latino representation in higher education, addressing cultural, historical, and academic needs. It aims to uncover how the curriculum can be enhanced

to better support the educational journey of Latino students, tackling three central themes: school segregation, language, and economic barriers, along with the challenges posed by undocumented status.

Abstract Name: Regional Differences of Stress-Induced Increase in Intestinal Permeability

Intestinal epithelial permeability has been proven to be impaired by stress, which contributes to conditions such as irritable bowel syndrome (IBS). Despite this finding, regional differences in epithelial permeability along the intestinal tract and their responses to stress have yet to be explored. Male and female mice were utilized to compare the regional permeability differences amongst sex and their responses to stress. Mice in the stressed groups were placed in restrainers for one hour per day for five days as a form of stress. Control mice remained in their primary cage without undergoing restraint stress. Following the last stress/control session, the duodenum, jejunum, ileum, proximal colon, and distal colon were removed, and the mucosa/submucosa preparations were mounted onto the Ussing Chamber System. Transepithelial resistance (TER) was recorded as a measurement of paracellular permeability. FITC-insulin (4kD) and horseradish peroxidase (HRP, 40 kD) were added to the luminal chamber, and the flux rates from luminal to basolateral side were used to assess the paracellular and transcellular permeability, respectively. Stress resulted in a significant decrease in TER only in the distal colon of male and female mice. FITC-insulin flux rate remained unaffected by stress in male mice; however, significantly increased in the distal colon of the stressed female mice in comparison to the control females. HRP flux rate was significantly increased in the proximal colon of the stressed male, while showing no significant effect of stress on the female intestinal tract. The results suggest that the epithelial layer in the large intestine is more vulnerable to stress compared to the small intestine, and male and female mice respond differently to stress. Aiming toward the specific regions impacted by stress may aid in the creation of regional specific medications that more specifically target IBS or other stress related gut problems.

Abstract Name: Words Speak Louder Than Actions: How National Leaders Use Rhetoric to Frame the Issues of National Security and the War on Drugs

In the preamble of the 2024 presidential election seasons in both the United States and Mexico, there has been an increase in aggressive outspoken expression by national leaders regarding how to best handle the

issue of drugs and drug use across the hemisphere. These types of sweeping policies are often credited to President Richard Nixon, who on June 18th, 1971 initiated his “War on Drugs,” a global policy campaign intended to address the production, distribution, and consumption of the illicit drug trade. Existing scholarship on this topic has extensively analyzed the early years of the American war on drugs during the Nixon administration and the institutionalizing effects of the “drug problem,” however, there is a gap of knowledge covering sanctions of administrative strategies between 1992-2012, specifically any analysis on the power of the presidential rhetoric and, consequently, its influence on setting the agenda for domestic/foreign drug policy between the U.S. and Mexico. Drug control is an enduring and evolving issue, with the presidential rhetoric surrounding narcotics constantly shifting to adapt to the political climate and to define social reality for its citizens, with the president often merging moral and ethical reasons to establish their constitutional authority and role as a leader. Using critical analysis on archived presidential public statements of Bill Clinton, George W. Bush, Vicente Fox, and Felipe Calderon, along with historical context on narcotic reform in the United States and Mexico, this multi-national research argues that presidents utilize rhetoric in the contemporary war on drugs to shape punitive policy reforms.

Abstract Name: Evaluation of the Family Therapy Program: In This Together (ITT) for Survivors of Domestic Violence

Domestic violence affects one in every four women in the United States. Previous research shows the importance of group therapy for those who have experienced this trauma. The purpose of this study is to evaluate the “In This Together” (ITT) program that takes place in Marin County, CA, through the organization Center For Domestic Peace (C4DP). This quantitative analysis consisted of 10 cohorts, with a total of 65 participants. Eligibility criteria for survivors of domestic violence included being a parent and fluent in English or Spanish. Scaled questions were asked before and after the 10 week ITT therapy program. The questions were based on the Regulating Emotions in Parenting Scale (REPS), and Hope for Parenting Scale (HFPS) measurement tools. By asking participants before and after ITT, it allowed the researchers to measure the impacts of the program. Based on preliminary results, show that on average, individuals who completed the ITT program were better communicators, strengthened their relationships with their children, and felt empowered against their abuser. Both the REPS and HFPS scales were statistically significantly improved after the 10 week therapy program (p>0.05). Further analysis is underway to understand the components of these scales and how those were impacted by ITT. ITT has shown to have impacted participants by improving their parent-child relationship after the trauma of domestic violence. Being more aware of feelings and finding empowerment gives survivors of domestic violence more tools to better their lives in many ways. Implementing ITT into different group therapy settings for other populations who have suffered traumatic experiences is crucial and encouraged.

Abstract Name: The ways a logo is successful

Logo design is one of the most important things a brand or company needs in order to start providing their goods and services to the world. A logo needs to be recognizable and relevant to the market that the business is trying to target. This idea often uses color theory, a study that shows how colors work together and represent emotions and perceptions. For example, warm colors can represent high energy emotions, while cool colors can represent low energy emotions. It is very important for a design to stay consistent and relevant when it comes to logos. What this means is that the design has the same idea or target audience as the years go by. Many companies have been able to achieve this characteristic. From Apple to McDonalds, they have remained the same in terms of their logo design and targeted audience for their products. The most significant visual element is the logo. The logo must show the company's essence. But what makes a logo stand out from other companies? The design needs to have a balance between artistry, inventiveness, and elegance. In order to have a successful logo, a designer needs to challenge themselves to create an image that stands out and has not been done before.

Abstract Name: Lights Out: Mechanization and Metaphors for Worklife

One can hardly play a role in society in which it is not fitting to be busy. Overcommitment is the mark of success; in fact, hustle culture demands what marketable value can be extracted from an unbusy life. My project breaks down the phenomenon of burnout through a metaphorical lens, empowering my audience to reject its hold on us. Partnering with Dr. Sarah Higinbotham, my research into conceptual imperialism and the origins of burnout have led me to conclude that, more than an innocuous metaphor, "burnout" has fundamentally changed the way we see our work (and not for the better). Besides breaking down burnout as a cultural, psychological, and productive phenomenon through a metaphorical lens, I also hope to gain visibility for my own metaphor ("low tide"). By challenging the language surrounding burnout, and proposing an alternative metaphorical angle, I hope to publicly rework a destructive thought pattern into a more life-giving worldview—one I hope will be a step towards recapturing purpose in our lives. To my knowledge, this project is completely original and very timely. Burnout and workplace dissatisfaction are at all-time highs across age groups, and mental health challenges do not discriminate: we all live and work in a culture of chronic stress; one that prioritizes output over the out-putter, equates work with worth, and glorifies toxic busyness. However, my proposal—that a simple paradigm shift, accompanied by a change in language, can significantly improve our outlook on energy expenditure—rejects the conviction that our personal fulfillment relies on blind external forces. At the most basic level, we are responsible for our own well-being; and sometimes that means working against the odds and empowering ourselves to say "no." By flipping the narrative on burnout, we reclaim our power (and our responsibility) to choose how we see the world.

Abstract Name: The Complexities of Online Gambling Addicitons

Gambling has been around for centuries in various cultures and societies, from playing poker to betting on horse races. In this new technological age, gambling has diversified and become more accessible by expanding to online platforms. Unfortunately, online gambling takes the complexities that come with gambling addictions. It essentially amplifies it by taking an intrinsically addictive behavior, gambling, and putting it on an addictive platform, the internet, for even more people to access. Gambling in itself is extremely addictive, and so is participating in activities over phones and computers. The convenience and design of gambling sites and apps are intestinally made so users can easily access wagers and are enticed to do it more often. Regulations on online gambling platforms are not nearly as regulated as casinos or other locations for in-person gambling which introduces the risk of allowing extremely inebriated individuals and minors to access to participate in wagers and bets. The internet permits individuals to anonymously gamble wherever and whenever if they have Wi-Fi and an electronic device. When one gambles at home, they are not being monitored, so they can gamble heavily under the influence of drugs or alcohol which impedes their decision-making skills and emotional regulation. Also, minors are prohibited from doing things such as buying lottery tickets, entering casinos, and more because adults and security are verifying ages and checking IDs. While online gambling sites do check for ages, verification checks online can be easily bypassed so that minors can partake in gambling. All the factors above make gambling even more addictive, but it also is more accessible and appealing. Overall, online gambling raises concerns that deserve more attention because it has the potential to majorly affect the newer generations in a way traditional gambling has before.

Abstract Name: Reducing Pathogenicity of Candida auris Through Biofilm Disruption

Candida auris is an emerging multi-drug resistant hospital acquired pathogen. Candida species are the third most common cause of healthcare related bloodstream infections, with a mortality rate of 30-60%. Candida albicans was previously thought to be the most pathogenic species of its genus. However, new studies have shown that C. auris produces biofilms at 10-fold greater burden than C. albicans on cutaneous surfaces, and exhibits a unique stress resistance profile allowing it to adapt and survive in the skin niche more effectively than other Candida species. Prior work has shown that both filastatin and taurolidine can inhibit C. auris biofilms. In a clinical setting C. auris has shown a strong resistance to fluconazole due to the biofilm the organism produces. In this study porcine skin cultures will be used to test the efficacy of these drugs in inhibiting biofilm formation and possibly cutaneous infection. Biofilm production, as well as infection severity, will be assessed through measuring colony counts and performing electron microscopy. Furthermore, susceptibility testing will be performed using broth dilutions to evaluate if taurolidine and filastatin increase the efficacy of fluconazole. We expect that the use of an intermediary substance which weakens the biofilm, combined with an antimicrobial, will kill the fungus more effectively than an antibiotic

agent alone. We hypothesize that the use of taurolidine and filastatin will inhibit biofilm production and allow fluconazole to inhibit the organism.

Alicia van de Bor

Abstract Name: Women in History Ceramic Dishware

My name is Alicia van de Bor and I am a visual artist. I am making handmade ceramic dishware that celebrates women's achievements throughout history. The feminist movement inspires this body of work, the ongoing struggle for gender equality, and the lack of representation of women in history and the arts. American feminist artist Judy Chicago and her installation The Dinner Party, 1974–79 inspired my work. Each dinnerware set is used as a canvas to depict an inspiring woman and highlight her achievements. I use a red earthenware clay on the pottery wheel, a white slip, and sgraffito an image of each woman. Each piece uses only one color that relates to either the woman or the work she has done. In determining who to research, I ask my audience to provide the name of an inspiring woman in history or the present day. I then researched the proposed woman to learn about her origins and the impact she made. During my research, I have spoken with immigrants and learned about inspiring women from their native countries. For future pieces I plan to create and display a Q.R. code that allows viewers to submit women's names. My plan for this work is to expand the number of women depicted and show them as an installation piece during Women's History Month at the Women's Museum of California in San Diego, California, and the National Museum of Women in the Arts in Washington, D.C. My goal as an artist and with this body of work is to inspire others to learn more about the lives and accomplishments of women throughout history.

Abstract Name: Building an Aquatic Actinomycete Library: Identification and Secondary Metabolite Profiling

Actinomycetes are a group of gram-positive bacteria that have an array of genes in their genome that are devoted to constructing metabolites. While they are classified as bacteria, their morphology resembles fungi as they form aerial hyphae or spores which are smaller than those of fungi. Actinomycetes have been found in both terrestrial and aquatic (saltwater and freshwater) habitats. Aquatic actinomycetes really shine because their genome is specifically encoded to create a variety of secondary metabolites not seen from terrestrial species. Secondary metabolites, or the small molecules produced by bacteria, have been used by humans extensively as antibiotics, herbicides, immunosuppressants. The most well-known FDA approved drug from actinomycetes is streptomycin which was discovered in 1943. The Carlson lab has been hard at work isolating novel actinomycete strains. I am interested in fully cataloging, identifying (via 16s rRNA),

preserving, and extracting the secondary metabolites from these strains. I also plan to use multiple media types to see if we can elicit more compounds from the bacteria by altering the carbon and nitrogen sources in the media, this is known as One Strain Many Compounds or OSMAC approach. In the laboratory, we will test for any antimicrobial compounds present and look for biofilm inhibitors, specifically E. coli, Staphylococcus aureus, Bacillus subtilis, and a collection of marine Vibrio spp.

Abstract Name: Learning from Anthropomorphic Stories: Teaching Preschoolers Acquired vs Inheritable Traits by Varying Character Realism

Nearly all children's education media contains at least one fictional aspect. When trying to teach a scientific lesson, the fictional element could blur the lines between what is real and what is fantastical. To test the influence of fantasy on the ability to learn a scientific lesson, we read to children ages 4-6 years old with stories that varied by having human or kangaroo main characters and realistic or anthropomorphized target animals. The text for each story was consistent, with the main characters teaching about the difference between inheritable and acquired traits between parent-child target animal pairs. Each child's independent preference for fantasy or realism in their media consumption, play style, and educational activities was recorded through a parent questionnaire, determining if an interaction between their fantasy preference and their ability to learn from different materials had any correlation. The goal is to determine if there is an ideal amount of fantasy to include in a story to capture the child's attention while not interfering with the educational information. We expect to find that moderate inclusion of fantasy elements would have the most positive effect on learning about traits.

Abstract Name: Body Mass Index is a Poor Prognostic Factor for Function in Individuals with Plantar Fasciopathy: A Longitudinal Observational Study

Research Context: Plantar fasciopathy (PF) is a condition most common in athletes, characterized by pain and tenderness of the calcaneal region. In non-athlete cases, higher body mass index (BMI) has been observed as a potential risk factor for developing the condition due to increased mechanical load on the plantar fascia.Central Aims: The aims of this study are to investigate if BMI influences the performance of clinical tests and clinical presentation of individuals with PF, and to determine whether BMI and clinical tests predict the clinical course of PF over a 3-month follow-up period.Methodology: 52 individuals with PF were grouped according to the median BMI, into low and high BMI. Participants showed a mean age of 49.4 ± 12.0 years, and a mean BMI was 28.1 ± 4.5 kg/m2. At initial assessment, assessors evaluated eligibility criteria and demographic and anthropometric data were collected, including sex, age, education level, height, and weight for the calculation of BMI. Pain intensity and function were measured at baseline and at the 3-month follow-up via Ankle dorsiflexion Range of Motion (ROM), Navicular Drop Test, Heel Rise Test, and Step-Down Test.Results: We found that the low BMI group showed better function (Mean Difference (MD) = 11.8; 95%CI: 1.9; 2.16) and lower pain intensity (MD = -1.5; 95%CI: -2.6; -0.3) than the high BMI group. In the multivariable regression model, higher BMI predicted lower function (Beta coefficient = -1.20; 95%CI: -2.3 to -0.3).Conclusion: Individuals with PF with higher BMI reported higher pain and lower function compared to those with lower BMI. Although BMI was found to influence PF clinical presentation, it was considered a poor prognostic factor for function in individuals with PF.

Abstract Name: Assessing Neuromuscular Fatigue in Childhood Cancer Survivors

As a result of remarkable progress in oncology, over 80% of children diagnosed with cancer are expected to be long-term survivors. Unfortunately, chemotherapy side effects are significant and may involve life-long consequences. Specifically, the drug vincristine can cause peripheral neuropathy (nerve damage). While sensory impairments due to neuropathy have been well documented, we aim to know more about its effects on motor function. One previous study found that within months of completing vincristine treatment, children walked slower than age-matched controls and kept their forefoot in contact with the ground for a longer time during each step. We hypothesize that this finding reflects susceptibility to fatigue brought on by neuromuscular damage and want to determine if such deficits persist long-term. We recruited recovering pediatric oncology patients and age-matched controls, having them complete surveys assessing subjective experiences of daily fatigue, clinical tests of nerve function, and a six-minute walk test. Additionally, we measured strength and muscle fatigue in their hands and feet. During fatiguing trials (40 sequential repetitions of a 3-second maximal contraction and a 3-second rest period), we recorded electromyograms (EMGs) to measure muscle activity while using dynamometers to test hand grip and dorsiflexion forces. At present, we have tested five cancer survivors who received vincristine therapy (age range = 12-22 years; average age = 18.2 years; average time since treatment end = 5.7 years) and 33 control participants (average age = 18.0 years). While we plan to recruit more participants, our preliminary results suggest that even more than 5 years after finishing chemotherapy, survivors continue to experience more daily fatigue, cannot produce as much hand grip force, and have reduced gait speed. These findings suggest health care providers should conduct long-term follow-ups on the neuromuscular function of cancer survivors administered vincristine.

Abstract Name: EXPERIMENTAL INVESTIGATION OF WATER EVAPORATION ON POROUS MEDIA WITH METALLIC OXIDES COATINGS BY ATOMIC LAYER DEPOSITION

Porous media, such as polypropylene (PP) and carbon foam, have been previously studied for enhancing water evaporation by their strong capillary forces and capabilities of heat localization when being exposed to solar radiation. Meanwhile, it is reported that enhancing hydrophilic properties of a porous surface allows greater water evaporation rate than untreated porous surfaces. For example, the contact angle of water on nitric acid-activated PP is decreased from 110˚ to 66˚ and 76˚, and the total water evaporation rate on a bare PP membrane is more than doubled from 250 L h-1 m-2 bar-1 to 487 - 509 L h-1 m-2 bar-1. We would like to propose a treatment of porous metal media by atomic layer deposition (ALD) of metallic oxides, including titanium dioxide (TiO2) and aluminum oxide (Al2O3), to induce superior hydrophilic properties and investigate the water evaporation enhancement on the treated porous media. This work will focus on establishing a quantitative correlation between various ALD coatings and the enhanced water evaporation on porous media that are exposed to various heating. It is expected that a greater thermal efficiency of metal porous media will have a better heat transfer to support the water evaporation than that on non-metal porous media, and a hydrophilic ALD coating will yield a smaller contact angle and greater water evaporation flux due to the combined effects of enhanced hydrophilicity on the surface of porous media and heat transfer in the skeleton of porous media by more than two times of that on untreated porous media when being exposed to the same heating conditions.

Abstract Name: Design of Pressure Device to Aid in Alleviation of Anxiety Symptoms

How can wearable devices be used to offer support to those who suffer from moments of anxiety? The number of people diagnosed with anxiety has been on the rise; it is currently the most diagnosed mental illness. With this, many people with said diagnosis say that pressure helps alleviate moments of anxiety. Furthering that, there are pressure points in the human body that, for centuries, have been used to control feelings and sensations within the body—including feelings of anxiety. This project focuses on creating a wearable device that utilizes applied pressure to bodily pressure points to alleviate anxiety. The physical product works alongside a Bluetooth connected phone app. Through the app, device wearers can set the device to their preferred preferences, track triggers of anxiety, and find resources for greater support. Especially when in public, it is crucial not to call attention to the fact that the user is currently having an episode of anxiety. The design of this product makes it appear more similar to a jewelry piece than a medical device. Visual language is largely inspired by the work of James Jean. This, combined with normalized phone use allows for discrete and non-stigmatized activation and use case scenario. This project uses research conducted through secondary data analysis; individuals' personal anecdotes is considered as well; the

traditional Industrial Design development process is fundamental to the creation of this project. Included in this process is intensive sketching, CAD modeling, 3D printing and user comfort testing. Through findings and development, it is expected that the combination of pressure and pressure points will help to minimize some feelings of anxiety. This development could allow for a healthy way to momentarily alleviate symptoms of anxiety is a discrete way.

Abstract Name: Thalamo-cortical functional connectivity in developmental disorders

One of the earliest neurobiological findings in autism has been the differences in the thalamocortical pathway connectivity, suggesting the vital role the thalamus plays in human experience. Since then, studies on thalamic connectivity have been sporadic and especially rare in comparing disorders like autism and attention deficit hyperactivity disorder (ADHD). The thalamus is implicated in relaying sensory information, monitoring and maintaining mental constructs, and executive functioning, among other cognitive functions. Hence, any neurological or neurodevelopmental condition associated with structural and functional differences in the thalamus may accompany alterations in neurocognitive abilities. The present functional MRI study investigated resting-state functional connectivity of the thalamus in 49 (autistic, ADHD, and neurotypical) young adults. All participants underwent structural MRI and eyes-open resting state functional MRI scans on a Siemens 3T Prisma scanner. After preprocessing the resting fMRI data using Conn's connectivity toolbox, a seed-based functional connectivity analysis was conducted using the bilateral thalamus as primary seeds. The main findings demonstrate extensive functional connections of the thalamus to a diverse range of cortical areas. Autistic participants showed stronger thalamic connectivity, relative to ADHD and neurotypical participants, between the right thalamus and various cortical regions, including the somatosensory cortex, motor cortex, and SPL, as well as the left thalamus and the right precentral gyrus. Furthermore, regression analyses revealed a significant relationship between autistic traits and left thalamic-precentral connectivity ($R^2 = 0.1113$), as well as between autistic traits and right postcentral gyrus and RSPL connectivity ($R^2 = 0.1204$). Autism and ADHD often co-occur with overlapping symptom profiles. This study is unique as thalamic connectivity profiles of autistic and ADHD participants are compared, which can be utilized to differentiate neurobiological mechanisms underlying autistic traits. Ultimately, these findings provide significant insights into the role of the thalamus in coordinating neural information processing and its alterations in neurodevelopmental disorders.

Abstract Name: The Life of Women on the Oregon Trail

The Oregon Trail in the years 1840 to 1867 symbolized the desire for many to gain access to a better life and wealth. These individuals headed West in search of gold, land, and opportunity. However, getting west required a long and treacherous journey. These pioneers traveled hundreds and thousands of miles through great danger to reach their idea of the West. Groups that traveled often included families, women, and children. The covered wagons housed the entirety of a family's belongings.The reality of this journey included sickness, disease, and often a lack of food. Partaking in such a journey, especially for young children, required a level of toughness and grit. These families trudged through the wilderness and fought for survival. Some families used covered wagons, while others pulled carts on foot. Many families faced death and starvation from the conditions. In addition, there were great safety concerns for these families. Either way, the journey through tough terrain and wilderness were difficult and grueling. This treacherous journey along the Oregon Trail provided many challenges for women, whether this included leaving behind their families, homemaking along the trail, and partaking in chores that would have previously been understood as unladylike. Many of these families embarked on this journey in the hope of the opportunity given by the West. While women were allowed to act more independently and to learn new skills, the jobs women accumulated along the Oregon Trail were often exhausting and difficult in labor.

Abstract Name: NP-PB2 Interaction as a Viable Target to Inhibit Influenza Replication

The influenza virus continues to hold pandemic potential. Antiviral treatments are important to stop novel emerging influenza viruses, fueling the need to investigate essential viral protein interactions as a first step in developing new antivirals. Influenza nucleoprotein (NP) is essential for viral gene expression and highly conserved across influenza viruses. We previously reported alteration of 5 amino acids of NP to glycine, termed NPbd3, results in no viral RNA expression but maintains oligomerization and RNA binding. Here we use sucrose gradient ultracentrifugation to demonstrate wild type NP and PB2 co-sediment when expressed alone in 293T cells, but altered NPbd3 does not, evidence NPbd3 cannot interact with PB2. To investigate disruption of NP-PB2 interaction as an antiviral target, we engineered DNA to express a small NP peptide encompassing the 5 amino acids identified. Transient transfection of 293T cells reveal expression of wild type NP peptide followed by influenza A virus infection results in little cytopathic effect (CPE), while expression of NPbd3 peptide domain results in CPE. This supports wild type NP peptide binds PB2 to block NP-PB2 interaction and inhibit influenza infection while NPbd3 peptide cannot interact with PB2, does not block NP-PB2 interaction, and does not inhibit influenza infection. To build on these findings we engineered single integration lentiviruses to integrate the gene to constitutively express the NP peptide fused to GFP to monitor NP peptide expression and location. Clonal populations will be propagated and the resulting NP peptide expressing cell lines will be infected with influenza A virus. We hypothesize engineered cell lines expressing wild type NP peptide will be protected from influenza infection while NPbd3 expressing cell lines will not. This research defines the domain of NP involved in an essential NP-PB2 interaction and validates disruption of this interaction as a viable target to develop new antivirals.

Abstract Name: The Effect of Sodium Chloride Stress on Floral Nectar Sugar Concentrations and Nectary SOS1 Gene Expression in Brassica

Nectar is a nutrient-rich solution produced by the nectary glands of flowers to attract pollinators such as bees and hummingbirds. Nectar is primarily composed of sugars (sucrose, glucose, fructose) and other metabolites such as amino acids, lipids, proteins and metal ions. Plants uptake nutrients and water from the soil, but excessive salts such as sodium chloride (NaCl) can stress them. Road salt, containing NaCl, is used in the winter to mitigate icy roads, which infiltrates the soil and is absorbed by plants. This raises concerns about its impact on nectar production and pollinator interactions. Our research focuses on the effect of NaCl on floral nectar production. Our hypothesis is that increasing NaCl will alter nectar sugar composition and nectary gene expression of the salt membrane transporter, SOS1 (Salt-Overly Sensitive 1). Brassica rapa plants were grown in a hydroponic system (with no soil) with added NaCl and nectar sugar composition was analyzed. We optimized growth of Brassica rapa (Wisconsin Fast Plants) on two different hydroponic solutions, Masterblend and Floragro, with or without NaCl. Masterblend exhibited better plant growth, leading to further experimentation with increasing NaCl treatments (0, 0.5 and 1%) in a similar setup. Nectar from flowers of each treatment were collected for sugar composition analysis using the Megazyme Sucrose/D-Fructose/D-Glucose Assay Kit. Our results suggest temporal changes in nectar sugars with an increase in hexoses (glucose and fructose) in salt-stressed plants. SOS1 gene expression from the nectary glands is in the process of qRT-PCR analysis. Changes in nectar composition due to salt stress could negatively impact plant reproduction and pollinator food sources. Hence this research can better inform road salt usage patterns.

Abstract Name: Re-Mourning Slavery's Memory: Agency, Grief, & Desire in Beloved

My research examines Beloved, a novel where a formerly enslaved woman named Sethe is haunted by the child she murdered to avoid its enslavement. The novel explores the grief Sethe for the loss of her child which is a metaphor for African American grief towards the familial losses incurred as a result of slavery. In the discourse of literary criticism, Beloved is often examined using a psychoanalytic framework which categorizes the novel as a melancholic text. The psychological understanding of melancholia comes from Sigmeund Freud who described the state as a pathological condition where an individual experiences unresolved long term grief. However, in the novel, it is precisely through grief that Sethe channels the energy to move forward rather than stay in her misery. Thus, my work pushes back against the long standing view that grief is pathological. I argue that psychoanalytic terminology is insufficient for understanding the transformative qualities of grief and hinders our understanding of how melancholia can be useful. I present the term “re-mourning” to bridge this theoretical gap in the language and demonstrate that in order for a

grieving subject to move forward, they must draw motivation from their loss. Through close reading, I examine how characters who are psychologically and physically debilitated by their memory of slavery find a way to transform this unresolved grief into a source of power to enact change in their life. My questions include: how do the characters develop a “healthy” relationship the past without completely abandoning the it either? And, if grief becomes a source of power, what are its dynamics and manifestations? The importance of this work is that it grants the current discourse a new theoretical lens to understand the role that grief plays in relation to the memory of historical devastation.

Abstract Name: Immunohistochemical Detection of GLP-1 in the Mouse Hindbrain

Obesity, eating disorders, and type 2 diabetes are health concerns that can be fatal if left untreated. Pharmacotherapies targeting the body’s GLP-1 system promote insulin release, reduce appetite, and promote gastric emptying. In the brain, GLP-1 is solely produced from neurons in the brain's nucleus solitary tract (NTS). Several studies have established that these neurons are activated by large volume food intake, stress, and the exogenous administration of gut satiety peptides like cholecystokinin; however, there is still much we don’t know about how the NTS GLP-1 system is recruited by different behaviors or drugs. Therefore, we piloted a protocol using immunohistochemistry techniques to label GLP-1-expressing cell bodies and fibers in the NTS of mice brains. The primary antibody (1°) used in 1:2000 concentration (1°: PBS) was rabbit & anti-GLP-1, which adhered to present GLP-1 proteins. 0.1% sodium borohydride allowed for better visualization. The secondary antibody (2°), donkey & anti-rabbit, was used in a 1:1500 concentration (2°: PBS); this adheres to the primary antibody with its red fluorescence. The sections were microscopically analyzed and revealed GLP-1 proteins in the NTS. Our work contributes to an improved protocol for IHC to locate GLP-1 proteins in the NTS. We will use this protocol combined with Fos immunolabeling (double IHC) to look at the activation of NTS GLP-1 neurons in response to other stimuli. Also in the future, we can measure changes in GLP-1 protein after different chronic manipulations like high-fat diet, chronic stress, or manipulations of the NTS GLP-1 system.

Abstract Name: Incubator of Evil: On Historical, Post-Nazist, and Digital Right-Wing Extremism in Austria

This research project delves into the deep-rooted history of right-wing nationalism and authoritarianism in Austria, seeking to understand its connection to modern-day politics and collective memory. While Nazism and its deleterious legacy are often the lodestars of discussions on Austrian — if not European — political

history, this project aims to uncover the centuries of conservative politics that have contributed to the development of reactionary ideologies in the country.Austria's position as a unique locus between competing European powers has fostered a distinct form of nationalism, based on a vaguely Alpine-Danubian culture and Catholic religion rather than a historically grounded "we-feeling." The multi-ethnic and multi-lingual makeup of the Austro-Hungarian Empire has added another layer of complexity to the development of this nationalism, laying the groundwork for a virulent strain that persists to this day.Through archival research, political theory, sociological analysis, and discursive analysis, this research examines the connections and continuities between historical right-wing movements in Austria and their modern-day incarnations. It also includes interviews with passers-by, academic scholars, and persons affiliated with the Austrian government, providing a multifaceted understanding of this understudied facet of Austrian history.Ultimately, this project sheds new light on the complicated history of Austria and its political landscape, offering insights into the development of nationalism and authoritarianism in the country. By situating developments like pan-Germanism, Austrofascism, and the Neue Rechte (New Right) in their specific Austrian context, this endeavor analyzes connections and continuities between historical right-wing movements and their modern incarnations. Through a thorough deconstruction and internalization of this history, the international community can gain a deeper understanding of contemporary Austrian politics and collective memory in the post-World War II era of Austrian statehood. This project is essential for anyone seeking to comprehend the complex and nuanced nature of Austrian politics and nationalism.

Abstract Name: “Austrians” in Austria: On the Origins, History, and Survival of the Austrian School of Economics in Contemporary Austria

The Austrian School of Economics has long been a critical player in the world of economics, with its heterodox beliefs and laissez-faire ideology. However, its operational validity and rejection of mathematical models, econometrics, and macroeconomic analysis have been the subject of scathing scholarly critique. Through an extensive archival research project, this study aims to explore the origins, history, and survival of the Austrian School of Economics in contemporary Austria.This research delves into the archives of the Austrian National Library, the Austrian State Archives, and the University of Vienna, where the likes of Ludwig von Mises, Friedrich Hayek, and Carl Menger have a long history. Through this exploration, it becomes evident that Austrian policy-makers and politicians have widely cited the Austrian School's theories to justify their rejection of Eurobonds, so-called "corona bonds," and debt mutualization.The findings of this study reveal the Austrian School's significant impact on the current conservative fiscal policies of the modern Austrian state, leading the country to be a part of the Frugal Four, an informal cooperation of four fiscally conservative EU countries. The study also reveals the Austrian policy-makers' strong adherence to the EU's Stability and Growth Pact (SGP) and a one-percent-maximum budget contribution to the European Union.This study's main contribution is to highlight the continuity of theory and policy in Austria, where policy-makers and politicians have established an asynchronously continuing "Austrian tradition." The study shows how the Austrian School's theories have found usage in justifying Austria's fiscal decisions, which yield significant implications for the world economy.Overall, the Austrian School of Economics played a central role in shaping the current fiscal policies of the Republic of Austria. This project offers insights into the Austrian School's origins, methodology, and business cycle theory (ABCT), whilst highlighting the significance of theory-policy continuity in shaping economic policies.

Abstract Name: Financial Literacy, Risk Perception, and Risk Taking among College Students in America

The current study investigates the relationship between financial literacy, risk perception, and risk-taking among undergraduate students at a small midwestern university in the United States. It contributes to the broader literature on the determinants of financial literacy among college students. Data were gathered using a survey that contained questions on financial literacy, risk perception, and risk-taking, along with proxy questions to assess prior financial knowledge, financial knowledge gained through life experiences as a college student, and financial knowledge learned from classroom instruction. The average level of financial literacy among college students is found to be low. Furthermore, financial literacy among the four student levels is not statistically different, indicating that undergraduate students' life experiences do not significantly contribute to their financial literacy. We find that financial literacy among students who reported taking a high school finance course is no different from those who reported not taking one. However, taking at least one college level finance course is found to significantly improve financial literacy, indicating that some financial knowledge is learned. Our findings are similar to those reported in prior research and indicate that a mandatory college-level personal finance course may benefit all students. We also analyze the relationship between financial literacy and risk perception, and risk perception and risk tolerance. We find that financial literacy contributes to better risk perception and that students, in general, are risk averse. Existing literature notes that financial literacy leads to better financial outcomes; our findings underscore the importance of reinforcing financial education at the college level when students make their first financial decisions.

Abstract Name: Multi-Modal Brain Tumor Segmentation Model to solve Mutual Inhibition between Modes

Medical image segmentation has become a key research area in the machine learning community, with brain tumor segmentation being one of the most challenging problems in the field. Utilizing machine learning models for brain tumor segmentation can aid in the diagnosis, treatment, and monitoring of brain tumors, significantly improving the medical care of patients. Magnetic Resonance Imaging (MRI) can generate images of the brain by altering the influencing factors of the signals, providing multiple modalities. These multimodal MRI images can be used to train machine learning algorithms, including those developed by authors in the field, such as the Siamese self-supervised learning framework and 2D convolutional neural network, to segment brain tumor images. In this work, a 3D U-net architectural neural network was developed on the BraTS 2019 dataset (provided by the Perelman School of Medicine at the University of Pennsylvania) of multi-modal brain tumor images to segment brain tumors. The BraTS 2019 dataset comprises 335 MRI scans of low-grade and high-grade brain tumors, manually annotated into tumor core, enhancing regions of the tumor, and edema regions. The 3D U-net model was developed to accurately segment these regions of the brain tumor. The 3D U-net model was trained, tested, and validated on the BraTS 2019 dataset by dividing it into appropriately sized chunks. This model was then evaluated based on

accuracy, precision, sensitivity, specificity, and dice coefficients. In conclusion, the 3D U-net model performed well on the BraTS 2019 dataset, successfully predicting the tumor core, edema regions, and enhancing tumor regions with high accuracy. Thus, this brain tumor segmentation model can help automate the medical diagnosis of brain tumors with high accuracy. Future work could include developing models for other types of cancer.

Abstract Name: The Characterization of Mistrust in Native American Communities

Adverse mental health outcomes such as depression, anxiety, and suicide have disproportionately affected Indigenous Peoples, due to a legacy of historical and ongoing systematic oppression; this has resulted in less access to formal quality healthcare services (CDC). A potential mechanism for these persistently high rates may be attributed to the high levels of mistrust (Goetz et al., 2023). Mistrust/distrust is the idea that the source being trusted will not act in one's best interest and/or act against their best interest (Williamson and Bigman., 2018). The present study aims to characterize the mistrust that Native Americans have for mental healthcare services and provide recommendations to increase engagement in mental healthcare for Native Americans. We seek to conduct a rigorous narrative review of the scientific literature published in English within the last 20 years on various reputable databases: PubMed, PsycINFO, and Web of Science. Search terms included, and were related to: American Indian, Mental Health, and Mistrust. The research returned 88 results. Taking into consideration the criteria established, 77 articles were excluded because they were not empirical, unrelated to mental health or mistrust, or not focused on Indigenous peoples in the United States. A preliminary qualitative synthesis of 11 articles indicated the following themes: historical loss was positively related to mistrust, culturally competent care reduces mistrust, and barriers to healthcare leads to actively putting off treatment. This narrative review will improve our understanding of mistrust as it relates to indigenous peoples and is part of a larger project to identify facilitators and barriers to mental health services. Based on the narrative review, recommendations will be made to improve trust through an increase in cultural competency among healthcare providers and increasing community-centered approaches.

Abstract Name: Restricting Ice Formation Under Isochoric Conditions

When it comes to cryopreservation, the threat of ice formation during both cooling and rewarming has been an ever present obstacle, causing damage and decreasing viability rates from cells to organisms. A new perspective was taken to restrict ice formation by enclosing cryogenic solutions in a constant-volume

(isochoric) chamber (Powell-Palm et al. 2020). As water's nature is to expand when transitioning from liquid to solid, the isochoric chamber inhibits this complete phase change. In this work, we present the design and development of a new isochoric chamber with the addition of sapphire windows to be able to visualize the behavior of cryogenic solutions and their phase changes. The chamber consists of the cylindrical main body, screw-in covers, and an o-ring seal to maintain pressure to truly make the chamber isochoric. We tested the chamber by introducing DI water inside and submerging it in liquid nitrogen, where a partial freeze of the water was observed. While an ice ring formed on one of the chamber windows, the remaining liquid water was prevented from freezing even in subzero conditions. This implies that inhibiting ice formation via isochoric means might be a prospective outlook to cryopreservation. In future work, Interferometric Digital Holography Interferometry (DHI) will be utilized to further analyze the visual changes we can currently observe.

Abstract Name: Sensory Design Features for Glaucoma

Creating a home that caters to the specific needs of a family with members diagnosed with glaucoma requires careful consideration of various elements. Glaucoma is an eye disease that can cause impaired vision due to damage to the optic nerve. This eye disease alters vision perception by creating a tunnel with floating black specks at the center. When concluding research, it was necessary to help with issues which are contrasting colors due to contrasting sensitivity, round edges for furnishings, abundance of lighting, and reducing slippery materials and furnishings. The residence incorporates accessibility features such as cove lighting in the entrance, diverse ceiling heights for spatial orientation, textured walls for wayfinding, under-cabinet lighting for task areas, and contrasting colors for clear differentiation. The furnishing with lightweight and rounded edges was selected for prioritizing comfort and safety. The fireplace is a bespoke design with a smart device controlling the TV's visibility, minimizing potential disturbances for a toddler with glaucoma. A custom round bookshelf is incorporated, to provide a designated spot for their book collection and reduce the risk of accidents. The mudroom is custom-built with contrasting colors, aiding in identifying different storage areas. By combining custom furniture, innovative lighting solutions, and tactile design elements, this home caters to the unique needs of a visually impaired family. The emphasis on rounded shapes and contrasting colors enhances safety and ease of navigation. The thoughtful integration of technology, such as the smart fireplace, reflects a commitment to creating a comfortable and accommodating environment for this family, ensuring their home is both functional and aesthetically pleasing.

Abstract Name: An Analysis of Youth in an Upward Bound Program

The focus of this research project is on the lived experiences of high school-level youth enrolled in Upward Bound—a federally funded program in the midwestern region of the United States. This program at the University of Wisconsin-Eau Claire provides academic and social support to students from racially and economically marginalized groups with the overarching goal of preparation for the pursuit of post-secondary education.The role of the researchers was to utilize both qualitative and quantitative approaches to data collection. The researchers initiated this process via a semi-structured interview protocol which includes questions about home life, school environment, and residing neighborhoods. Participants were then asked to create a personalized ecomap to visualize their communal support, a genogram to describe their family structure, and a timeline to showcase meaningful life events. In addition to this, researchers chose to distribute a strengths-based paradigm to participants which focuses on their assets and resources rather than strictly focusing on problems and deficits.Sixteen high school students, primarily freshmen and sophomores, participated in the research conducted during the summer of 2023. After data analysis, themes and patterns across the participants were identified. Some of the emergent key themes include how participants perceive themselves versus how others view them, the complexities of navigating social relationships, and the impact that school personnel have on connectedness within academic settings.

Abstract Name: Hippopotamus (Hippopotamus amphibius) Aggressive Interactions During Daily River Pool Use; Is Time of Day Important?

Hippopotamuses (Hippopotamus amphibius) are known to forage on land during the night and spend the daytime in shallow pools to thermoregulate and to protect their skin from UV radiation. Daily use of pools may lead to competition for space and facilitate aggressive interactions between hippopotamuses. In this study, we looked at the difference in occurrence of aggressive behavior in the morning and evening hours between hippopotamuses (hippos). We hypothesized that hippos would be more aggressive at different times of the day, and we predicted that the higher aggressive activity would be in the morning hours, as hippos return to the pool. Our data was collected at the Retima Hippo Pool, Orangi River, Serengeti National Park, Tanzania in May 2022. Aggressive behaviors were counted and recorded using transect methodology (six pairs of observers watched a transect across the pool and recorded at pre-set times). We defined aggressive behavior based on previous publications. Results showed that hippos were more aggressive during evening hours as compared to the morning (96 and 54 aggressive behaviors, respectively). Based on these results, our hypothesis was not supported. A potential explanatory factor might be that the annual spring rains did not occur in 2022, so the pool level was extremely low. This could have increased concentration of both hippos and fecal matter, and this may have altered when and how often aggressive behavior occurred. If we repeated this observational experiment, we would extend the study period to include more than one season.

Abstract Name: Development of a Memorability-Based Mnemonic Discrimination Task

The intrinsic ability of certain elements to be better remembered than others is known as memorability. Memorability can explain a large amount of variability in memory performance and appears to be an inherent feature of episodic memory. Episodic memory, or memory for personal events and experiences, relies on the hippocampus and surrounding brain regions. The hippocampus can perform pattern separation, or the ability to discriminate among similar experiences and store them as non-overlapping representations. It has been hypothesized that pattern separation could explain memorability variation; however, no study has investigated this interaction. To this end, participants were shown a series of images ranging in memorability (memorable and forgettable). Participants' memory was tested either immediately or 24 hours later. Participants were asked to identify new and repeated items among images that were similar but not identical to the images shown previously ("lures"), completely new images, and repeated images ("targets"). This provides two measures of interest: target recognition - one's ability to recognize a previously seen images and lure discrimination - one's ability to distinguish between stimuli with overlapping features and it is thought to tax hippocampal pattern separation. We found that memorable items were better remembered than forgettable ones across memory measures. However, memorability's impact on lure discrimination was present immediately but lost after 24 hours. These findings suggest that memorability's impact on episodic memory may not apply to all types of memory, in which memorability may not be predictive of more naturalistic memory conditions (e.g., memory at a delay and memory for details).

Abstract Name: Impact of Designated Players on Major League Soccer Attendance

Since the development of Major League Soccer (MLS) in the United States, the popularity of soccer has steadily increased. When the designated player (DP) rule, allowing teams to sign superstar players to contracts above the salary cap, was implemented in 2007, the MLS saw a turning point in attendance. In the league's first five years, there was an estimated loss of $250 million. Approximately 80% of revenue in the MLS occurs on gameday, meaning that attendance plays a significant role in financial success (Bradbury, 2020). Understanding the benefits of the implementation of the DP rule on MLS attendance is important to ensure the MLS does not dissolve like its predecessor, the North American Soccer League (NASL). We employed linear regression analysis using data from worldfootball.net, MLS Player's Association, and other sources to analyze the relationship between both player- and club-level variables on season attendance for teams in the MLS. Preliminary results show that the COVID-19 pandemic and the age of the MLS club are important variables in determining season attendance. Continuation of the definition of variables will help achieve the most accurate results. In addition, this study looks at the variation of population makeup near the home fields of MLS teams and how that may affect attendance.

Abstract Name: The Pride Pipeline: Violent Nationalism in the United States

A striking rise in American Nationalism has emerged due to varying factors; however, a particular selection of identities have acted as primary contributors to this phenomenon. This piece navigates the increasing application of violence in the political arena in tandem with the impacts of racial, socioeconomic, and social factors that have fueled this collective aggression. Previous research points toward the hyperpolarization that has been perpetuated by political figures and media outlets, the augmentation of a psychological us-vs.-them mentality, and the perceived threat to American hegemony across the globe. Through an analysis of data provided by the 9th edition of the Chapman University Survey on American Fears in addition to a selection of the 6th edition, this phenomenon is dissected further. Extracting the responses to a given respondent's partisan affiliation and their individual consensus regarding the use of force to restore political power, this piece amplifies the present beliefs of scholars, adding the significance of recent resurgences in violent movements and extremist political groups. Upon examination of current data, it is proposed that while religious and social factors intersect uniquely to contribute toward the presence of violent patriotism, the most prominent factor is the growing belief of white supremacy and the perceived threat that marginalized groups pose to their ideal nation.

Abstract Name: Bollywood the Underdog

Asian Americans stigmatization has long been established to disparage their cultures while uplifting America in the process, especially through film and media and it continues to adhere to that antiquated pattern today. "There is a greater flow of information from first to third world countries" like America to India "but very little representation" vice versa (Ramasubramanian 245-246). This information imbalance displays the problem of representation from India to America, specifically analyzing Bollywood and Indians and their representation in American media and Hollywood. Bollywood has increased its income and prestige to Hollywood's level and is a market that Hollywood has sought to pursue for years, but regardless of Bollywood's popularity, its recognition in America has been distorted. With the survey I conducted analyzing American perceptions of Bollywood at Virginia Commonwealth University, I came to the conclusion that Americans who were unaware or had misconceptions of Bollywood, were so due to their reliance on the media for such definitions. The progression of Bollywood's identity has stayed constant over time, showing a lack of growth and development. There is also a lack of research regarding this topic of Bollywood and Indian representation in general as sources date back to nearly 20 years ago. Why is there a lack of representation of Bollywood in American media and Hollywood and how should we address this issue? American media as well as Hollywood, create misrepresentation or under-representation of Bollywood and Indians, thus creating a divergence of the world through the media versus reality, affecting Indians through restricting their behavior, shaping their acceptable conformities, and treatment everyday. Hollywood's

priorities should align with diversity and inclusion rather than wealth and dominance in order to accept Bollywood and Indians for their true selves so as to depict a truly universal audience and maintain its throne as a world superpower.

Abstract Name: Epiphytic diatom production on the seagrass (Thalassia testudinum) in northern Gulf of Mexico

Seagrass provides coastal protection, habitat and food resources for many economically important marine organisms (e.g. fish larvae), and sequesters considerable carbon (i.e. a“bluecarbon” system). Seagrass epiphytes (e.g.microalgae, vascular plants) provide food for marine organisms. Some epiphytes, e.g. diatoms, play a role insystem carbon cycling. For example, in Ruppia maritima and Halodule wrightii seagrass beds in the northern Gulf of Mexico, seagrass-associated diatoms were shown to contribute 70-80% of benthic net community production (NCP). For other regionally-important seagrass species, e.g.Thalassia testudinum, there are nodata reporting the epiphytic diatom contribution to NCP. Building on these earlier studies, we aimed to answer the question:what is the importance of epiphytic diatoms to Thalassia testudinum NCP? During the summer 2023, seagrass was collected from Pensacola, Florida (United States) and transported to Dauphin Island Sea Lab (160 km away) where experiments were run in an outdoor mesocosm. Germanium (Ge) was used as a diatom-specific inhibitor to quantify the NCP and compare it to unamended (no Ge) controls, thus allowing us to quantify the difference in contribution to NCP due to diatoms. During three experiments over four weeks, NCP decreased with time, potentially due to increasing nutrient limitation.The epiphytic diatom contribution was resolved in one experiment (which had the highest ammonium concentrations) to be ~20%. Our results demonstrate that, at times, epiphytic diatoms can be significant for Thalassia testudinum NCP, although this contribution was not as high as reported in previous studies for other seagrass species. Also, the rapid shift in epiphyte assemblage productivity (diatoms as significant producers toward insignificance over 4 weeks) may affect the local seagrass food webs, specifically grazers which rely on epiphytes for nutrition.

Abstract Name: Cold War Era Cultural Exchange: How Ballet Lifted the Iron Curtain on and off the Stage

Throughout the mid and late twentieth century, the United States was knee deep in confrontation with the Soviet Union. In response to the growing tensions, the two nations signed an agreement allowing for an exchange of cultures with the hopes of opening lines of communication and understanding. Ballet was only one of the many cultural components that participated in the exchange, and this participation not only aided in the foreign relation objectives, but it also changed the trajectory of ballet history. American and Russian ballet companies toured each other’s cities on numerous occasions, even amidst some of the most major crises of the Cold War. This research analyzes the artistic and political impacts of the international tours and is supported by the historic examination of ballet during the war by dance scholars such as Anne Searcy, in

addition to the political outlook of the Cultural Exchange by scholars such as Yale Richmond. This paper centers around the question of how ballet affected the political atmosphere of the Cold War within both the United States and the Soviet Union, in addition to the affects of the Cold War politics on the artistic atmosphere of ballet. Through this research, it can be argued that the exchange forged a unity between the arts, resulting in an easing of harsh tensions and contributing to the future relationships of the nations following the war. In the world of ballet, it can be argued that the sharing of cultures allowed for insight into differing artistic values and approaches, opening doors to deeper creativity, and allowing for shared experiences to bleed into future works – uniting these cultures in unique ways. These events are a significant part of dance history because of the way that ballet was used diplomatically to facilitate transnational communication and relationships.

Abstract Name: Techno-Economic Optimization of a Hybrid Energy System that Prioritizes Energy Resiliency: A Case Study in Puerto Rico

Puerto Rico has an energy system that often experiences interruptions and outages. This is due to Puerto Rico's location in the Caribbean, which makes this U.S. territory susceptible to extreme weather events such as hurricanes, tsunamis, and tropical storms. Power outages can be detrimental to quality of life, particularly for those living in more isolated rural areas, since these areas typically take longer to be reconnected to the power grid. Therefore, there is a need for more resilient energy sources in remote areas that can provide reliable energy in the event of extreme weather conditions. Recently, a popular approach towards providing electricity to remote regions has been the implementation of Hybrid Renewable Energy Systems (HRES). Hybrid Renewable Energy Systems are power generation systems that utilize multiple energy sources. They typically include a conventional energy source such as a diesel generator, renewable energy sources such as PV and wind turbines, and an energy storage device. The primary objective of this research is to assess the feasibility of deploying a hybrid renewable energy system in Puerto Rico using mathematical modeling. Furthermore, this work aims to determine the optimal configuration and hourly dispatch of the energy system considering the resiliency and quality of the power supply. There is limited research on hybrid renewable energy systems in Puerto Rico; therefore, this work seeks to fill the gaps in this field and advance the understanding of energy resilience in extreme weather conditions. The results of this study may be applied to other regions that struggle with similar energy challenges.

Abstract Name: Role of Galactosylceramidase (GALC) of the Manifestation of Parkinson Disease

Deficiencies in the lysosomal galactosylceramidase enzyme (GALC) activity lead to GALC failing to metabolize psychosine and galactosylceramide, resulting in severe breakdown of myelin in the central and peripheral nervous system, triggering Krabbe Disease (KD). In addition, KD brains from either animal models or patients exhibit a marked aggregation of α- synuclein, the main pathological hallmark of Parkinson Disease (PD). Interestingly, our lab has previously shown that α-synuclein aggregates directly when it interacts with psychosine, and importantly, genetic restoration of GALC entirely eliminates the formation of α-synuclein aggregates. Noteworthily, although glycosphingolipid metabolism deregulation has been reported in several cases of PD, it is unknown whether there is an interrelationship between glycosphingolipid metabolism and the pathogenesis of PD. Thus, in this work, we will challenge our hypothesis that an absence of GALC impairs α-synuclein degradation, and promotes the manifestation of PD. Through immunofluorescence, western blotting and biochemical approaches, we found a decreased number of TH neurons, and decreased levels of dopamine in TWI brains. Specifically, lesser levels of DOPA decarboxylase were found, whereas Tyrosine Hydroxylase was hyperactivated, suggesting an alteration in dopaminergic synthetic pathways. Next, we will attempt to evaluate the cell-specific effect of GALC deficiency on PD onset by employing our TH-Cre-ERT2/GALC-flox transgenic mouse. Therefore, this study will lead to further understanding of the relationship between psychosine, α-synuclein, and the GALC gene, in the impact of dopaminergic neurons and the manifestation of PD.

Abstract Name: Unveiling Inclusivity Disparities in the Fashion Industry: A Closer Look at Affordability and Representation

More than half of Black consumers grapple with the arduous task of sourcing beauty products that authentically mirror their distinct skin tones. This glaring disparity highlights a pervasive lack of inclusivity. Similarly, Muslim women find themselves financially burdened in their pursuit of modest clothing, navigating a market where the price tag for such attire is twice as high as mainstream alternatives. This economic barrier raises questions about the true accessibility of inclusive fashion and the equitable representation of diverse religious and cultural attire. By meticulously investigating the scope of the fashion industry, economic disparities are noticed as there is a markup or lack of goods marketed to more ethnic individuals. Despite the American narrative promoting its rich cultural mosaic, inclusivity in fashion remains exclusive for many, prompting a reevaluation of Western fashion as a representative amalgamation of diverse cultures. The research discusses the evolution of beauty standards within the past few years. Specifically, a discernible shift has occurred, challenging the traditional norms that predominantly favored paler tones. Despite the fashion sector seeking to embrace a broader spectrum of skin colors, the study reveals that the inclusivity momentum has not fully translated into equitable representation with affordability in mind for all. The findings aim to highlight the challenges faced by minority communities within the intricate tapestry of the fashion industry. It is imperative for the industry to recalibrate its practices, ensuring that it authentically reflects the cultural richness inherent in the diverse fabric of American society. There needs to be a paradigm shift within the fashion landscape—one that prioritizes inclusivity and affordability for underrepresented communities, while also aligning with the evolving and more inclusive beauty standards of the contemporary

era.This study aims to highlight the challenges faced by minority communities within the intricate tapestry of the fashion industry.

Abstract Name: Moderates, Radicals and the Making of Indian Anti-Colonial Narratives in post-World War I United States

The purpose of this research paper is to analyze the discourses surrounding the Indian anti-colonial movement in the United States directly after World War I, as a means of understanding how ideological differences among activist groups like the India Home Rule League of America (IHRLA) and Friends of Freedom for India (FFI) were reflected in the language and methods adopted by them to garner support for the cause of Indian independence. While previous scholarship on anti-colonial activism focuses on the interactions of these activist groups with the government, courts, and security apparatus, this paper examines how these activists engaged with various sections of the American public. Their discourses made comparisons between India's struggles and aspirations and American history, society and freedoms. Within the discourse analysis methodology, this paper uses thematic coding and typological analysis to categorize the narratives of anti-colonial organizations based on their nationalist or internationalist approaches, and their stances on issues like labor rights, fiscal freedom, race/caste movements, and political liberties. The main sources of these narratives are editions of Young India, a monthly magazine published by the IHRLA between 1918 and 1922, pamphlets, articles and essays from the FFI, and public-facing media distributed by the anti-colonial movement on the eastern coast of the United States. Findings suggest that the IHRLA and activists with moderate views adopted a more internationalist approach to anti-colonial activism – such as calling on other countries to apply pressure on the British Empire - while the FFI and more radical activists adopted a nationalist approach that prioritized autonomous struggle and believed less in the ability of international forces or diplomacy to change India's colonized state. These findings add a valuable historical perspective to the literature on diaspora activism and the internationalization of regional movements, which is an ever expanding field in today's globalized world.

Abstract Name: 1984: The Story of How Larry Bird and Magic Johnson Saved the NBA

Before 1984, the National Basketball Association (NBA) had struggled to gain momentum. For one, in the 70s and early 80s, the league's image suffered from allegations of widespread drug use among players. The LA Times had estimated that 40-75% of players were using cocaine. Financial problems also plagued the NBA, and players' unanswered demands for more economic freedom placed the league's future in jeopardy.

But in 1983, just days before a planned players' work stoppage, the NBA and players union agreed on a revenue-sharing plan, avoiding the strike and setting the stage for the league's success. That same year, the NBA Drug Act was introduced, formally penalizing players who engaged in drug use. But more than anything, it was the face-off between the Boston Celtics and Los Angeles Lakers during the 1984 NBA Finals that would transform and ultimately save the NBA. During a time when racial tensions were high, particularly in the aftermath of Boston's busing crisis, the teams somewhat personified the racial dynamic of the time. The Celtics's overwhelmingly white team contrasted with the Lakers, who, like the rest of the NBA, were predominantly Black. This contrast was further reflected in the demographics of their fan bases, adding a racial dimension to the Celtics-Lakers rivalry. Additionally, the ongoing duel between legends Larry Bird and Magic Johnson captivated American audiences across the country. The present research seeks to analyze the widespread interest generated by their rivalry, which helped transform the NBA from a minor sports league with poor attendance, low television ratings, and drug scandals at the start of the 1980s into a popular global brand by the end of the decade.

Abstract Name: Computer vision-aided electronic skin

Carbon black-based pressure sensor has been widely used in robotic sensing. However, most sensors on the market are customized to either flat surface or point touch. There is a lack of flexible sensors that fit irregular surface areas such as finger tips. Furthermore, to generate standardized electrical signals, most sensors contains layers of electrodes, thereby are hard to customize. The development in machines learning makes it possible for computer to understand non-standardized electrical signals in complex environment. This project intends to utilize economical materials on mass market to produce non-standardized flexible sensors to facilitate robotic hand tasks, such as grasping, holding and manipulating objects. The precision of motion is controlled through computer vision and machine learning models. Existing studies have explored the use of carbon black materials for pressure sensing, establishing their composition, functionality, and limitations, addressing challenges in testing procedures to properly evaluate foundational information and maintain consistency. Current research hurdles include limited resource availability, ensuring consistent durability and quality, and effectively integrating the sensor with robotic systems. Our methodology includes a series of tests designed to evaluate the sensor's properties and performance. These tests include the multipoint probe measurement for assessing resistivity and conductivity, sheet resistance measurement to determine resistance per unit area, mechanical compression test for analyzing the material's response to varying pressure levels, and durability testing to evaluate long-term stability under repeated pressure cycles. The ultimate aim of this research is to create a low-cost, carbon black-based sensor capable of moderate pressure sensing in robotic arms. Such a design will benefit robotic enthusiasts to pursue cost-effective automation. Future research directions may involve exploring software solutions to leverage sensor data for more refined control of the robotic hand, thereby advancing the field of robotics in laboratory environments.

Abstract Name: Experimental and Numerical Analysis of Droplet Motion Within Rectangular Microchannels

Droplet-based microfluidic systems are involved in numerous applications, including medical diagnostic devices, microreactors, lab-on-a-chip devices, and high-throughput cell screening. Imperative to designing these systems is an understanding of droplet dynamics, especially within rectangular microchannels. Important parameters affecting droplet dynamics and microfluidic flow include the Reynolds number (Re), capillary number (Ca), viscosity ratio between drop/bulk phases (λ), channel geometry, and drop-to-channel size ratio. This investigation replicated microfluidic droplet behavior in an experimental flow cell, which has been scaled up macroscopically while preserving nondimensional parameter values and density-matching fluid phases. These experiments are compared to in-house numerical simulations, which employ a boundary-integral algorithm with a moving frame that reduces computational intensity for simulating viscous droplets in channels. Results indicate good qualitative and quantitative agreement between experiments and simulations. Increasing Ca results in more deformable drops that move faster, while increasing λ results in more deformable drops but with slower motion. Increasing drop size interestingly has different effects on steady-state velocity depending on λ. High λ droplets go slower as drop size increases, while very low λ droplets speed up with increasing drop size. Increasing channel aspect ratios predictably result in slower-moving droplets due to a lower maximum velocity of the Boussinesq flow profile. We also found that increasing the drop size leads to more deformation. Our findings suggest that it is possible to accurately replicate microfluidic phenomena on a macroscopic scale, making it easier and more cost-effective to prototype microfluidic systems.

Abstract Name: Progress Towards Three-Node Ion Trap Quantum Network

Quantum networking enables scaling of ion-trap-based quantum computers, where individual ion chains in separate traps can be entangled via photonic interconnects. Here we report our progress towards a quantum network consisting of three multispecies ion traps in separate vacuum chambers. Each node of the network contains barium ions for remote entanglement generation and nearby ytterbium ions for quantum memory. Using different species avoids crosstalk between communication and memory qubits and allows us to benefit from individual strengths of each ion species. Barium is well-suited for communications since it emits single photons in the visible range of the electromagnetic spectrum. Ytterbium features long coherence times allowing for long-lasting quantum memory. This approach offers potential for the creation of larger quantum networks for quantum computing scaling, quantum communications and other applications of quantum technologies.

Abstract Name: The Evolution of Architectural Skin - Adaptive & Reactive Architectural Facade

How can architecture employ modern technologies to adapt and react to its local climate? How can the complex evolution of various animal skins inform the design of an adaptable architectural skin?For centuries architects have strived to design structures that resist the environment. Many of the structures we observe today act as a seal between the two diverse environments (Exterior & Interior) and rely solely on mechanical systems to create this artificial environment. This artificial environment comes at a high energy and emissions cost. As a result, the built environment is responsible for 25% of global emissions; 18% of which comes from mechanical conditioning. Therefore, there is an extraordinary opportunity to create a global impact by exploring designs that dramatically reduce thermal conditioning demands.The research aims to first understand the complexity of the cross sectional and surface qualities of certain animals' skin; specifically, those that thrive in harsh environments. Through this process knowledge and inspiration for an adaptive facade system will be extracted. The research will then focus on looking into evidence-based adaptive facade systems to understand what has been done and is truly successful. Having these diverse research contributors will then lead to an intersection of design, balancing between what existing systems currently are and what they could become. Lastly, a model will be built and tested against a typical facade design / assembly. I expect to discover an opportunity for the evolution of architectural skins within this design process. An opportunity to leverage modern technology to reduce our dependency on mechanical systems and artificially manufactured environments. The severity of energy consumption globally suggests that even a marginal difference could have a dramatic impact on the world. In conclusion, the design of architectural skin has become complacent, and we must strive to manufacture a system that brings architecture to life.

Abstract Name: A Lesson on Sexism: Saunder’s Unintentional Gender Discrimination in Liberation Day: Stories

George Saunders is one of the most influential U.S. short story authors of the 21st century. His short stories often examine and criticize aspects of modern society, and his collection Liberation Day: Stories is no different. Throughout these short stories, he comments on technology, politics, conflict, morality, and income equality. Even with the inclusion of so many modern problems, the collection of short stories curiously avoids any comment on issues of gender and sexism. However, two of his stories with female protagonists seem to include a gender bias: “The Sparrow” and “The Mom of Bold Action.” Interestingly, while having a female lead, each story views the woman as inferior due to an inadvertent gender bias written in by Saunders.

In each story the secondary character, a man, overshadows the main character while the woman conforms to gender stereotypes. The female and male characters are divided by their gender in numerous ways throughout the story. Their names and titles, the types of relationships they hold with characters of the opposite gender differ, and their general roles throughout the story are all influenced by gender roles and stereotypes. Both follow the same pattern of the female character's unique identity and characteristics being overshadowed by the man regardless of their significance in the story. Their career goals, the way society describes them, and even their own names are given less importance than those of the male character. While each story contains its own intended societal commentary, there is an underlying lesson on sexism and gender roles to be found beneath the surface.

Abstract Name: Violence Against Women In Early Modern Drama: A Present Problem

When analyzing four plays from the early modern period, certain patterns of violence against women become apparent. The different violence typologies at play in these works reveal that the female body is perceived as a dangerous weapon that must be policed and trafficked to uphold patriarchal worldviews at women’s expense. The violence that these female characters experience exemplifies the oppression of patriarchal systems, many of which are still relevant today. Then and now, it is evident that the traffic and desecration of female bodies act as outlets for male anxiety about female agency and sexuality. In my research, I argue for alternative staging practices that either emphasize the pain the victims went through or elevates the irony of the men focusing on their emotions in the face of women’s dismemberment and death.

Abstract Name: Development of a method for the detection of U(VI) using an affordable light-emitting diode spectrophotometer

Uranium is a radiologically and chemically toxic element that occurs naturally in water, soil, and rock at low levels, but additional uranium can leach into groundwater sources as a result of mining operations, including uranium mining and processing for nuclear power, and improper nuclear waste management. Over the last few decades, a variety of methods for the detection of uranium have emerged, however, most of these techniques require skilled scientists to run samples on expensive instrumentation for detection or require the pretreatment of samples in complex procedures. With an increase in reliance on alternative power methods, including nuclear power, it is essential that a facile test for uranium contamination which can be completed

by a layperson be developed. In this work, a Schiff base ligand (P1) is used as a model system for the use of a simple spectrophotometric method on an accurate and affordable LED spectrophotometer for the detection of uranium (VI). Analysis of the data was performed with polynomial regression to test the fit of acquired calibration curves using a Python program on a Raspberry Pi. Herein, we report a line of best fit and equation for the prediction of uranium (VI) concentration for several prepared "unknown" absorbance values with acetonitrile (MeCN) as our solvent. Moving forward, we will be attempting to obtain a similar protocol and linear fit in a system with water as solvent, with the end goal of being able to replicate this detection with uranium present in a given sample of well water.

Abstract Name: Social Status Scuffle: Aggressive Behavior Used to Establish Dominance Between Male Lythrypnus dalli

Species that live in a linear social hierarchy use a combination of visual and violent aggressive behaviors to gain and emphasize status within a group. In the sexually plastic fish, the bluebanded goby, Lythrypnus dalli, three aggressive intensities are displayed by all fish in groups of two males and one female. Low and medium intensity aggression may include the use of sexually dimorphic traits such as dorsal fins and size to emphasize dominance, whereas high intensity aggression may include physical contact interactions. We investigated the impact of each aggressive intensity in groups of two dominant males and one female, all size mis-matched, on Days 1, 3, and 5 of the Dominance Phase during hierarchy resolution. We used the software KINOVEA to analyze 10-minute videos to reduce speed of movement and zoom in up to 600%. Fish of each status performed different proportions of each aggression type. There was a positive relationship between duration and rate of dorsal fin raise. Medium intensity aggression was a good indicator of status, as in previous studies. Males that won the dominant position in their groups displayed higher rates of high intensity aggression on Days 1, 3, and 5 compared to males predicted to change sex into females. This is an indication that physical contact aggression drives hierarchy resolution in this social context.

Abstract Name: Physarum Polycephalum: Solving Houston’s Traffic Problem with Cellular Intelligence

This research analyzes how to optimize Houston’s public transportation systems using the slime mold Physarum polycephalum and its efficient and replicable growth patterns. The World Bank reveals that, despite Houston and Tokyo’s similar area and commute times, Tokyo’s transportation systems can support a

population density eight times that of Houston. Using a simple food source such as oatmeal flakes, Physarum polycephalum is able to create optimal pathways between multiple points in linear time and expedites urban planning processes while accounting for possible variation, a goal valued by urban planners. Atsushi Tero, head of mathematics at Kyushu University, utilized Physarum polycephalum's evolutionary path-finding capabilities to recreate Japan's Railroad system. Tero's foundational literature established three benchmarks for Physarum polycephalum systems: minimum distance between high population densities (efficiency), amount of road used (cost), and ability to prevent isolation when a connection breaks (fault tolerance). Subsequent literature led by Masashi Aono has utilized Tero's benchmarks for Amoeba TSP, a computer interface containing slime mold to solve optimization problems. The proposed experiment starts with a to-scale topographical agar plate of Houston, Texas. Oatmeal nodes, representing the food source, are placed to simulate high population densities, and LED lights, which repulse the mold, are used to represent barriers to avoid. Physarum polycephlum will produce a thin film of tendrils accessing the most efficient routes between nodes. Over seventy-two hours, the most efficient routes will become prominent tendrils and the resulting tendril array will be placed onto a current road map of Houston. Comparing Houston's current road infrastructure to the pathways made by the Physarum polycephalum, urban planners will be able to balance optimal efficiency, cost, and fault tolerance for the system. Possible outcomes include a customized transportation network and replicable algorithm to determine expedited escape routes in disaster events and optimize roadways in underdeveloped areas.

Abstract Name: Investigating Numerical Methods for Integration Problem Resolution: A Comparative Analysis of Nonanalytic Techniques and Assessing Each Methodology and Identifying their Applicability in Real-World Scenarios.

Since integrals appear throughout academia and industry, the task of solving them is of paramount importance. Although integrals taught in introductory calculus classes can be easily solved, evaluating definite integrals of functions is challenging when either their antiderivative does not exist or is too computationally intensive for practical use. Many algorithms have been developed to numerically compute integrals; however, these results are imprecise and have tradeoffs between accuracy and speed. The differences that each algorithm has (in terms of precision as well as efficiency) dictate when they are useful in different situations. This study will investigate various techniques such as Newton-Cotes formulas and Monte Carlo methods, as well as techniques from differential equations like Runge-Kutta methods. Comparing this variety of formulas will help determine which methods are effective in their respective scenarios, allowing for gaps in effectiveness to become evident. From a computer programming perspective, the finite bit representation of numbers in computers makes it difficult for most calculations to be exactly represented, leading to the need for rounding (Goldenberg). This inherent rounding error in floating-point computation is a defining feature of numerical calculations, affecting their accuracy and reliability. To mitigate this type of error, strategies such as grouping multiplications and divisions before additions and subtractions and adding

smaller numbers together before adding them to larger numbers have been developed to create more accurate results. We evaluate the technical implications of each method while considering the complications of floating-point arithmetic; the research will highlight errors, numerical stability, and trade-offs between speed and accuracy when using float, double, and arbitrary precision arithmetic. Knowledge of the nuances of different algorithms, and different implementations of the same algorithm, helps applied mathematicians find the most suitable tool for any particular situation.

Abstract Name: Hemp's Growing Potential: Analyzing the Environmental and Socioeconomic Dimensions of National Hemp Production Post-Farm Bills

In the context of accelerating global climate change, stakeholders and institutions often undervalue the potential of industrial hemp. However, this underestimation disregards the thousands of possibilities that hemp can and has historically offered. Recognizing this, the United States' 2014 Farm Bill granted higher education institutions the right to cultivate and jumpstart research on hemp. In 2018, the Farm Bill removed hemp from the Controlled Substances Act given its minimal content (below 0.3%) of the psychoactive tetrahydrocannabinol (THC), effectively legalizing it as an agricultural commodity. The passing of these legislative benchmarks, driven by a more positive public perception, has sparked enthusiasm and capital investments in the wide-ranging applications of hemp, from pharmaceuticals to construction, textiles, biofuels, environmental cleanup, and climate change mitigation. Nevertheless, misinformation, bias, data inconsistency, and a lack of research have hindered the progress of hemp utilization. This paper will provide an improved exploration of the direct social, economic, and environmental impacts of hemp production in light of the 2018 Farm Bill and the approaching 2023 Farm Bill. By quantifying the various facets of hemp, this research examines the market and non-market values of hemp to develop a cost-benefit framework. This study draws data from the United States Department of Agriculture, the National Institute of Health, and the United Nations Office on Drugs and Crime to question if hemp's strengths and market promise are greater than its demonstrable costs and challenges. By comprehensively analyzing the net effects of increased industrial hemp funding and legalization, this paper offers valuable insights for stakeholders and institutions to consider when developing agricultural initiatives and policies.

Abstract Name: Pre-Columbian Art and Symmetry: An Experiment with Culturally Relevant Lessons

This study focuses on the understanding about symmetry young Latinx children develop using pre-Columbian art. The authors introduced Incan, Mayan, and Aztec art (as well as other cultural aspects), as an avenue to teach geometry and support the children's mathematical discourse. Authors explored how seven and eight-year-old Latinx children who were participating in a literacy summer program can demonstrate a deeper mathematical understanding of the topic, using Latinx culture to support the development of that knowledge. The questions guiding this study are: What are the early understandings about symmetry that Latinx children demonstrate before receiving any instruction on the topic? How do culturally relevant lessons revolving around Aztec, Inca, and Mayan art support the development of understanding of symmetry by those students? Data from 20 Latinx children was analyzed. The authors found that 85% of them created an almost symmetric design by the end of the intervention (up from 60% mid-intervention). But only 71% of those kept symmetric "halves" the same size (up from 67%). 65% of the children who created the almost symmetric design did discuss the need for there to be 2 parts that had to be "the same" or "equal". Finally, 53% of those children could also identify corresponding symmetric points on their designs. In addition to that, anecdotal data showed that children enjoyed learning about pre-Columbian cultures. They continued to mention them throughout the interviews, especially Mayan culture, when they described their designs. They claimed it was important for them and others to learn about these Incans, Mayas, and Aztecs and demonstrated pride in their connection to those pre-Columbian cultures. Classroom observation data is still being analyzed.

Abstract Name: How Can Genome Testing Help Save the Lives of Newborn Babies in the NICU?

What if there was an effective way to keep critically ill newborns out of the neonatal intensive care unit (NICU)? How may medical professionals determine which neonates require more attention than others? What if I told you that there is already a way to accomplish this? Let's talk about genome testing. The NICUs represent the principal application area for genomic medicine. Genome testing allows for parents to be assured that doctors have properly diagnosed their child and have the right course of action for treatment. Studies and research have demonstrated the benefits of using genomic medicine. By incorporating genome testing into best practices for NICUs and leveraging implementation science and quality improvement, a Genomic Learning Healthcare System may be put into place to assist reduce the incidence of neonatal and infant deaths. Early diagnosis and treatment of such illnesses can lead to a number of benefits, including improved health outcomes and the potential to avert severe, lifelong disabilities. Although parents who signed their child up for a genome sequencing randomized controlled trial were aware that there was a psychological risk associated with the procedure, they often had positive views toward genome testing and believed the advantages exceeded the risks. Scientists thought that genome testing would be extremely beneficial in the NICU, assisting physicians in prioritizing patients who needed the most care.

Abstract Name: Age-Dependent Alternative Splicing of Mapt in the Developing Mouse Cerebellum

The MAPT gene encodes the tau protein that is responsible for the assembly of microtubules and axonal stability in neurons. MAPT mRNA is extensively regulated by alternative splicing; splicing of exons 2 and 3 give rise to tau isoforms with 0 (0N), 1 (1N), or 2 amino-terminal repeats (2N), and splicing of exon 10 give isoforms with 3 (3R) or 4 microtubule-binding repeats (4R) in the carboxy-terminal of tau. Our early study demonstrated that in the mouse cortex/hippocampus, 3R variant was detected only at postnatal day (PN) 0 and 7 while 4R appeared at PN7 and was exclusively expressed by PN14. Concomitant with the age-dependent inclusion of exon 10, mRNA levels of two Mapt exon 10 excluders, splicing factor, suppressor of white-apricot (Sfswap) and RNA-binding motif protein X-linked (Rbmx), decreased a week after birth. In the current study, we aim to determine if the developing mouse cerebellum shows similar age-dependent changes in Mapt splicing and expression of splicing regulators required for processing Mapt transcripts. To address this, we have extracted RNA from the cerebellum of male and female C57BL/6J mice at PN0, 7, 14, and 21 days. Using RT-PCR, we first found that the developing cerebellum expressed only 3R at PN0 while 3R and 4R (with exon 10) both were present at PN7 and PN14. By PN21, only 4R was detected in the cerebellum. The developmental transition of 3R to 4R seems to last longer in the cerebellum than the cortex/hippocampus. In addition, 0N transcript was dominantly present throughout the first three weeks after birth, and traceable 1N and 2N were not detected until PN14. We will next use RT-qPCR to profile the expression patterns of the Mapt exons 2, 3, and 10 as well as the splicing regulators for inclusion of these exons in the developing mouse cerebellum.

Abstract Name: Libertad Estila Villana (Freedom through Villano's Perspective): Exploring Trans* Gender & Sex Politics within Reggaetón

Since its popularization, reggaetón has provided its audience with its amalgamation of music genres, influencing U.S. popular culture, evidenced by a rise of Reggaetón listeners on global streaming platforms. However, much of the vogue was initially propelled by cis-gender men reggaetóneros; however a new generation of women and queer folk are leading representation within the genre. In Hay Espacio Aquí, I explore Reggaetón's beginning stages of popularization with Puerto Rican youth and methods on how the archipelago attempted to remove deviancy, like queerness and sexuality. I explore how gender queerness and sexuality occupies space in reggaetón, focusing on the Puerto Rican transqueer femme musician, Villano Antillano. Their unapologetically queer lyrics and visuals effectively invites the audience to interject the queer experience within a male-dominated music genre. I draw connections with Deborah R. Vargas' queer theory of lo sucio, and Villano Antillano's technologies, emphasizing the importance of bringing intersectional identities of queer, gender and ethnic studies into the forefront of research.

Abstract Name: Differential effects of beta-amyloid deposition and diagnostic status for changes in hippocampal subfield volume across Alzheimer's disease continuum

Alzheimer's disease (AD) is a neurodegenerative disorder characterized by cognitive impairments co-factored with beta-amyloid (Aβ) plaques, neurofibrillary tangles, and atrophy in medial temporal areas of the brain—such as the hippocampus. The hippocampus is a brian structure relevant for learning and memory and consists of subregions (subfields). Whether and how hippocampal subfields are differentially affected by Aβ levels remains elusive. In addition, it remains unknown whether such relationships differ with diagnostic status across the AD continuum. This work investigates volumetric changes in hippocampal subfields and their relation to Aβ positivity status across the AD continuum. We evaluated 281 participants (ages 57-94 years) from the Alzheimer's Disease Neuroimaging Initiative Year 2 (ADNI-2) dataset. ADNI-2 is a longitudinal study developed to analyze the effects of cognitively normal (CN) aging, early and late mild cognitive impairment (EMCI, LMCI), and AD pathologies. High resolution images of the hippocampus were obtained using structural magnetic resonance imaging (MRI) and Aβ presence was detected using positron emission tomography (PET) scans. Statistical analysis of data revealed significant hippocampal subfield atrophy across a range of diagnostic groups. When comparing AD to CN diagnoses, there were significant decreases in the volume of several hippocampal subfields, including CA1 and the entorhinal cortex (ps<0.001). LMCI groups were associated with significantly decreased CA1, CA2, and entorhinal cortex volumes (ps<0.001). Finally, data indicated significant interactions between amyloid positivity and EMCI diagnoses for decreases in right entorhinal cortex and dentate gyrus volumes (ps<0.05). These results show specific relationships between hippocampal subfields and diagnostic status as a function of the presence of Aβ positivity. Assessing volumetric differences in specific hippocampal subfields across the AD continuum could help identify individuals at an earlier stage of AD development and further our understanding of the pathology of this debilitating disease.

Abstract Name: GYNECOLOGIC HEALTH PROMOTION AND DISEASE PREVENTION AMONGST LATINAS IN ALABAMA

The health of a population is influenced by its social and economic circumstances and the health care services it receives. Hispanics/Latinos living in the United States face a variety of barriers to receiving health care services of high quality that lead to consequential health disparities. These include lack of health insurance, inability to receive preventative care, and social and economic factors such as language and cultural barriers. The goal of my service learning project was to aid in the reimplementation of a health outreach program to promote health and wellness among Latinos in Alabama with a focus on women's health. "Sowing the Seeds

of Health" is a program designed by researchers in the UAB Department of Obstetrics and Gynecology to educate and provide health promoters and Latino patients with the knowledge and skills to promote gynecologic health and prevent disease in the Latino community and make a measurable impact on modifiable health behaviors in the Latino community. In partnership with UAB, we implemented programs that educate and provide health promoters with the knowledge and skills to promote health and prevent disease in the Latino community. Additionally, we provided various resources and programs free of cost such as breast and cervical cancer screening events catered to Latinas and information in both English and Spanish to aid them in navigating the healthcare system to get the care they need.

Abstract Name: Development of PROTACs to Study Peroxisomal Biochemistry

Peroxisomes are organelles found in most eukaryotic cells. The peroxisome specializes in oxidative reactions that produce reactive oxygen species (ROS). These processes often are similar to mitochondrial oxidative reactions except that instead of oxygen being reduced to two water molecules in a four electron process as the final electron acceptor, peroxisomal processes produce hydrogen peroxide from water in a two electron process. One example of this is fatty acid beta-oxidation which occurs in both the mitochondria and the peroxisome. Despite peroxisomes mirroring many mitochondrial processes that are known to be important to normal cell function, peroxisomes are poorly studied. Our group hypothesizes that this is due to a lack of tools to study the peroxisomes. Thus, we present the synthesis and biochemical characterization of PROteolysis-TArgeting Chimeras (PROTACs)-based tools to study key peroxisomal biochemical processes. We believe that by having more tools to study the peroxisome, we will enable studies that result in a better understanding of the peroxisomes and their role in cellular metabolism.

Abstract Name: Impact of Air pollution Exposure in Latino Communities: An Equity-based framework for Environmental Engineering

Hispanics make up the second-largest ethnic group after whites, yet these communities live in more polluted environments than their white counterparts and have higher rates of poverty. With low-income neighborhoods come unsafe and often hazardous environmental factors that harm the health of their inhabitants. Environmental engineering, a newer branch that combines civil and chemical engineering ideas, could offer a

variety of different solutions to environmental issues relating to air and water pollution. In A Terrible Thing to Waste by Harriet A. Washington, the author discusses the cognitive damage environmental racism can have if left to fester and I will further explore the other effects on this specific group. Previous reports have found strong connections between race and pollution in a neighborhood, but fail to propose solutions to these issues. Purpose: This research examines the effects of environmental racism and how that harms the health of Latino communities, as well as investigates possible solutions that environmental engineering practices can offer. Method: To answer this question, I will gather data from previous relevant studies about environmental health and then analyze and compare to data from a more affluent and predominantly white area.Results and conclusions: The expected conclusions that this research would have include establishing a stronger connection between the environment and sociocultural factors of Latino immigrants and proposing how an exciting new field of engineering can aid in providing solutions to improve the life and wellbeing of these individuals.

Abstract Name: Screening for Increased Cyanobacterial Growth in a Mutant Library

Arthrospira platensis (A. platensis) is a species of cyanobacteria that uses carbon dioxide, light, and water to create glucose and oxygen, and alongside an engineered Escherichia coli (E. coli) can be used to create 2,3-butanediol (2,3-BDO), a rocket propellant that can aid in the colonization of Mars. This engineered E. coli uses sugars created by A. platensis and carbon dioxide to create 2,3-BDO. This process is limited by the reduced growth rate of A. platensis in the presence of high glucose concentrations. A. platensis cells and growth media were purchased from University of Texas at Austin Culture Collection (UTEX 3086). A. platensis was grown in nutrient media for seven days under continuous (24-hour) 200 μmol m-2 s-1 light intensity, then was exposed to UV rays (UV-C 254nm, 15W, Philips) for 20 minutes in a sterile petri dish. The UV-irradiated cells were spread on Petri dishes with solid growth media and were grown under continuous light until colonies were formed. Individual colonies were picked and transferred to falcon tubes containing growth media supplemented with 40g/L glucose. The colonies were grown for seven days in falcon tubes and biomasses were estimated using a spectrometer at 680 nm wavelength. Subjecting A. platensis to UV-induced mutations created a mutant library, and we are currently screening the mutant library for strains with enhanced growth rates. Genetic analysis can be performed on mutant strains to engineer a highly productive variant, which can contribute to the sustainable production of 2,3-BDO, which can kickstart sustainable space travel.

Abstract Name: Classifying Patient Survival Rate with the Use of Machine Learning Models

In biomedical research and clinical applications, machine learning algorithms play a crucial role in automating analysis and providing better support in diagnostics. This project uses various algorithms to classify patient survival and rank features that determine the most significant risk factors in the Heart Failure Clinical Records dataset from the UCI Machine Learning Repository. This dataset contains the medical records of 299 heart failure patients, including 12 features that document clinical, body, and lifestyle information. Based on comprehensive literature reviews and analyzing the varying accuracy results from different studies, the selected machine learning models are Random Forest (RF), Support Vector Machines (SVM), and Long Short-Term Memory (LSTM) Recurrent Neural Networks. LSTM models can retain important information and long-term dependencies while discarding irrelevant information. Their ability to recognize and respond to such patterns in the dataset enables them to be very effective models. SVM was observed to outperform most models in several other studies concerning cardiovascular diseases and is an ideal model because of its ability to process complex and non-linear data by creating a hyperplane that separates features. Among many research papers, RF was a commonly used model because of its ability to take the average set of decision trees, which helps mitigate the impact of outliers. Each model was evaluated based on accuracy over 100 iterations, with various parameter tuning options for each method. The results of this study showed that LSTM displayed the highest accuracy, with RF displaying the second highest, and SVM had the lowest accuracy of these selected models.

Abstract Name: Cosmic Muon Station for Outer Tracker Module Testing

The Outer Tracker (OT) is an essential component of the CMS High-Luminosity Large Hadron Collider (HL-LHC) upgrade project at CERN, Switzerland. OT module performance measurements typically rely on internal charge injection in lieu of an external source, limiting the extent to which the entire end-to-end system can be tested. By using cosmic muons as a real source of ionizing particles, we fill this gap and assess the synchronous performance of the modules. A cosmic muon station interfaced with simple scintillators / photomultiplier tubes (PMTs) allows us to understand the behavior of the silicon module in the presence of an external trigger and characterize key metrics such as position-dependent efficiency and resolution. The project primarily focuses on the hardware setup (e.g., detector setup, frontend-backend connection, DAQ) and the analysis software (e.g., DAQ, data analysis, script automation) that help utilize cosmic ray muons as external triggers to test the efficiency of OT modules.

Abstract Name: Corrosion Studies Of An Additively Manufactured Aluminum Alloy

Additively manufactured aluminum alloy 6061 (A6061-RAM2) in the as-printed and heat-treated conditions were the materials of interest in this study. Test coupons of these materials were exposed to a 3.5 wt.% sodium chloride (NaCl) solution. They were then subjected to electrochemical tests to determine open circuit potential and linear polarization resistance. Potentiodynamic polarization scans were also conducted. As a comparison, conventionally processed aluminum alloy 6061 (AA6061-T6/T6511) was also exposed to 3.5 wt.% sodium chloride (NaCl) solution and tested. The corrosion response of the conventional and additively manufactured alloys will be reported. Insights from this study should be useful for process improvements and materials selection.

Abstract Name: MOLECULAR DYNAMICS SIMULATION FOR THE MECHANICAL PROPERTY OF DNA MOLECULES USING THE DENSITY FUNCTIONAL THEORY

The field of Biophysics is rapidly growing, as physicists have found it to be a new lens through which to view the human body. Molecular dynamics simulations performed on the stretching of DNA molecules have revealed changes in their structure. This research supports our theory that as a DNA strand's length increases, its structure warps and changes will be observed in the backbone, plate, and base-base interactions. The most significant observed change thus far is the rotation of Carbon-5 at many sections along the backbone, occurring more readily at regions of the backbone immediately superior or inferior to a Guanine nitrogenous base.

Abstract Name: KPC Mouse Pancreatic Cancer Cells Demonstrate Thermal Sensitivity

Pancreatic cancer is a devastating disease with an extremely low survival rate of 12%. Hyperthermia, a class of treatment using heat, can enhance standard of care cancer therapy and may offer advantages in treating pancreatic cancer. Magnetic iron oxide nanoparticles can be selectively injected into tumors and heated with alternating magnetic fields. When considering this type of therapy for future studies in mice, it is important to know the appropriate thermal dose that inhibits the growth of pancreatic cancer cells. We used water bath hyperthermia and clonogenic survival assays to determine a surviving fraction of KPC cells, a mouse pancreatic cancer cell line, based on their ability to form colonies after exposure at various thermal does, 37, 39, 41, 42, 43, and 44°C for one hour. We found that KPC cells show a median 50% decrease from control in their ability to grow after a thermal dose of 42°C for one hour and a median 99% decrease from control after 43°C for one hour. We conclude that KPC cells are thermally sensitive, motivating future studies with these cells.

Abstract Name: In the Middle: Birth Order and Childhood Experience

Background. This cross sectional mixed-methods study collected data from adults (n = 140) about their emotional and cognitive childhood experiences based on birth order. Comparative baseline scores of subjective well-being (emotional and cognitive) (Diener et al. 1985) using the satisfaction with life scale (SWLS) (Andrews & Withey, 1976) were used to see differences between groups. The SWL scale looks specifically at emotional and cognitive outcomes (Diener, 1984; Veenhoven, 1984) which are paramount in understanding childhood outcomes. This study also asked participants to share their most memorable childhood experience. Anticipated Outcomes. With data collection still in progress, this study hypothesizes that there with be statistically significant group difference with the SWL baseline measure. A hierarchical linear regression model will be implemented to determine significant correlations between demographic (independent) variables and SWLS scores (dependent variable). Additionally, this study expects to find qualitative themes related to emotional and cognitive childhood experiences based on demographic variables. Methods and Preparation. This study has IRB approval. Participants are college students recruited in the PI's Fall 2023 and Spring 2024 courses with a hyperlink for the Qualtrics survey. Students in the PI's courses will be offered a minimal extra credit incentive. Additionally, adult participants not affiliated with the PI's Fall 2023/Spring 2024 courses are being recruited via social media platforms (e.g., Facebook). This study recognizes the use of a convenience sample and encourages participants to forward the survey link to applicable families (e.g., snowball sample). Study Progress. This study will stop collecting data by the end of January 2024 and begin data analysis the first week of February, 2024. Discussion and conclusion sections will be completed by early March. Oral presentation preparation will be completed well before the NCUR conference.

Abstract Name: Glitter’s Future – Not As Bright As Its Shine

Glitter is all around. We find sparkle in children’s toys, beauty products, and even within us. The manufactured microplastic averages 200 μm in size and is composed of plastic, a PET core, and aluminum. The product comes in a variety of size, color, and shape combinations which makes each variation and property unique. While having beneficial uses in areas such forensic and veterinary science, glitter causes a slew of problems for the environment, marine life, and human health as it negatively affects different species' nutrient intake and organ systems. Regulation for a similar product has been put into place before in the Microbead-Free Waters Act of 2015, which bans the use of microbeads in wash off beauty products. In order to prevent our future generation from continually being born with plastic already inside of them, the use of glitter in children’s toys must be banned.

Abstract Name: Understanding the Role of AI and Large Language Models in Catfishing on Dating Sites: A Multi-Dimensional Study

This research project aims to explore the intricate relationship between Artificial Intelligence (AI) and Large Language Models (LLMs) in the context of catfishing on online dating platforms. The central research question investigates how AI and LLMs are utilized in catfishing activities and the effectiveness of AI-driven solutions in combating this form of digital deception. The study is positioned within the broader scope of AI ethics, cybersecurity, and online social interactions, seeking to make a unique contribution by unraveling the dual role of AI as both a facilitator and a defender against catfishing. The methodology combines qualitative and quantitative approaches. Qualitative analysis involves interviews with victims of catfishing, psychologists, and cybersecurity experts, providing a multi-faceted view of the problem. It seeks to understand the psychological and social consequences of catfishing, as well as the technical nuances of AI involvement. Quantitative analysis entails examining data from dating platforms to identify patterns distinguishing AI-generated fake profiles from genuine ones. In terms of research context, existing studies have primarily focused on the social and psychological aspects of catfishing, with limited exploration of the technological mechanisms enabling it. This study fills this gap by focusing on AI and LLMs' role in this phenomenon, thus offering new insights into the interplay between technology and human behavior in the digital dating arena. The expected results include detailed insights into the operational mechanisms of AI and LLMs in catfishing, an evaluation of the current AI-based defensive measures on dating sites, and recommendations for improvements. Additionally, the study aims to propose guidelines for users to recognize AI-generated catfishing attempts. Findings will be discussed in the context of enhancing online dating safety, AI ethics, and user education, contributing significantly to the understanding AI-facilitated digital deceptions in online dating environments.

Abstract Name: Investigating Gene Expression of Inflammatory Markers in the Adventitia as Potential Indicators of Early-Stage Diabetic Vasculopathy in a Tissue Engineered Model

Introduction: Diabetic vasculopathy, characterized by the dysfunction and damage of blood vessels due to diabetes, remains a major complication and leading cause of death in diabetic patients. Currently, early detection of diabetic vasculopathy is limited and difficult to achieve. In this study, we investigated the potential of using a selection of associated biomarkers to determine early indicators of diabetic vasculopathy. With the final goal being to develop a viable disease model of the disease.Materials and Methods: The vessels were constructed using our lab's techniques regarding the isolation of patient derived fibroblasts (PtFibs) in addition to the formation and stacking of vascular tissue rings. The vessels were subjected to three varying blood glucose levels, two of which being hyperglycemic conditions and one being a control. For a given time period, media is changed daily and blood glucose measurements are taken to ensure stable test conditions and to monitor cell activity. Afterwards, real-time polymerase chain reaction (RT-PCR) testing is conducted to see if the chosen inflammatory markers are expressed.Results and Discussion: Throughout the given duration in which cells are exposed to the given hyperglycemic and control conditions, blood glucose measurements show the vessels to be in a consistent state of hyperglycemia. In addition, it can be noted that some groups experience an overall drop in blood glucose concentrations as days of exposure increases. This can be indicative that within the vessels, there is a high count of living cells digesting the glucose present within the media.Conclusions: Our study provides novel insight into the molecular mechanisms underlying early-stage diabetic vasculopathy. The creation of a working disease model of early-stage diabetic vasculopathy is essential for the development of pharmaceutical treatment and underlying knowledge surrounding the disease. Our findings are leading to the completion of a working model of diabetic vasculopathy.

Abstract Name: Editing CDKN1A and RASD1 In a Cell Culture System

As an individual ages, there is a higher incidence of cancer and infertility. Testicular germ cell cancer rates have been rising year after year. According to the American Cancer Society 1 of every 250 males will develop testicular cancer during their lifetime. In this research project, we aim to develop a molecular toolbox to analyze gene function in male germinal cells using a CRISPR/Cas9 cell culture system. This biotechnology allows for the targeted alteration and cutting of specific DNA strands. To achieve this, we will utilize cancer cell lines (SUSA and NT2/D1 testicular cancer cell lines) and knock out two genes of interest: cyclin-dependent kinase inhibitor 1 (CDKN1A) and ras-related dexamethasone-induced 1 (RASD1). Our objective is to investigate the effects of gene knockout on cell proliferation. For this purpose, we designed primers and

single-guide RNAs using bioinformatic databases: Benchling and Chop Chop. The tools we used were employed to amplify human genomic DNA and assess the effectiveness of the guide RNAs through in vitro cutting of our genes of interest, followed by gel electrophoresis observations. Based on the results obtained from these experiments, our next step is to electroporate the guide RNA and Cas9 complex to alter gene function in our cell culture system. Through a better understanding of gene function in testicular cancer cell lines, we hope to inform future therapeutic targets for both testicular cancer and age-related infertility.

Abstract Name: Parametric Study to optimize Thrust of a Small Scale Dual Rotor Helicopter

Recent work presented at SCCUR-2023 involved investigating the impact of distance between two rotor blades of a toy helicopter on its thrust. A thrust stand was built that consisted of a load cell and sensor to measure the rotational speed of the propeller. The helicopter was attached with a Degraw 5 kg load cell that was attached to a HX711 load amplifier. The thrust stand was calibrated using load weights, and the calibration curve was used to determine the required thrust at varying operating conditions. Initial experiments revealed that the thrust generated varied from 1 to 5 N, as the rotation speed increased from 1000 to 3000 rpm. Higher rotational speed for both rotors produced higher thrust that ranged from 10 to 35 N. The current experiment is now extended to a larger dual rotor helicopter (DEERC-DE51) that is modified to take its input voltage from a power supply. This gave the flexibility of changing rotational speeds without any fluctuations. For this application, a different load cell (CALT DYLY103-S beam load cell sensor) with the capacity to measure up to 50 N is used. An optical bench is used to hold the z-shaped load cell and for the calibration, known weights are being used to operate the load cell in a tensile mode. The signal from the load cell is further amplified by an amplifier and the readings are monitored and recorded on a microprocessor (Arduino). The helicopter design is flexible enough to change the distance between rotors and experiments are being performed to optimize the thrust by varying the blade separation. Preliminary results show promising trends as the separation between blades does impact the overall thrust of the helicopter. New results are being compared with the previous optimization data and will be presented in the conference in greater detail.

Abstract Name: Queens, Scientists, Creations, and Aliens: an Afro-futurist Intervention into the Horror of Dr. Frank N Furter’s Colonial Fantasy

“The Rocky Horror Picture Show” is a tribute to the history of pop rock, sci-fi, and horror culture; it is also a challenge to the lack of queer representation in these genres. Through its integration of camp aesthetics and

overt queerness with pop-cultural tropes, the film presents the ways queer art has been inspired by and inspires the mainstream pop cultural mythic while highlighting how queer people and identities have been historically omitted from and/or subtextually vilified by its narrative worlds. 50 years after the release of Rocky Horror, the film has become a cult classic and cemented itself in the canons of queer culture and camp art, and its radical intervention into the queer shadows of pop-culture begs to be translated into the contemporary context of our age. Ileana Waddy seeks to give this new life to the text. By applying an intersectional, decolonial lens to her dramaturgical work, she argues that the film's science fiction tropes are influenced by cultural ideologies of white supremacist pseudosciences, manifest destiny, racialization, alienation, racialized gender construction, and practices of eugenics, and produce a metaphorical narrative that represents the oppression and violence that such ideologies and fictions justify in the cultural imagination. Guided by the question, "how would it change the story to make apparent the unspoken presence, the phantom of Blackness and anti-Blackness that haunts The Rocky Horror Show," she arrived at the idea that if read critically, a production of Rocky Horror could provide a critique of white supremacy and colonial violence. By reframing the familiar dynamics of the story through changes in theatrical aesthetic elements, she reimagines Richard O' Brien's legendary original script as an afrofuturist musical that reflects Black queer expressions of joy and experiences of oppression, marginalization, exploitation, and resistance within and outside of the queer community.

Abstract Name: Two-Step Synthesis of a Novel Phthalein Based pH Indicator

Conventional phthalein dyes are used as pH indicators due to their distinct color change in solutions of different pHs. For example, a solution of phenolphthalein in water turns from colorless to pink as the pH of the solution is increased from acidic to basic. Here, we propose a two-step synthesis of a novel phthalein based pH indicator from commercially available materials that utilizes reactions commonly encountered in undergraduate organic chemistry courses. In step one, the pure product of 1-phenyl-2,3-naphthalenedicarboxylic anhydride was obtained which was then used in step two by reacting it with phenol. The final product obtained contained acid base color change indicator properties similar to phenolphthalein. However the final product was unable to completely solidify which indicated that phenol was still present. Currently, we are attempting to purify the final indicator product to better characterize it through NMR and melting point analysis. Once the pure indicator product is obtained, the synthesis will be incorporated into the organic chemistry and quantitative analysis laboratory curriculum at Georgia College with the aim of enhancing student learning outcomes through a student-centered hands-on pedagogy.

Abstract Name: Microwave Assisted Solid-State Synthesis and Characterization of RuMo5Se8 and Preliminary Proton Adsorption Studies

With growing energy demands it is apparent there is a need for green energy solutions that transition away from fossil fuels and aid in the lowering of carbon dioxide emissions. Chevrel phase (CP) chalcogenides are candidates for this due to their potential as catalysts for energy conversion and storage materials. CPs have shown promise as electrocatalysts for hydrogen evolution reactions (HER) and carbon dioxide (CO2) conversion, however efficient and selective electrochemical conversion is hindered by achieving controlled bonding affinity of key intermediates. CPs have the generic formula MyMo6X8 (M = alkali, alkaline, transition, post-transition metal; y = 0 – 4; X = S, Se, Te), and are described typically as a molybdenum octahedron surrounded by a chalcogen pseudo cube. Due to the tunable nature of CPs, it allows changes in the electronic structure that influence charge transfer and binding of intermediates at the catalyst surface. One way the structure of Chevrel phases can be tuned is through substitution of the molybdenum octahedron with another metal like Ruthenium, Rhodium, and Rhenium. RuMo5Se8 has been studied as catalysts for the oxygen evolution reaction (OER) and shown increased activity compared to Mo6Se8. This work reports the utilization of microwave-assisted solid-state techniques to optimize the synthesis of RuMo5Se8 as well as preform hydrogen evolution reaction (HER) experiments on Mo6Se8 for comparison against ruthenium substituted Chevrel phases to probe proton adsorption as a function of substituting molybdenum for ruthenium.

Abstract Name: Effect of Stress and Physical Activity Levels on Cardiometabolic Risk Factors in Student Physical Therapists in Los Angeles County

During graduate medical education, student experience high stress due to demanding curriculum and performance expectations. Most studies on stress and graduate healthcare education have been performed on medical students, but not Physical Therapy students (STPs). High stress has been connected to increased cardiometabolic risk factors (CRF), but exercise has been shown to lower stress levels as well as mitigate some of these CRF. This project's purpose is to explore the relationship between stress levels, exercise, and exercise-related CRF in SPTs. Specifically, the aim of this project will examine exercise-related indices of cardiometabolic health in SPTs compared to undergraduate students. We hypothesize that SPTs will exhibit higher stress scores and more exercise-related CRF, including lower aerobic fitness, decreased muscular strength, and lower physical activity levels, and have a greater number of exercise-related CRF than undergraduates. Currently enrolled SPTs and undergraduate students between the ages of 18 – 45 were recruited and tested on the following outcomes: 1) stress as measured by perceived stress scale (PSS), 2) 7-day moderate-to-vigorous physical activity (MVPA), 3) strength as measured by isometric hand grip strength, 1-rep max leg and chest press, and aerobic fitness as measured from cycle ergometry VO2peak, 4) blood pressure and fasting glucose. T-tests were used to compare the means of outcomes between groups. Forty-five SPTs and eight undergraduate students enrolled in the study. Undergrads were younger and had higher BMI compared to SPTs No differences in stress score, strength, blood pressure or fasting glucose were observed between groups. Compared to undergrads, SPTs demonstrated significantly lower MVPA but higher aerobic

fitness. The results showed that our hypothesis was false undergrads had more exercises-CMF and no difference in stress levels than SPTs. Future research on specific exercises that have the most significant impact on these risk factors and stress could be explored.

Abstract Name: When and why do they alarm call? : Insights from naturalistic and automated monitoring of California ground squirrels

Many animals living in social groups emit antipredator signals, including vocalizations called alarm calls, in response to danger. Although these calls are well-documented in many animals, most studies have focused on their production during the day. California ground squirrels (Otospermophilus beecheyi) represent one such social mammal that produces alarm calls when threatened. As part of The Long-term Behavioral Ecology Project at Briones Regional Park, the focus of this study was to characterize the duration, ecological context, and timing of these alarm calls. As a major prey species for coyotes, rattlesnakes, and birds of prey, we predicted ground squirrels should produce alarm calls to warn other nearby squirrels of these natural predators. In addition, anthropogenic disturbances may also pose potential threats to squirrels and trigger calling. To understand at what times and under which circumstances the ground squirrels produce alarm calls, we investigated the specific stimuli that triggered individually marked squirrels to call. The calls were most strongly associated with natural predators (e.g., coyotes, off-leash dogs) but not humans, and that some individuals consistently called more often and for longer bouts than other individuals. We also utilized an automated passive monitoring system to record acoustic information over the 24-hour cycle. Monitoring equipment was set up in a central location of the study area and squirrel calls were recorded. We analyzed the acoustic recordings in a software system called Raven Pro. These recordings, along with natural observations, offer novel insights into the temporal patterning of alarm calls, the stimuli triggering alarm call production, and the individual differences in calling propensity. Our findings confirmed our hypothesis that ground squirrels mainly call during daylight hours, following an alarm-calling “schedule.” This data offers new insights into not only what triggers squirrels to call, but also the temporal patterning of fear responses over time.

Abstract Name: Assessing soil lead contamination in Hispanic neighborhoods around Norristown, PA

Lead contamination in soil is an environmental justice concern in minority communities. Anthropogenic sources of lead in soil include fossil fuel combustion, fertilizer/pesticide use, present or past industrial activity and mining, incinerator, smelters, lead-based paint residue from exterior paint, and urbanization. Children's blood lead levels are generally higher in Hispanic communities than those in white neighborhoods, which is concerning due to the adverse health effects of lead exposure such as cognitive and behavioral developmental delays and long-term sequalae of anemia, hypertension, and renal impairments in adults. A collaboration between scientists from Villanova University and a local community organization was carried out to assess lead soil contamination in residences and parks of a Hispanic neighborhood in Norristown, PA. A total of 78 soil samples were collected from 38 households. Lead concentration was analyzed by X-Ray Fluorescence (XRF) and Inductively Coupled Plasma Mass Spectrometry (ICP-MS). The mean lead concentration in soil based on ICP-MS analysis was 271.54 ppm (Range: 0.47 – 3396 ppm). About 19%of the soil samples exceeded US EPA's standard of 400 ppm lead in soil. Norristown may be subject to legacy pollution due to many industries such as textile and paper mills established during the late 1800's and early 1900's. There seems to be an association between the historical mill locations and the soil Pb concentration in Norristown. Alongside assessing soil lead contamination, this project aims to inform the community about lead risks and ways to mitigate lead exposure.

Abstract Name: Synthesis and Characterization of Chemical Tools to Study Human Carboxylesterases (CESs)

The efficacy of drugs can vary person to person due to factors that influence the activity of drug metabolic enzymes. Human serine hydrolases called carboxylesterases (CESs) are such enzymes which are known to have several factors that can modify their activity. Despite clinical studies linking interindividual variability in CESs to adverse outcomes when treated with drugs known to be metabolized by CESs, they are understudied compared to other enzymes involved in drug metabolism. To address this need for methods to study CESs, fluorogenic chemical tools for studying CESs have been reported, however, many have not been fully characterized to determine their suitability for studying CESs in live cells. Our group is interested in developing new chemical tools for CESs that can be used in live cells. To this end, we report the synthesis and characterization of a series of chemical tools based on esters that are known CES substrates. These

chemical tools will eventually lead to a better understanding of the factors that influence CES activity and a person's ability to metabolize certain drugs.

Abstract Name: Collaborative scholarship in action: Engaging students and faculty in an authentic research partnerships

Recent scholarship suggests that Course Based Undergraduate Research Experiences are associated with numerous academic benefits, such as higher course averages and increased engagement for underrepresented students. Despite these benefits, CURE courses can be time-consuming to plan and implement. This is a challenge for faculty who also need to research and publish to be successful in tenure and promotion. In fact, prior studies have shown that faculty desire more guidance on combining their research with their CUREs. Our study aims to fill a gap in the scholarship on how faculty can effectively balance their teaching and research obligations. The following research question guided our study: What faculty strategies and course design elements best support collaborative student and faculty CURE research that can lead to publishable results? The study was quasi-experimental, and it utilized qualitative methods. Data collection included pre-post interviews with students, collection of students' research diary entries, and interviews with CURE course faculty. The student data were collected during an upper-level undergraduate psychology course on Bilingual Cognition. Students collaborated with faculty to conduct an empirical study on the effects of bilingualism on false memory. Researchers gathered data from student participants regarding their experiences collaborating with faculty on the Bilingual Cognition study. Following data collection, researchers used an inductive method to conduct conventional content coding of the qualitative data. Both researchers analyzed and discussed the data and identified emergent themes. Researchers expect to present findings about how to communicate to students about the scope of the project and students' role in the project. We also will discuss findings related to creating a timeline for training students and data collection, analysis, and eventual dissemination. In sum, the study will report several best practices for conducting collaborative research with students in the classroom that can be disseminated at conferences and in scholarly journals.

Abstract Name: Physical Activity and Perceived Stress among University Employees

Physical Activity and Perceived Stress among University Employees Regan Walker, Melissa D. Powers University of Central Oklahoma, Edmond, OK Physical activity has direct links to lowering the risk of chronic health conditions and aids in the ability to cope with stress. Some of the top stressors in life are

building a career, finances, and fear of losing a job. The purpose of this project was to study the relationship between volume of physical activity and perceived stress among university employees (n = 85). Participants completed an online survey that included the International Physical Activity Questionnaire (IPAQ), the Perceived Stress Scale (PSS), and demographic questions. The IPAQ gives a measure of weekly volume of vigorous-intensity physical activity (VPA), moderate-intensity physical activity (MPA), walking physical activity (WPA), and total physical activity (TPA; the sum of VPA, MPA and WPA). The PSS is a validated instrument for assessing perceived stress that includes 10 items with a range of scores from 0-40. Pearson correlation coefficients were conducted to analyze the relationships between physical activity variables and PSS. Demographic information collected from participants indicate that 72.9% were female, 87.1% reported being white or Caucasian, and their mean age was 45.18 years. The results show an average PSS score of 16.26±7.30. Non-significant, weak, inverse relationships were observed between PSS and VPA ($r = -.069$, $p = .529$), MPA ($r = -.188$, $p = .084$), WPA ($r = -.178$, $p = .103$), and TPA ($r = -.200$, $p = .066$). These results indicate that volume of PA is not related to PSS, although the weak relationship did approach significance for the total PA variable. In conclusion, further study of this relationship is warranted in a larger, more representative sample.

Abstract Name: Localization of rDNA during metaphase in Saccharomyces Cerevisiae

Saccharomyces cerevisiae is a unicellular fungus that is often used for basic research. S. cerevisiae's nuclear genome is organized into 16 chromosomes. During metaphase, the DNA stretches out between the mother and the bud, with the bulk chromatin spanning the neck and stretching into the mother cell. The ribosomal DNA in the mother often appears as a loop. The long-term goal of this project is to describe the distribution of rDNA during metaphase, specifically when the role of one or both topoisomerases has been affected by either genetic modification or the addition of chemotherapeutic drugs. This project came about after establishing a procedure for DAPI staining of DNA and noticing a quasi-agglomerated appearance to the loop in the mother. Our goal is to determine what is causing that inconsistent appearance.

Abstract Name: Why the Iroquois Confederation Allied with the British During the Beaver Wars and Not the French

From the early 1600s to the 1700s, the Iroquois Confederation allied with the Dutch and English during the Beaver Wars, a series of conflicts centered on the fur trade fought between the French and their Indigenous allies and the British and the Iroquois. Why did the Iroquois Confederation fight with the British instead of the French during the Beaver Wars? Using travel journals from New France explorers and French

missionaries, and the treaties that ended the conflict, this paper argues that the Iroquois Confederation opposed the French because of their trading alliances with rival tribes, and the French had previously massacred an Iroquois army to assist the Hurons, one of their ally tribes. The French had superior weapons, such as steel and firearms, and the Iroquois needed guns to fight the French. As a result, the Iroquois became allies with the Dutch and then the English after the fall of New Netherland. This alliance with the British gave the Iroquois the weapons they needed to expand their territory and weaken the French fur trade and the French's Indigenous allies. This alliance between the British and the Iroquois would create future alliances, as they would unite against the French again during the French and Indian War.

Abstract Name: Ethical Issues in Pharmaceutical Marketing

The opioid epidemic has rattled the US and shows the drastic realization of addiction. It is disheartening to see the effects of this crisis radiate throughout communities everywhere (Cortes, 2021). The cause for concern is the problem of a manufactured crisis: companies such as Purdue Pharma lied in their marketing of dangerous drugs and many people became sick (Chow, 2019). In this project, utilizing frameworks provided by Hartman et al. (2024), I examine the ethics and legal implications of pharmaceutical marketing. Through examining primary and secondarily-sourced case studies of pharmaceutical marketing, I will show the ethical quandaries that exist in this discipline. Ultimately, I argue, today's pharmaceutical marketing should receive the negative attention it deserves as when unchecked it becomes a force of unfathomable harm. The cracks within law and regulation show how easy it is for goliaths of industry to corrupt a system of health service that its intentions are supposed to help not harm. The use of profits to faultily market products should not be allowed, these groups targeted by the industry are often vulnerable and susceptible to the large influence of these companies (Mitchell et al., 2020). According to Hartman et al. (2024) there are both utilitarian and Kantian ethical concerns raised in marketing. Legally, too, Hartman et al. (2024) shows there are legal issues of negligence and strict liability. Solutions exist with proper conversation and action, but will we ever get to the point where we place the locus of attention on the topic? The consequences of pharmaceutical marketing pose a problem because it could slowly erode trust and sentiment towards our healthcare system (Spielmans, 2015). This system should be trusted by people and be a beacon of hope as when done right, it is a force for good.

Abstract Name: Impact of State Government Revenue Diversification on Income Equality

This paper analyzes the impact that tax-revenue diversification has on income equality in the United States. This paper builds on Carroll's (2009) research regarding how state government revenue diversification impacts revenue stability. This paper also builds on existing literature of income inequality, but instead of looking at revenue stability as the dependent variable, examines how state-level tax revenue structures impact income equality. Theoretically, revenue stability should translate into progressive government programming that reduces income inequality. The independent variable of revenue diversification is measured using the Hirschman-Herfindahl Index (HHI) and data is collected from the Urban Institute state-level government data in FY21. The dependent variable of income equality is measured using the Gini Index and collected from the U.S. Census Bureau.

Abstract Name: Invisible Illness: The Silent Epidemic For Women

Background: The following study examines the experiences, including the treatment, diagnosis, and marginalization, that women with invisible illnesses, specifically, autoimmune diseases, have had with medical professionals. Uncovering the experiences that women with chronic illnesses have had with physicians, the following research reveals how these interactions have impacted their mental and physical well-being in their respective social lives. Ultimately, this study brings awareness to the real-life implications for women with invisible chronic illness. Methods: The method used in this study consisted of a content analysis of social media discussion platforms. The data was collected from the semi-public Facebook group, "Girls with Guts Private Forum: Support for Women with IBD and/or Ostomies," and the public Reddit groups consisting of "TwoXChromosomes" and "Ankylosing Spondylitis." The data was analyzed using a qualitative thematic analysis of 19 responses. The sample comprised of all women ages eighteen and older with any autoimmune condition, however, there was a special emphasis placed on inflammatory bowel disease and ankylosing spondylitis. Results: The findings of this study revealed three major themes: misdiagnosis, patriarchal healthcare, and social implications. Doctors rely on orthodox andronormative diagnosis standards to account for women's symptoms, which often delays an accurate diagnosis for women patients. Often, women's pain is attributed to emotional dysfunction and side effects of their physiology, like menstruation. Overall, women with chronic illness are continuously marginalized in healthcare simply because they are women. Conclusion: This study exposes how women with invisible illness experience a healthcare system with the inherent gender biases in diagnostic processes and pain management. It is imperative to end the delays in diagnosis and disbelief of women's pain so that they can live with dignity and purpose.

Abstract Name: Enhancing Environmental Education through Virtual Tours

Virtual tours act as a means to explore diverse environments and phenomena from anywhere in the world. Particularly beneficial for individuals facing physical limitations or geographical barriers, virtual tours provide an opportunity to visit remote areas, historical sites, and other locations that may be challenging to access. They also serve as a safe and controlled environment for exploration, catering to individuals with limited mobility or those unable to undertake long-distance travel. While nothing can replace the in-person experience, virtual field trips enable those unable to attend physically to participate virtually, reducing anxiety and providing an opportunity to prepare for the trip. Such Virtual tours are already in use by the Stanford University. The project's primary focus is on creating virtual tours for the Bad River's tribe regarding Pipeline 5. The tour for the Bad River tribe aims to spread public awareness of the dangers Pipeline 5 poses to the tribe's wellbeing. Secondary objectives include creating virtual tours for the University of Wisconsin Whitewater's (UWW's) Nature Preserve, the Whitewater Effigy Mounds Preserve, the Koshkonong Effigy Mounds, and the UWW's campus garden. UWW Nature Preserve and UWW campus garden will act as a resource for promotion of the UWW Sustainability Office as they will highlight the efforts towards a sustainable future. Finally, the virtual tour of the two effigy mound preserves will foster respect for the area and aid in its preservation. Future work involves enhancing these tours by adding more information and tailoring them to specific classes or projects. In conclusion, virtual tours offer invaluable opportunities for individuals with physical or medical limitations to participate in field trips and explore hard-to-reach locations. While nothing can fully replace the in-person experience, virtual field trips reduce anxiety, help individuals prepare for the trip, and boost confidence.

Abstract Name: Alternative Green Synthesis of the Green Pesticide

Carbaryl is a wide-spectrum synthetic insecticide used outdoors to control a wide variety of insect pests both in largescale farms and in small gardens and lawns. Unfortunately, the synthesis route used in the industrial production of carbaryl requires the use of the highly toxic and poisonous methyl isocyanate (MIC). In 1984, the leakage of MIC from the Union Carbide chemical plant in Bhopal, India was the cause of thousands of fatalities. Due to the toxicity of MIC, the synthesis of carbaryl and its derivatives also poses a huge challenge for teaching and research labs curtailing structure and activity studies. In order to develop a "greener" synthesis of carbaryl without the use of MIC, a pure carbaryl standard must be established and compared

against the synthesized product. Commercially available Sevin® pesticide, which contains carbaryl as the active ingredient, was used as a source of carbaryl. The carbaryl in Sevin® was isolated from the inactive ingredients and characterized by proton and carbon NMR and melting point analysis. Since the standard carbaryl has been isolated, the synthesis of carbaryl using safer reagents is the next objective. Future plans for this project involve the synthesis of carbaryl via a 4-nitrophenyl carbamate intermediate in a two-step reaction. The synthesized carbaryl will then be compared spectroscopically to the carbaryl isolated from Sevin®.

Abstract Name: Hydrothermal Alteration Related to the Brittle-Ductile Transition at the Sierra Crest Shear Zone, Eastern Sierra Nevada, California

The Sierra Crest Shear Zone (SCSZ) is a dextral-oblique fault that documents hydrothermal alteration patterns at the brittle-ductile transition along the eastern Sierra Nevada. This shear zone is along the eastern boundary of the Tuolumne Intrusive Complex (TIC) and its contact zone. Hydrothermally altered andesitic to dacitic metavolcanic units of the Triassic Koip Group and the calc-silicate metasedimentary Jurassic Sawmill Canyon sequence are the two major units that host the SCSZ. Metamorphic grade increases from greenschist to amphibolite facies toward the TIC. The origin of hydrothermal fluids at the brittle-ductile transition in strike-slip faults, such as the SCSZ, is poorly understood. Documentation and analysis of alteration mineral assemblages done in conjunction with isotopic studies provides clues to fluid chemistry and fluid sources. Infrared spectroscopy identified muscovite, chlorite, tremolite, biotite, actinolite, calcite, phengite, and epidote in both the Koip and Sawmill Canyon sequences. Petrographic analysis and field observations reveal that alteration related to brittle deformation is characterized by undulatory extinction of quartz, 0.5 to 5 cm-thick bleached zones with chlorite and sericite adjacent to quartz±tourmaline veins, and breccia fillings containing epidote, tourmaline, and chlorite. Ductile rocks also display chlorite, epidote, and sericite as alteration minerals, but quartz experienced dynamic recrystallization and biotite appears shredded and is altered to rutile, chlorite, and sericite. Within the Koip Group, plagioclase is fractured with a preferred orientation and displays alteration to epidote, actinolite is heavily altered to biotite and chlorite and is nearly perpendicular to quartz veins. Biotite is also heavily altered to chlorite along cleavage planes. Epidote alteration of plagioclase and amphibole is prevalent in the Sawmill Canyon sequence. Biotite that defines lineation is almost completely altered to chlorite and quartz has undergone dynamic recrystallization. Stable isotope data indicates that magmatic fluids from the TIC and meteoric-hydrothermal fluids are responsible for the SCSZ-related alteration.

Abstract Name: Identifying Potential Oxygen Transport Membranes Via Structural Analysis of B-Site

Dependent Perovskites Oxides

Oxygen Transport Membranes (OTMs) are crystalline solid materials that allow for oxygen to move through their structure. OTMs due to their catalytic properties can be applied to several fields of interest, such as alternative fuel production, chemical looping processes, catalytic converters, and medical devices. The widespread implementation of OTMs has been hindered by a lack of understanding of the mechanism that allows perovskite oxides to repeatedly perform these specific redox reactions. In this research, we seek to provide an explanation of how structural changes to a perovskite oxide's B-Site may affect a crystalline solid's ability to function as an OTM. End members of the perovskite oxide lanthanum iron nickel oxide (LaFe1-y Niy O3-∂) were synthesized at specific mole ratios and characterized using X-Ray powder Diffraction (XRD). The software Vesta and SoftBV analysis create an accurate molecular representation of perovskite oxide structure based on powder diffraction data and allows for the analysis of potential oxygen movement through the perovskite structure. We hope to understand, by means of Vesta analysis, how perovskite oxides can serve as OTMs.

Abstract Name: Traditional Chinese Medicine's Approach to Chronic Illness: A Discussion on Asthma

This presentation will discuss how Traditional Chinese Medicine (TCM) addresses chronic illness, and how this shift in approach might be better suited for managing similar illnesses than current clinical practice. TCM is rooted in ideas of balance and imbalance between the body and its environment as well as within the body between each of the organ systems. When imbalances occur within the body, illness results. Correcting this imbalance and helping the body return to equilibrium is the goal of any TCM treatment. A combination of ethnographic and literature data will be used to present an overview of the world view that shapes Traditional Chinese Medicine and discuss how that worldview has shaped the medical system as a whole. The ethnographic data was obtained during a group interview process with an expert in TCM and served to guide the research process, while the literature data was used to support and add depth to the points made throughout the interview. This presentation will use asthma to highlight TCM's approach to illness by discussing the different types of asthma, their causality, and their treatment processes. A focus on food therapy will be taken when considering the treatment process in order to further showcase TCM other principles and the character of both the foods and the organ systems being treated. This discussion on asthma serves as an example of how the approach that Traditional Chinese Medicine takes in order to treat such chronic illnesses transforms the illness from a debilitating condition to something that can be managed through careful dietary choices. Chronic illness is never going to be something easy to manage, but this management doesn't always have to be crisis control or pain alleviation. TCM demonstrates that lives can be lived despite the presence of chronic conditions.

Abstract Name: Altering Phosphorylation of HP1a Induces Sterility and Excites Early Death in Drosophila melanogaster

The Heterochromatin protein 1 (HP1) family are non-histone chromosomal proteins that are key factors in the formation of heterochromatin and in transcriptional regulation. HP1 proteins are found in many eukaryotic organisms including plants, animals, and fungi. HP1a from D. melanogaster was the first HP1 protein discovered, and it has been intensively studies for more than three decades. HP1a can act both as a repressor and an activator of transcription. Like many other proteins, HP1a undergoes post-translational modifications such as phosphorylation. However, little is known about the functions of HP1 post-translational modifications, including phosphorylation. To advance our understanding of HP1a's post-translational modifications, we produced two HP1a mutants that either mimic or block phosphorylation. We replaced serines (S) 88/89/91 (S88/89/91) either with glutamic acid (E) to mimic permanent phosphorylation or with alanine (A) block phosphorylation. Using these mutants, we investigated how phosphorylation of HP1a impacts its known functions. Western blot demonstrated that the phospho-mimic HP1a protein is stable but accumulates in decreased levels compared to wildtype HP1a. A position effect variegation (PEV) assay indicated that both mutant HP1a alleles act as suppressors of variegation. On the organismal level, we found that homozygous phospho-mimic HP1a mutants have a significant reduction in fertility for both sexes compared to heterozygous and wildtype animals. We observed a significant decrease in ovary size for the homozygous phospho-mimic HP1a mutant females when compared to heterozygous and wildtype animals. Parallel experiments with the HP1a phospho-block mutant strain are ongoing. Overall, our results show a significant fertility decrease, due to the decreased ovary size in homozygous mutants, a decrease in overall mutant protein concentration with an increase in suppression of variegation when compared to control. These results suggest that phosphorylation of HP1a proteins at the modified site (S88/89/91) have specific functions in the Drosophila germline.

Abstract Name: From Supply Chain Optimization to Autism Spectrum Disorder Screening: Engaging Undergraduate Students in Cutting-Edge Research

In this presentation, I will share my personal experience of leveraging university resources and supporting mechanisms to engage undergraduate students in cutting-edge research. Research topics vary from supply chain resilience, inventory optimization, to developing machine learning models for screening autism spectrum disorder in young children. I'll share stories and results of mentor-student collaboration in this journey, best practices and lessons learned.

Abstract Name: Strategies for Including Individuals with Disabilities in Clinical Trials

The Americans with Disabilities Act describes a disability as any mental health or physical condition that can cause impairment when performing major life activities. Disabilities often co-occur with chronic illnesses. People with disabilities are regularly excluded from research that typically focuses on a single specific condition. Exclusion poses a challenge to advancing care - it reduces scientific attention to people with disabilities, which contributes to a lack of data about this population, limiting their prioritization in health research. The risk associated with excluding individuals with disabilities from participation in clinical trials perpetuates health disparities by limiting the generalizability of findings and having clinical trial results that do not accurately reflect the efficacy of treatment for populations with diverse health care needs. For this project, a literature, policy, and resources review was conducted to identify strategies for improving the inclusion of persons with disabilities in clinical trials. Recommendations highlight methods for improving inclusivity and proposing new solutions with an emphasis on increasing the communication of resources for individuals with disabilities to access clinical trials. The discussion focuses on how implementing these changes can further the mission of improving healthcare equity and enhancing the safety and effectiveness of treatments for everyone.

Abstract Name: Correcting the stiffness calibration for optical traps

Optical trapping is an experimental technique used to apply piconewton scale forces onto model membrane systems. This allows us to measure changes in key physical properties as membranes undergo dynamic processes such as shape changes. To obtain accurate measurements of force, the “stiffness” of the trap must be determined through a calibration step. The equipartition calibration method calculates the stiffness by algorithmically tracking the position of a trapped bead over time. Camera readout noise creates inaccuracies in tracking which are propagated to the calibration step. We describe a mathematical model to correct for such inaccuracies and obtain a better calibration estimate. We use simulations based on empirical image data to determine the parameters in this model, and we demonstrate that our model indeed leads to improved calibration. With this new equipartition calibration method, we will be able to adapt our optical trapping setup to perform experiments investigating how the insertion and removal of lipids and proteins in model cell membranes affects membrane properties. These studies ultimately provide insight into the interplay between the multitude of processes occurring at the cell membrane.

Abstract Name: Susceptibility of Mycoplasma genitalium Clinical Isolates to Tinidazole

Mycoplasma genitalium (MG) is a sexually transmitted bacterial pathogen commonly associated with urethritis in men and cervicitis, endometritis, pelvic inflammatory disease, infertility, and preterm birth among women as it invades the upper reproductive tract. Infections can persist for months to years without effective treatment. MG has developed resistance to first-line drug choices which are now effective in less than half of patients. Recent data suggests that MG is susceptible to tinidazole (Tdz), a nitroimidazole-type antibiotic. The Tdz minimum inhibitory concentration (MIC), the concentration that inhibits growth by 99%, for 10 MG strains has already been determined but additional MICs are needed to predict in vivo efficacy as strains can vary in their susceptibility to particular drugs. This project will determine if an additional 10 MG clinical strains are susceptible to Tdz, what the range of MICs is, and if current strains have already developed resistance. Twofold dilutions of Tdz will be added to MG clinical strains in 48-well plates containing Vero cells required for MG growth. Doxycycline (DOX), a first-line drug choice, will serve as a control for correct assay performance as DOX MICs are already known for these strains. After incubation at 37 C/ 5% CO2 for 21-28 days, MG growth in individual wells will be quantified with qPCR and the percent growth inhibition in duplicate Tdz wells will be compared to quadruplicate “no drug” control wells. Calculated percent inhibition and MIC data will be compared to known Tdz pharmacokinetics to predict which antibiotic concentrations are useful for treating infected patients. As physicians are already beginning to treat MG patients with Tdz, data regarding the susceptibility of multiple isolates is crucial in informing dosing regimens. Tdz may fill the urgent need for effective MG treatments as it is already FDA-approved for the treatment of other infections.

Abstract Name: Variations of Magic Labelings on Zero-Divisor Graphs

A zero-divisor graph is a graph whose vertices are non-zero, zero-divisors of a commutative ring R with unity and two distinct vertices are adjacent if and only if they multiply to be zero in R. Like on any graph, we can assign values to vertices and edges given certain constraints, which we call labeling. We investigate magic type labeling of zero-divisor graphs. In particular, we turn our attention to semi-magic, magic, and super-magic labelings. We are able to find infinitely many rings which admit these magic type labelings as well as infinitely many rings which do not have these magic type labeling. We further proceed to determine all of the rings which have zero-divisor graphs with up to 14 vertices as to their magic type properties. We then are able to make some conjectures about how these patterns may continue for larger zero-divisor graphs.

Abstract Name: Cold Stunned Sea Turtle Standings in Cape Cod, Massachusetts

Cold stunned sea turtles strandings are a natural phenomenon. When sea turtles become caught in cold waters and are prevented from moving into warmer waters, they endure a form of hypothermia called cold stunning. Onshore wind blows several species of sea turtles onto beaches, which is also called stranding. Cold stunning is fatal for sea turtles unless they are rescued and rehabilitated. Strandings most often occur in shallow bays and lagoons, and in areas where geography blocks a sea turtle's migratory path to warmer water. The geography of Cape Cod makes it a natural place for turtles to strand. This Massachusetts peninsula is the site of the world's largest recurring annual sea turtle stranding. However, the number of cold-stunned turtles in the area has drastically increased in the past few decades. This spike may be linked to warming ocean currents from climate change that cause a delay in sea turtles' migration south combined with Cape Cod's hook shaped geographical features.

Abstract Name: Crimes of the Future: The Case for a Trans Look

This research project seeks to prove the existence and capabilities of a unique "transgender look" which allows transgender individuals to alter filmic reality and generate visual pleasure for themselves. The transgender look, as this research aims to assert, is a (sometimes oppositional) gaze that reclaims the power of looking, which has so often been weaponized against the transgender individual by cisgender filmmakers and viewers. The existence of the trans look is built on Laura Mulvey's ideas of visual pleasure, bell hooks' writing on oppositional gazes, and Jack Halberstam's inception of the transgender gaze. Though illuminating, Halberstam's theory of a trans gaze focuses on how cisgender viewers could adopt said gaze, and fails to take into account actual trans viewers and how ostensibly "cisgender" films could be "made trans" via a trans look. This is a gap in Halberstam's theory— one that this research will fill by expanding his notion of a transgender gaze in order to include actual trans viewers. By analyzing David Cronenberg's 2022 film Crimes of the Future, and by applying and expanding the theories of Mulvey, hooks, and, chiefly, Halberstam, this research will assert that trans viewers are able to indulge in cinematic fantasy by applying their own experience to films, even those which do not include explicitly transgender characters. In doing so, this research and the resulting research paper will assert that transgender viewers are generating a unique trans look that has the power to redefine films, create alternative forms of visual pleasure, and change the course of cinematic history.

Abstract Name: The Genetic Viewpoint of Environmental Sex Determination in Plants: RNA Extraction of Striped Maples

Many land plants reproduce through flowers. These flowers express the sex of the plant, based on the reproductive structures within the flower. Male structures produce pollen and female structures produce seeds. How these flowers are arranged on individual plants comprises the sexual system. There are three main sexual systems: hermaphroditic, monicious, and dioecious. With the increase of stressors brought about by extreme weather events occurring under climate change, dioecious plants are predicted to be most affected. To better understand how plants are being affected by the changes in the environment, the lab is studying the reproductive evolutionary process seen in plants. Plants may get their cue to be male or female through genetics or through the environment; these two routes are considered genetic sex determination and environmental sex determination. Historically, these two pathways to sex expression have been researched separately. Most research on environmental sex determination has been ecological, and the genes of plants have not been studied. This lab has chosen a native maple tree to look at the expression of genes to better understand the genetic component for when sex is determined by the environment. To investigate this, we used Striped Maple, a species that possesses the ability to change sex from year to year. Using this fluidity, the lab is looking for differentiation between the expressed genes between the sexes. The lab went out into the woods and collected flower and leaf samples from striped maple trees at sites in Northern Michigan. The tissue samples were brought to the lab, where we extracted RNA. Future work will be to sequence the RNA, analyze the results, and run comparisons between the two tissue types and the two sexes. These results will help us better understand the genetic basis for environmental sex determination.

Abstract Name: Will You Be My Friend?: How K-Pop Expanded Into the United States

This thesis examines the history of Korean Pop (K-Pop) to define strategies industry leaders utilized to expand the market of K-Pop music in the United States. The researcher analyzes existing studies to identify four main tactics: multi-domestic and transnational marketing strategies and persistent usage of social media to create awareness of the genre and to cultivate strong fan loyalty. This thesis also applies the Uses and Gratifications theory to examine why these strategies aided in successful market expansion. The researcher examines how the industry meeting audience's needs of surveillance, cultural transmission, entertainment, and social interaction enabled people to gain interest in K-Pop; this maintained interest allows the industry to expand its market as companies gain and sustain money, public attention, and fans. This thesis reveals the importance of figuring out how to inform an audience of a foreign industry's existence and, in turn, gain an engaged audience and a place in intenational markets. As the world becomes increasingly connected, this

thesis provides an example of how future industries can use similar tactics when introducing a foreign business or concept to other countries across the globe.

Abstract Name: Chromatic Continuity: The Historical Evolution and Influence of Bauhaus Design in Graphic Art

The Bauhaus design movement, originating in the early 20th century, stands as an enduring symbol of innovation and artistic prowess, leaving an indelible mark on the world of design. Its historical inception marked a pivotal moment that sparked a transformative evolution, redefining the very essence of creativity and craftsmanship. Through a revolutionary approach that emphasized functionality, minimalism, and aesthetic appeal, the Bauhaus movement revolutionized design and artistry. This movement's inception and formative years serve as a cornerstone for understanding its profound impact. Delving into its core principles reveals a paradigm shift that introduced clean lines, geometric forms, and the skilled utilization of primary colors, reflecting an ideology rooted in purposeful design and aesthetic harmony. This paper undertakes an exploration of the foundational principles and early stages of the Bauhaus movement, shedding light on its revolutionary concepts that continue to shape and inspire contemporary graphic design. By unraveling the ideology behind Bauhaus design, it underscores how these principles persist as a driving force, reinforcing the movement's relevance and influence in today's ever-evolving design sphere. The enduring impact of Bauhaus design extends beyond its historical context, resonating profoundly in modern graphic design practices. Understanding its historical underpinnings allows for an appreciation of its timeless relevance, as Bauhaus principles continue to serve as a source of inspiration and guidance for designers navigating the complexities of the present-day design landscape. Consequently, the Bauhaus movement stands not merely as a relic of the past but as an enduring beacon guiding the trajectory of design innovation and artistic expression.

Abstract Name: The Probability-Conserving Marble Bag: Maintaining a Constant Probability of Selecting a Color Pair with the Addition of New Colors.

Two marbles are drawn without replacement from a bag of red and green marbles. We add marbles of a new color to the bag and draw once again, then add marbles of a further new color and re-draw, etc. Can the numbers of new marbles added be chosen in such a way that the probability of drawing two marbles of the

same color remains constant at each stage? In this paper, we deduce the initial numbers of red and green marbles for which the answer is yes.

Abstract Name: The Simulacra: Fragmented Survival Through Storytelling in Soviet Occupied Georgia

Once Upon a Time in Georgia by Aka Morchiladze borrows its namesake from the much more familiar Sergio Leone film, Once Upon a Time in America; assuming its identity in the process as a bid for survival. It is set in the time of perestroika near the end of the Soviet occupation of Georgia, the storytelling presenting a distorted, at times rambling retrospective, written as if active history is myth and the storytelling of Leone's movie is concrete fact. However, intermingled within the text, there are factual truths alongside the emotional ones. American media trickles into the landscape; Sergio Leone is rumored to be filming a movie in Georgia, and tales Bob Dylan and Robert De Niro appear as if magic, though all the factual. The narrator's focus flows from famous actors and musician into Russian politics, American politics, and perestroika with each given the gravitas of the other. In every discussion, fact and fiction fight with censorship and public pressure. Press critical of the Union is shut down while a picture of America, fashioned as a propaganda tool from the ultra-violence of Sergio Leone, becomes as real as the occupation itself. After fixating on American violence, Soviet occupation, the ending note is hopeful, undercutting the genre-typical cynicism much needed in our current global dialogue. Once Upon a Time in Georgia highlights the brutalism of the Soviet Union's rule of Georgia by transplanting the story into a digestible series of myths, false realities, and truths that reflect its national identity—a truth that has only become more relevant to our own modern lives than ever before.

Abstract Name: April Greiman: The Start of the New Wave

April Greiman is known to be one of the leaders of the New Wave design movement created in the 1970s. She is credited with bringing the distinct style to Los Angeles after studying at the Kansas City Art Institute and the Basel School of Design in Switzerland. She was taught by successful designer Wolfgang Weignart who is attributed with the creation of the New Wave. Greiman's style was defined by her unique use of typography, colorful shapes, layering, and chaos combined with structure. Her application of the computer is what set her apart from designers at the time. Many were opposed to her use of the MacIntosh computer, but she quickly proved that her knowledge and means of exploration would create a path for innovation. Greiman continued her work despite critics who found her work overly personal and lacking true design. These responses only empowered Greiman to create more conceptual works and show the graphic design community what she was capable of. Her most famous work is, "Does it Make Sense" a life-size print of Greiman herself depicting a timeline of both personal and nonpersonal points in her life which was viewed as

radical at the time. Combining science and design would lead to her own individual style that has stood the test of time. Greiman has won numerous awards such as the AIGA gold medal for lifetime achievement and other prestigious accolades that put her at the forefront of design pioneers.

Abstract Name: The Silent Killer: Hypertrophic Cardiomyopathy

Heart disease, one of the most prominent diseases that the human population faces, discriminates against no one and attacks some of the healthiest individuals in the modern population. In this project, one heart disease, Hypertrophic Cardiomyopathy, is investigated. Hypertrophic Cardiomyopathy (HCM) affects one in 500 people, making it a common genetic disease. However, most individuals are unaware they have the disease until it is too late. The genetic presentation of hypertrophic cardiomyopathy presents as a single base pair change in the genome, and an individual requires just one faulty gene within one chromosome to inherit the disease. While there are numerous treatment options, such as pharmacological options, surgery, CRISPR splicing, or even heart transplants, there is no simple cure for HCM. Countless patients have become activists and spokespersons for the disease, addressing what life is like for them and their disease and advocating for change. Chronic illnesses are not easy to live with, and patients are bravely wearing their disease as a badge of honor and fearlessly telling their stories so others will be able to recognize the signs of HCM and get help before it is too late. The outlook for HCM is the reality that a lack of treatment and diagnosis will leave numerous individuals desperate for answers. Athletes, performers, and everyday individuals are collapsing with heart issues that they have never before been diagnosed with: it is then determined to be Hypertrophic Cardiomyopathy. Further screenings need to occur for all individuals to get appropriate diagnosis and data surrounding HCM, as well as continuing research and understanding of the effects of HCM, such as genetic inheritance, sudden death, and potential treatments.

Abstract Name: Reverberations of Medical Racism: Exploring the Legacy of VCU School of Medicine through the EMSW Project

In Reverberations of Medical Racism, we will present our ongoing work at Virginia Commonwealth University (VCU) as Health Humanities Lab Research Fellows within the East Marshall Street Well (EMSW) Project. The EMSW Project documents the history of medical racism at the Medical College of Virginia

(MCV, now VCU School of Medicine) and its ongoing impact on health inequities today. The EMSW Project takes its name from a well at MCV where, in 1994, human remains from more than fifty individuals were discovered during construction of a new medical building.Historical and scientific research revealed that the remains were of Black Richmonders whose bodies were stolen by MCV professors between 1848 and 1860, used for dissection at the school, and then discarded in the well. The EMSW Project was founded in 2013, and works to analyze the ramifications of medical racism in Richmond, as well as to enact the recommendations of the Family Representative Council that seeks to represent the voices of those found in the well. The recommendations prioritize ethical research, memorialization, and burial of the ancestors with dignity. They also include an emphasis on contextualizing the broader history between Richmond's medical establishments and the city's African American community to address healthcare disparities and to better understand their historical roots within the Richmond community.As Health Humanities Lab Research Fellows, we have joined this important project and are helping to advance an ongoing oral history and memorialization initiative. In this presentation, we will provide the historical context for this work and present our ongoing research to uncover the history of racism in medicine and its ongoing effects on health inequities today.

Abstract Name: Thinking of Thrasychirus: Evolutionary and Phylogenetic Analysis of South American Long-Legged Harvesters (Arachnida, Opiliones, Neopilionidae)

The vast majority of life on this planet remains undiscovered or undescribed; for instance, around 80% of insect and arachnid species are still undescribed. Harvesters, colloquially known as "daddy long-legs", are especially in need of taxonomic revision as their diversity is highly underestimated due to their limited geographic dispersal. The Gondwanan long-legged harvester family Neopilionidae consists of over sixty species spread over South America, Africa, Australia, and New Zealand, with many described over fifty years ago without molecular techniques. Currently, we lack a published in-depth phylogenetic analysis of South American long-legged harvesters within the genera Thrasychirus, described in 1884, and Thrasychiroides, described in 1947. In addition to this, the three known species of Thrasychirus have only been recorded from the southern tip of Chile, whereas specimens of Thrasychirus have been collected and recorded from all across Chile and the residing Andes mountain range (with Thrasychiroides in Brazil). In this project, we use Sanger sequencing of COI and 18S for phylogenetic analyses, adding to previously sequenced data. Using integrative taxonomy combining genetics and qualitative morphometrics, we then determine whether genetic lineages within these broader clades can be considered as separate species. Our findings indicate that there are at least four broadly distinct clades, most with high levels of genetic variance indicative of species. Through furthering our knowledge of the systematics and phylogeny of Thrasychirus and other Gondwanan members of Neopilionidae, we contribute to our understanding of harvester diversity and reaffirm that there remains a great deal of diversity left to describe.

Abstract Name: Producing Magnetic Field Windings Using Solid Harmonic Polynomials

Solid harmonics (solutions of the Laplace equation) can be fit to the any magnetic field profile, so that the corresponding scalar potential can be used to design intricate coils to implement these fields in a variety of experiments. The first step is to obtain the magnetic field measurements. Our measurements included the x, y, and z components of the B-field at 63 different specified points. The field was measured inside a 1 m × 1 m × 1 m cube, with 33 cm between each indexed measurement point. Solid harmonic polynomials were fit up to 5th order (35 degrees of freedom) were fit, allowing to model the magnetic field everywhere in the volume. Multiphysics simulation software COMSOL was used to solve Laplace's equation and design the wiring pattern needed to actively cancel this field. This set of windings will be fabricated and sent to the Nuclear Reactor Program Center (NRP) at North Carolina State University in Raleigh, North Carolina to be used the PULSTAR facility.

Abstract Name: Design Hero: Rob Janoff

This paper covers the life, career, techniques, and influence of Rob Janoff, a Culver City-born graphic designer. The first part of the paper is about where he grew up and why he changed his major from industrial design to graphic design at San Jose State University. Following that it details his technique of keeping things simple. This defines one of Rob Janoff's guiding concepts. He felt it was best to choose something easy to remember and simple because complex things were difficult for people to remember. Your logo will stand out because of this. That's how you leave your mark. Third is how Rob was hired to make a new logo for Steve Jobs' new computer, the Apple II in 1977. This part goes into more detail about his first meeting with Steve Jobs, and the design process. I also briefly talked about the previous Apple logo and the man who designed that version, Ronald Wayne. The fourth part of the article discusses what he did after working at Apple. Since then, Rob has established multiple contacts and clients in Chicago, IL, and New York City. Rob has formed a company with a business partner and has worked with many companies all over the world like Italy and Japan. Finally, the article discusses the impact of his work and his advice to young designers.

Abstract Name: The Effect of Silver on Agrobacterium Tumefaciens

The purpose of this experiment is to determine which silver; silver colloids, silver dendrite, or silver nitrate is most effective against the growth of Agrobacterium Tumefaciens (A. Tumefaciens). A. Tumefaciens is a soil-borne pathogen that is widely studied for its genetic transformation capabilities. Although it is studied for its positive aspects, A. Tumefaciens causes a neoplastic disease, Crown Gall Disease on various plants. This disease is transferred from the bacterias Ti (tumor-inducing) plasmid, TDNA, into the host plant. A. Tumefaciens manipulates its host by altering the plant's DNA by adding new instructions that keep the bacteria alive. Plants infected with Crown Gall Disease receive less nutrients to thrive. For this experiment, A. Tumefaciens was used in liquid and gel form. Nutrient broth agar plates were made to apply the two forms of A. Tumefaciens onto separate plates. Concentrations of silver colloids, silver dendrites, and silver nitrate were kept consistent with both forms of bacteria. It was found that the silver colloids were most effective against A. Tumefaciens in the gel application. Silver nitrate and silver dendrite were partially effective against A. Tumefaciens. In an effort to protect plants from Crown Gall Disease, farmers may now have the opportunity to use silver such as silver colloid, dendrites, and nitrate.

Abstract Name: Addressing Medical Mistrust in the Black Community to Improve their Health Outcomes

The consequences of medical mistrust among the older Black population are associated with adverse health outcomes, including delays in preventative care, seeking treatment, and compliance. Before 1968, healthcare facilities were separate but equal. Despite desegregation, low-paying jobs and uninsurance contributed to the Black population's poorer health care quality. In light of this, the older Black population has an intriguing role to play in the study of medical mistrust as they were exposed to unequal and unethical treatment in healthcare during their lifetimes. The aim of this study was to investigate medical mistrust to find ways to improve health outcomes among the older Black population. A mixed-methods approach was used for this study. Twenty-one participants completed a Group-Based Medical Mistrust Survey (GBMMS), with 5 participants who completed a semi-structured interview. Descriptive and correlation analyses were conducted. The GBMMS was separated into 3 subscales: 1) Suspicion, 2) Group disparities in healthcare, and 3) Lack of support from healthcare providers. The mean score for the GBMMS was 3.41 (SD=0.74). Significant correlations were found between Factor 1 and income ($r=-.459$, $p=.048$). Results from the in-depth interview indicated 5 primary themes, including 1) Historical references to racism in the healthcare system, 2) Racial discrimination common in a doctor's office, 3) Assumptions made about health issues amongst Black patients, 4) Not seeking medical attention when needed, and 5) Utilization of primarily Black doctor. This study found that medical mistrust is multi-factorial and influences the willingness of Black people to seek treatment. Medical mistrust can be reduced by intervening at the micro and macro levels. Public health initiatives should be implemented at the micro level and at the macro level, implementing cultural competency training, physician outreach with trusted community groups, and increasing minority representation in healthcare.

Abstract Name: Deintercalation Studies of a Layered Intermetallic in the K-V-Sb Ternary System

Crystal structures incorporating a two-dimensional layered architecture are interesting due to their potential for providing synthetic access to new materials. A notable example is the LiCoO2 layered compound used as a cathode material in commercial Li-ion batteries. KV6Sb6 is also a layered compound consisting of covalently bonded [V6Sb6] layers separated by K+ ions. The recent interest in this and similar types of compounds is due to the identification of exotic magnetic properties due to the trihexagonal arrangement of vanadium atoms, known as the Kagome lattice. Previously, our group synthesized and fully characterized this compound, utilizing various structural and property characterization techniques. The synthesis was carried out via the unconventional hydride route, a solid-state synthetic technique where the salt-like alkali metal hydride (KH) is used instead of the metal (K). This technique enables higher diffusion compared to elemental methods, leading to shorter reactions at lower temperatures. The structural modification of layered compounds using mild synthetic conditions to manipulate material properties and access unique metastable phases has prompted the research reported herein on the topochemical deintercalation (ion removal) of K+ from KV6Sb6. We have successfully performed deintercalation and an extensive structure-property characterization of the subsequently formed metastable K1-xV6Sb6 phase will be performed. Thorough structure elucidation will be performed utilizing a multi-tool approach to determine the compound's bonding, atomic arrangement, composition, and morphology through techniques such as solid-state NMR and scanning electron microscopy (SEM). We will also be focusing on the investigation of the physical properties of the deintercalated phase, including magnetic and thermoelectric properties. Our ultimate goal is to develop a methodology to access materials employing soft chemistry on layered materials, enabling the study of the structure-property relationships in the obtained phases.

Abstract Name: Abraham Lincoln: Celebrated Hero, Complicated Human.

Abraham Lincoln is, perhaps, the most celebrated president in American history. His name brings an aura beyond any in the country's history. Historians have long debated the true intentions and moral basis behind Lincoln’s crowning achievement: The Emancipation Proclamation. Lincoln’s true moral stance toward slavery and abolition has long been debated by historians such as Henry Gates, Eric Foner, and David Donald. Some viewpoints of Lincoln’s morality have been skewed to the point of missing the moral height of Lincoln’s views. Gates, Donald, and Foner all argue points that suggest Lincoln’s views on slavery and African Americans greatly shifted throughout his life and political career. When looking at the words of Lincoln himself and through analysis of his dialect choices, it can be concluded that not only did his views not shift in as significant of ways as commonly believed, but in reality he always had the moral capacity to end slavery. While economic and wartime motivations were undoubtedly at play, it was his moral indignations against slavery that ultimately was his reason for signing the Proclamation. A deep dive into Lincoln’s words throughout his time in politics, both prior to and during his presidency, showcases the strong

moral stance that Lincoln had throughout his political life that suggested he was always a man with a much more strongly rooted moral compass against slavery than many scholars claim.

Abstract Name: Cost-Effective Purification of RNaseH1 D210N Mutant

R-loops are triple-stranded nucleic acids that are usually formed during transcription and have key physiological and pathological roles in cells. When R-loops are not removed timely, it leads to DNA damage, with an increase in DNA double-strand breaks, chromosome rearrangement, and mutations that result in degenerative diseases. Due to their volatility, it is imperative we have a quick and efficient way of imaging R-loops in the cells for study. Currently, the S9.6 antibody is the most commonly used method of detecting R-loops, however, its binding specificity favors dsRNA over DNA-RNA hybrids. Ribonuclease H are a class of enzymes that cleave the RNA of DNA-RNA hybrids. Our study has shown that a catalytically inactive form of RNaseH1 (containing a D210N mutation) binds strongly to DNA/RNA hybrids, but not dsRNA, therefore, the mutant RNaseH1 is more specific in identifying R-loops than the S9.6 antibody. We designed RNaseH1 D210N mutant protein to tag with tandem His and GFP tags– His tag for protein purification and GFP tag for cellular imaging. When expressed in bacterial cells, His-GFP-RNaseH1 can be produced quickly and inexpensively on a large scale. To purify RNaseH1, a two-column purification strategy was utilized, starting with a Ni-NTA metal-chelating affinity column and further cleaning up by an SP Sepharose strong cation exchanger column. Purification fractions from each column were analyzed with protein gels to confirm the presence and purity of the mutant protein. Fractions with a higher amount and cleaner proteins were combined, dialyzed into a storage buffer, and quantified by protein gel analysis with BSA (bovine serum albumin) standards. We purified a significant amount of protein, about 115 ug of RNaseH1 mutant protein from 100 mL of bacterial cells with good purity.

Abstract Name: Prestige and Faculty Unions: Social Structures of Accumulation Theory and Status Reproduction Among Higher Education Professors

Some higher education faculty believe that unionization, as a “blue collar” activity, is beneath their status, despite their similarly lacking ownership of the means of production. While the higher education institution experienced increasing cultural and economic importance in the United States during the twentieth and twenty-first centuries, faculty unionization saw periods of both growth and decline. From a macro-level framework in social structures of accumulation (SSA) theory, with additions from Marx, Ehrenreich and

Ehrenreich, Bourdieu, and Simmel, my research develops a theory to explain the impact of changing social conditions on status reproduction and faculty unionization. SSA theory provides historical accounts of shifting social structures, contrasting and explaining periods of consolidation and growth with unstable periods of decay and exploration. Marx's class relationships, elaborated upon by Ehrenreich and Ehrenreich's Professional-Managerial Class (PMC), describe the relationship between faculty as PMC and the working- and ruling-classes. Bourdieu's social and symbolic capitals explain the developments and exchanges of prestige as a form of capital during an SSA's consolidation. Simmel's group affiliations from common interests during conflict expands on both prestige and unionization as a development of capital through the exclusive associations of those-with and not those-without. My theory explains that faculty, like capitalists, invest in symbolic capital during an SSA's consolidation due to increased confidence in status reproduction, but unionize during phases of decay and exploration, when their PMC status association is jeopardized. My methodology consists of a historical review of social structures that influenced higher education, the forms of prestige faculty experience, and an analysis of unionization data. By analyzing the exploration, consolidation, and decay phases of various SSAs in the United States, I describe the changing environments of status reproduction and faculty's choices within it

Abstract Name: Function conservation of the BMP pathway in planarians

Planarians are an important model for studying regeneration and stem cells. The function of ciliation in planarian regeneration is unclear, despite cilia's other known important functions in developmental biology. This project uses two planarian species, Schmidtea mediterranea and Girardia guanajuatiensis, and aims to uncover the role of a key ciliation and developmental pathway, BMP. Schmidtea mediterranea (S. med) is an important model for the planarian field, but progress has been limited by the lack of multiple models. This experiment uses a recently characterized planarian, Girardia guanajuatiensis (G. gua), which has significant differences in ciliary patterning and regeneration. G. gua displays unique ventral patches of cilia, compared to the uniform ventral ciliation in S. med. Previous work shows that knockdown of the BMP4 protein, a key regulator of ciliation, results in failed regeneration in S. med. Addditionally, worms display a phenotype called ventralization. Normally, in S. med, ciliary patterning is uniform on the ventral side only, but after BMP4 knockdown, both sides are ciliated. However, whether the dysregulated ciliation is the cause of failed regeneration in S. med is not known. To knock down the BMP pathway, RNAi is used, which uses dsRNA to degrade target mRNAs and block translation. This project has shown that impaired regeneration occurs in both S. med and G. gua BMP4 knockdowns, and the goal is to examine ciliation patterning in G. gua knockdowns to determine connections between altered ciliation and ventralization. Altered ciliation patterning is expected in G. gua, but whether uniform ciliation occurs or patches of cilia form on both sides will indicate possible connections between ventralization phenotypes and ciliation. Uniform ciliation would indicate that cilia dysregulation is independent of the other ventralization phenotypes, but formation of patches on both sides would indicate a likely connection between ciliation and other phenotypes. This result will elucidate the connections between the BMP pathway, ciliation, and planarian regeneration.

Abstract Name: A Characterization of the Archimedean Solids

In studying any family of mathematical objects, a fundamental issue is to understand how one object can "sit inside" another object in the family, preserving the mathematical structure. We are concerned with convex uniform polyhedra. Two famous families of polyhedra live in this class: the Platonic and Archimedean solids, as well as the prisms and antiprisms. Our main result geometrically characterizes the famed Archimedean solids among the convex uniform polyhedra by studying how they sit inside a regular tetrahedron.

Abstract Name: A High-Throughput Computational Framework for Investigating Protein-Polymer Bioconjugates with Molecular Dynamics Simulations

Protein-polymer bioconjugates are a promising class of hybrid biomaterials that combine the functional specificity of proteins and the synthetic modularity of polymers. These robust yet tunable biomacromolecules are highly suitable for applications in drug delivery, nanomaterials, and catalysis. However, despite the broad applicability of protein-polymer bioconjugates, there are few computational design tools available to predict their properties prior to in vitro experimentation. To optimally design and synthesize these hybrid molecules, the underlying mechanisms that influence their enhanced thermodynamic and kinetic properties must be understood at the molecular level. Computational approaches such as molecular dynamics (MD) simulations provide an excellent entry point for such studies, via the development of accurate molecular models for studying variations of the protein-polymer bioconjugate system.Herein, we showcase the development of a streamlined computational framework to systematically model and analyze the molecular behavior of protein-polymer bioconjugates using MD. This methodological workflow utilizes a breadth of in silico tools such as Python, CGENFF, Gaussian, ChemDraw, VMD, and GROMACS. Specifically, we built and tested this framework on bioconjugates constructed from the proteins bovine alpha-chymotrypsin and hen egg-white lysozyme conjugated with the zwitterionic sulfobetaine methacrylamide and biocompatible polyethylene glycol (PEG). These four discrete protein-polymer bioconjugates were then simulated in different chemical and biological environments using MD to evaluate the effect of conjugation on protein stability and function. These simulations investigated the behavior of each bioconjugate molecule (1) at the material interface of a silicon dioxide surface and (2) at the interface of a phospholipid membrane. The atomistic detail provided by MD simulations enabled an improved understanding of the effect of polymer conjugation on bioconjugate stability in these different biochemical contexts. Furthermore, analysis of the free energy profile of adsorption provided insight into the molecular driving forces governing bioconjugate behavior at these important bioengineering interfaces.

Abstract Name: Neutrophil-Mediated Transendothelial Delivery of E-Selectin Liposomes for Targeting Inflammatory Sites

Nanomedicine is an expanding field that is revolutionizing translational medicine. Among the various nanoscale carriers, liposomal nanoparticles have gained significant attention due to their ideal size for robust transport within the environment of the body. Cell-mediated drug delivery harnesses the unique capability of nanoparticles to transport therapeutic cargo to specific destinations, such as tumors or inflamed tissues. To exploit this potential, our laboratory has developed a strategy for conjugating the protein E-selectin (ES) to the lipid-PEG shell of liposomes. This approach is advantageous as white blood cells possess ES ligands on their surface, enabling effective attachment of the liposomes to these cells. Subsequently, the liposomes can hitch a ride with white blood cells to target cancer cells in circulation or reach inflammatory sites, leveraging the immune system's natural response. Our investigation has focused on neutrophils as carriers for this cell-mediated delivery method, given their role as the body's first responders to infection or injury. By utilizing the protein Interleukin-8 (IL-8) as a signaling mechanism, we have successfully guided neutrophils to specific locations. Through comprehensive experimentation using TransWellTM migration chambers and identification through confocal imaging, we have demonstrated the ability of liposomes to attach to neutrophils and facilitate their migration across endothelial-like barriers via IL-8 signaling. These findings highlight the potential of liposome-neutrophil conjugates as efficient drug-carrying nanoparticle carriers, offering rapid and targeted relief in various medical conditions.

Abstract Name: A Natural Advantage: An Eye-Tracking Analysis of Indoor and Outdoor Spaces

Contemporary architecture and design increasingly prioritize sustainable, healthy, and aesthetically pleasing indoor environments, acknowledging the fact that we spend most of our lives inside buildings. However, this research brings up a critical question: are we undervaluing the inherent beauty of the outdoors within our built environment? While the concept of beauty is a subject of heavy debate, the universal beauty of nature remains a constant. This study aims to substantiate the superiority of outdoor spaces over their indoor counterparts by comparing the visual appeal of AI-generated images. Specifically, it will create image pairs for five different activity categories: contemplation, recreation, social interaction, education, and creativity. Each image in the pair must embody essential elements: sunlight, biophilic components, and privacy.For each activity category, AI will be instructed to generate an outdoor space image and an indoor equivalent. Next, visual eye-tracking software will analyze these images, enabling us to quantitatively gauge their visual appeal. The analysis will provide insight into whether outdoor spaces surpass their indoor counterparts in

aesthetics. Anticipating that outdoor spaces will exhibit greater visual appeal, this research carries valuable implications for the architectural and design industries. In a world increasingly focused on enhancing the human experience, these findings will advocate for the greater incorporation and prioritization of outdoor spaces in built environments. Increasing our access to outdoor living spaces will undoubtedly improve the quality of human experiences.

Abstract Name: Titrimetric Fresh Water Analysis: Monitoring Salinity and Total Water Hardness in Locations along the Kinnickinnic River

The salinity and total water hardness of three sites on the Kinnickinnic River near Alverno College in Milwaukee, WI in parternship with Milwaukee RiverKeeper were monitored weekly for salinity and total water hardness. The locations were Zablocki Park, Wilson Park, and Jackson Park. Samples were collected and analyzed weekly for four weeks during the month of June in 2023. The water at all three sites were determined to be very hard (219-478ppm) and salinity levels (150-566ppm) to be considered fresh throughout the four collection dates. River water is expected to be soft and fresh. Samples were analyzed by titration with standardized titrants of silver nitrate for salinity and EDTA for total water hardness. Four replicates were collected for each sample, with percent errors being less than 5%.

Abstract Name: An EEG Investigation of the Implicit Effects of Social Media Notifications

Smart phones and their notifications have been demonstrated to significantly impair performance on tasks of attention and cognitive control. The purpose of this project was to determine if there are implicit, physiological reactions associated with the notification sounds of popular social media applications. In this experiment, we measured neural responses to specific app-associated sounds and determined whether the frequency of app use and age were associated with enhanced neural processing of the corresponding app sound. Participants completed a primary task (watching a silent movie with captions) while background sounds were presented via headphones. The background sounds consisted of a repeating tone with randomly embedded sounds from specific social media apps. Participants also completed a questionnaire in which they

ranked popular apps according to how much those apps were used. Neural responses were recorded with a 32-channel EEG system. The EEG data were time-locked to the app-related sounds to determine the size of an ERP component called the MMN (mismatched negativity). The MMN is elicited by deviations that occur within an otherwise regular auditory pattern, and it has the critical virtue of being sensitive to neural responses to unattended sounds. As a result, the size of the MMN can be correlated with specific application usage. The results indicated that the size of the MMN was affected by specific app sounds and the participants' reported frequency of social media app use. The results make a novel contribution in showing that sounds associated with social media applications can implicitly affect neural responses.

Abstract Name: How Fiction Authors Can Use Cultural Communication Differences to Enhance Conflict in Dialogue

This paper analyzes the dialogue of the American and "the girl with him" in Ernest Hemingway's "Hills Like White Elephants." Dialogue is a technique of fiction an author uses to add distinctiveness to their characters through the spoken word and through a silent language that enables people to communicate without the use of words, such as tone of voice, silence, body language, and facial expressions. The silent language of cultural communication is a complex, deep, and learnable artform. Awareness of cultural communication differences puts the onus on both parties to find common ground and a resolution that works for everyone. Hemingway's dialogue in "Hills Like White Elephants" demonstrates how conflicting communication styles and silent language enhances the friction between the characters, leading to a lack of resolution to their interpersonal conflict. This friction results from Hemingway's low-context speaker (the American) negotiating with a high-context speaker (the girl with him). By using research literature on high context versus low context, direct versus indirect, and formal versus informal communication styles, and my own close reading of "Hills Like White Elephants," I will explore how fiction authors can use silent language and cultural communication differences to enhance conflict in dialogue.

Abstract Name: Validating Horror

"Horror" is defined as a literary or film genre concerned with arousing feelings of fear. The purpose for this genre is to shock its audience or educate them. This education can be seen through many works as social commentary. Ranging from mental illness, politics, and sexuality, the genre has highlighted these issues, but is still denied in the field of literature. To elaborate, the terms "science fiction" and "fantasy" are clearly defined in, A Handbook to Literature, but "horror" is not defined. In this text and many others, horror is not seen as a piece of literary fiction. However, there are works of classic literature that could be viewed as

horror. Both Lord of the Flies and 1984 comment on the horrors of a society gone wrong, using many elements from the genre. This paper's purpose is to highlight the distinction between horror fiction and horror literature. In separating these two terms, the genre can be accepted in the field of literature.

Abstract Name: Eradication or Empathy: Dracula and Depictions of Disability

Since the release of Bram Stoker's Dracula in 1897, scholars have proposed varying interpretations of the vampiric Count's identity. Some scholarship has focused on his psyche, highlighting how Victorian theories about criminal psychology may have influenced the creation of his character, while other scholarship has examined his body, noting how its physical appearance speaks to antisemitic anxieties and racialized stereotypes. However, scholarship on Dracula has yet to examine him—and the other vampiric bodies in the novel—through a disability studies lens. I would argue, then, that rather than reading the vampiric bodies in the text as entirely nonhuman monsters, they can be read as an allusion to Victorian discourse on disability and as literally disabled human bodies. Even after becoming vampires, their bodies still appear distinctly human. While the state of their souls or psychology is less clear, the relatively unaltered state of their bodies is obvious. They do not assume "monstrous" non-human bodies after their transformation; their bodies merely have different needs, abilities, and vulnerabilities—in other words, they become differently abled or disabled. Vampiric disability is ultimately constructed through how other characters in the novel–whose voices dominate the text–depict and categorize the vampires as physically inferior or Other. The disability of the vampires is further highlighted through how they utilize certain prosthetic rituals (the consumption of blood, resting in earth, and hiding from sunlight) to accommodate the unique abilities and vulnerabilities of their bodies. However, Stoker's novel ultimately destabilizes the binary categories of abled and disabled. The many instances of physical similarities between the "humans"—or acceptably abled characters—and the "vampires"—or disabled characters—instead suggest that ability is a spectrum, and all human bodies fluctuate along that spectrum throughout their lives; thus, the categories of abled versus disabled are arbitrary and inherently unstable.

Abstract Name: Growing Pains: How Invasive Plant Species Impact Yeast Phenotypes

Microbes play a vital role in plant environments that vary with the conditions of the environment. Previous research has found yeast species diversity is negatively impacted by the presence of invasive plant species. The difference in diversity could be the result of invasive plant species directly or indirectly altering the soil environment or chemistry. However, little is known about how altered soil conditions impact the growth of

yeast species found in the soil of invasive plants. I propose to measure the effects of invasive plant species on yeast growth in the environment by simulating three variable conditions: carbon source availability, nitrogen availability, and antifungal exposure. I will compare the growth rates of yeast species isolated from invasive and native plant soils in each of these conditions. The observed differences in growth between these yeasts will allow us to draw conclusions about the impact of invasive species on the phenotypes of yeasts found within the environment. Invasive species can modify soil chemistry including specific sugar types, higher concentrations of nitrate, and more antifungal compounds. We expect yeast isolated from either invasive or native soils will express phenotypes matching the chemsitry of their environment. Understanding this variation could help us understand the functional role of yeasts in the larger microbial community in the environment. This research will also provide additional insights into our understanding of the yeast ecological niche.

Abstract Name: Traditional Urban Resurgence: A Blueprint for Mental Wellness in Modern Cities

This research delves into the transformation of urbanization over the past century, triggered by the influence of modern architectural concepts, and the potential ramifications for mental health. The primary objective is to investigate the neurological effects of specific urban layouts, with a particular emphasis on safety, social interaction, and aesthetic appeal, to gain insight into the human mind's urban preferences. A survey will be designed to capture subjective preferences in which respondents choose one of two anonymous center streets that are subjectively safe and attractive. Participants will favor the traditional street layout over the contemporary one, suggesting a preference for design associated with enhanced safety, aesthetics, and social appeal, affirming the statement by Allen Jacobs that optimal streets have paramount desirability. In parallel, eye-tracking software is utilized to objectively analyze subconscious neurological responses to diverse urban layouts and elements, providing a more scientific perspective on human perceptions of urban environments by revealing more balanced heat maps, and signifying a focus on aesthetic elements and reduced attention to potential hazards. The combination of survey and eye-tracking data presents a comprehensive argument in favor of traditional urban planning principles and expected to underscore the prevalent preference for traditional urban designs over contemporary alternatives. In conclusion, this research sheds light on the enduring human desire for both safety and aesthetic beauty in urban environments. Anonymous survey data ranging from 50 to 100 participants, coupled with eye-tracking simulations indicating balanced heat maps, highlights the potential of traditional design to cultivate healthier and more harmonious communities. Future research may delve into physiological measures, such as heart rate monitoring, to further validate the stress-reducing benefits of traditional urban planning. The findings from this survey are expected to provide actionable insights that can inform urban planning decisions and strategies that foster improved mental wellness and community well-being.

Abstract Name: The Correlation of Likability and Success

The concept of success is one that affects every person in every career and is, therefore, important to research. This research paper addresses the question of whether competency or likability is more important in business and how the two qualities are correlated in the context of success. The paper aims to study whether a sociable personality is enough to succeed in the business sector or if pure competency and excellence in the field is the key to success. Multiple studies are examined that address the correlation between likability and success, such as Belmi and Pfeffer (2018), who discuss reward interdependent environments and explain why likability is less important than competency in such environments. A study by Cohan et al. (2013) looks at the Myers-Briggs Type Indicator of successful project managers and discusses why ISFP is the most successful personality among project managers, determined by both subjective and objective data. The results of these studies show that likability is essential to success in most careers, but competency will ultimately reign in reward interdependent careers. This research paper concludes with psychological and physical keys that promote success and likability, specifically in the business sector. Van Edwards (2017) shares how liking others is the root of being likable and gives quantitative data on how and why likability can help everyone succeed in business.

Abstract Name: Investigating the Survivability of Prebiotic Molecules on the Lunar Regolith

One of the biggest questions from the Apollo era was the discovery of small amounts of prebiotic molecules on lunar dust samples. This research aims to quantify the survivability of amino acids on the lunar regolith through experimental simulation of lunar conditions under high vacuum, UV radiation and hydrogen plasma exposure. To achieve these goals, lunar-simulant JSC-1A samples are dosed with a curated and calibrated amino acid solution. The samples are placed under vacuum and irradiated with a Plasma Source Ion Implantation (PSII) apparatus to simulate solar wind conditions. Amino acid survivability is quantified via High Performance Liquid Chromatography (HPLC), UV fluorescence and quadrupole time-of-flight mass spectrometry detection in conjunction with NASA's Astrobiology Analytical Laboratory. Preliminary results suggest that amino acids are stable under vacuum conditions down to 1.5E-7 Torr. Samples tested under the PSII apparatus at 30W suggest that all five of the tested amino acids break down under plasma irradiation on JSC-1A. This implies that amino acids may break down under exposure to solar wind conditions. Investigating the reactivity and dynamics of large organic molecules on airless bodies such as the Moon has implications for the proliferation of prebiotic molecules across the solar system. Furthermore, understanding the survivability of amino acids on the lunar regolith can inform scientists about human impact on the lunar surface and beyond. Future studies will be directed at studying the survivability of peptides on the lunar regolith and better approximating lunar temperature conditions in our system.

Abstract Name: Evaluation of High Temperature Mechanical Properties, Physical Properties, and Energy Consumption of Fused Deposition Modeling of PEEK

The application of the fused deposition modeling (FDM) additive manufacturing has increased in the production of functional parts across all industries, especially in the biomedical industry. Due to its high compressive strength and biocompatibility, polyetheretherketone (PEEK) can be explored as a viable replacement material for bones using FDM manufacturing. PEEK has already been used in clinical studies for intervertebral cages and has seen success as a suitable replacement for bone, although minimal strength studies were conducted and analyzed. The challenge is that there are many process parameters that would influence the mechanical, physical, and energy demand of the PEEK FDM process. Many researchers have continued to investigate and address these challenges but one aspect that has minimal research undertaking is performance of PEEK components produced by FDM in a high temperature environment. This research will focus on investigating the influence of FDM process parameters on high temperature mechanical properties of FDM-PEEK, energy consumption, and surface roughness. The process parameters considered are print speed, infill density, infill pattern, layer thickness, nozzle temperature, platform temperature, and raster angle. Eighteen PEEK samples with three replicates each will be created in accordance with the American Society for Testing and Materials (ASTM) standards while adjusting the levels of the identified process parameters following the L18 Taguchi Orthogonal array design of experiments. Mechanical tests, surface roughness, and microscopic evaluations will be conducted on the samples with strict adherence to the ASTM standards. The Minitab software will be used to conduct mean effects and analysis of variance of the control factors on the quality characteristics.The results from this study will create opportunities for discovery and understanding of FDM of PEEK as biomaterial in a high temperature environment while promoting teaching, training, and learning by including students and faculty in the research.

Abstract Name: Suppressing biofilm production in Staphylococcus aureus using siHybrids targeting the codY gene

Staphylococcus aureus is a prominent nosocomial infectious agent, largely due to the production of biofilm that aids in antibiotic resistance. Organisms that produce biofilm possess a distinct biological advantage, and often coagulate on surfaces such as medical implants. These biofilms are a leading cause of post-operational infections and are difficult to treat due to their inherent resistance to antibiotics and the host immune system. One molecular pathway involved in S. aureus biofilm formation is the agr operon, which mediates the disassembly of bacterial cells from biofilms by regulating the quorum sensing system. In previous studies, CodY, a global regulatory protein, has been shown to repress this operon. For this study, 5 µg and 10 µg of codY-targeted co-suppressing RNAi oligonucleotides (siHybrids) were mixed with S. aureus cells in a 96-well microtiter plate to investigate whether they could suppress biofilm formation. After treatment, the cells were stained with crystal violet to quantify the amount of biofilm produced. Because CodY has been shown to repress the disassembly of cells from biofilms, treatment of S. aureus cells with siHybrids targeting CodY expression was expected to decrease biofilm production due to premature cell dispersal before a mature

biofilm could form. The results from this study indicate that inhibiting CodY has no significant effect on the amount of biofilm produced by S. aureus, contrary to the predicted results. Overall, this data does not support CodY's regulatory role in biofilm production.

Abstract Name: FIFA's Trek to Modernity: The Role of Muslim Women in Soccer

Muslim women in Arab countries long for participation in professional soccer, but personal identity creates a unique barrier from international competition. This research aims to identify how twenty-first century FIFA policy has evolved over time, working towards inclusive rhetoric to expand the involvement of marginalized populations, specifically Muslim women. Literature proves Muslim women treat and value physical fitness and participation in sports as a pillar for personal identity. Researchers have examined how feminism has propelled the involvement of Muslim women in soccer at international levels of competition. This research will utilize versions of Law 4 in the International Football Association Board's (IFAB) Laws of the Game from 1990-2023 to analyze change in inclusive rhetoric over the past three decades. This project will identify three case studies in the past two decades, and work alongside the Laws of the Game to identify any evolution in policy resulting from the case studies. The main conclusion might be that the inclusion of inclusive rhetoric was a direct result of Muslim women's increased participation in soccer since the start of the FIFA Women's World Cup in 1991. FIFA and IFAB policies attempt to create a diverse environment, but international soccer can only grow and diversify when women's soccer in Arab countries is recognized for FIFA's journey to modernization.

Abstract Name: The History of Music (Abridged)

Within the scope of Eurocentric Music History we learn in class – from textbooks, theory articles, and ensemble repertoire – the styles are often grouped into broad categories with perhaps overly generalized definitions. While there have been significant developments which happen between epochs of music history, one concept which is often underrepresented with these definitions is how each tradition developed or sprung from its predecessors. Through the composition of a "Theme and Variations" style musical work I will map the structural development from Plainchant – or as early as I can reasonably achieve – through the many eras of the Western canon (Renaissance, Baroque, Classic, Romantic, Modern, etc.) before dissolving through relevant contemporary styles and vanishing into the unknown of what styles have yet to develop. Based on the work of K Marie Stolba in her text The Development of Western Music, as well as supplemental journals along the way, I will write a common passage in as many of these styles as possible while maintaining a recognizable melodic base. This composition will provide a lens through which the audience may better

understand the structural relationships across European music history. A successful composition is intended to be enjoyable in its own right for a modern audience.

Abstract Name: The Influence of Political Affiliation on Academic Performance: An Examination on How Familial Political Beliefs May Impact a Child's Educational Outcomes

This study will examine the influence that parental political beliefs may have on students' academic performance. Decades of research have formed empirical links between social- contextual factors and student academic achievement, and this paper will seek to identify whether parental political values play a role in the academic achievement of their children (Lee and Shute 2010; Yamamoto and Holloway 2010). Parental attitudes, behavior, and stylistic approaches to their child's rearing and education have been extensively studied for how they impact educational outcomes (Pandey and Thapa 2017). This study fulfills the gap in research on the association between parental political beliefs and children's academic performance. This adds to the academic discourse on the impact parents can have on their children in an academic setting by answering the following questions: How can the political beliefs of parents impact a students' way of thinking and therefore ability to perform in school? Does the extremity of the parents' political beliefs make a difference in the outcome of the child's academic performance? A survey was distributed to a random sample of UVU students which measured their academic performance and the political beliefs of their parents. The statistical program SPSS will be used to conduct a multiple regression analysis to examine the relationship between the independent variable (parents' political beliefs) and dependent variable (students' academic performance) to see if there is an association between the two. I hypothesize that students with parents who have strong political beliefs are more likely to be impacted in their academic performance than students with parents who do not have strong political beliefs. Discovering the impact of parental political belief will open several important avenues of inquiry related to educational outcomes of students.

Abstract Name: Late-onset GALC Deficiency-Induced Susceptibility to Myelin Dysfunction: Insights into MS Pathogenesis

Deficiencies in the lysosomal enzyme galactosylceramidase (GALC) lead to consequent, toxic accumulations of psychosine due to the inability to metabolize it, which causes demyelination of axons in the central and peripheral nervous systems, resulting in motor and neurosensory deficits, paralysis, and death. In the twitcher (TWI) mouse, an animal model of infantile Krabbe Disease (KD) where the GALC gene is excised, treatment with AAV9-GALC gene therapy has been shown to delay the onset of demyelination, correct GALC deficiency, normalize psychosine metabolism, and prolong survival. However, focal microgliotic

demyelinating lesions developed in long-term surviving gene therapy-treated TWI, exhibiting accumulations of psychosine along with local losses of GALC and the AAV episome. These cells participating in late-onset focal lesions may have reverted to an untreated state, similar to those of multiple sclerosis (MS). GWAS analysis revealed a two-fold downregulation of GALC in MS brain lesions, suggesting a role of this pathway in MS neuropathology. Given these similarities, the role of GALC was investigated in adult-onset neurodegeneration. The PLP-Cre-ERT2 floxed GALC mouse was developed as a model for adult-onset GALC ablation in mature PLP+ oligodendrocytes. Data demonstrated that when given tamoxifen (TMX) to induce Cre expression, expression of the GALC enzyme is selectively prevented in mature oligodendrocytes, with animals displaying significant demyelination and decreased locomotion capability. When induced with experimental autoimmune encephalitis (EAE) to cause focal lesions, results showed that animals previously administered with TMX presented noticeably more impairment than their corn oil-treated counterparts. Mice treated with EAE and TMX displayed significant increases in PLP+ myelin debris in the brain and psychosine accumulation, and significant decreases in GALC. The deficiency of GALC within mature oligodendrocytes greatly increased susceptibility to myelin dysfunction. Hence, it was hypothesized that a functional GALC pathway is needed in the adult population of oligodendrocytes to decrease vulnerability to MS.

Abstract Name: The Effects of Storage on the Vitamin C Content of Oranges

This study thoroughly investigates the determination of ascorbic acid (vitamin C) content in commercially available orange juice using titration techniques. The main goal is to establish a reliable and efficient method for determining the ultimate storage conditions that result in the highest concentration of vitamin C, a crucial antioxidant in orange juice that plays a vital role in human health. The experimental approach involves titrating the four different orange juice samples: Frozen, Room Temperature, pasteurized, and Refrigerated. The titration employs 2,6-dichloroindophenol (DCIP) as the titrant, chosen for its ability to exclusively oxidize ascorbic acid without affecting other potential substances. Additionally, DCIP serves as a self-indicator in the titration process. For a substance to function as a self-indicator, it should exhibit one color when in the presence of excess analyte (i.e., ascorbic acid) and a different color when the analyte has completely reacted, which allows for the calculation of the amount of ascorbic acid present in the sample. The study explores the optimization of storage conditions, to enhance the amount of vitamin C concentration. The results indicate that frozen orange juice has the highest concentration of vitamin C.

Abstract Name: NIKE: THE COMPANY THAT CONTINUES to IMPACT MANY GENERATIONS

Often advertisements and design concepts are regarded as unimportant nuisances in our general life. Design has strong, impactful experiences to most people from buying, selling, and decision making as a whole. These positive attributes help companies sell their products by finding ways to connect with their audience and customer. This paper uses examples from different resources on how a simple concept and start up can grow into a multi-billion-dollar idea. Along with this, the paper also discusses specific examples of creative concepts used to grow a business. A simple dream based on a childhood memory can grow into a larger idea such as one of the largest shoes and clothing company nationwide. Through bbuying and selling items such as shoes and clothing, it can be more about the message than the actual purchase itself. The message of a purchase can helps mold the mindset of what an athlete or the general population. This can enable those who are exposed to the message of the company to start thinking of themselves with the same capabilities and strengths that the product says it offers. Nike consistently works remain competitive and keep with the ever-changing fashion industry. Nike has been able to do so with partnering with different organizations and impactful individuals to share their branding and ultimate mission statement of "Just Do It" and focusing on key campaigns such has Jordan which has a world-wide following of collections and novice shoe collectors.
Keywords: customer, selling, creative concepts

Abstract Name: The Curious Case of Sherman M. Stanage: The Rise of Free Speech and Activism on College Campuses in 1960s America

In the late 1960s, Trinity professor Dr. Sherman M. Stanage faced a university investigation—and eventual termination— because of his social activism on and off campus. Dr. Stanage was involved in multiple activist demonstrations against the Vietnam War and regarding student life at Trinity University and at his prior place of employment, Bowling Green State University in Ohio. Stanage also encouraged his students at both universities to fight for what they believed in. This paper uses a significant collection of rarely examined archival documents from the Trinity University Special Collections and Archives to explore the situations that Dr. Stanage found himself in at both Bowling Green and Trinity as a case study into faculty activism and academic freedom in the 1960s. It sets this case within the larger story of the emergence and growth of activism and free speech challenges on college campuses in that era and the effects that resulted from them, such as the development of student rights on college campuses. The issue of free speech on college campuses is still relevant today and has continuously elicited groups to protest both for and against it. By researching the movements of the 1960s, this paper seeks to better understand and conceptualize the importance of free speech advocacy in the past and the ongoing need for it in the present.

Abstract Name: Neuroinflammation Levels Measured by Microglial Cell Activation

Neuroinflammation is an inflammatory response in the brain that can be caused by different stressors such as diseases and/or external factors such as traumatic brain injuries. It is important to note duration and intensity of neuroinflammation levels when determining the impacts of these stressors to the brain environment. During neuroinflammation, a type of immune cell that becomes activated in the brain is called microglial cells. Microglial cells play a role in progression of the pathophysiological effects from the brain stressor. Studying changes in microglial cell shape provides evidence of the degree of neuroinflammation in the brain. Researchers can quantify neuroinflammation based on the visualization of microglial shape changes from highly branched, or ramified, shapes (inactivated microglial cells) to more spherical microglial cell shapes (activated microglial cells). The degree of microglial cell activation elucidates the degree of neuroinflammation in different brain regions after exposure to brain stressors. The goal of this study is to develop an image analysis workflow for microglial cell activation found in 40 µm rodent brain cryosections that were stained using the antibody to microglial cells, iba1, and a secondary antibody linked to Alexafluor 568 to stain microglial cells red. A Zeiss LSM 900 with Airyscan 2 confocal laser scanning microscope was used to acquire image data, and Imaris 10.1 was used to perform 3D rendering and microglial cell segmentation to identify and quantify microglial activation. The workflow we develop will be used to determine the degree of neuroinflammation from stress in rodent model systems.

Abstract Name: Coexistence of Traditional and Biomedical Medicine in West Africa: The Case of Senegal

Along with globalization, the spread of Western medical traditions has been introduced to cultures and people who have had longstanding medical traditions of their own. Traditional medicine is not very common in social discourse in the United States. We tend to have complete trust in our modern Western medical system. However, that is not the case in other parts of the world. Africa has a rich culture where traditional healers have been practicing and honing their knowledge and abilities of spiritual and herbal remedies for years. Unfortunately, Africa also has a deeply rooted history of colonization, and to some degree, still does. Regarding medicine, that meant the imposition and assimilation to the biomedical ways of Western European countries. The research I did in Senegal, during the Summer of 2022, focused not only on how modern and traditional medicines could coexist but also on the importance of them coexisting to provide comprehensive healthcare. The two-fold aim of this research is to first attempt to redefine traditional medicine in Senegal and how it persisted after colonization as well as provide an understanding of the effects and implications of the increasing number of biomedical centers in Dakar, the capital of Senegal, then emphasize the social dynamic between caregivers and patients in both types of medicine. Trust, personal connection, and contextualization of the social and cultural environment of patients being conducive to efficiency in healthcare, could traditional medicine in the case of Senegal, beyond being trustworthy to its people, also remain a plausible solution in fast-growing Senegal as coexistence with a dominant biomedical industry appears inevitable?

Abstract Name: Body Factors Predict Self-Injury Among Sexual Minority College Students

Non-suicidal self-injury (e.g., self-cutting, burning; NSSI) has an elevated prevalence among sexual minorities (Cox, 2016). Body relationship factors may play a strong role as a disregard for the body is needed to intentionally injure it (Muehlenkamp, 2012). Previous studies have found higher body consciousness in sexual minorities than in their heterosexual counterparts, suggesting body factors may be more important to NSSI risk within this community than other factors like depression and stress (Mahon, 2023). The purpose of this study is to examine the differences in body regard between heterosexual and sexual minority college students and evaluate if body relationship factors significantly contribute to NSSI frequency beyond the effects of depression, anxiety, and stress. Participants included 634 students (Mage = 19.85, SD = 1.85; 64.7% female; 84.9% white) and 51.7% identified as a sexual minority, recruited through email and advertisements sent through LGBTQ centers at two Midwestern Universities. We conducted a one-way ANOVA revealing significant differences among all the studied variables (all p <.001). We ran a stepwise hierarchical linear regression to test the study's hypothesis. Sexual Orientation (b = -.17, t = -3.47, p < .001), depression (b =.32, t = 4.13, p < .001), rumination (b = .12, t = 2.07, p < .032), and body regard (b = -.16, t = -2.81, p < .001) were all statistically significant predictors of NSSI frequency. Anxiety and stress were not statistically significant predictors. Body regard explained additional variance in NSSI frequency beyond the effects of the other variables. Therefore, our hypothesis was supported and aligns with existing studies showing that body relationship factors are important to understanding NSSI engagement. Understanding the complex relationship between cognitive emotional factors and body regard is essential for developing effective interventions and support systems to reduce the risk for self-injurious behaviors.

Abstract Name: Beyond the Scoreboard: Cultural Media Analysis of U.S. News Coverage of Spain’s 2023 FIFA Women’s World Cup Win

The research delves into an analysis of complex dynamics surrounding how U.S news sources covered the controversy involving the Spanish women’s soccer team's victory in the 2023 FIFA Women’s World Cup, where the Royal Spanish Football Federation (RFEF) president, Luis Rubiales, kissed player Jennifer Hermoso without consent. The study employs a cultural studies perspective to analyze 30 U.S. news articles published between August 20, 2023, and September 23, 2023. The analysis uncovers eight prominent themes, addressing two main research questions. The first question investigates how U.S. news coverage frames Spain’s women's team incident. The findings reveal a multifaceted perspective, including a comparison within the American women’s soccer team, negative framing of key figures within the RFEF, a conceptual shift in Spanish soccer culture, and the supportive role of the Spanish government in promoting gender equality. The second question delves into how gender roles are discussed by U.S. news coverage of Spain

winning the women’s World Cup. The results highlight discomfort surrounding discussions of equality, integration of cultural norms, and the notion that winning serves as a catalyst for change in women's soccer. The analysis contributes to valuable insights into the intersection of sports, gender, and culture, providing a foundation for further research and discussions in sports media representation. The paper sheds light on the process of social change within the realm of women's soccer from an outside culture of its own, so not only does it contribute to the conversation of gender dynamics in sports but also the framing of an outside culture from a U.S. perspective.

Abstract Name: Beyond Individuals: Understanding COVID-19 Risks through a Multigenerational Household Lens

Existing studies emphasize the connection between individual risk perception and COVID-19 protective behaviors. However, few studies have examined how individuals assess their risks and vulnerabilities for their households. This study investigates how a member from crowded multigenerational households (MGH) evaluates risks their households are vulnerable to—or what I call "collective risk." I will also examine the protective measures adopted to mitigate these risks and feelings of vulnerability. Methods: The study will use the constant comparative approach to analyze preliminary data from interviews with 50 multigenerational households residing in California conducted in the Fall of 2021 and Fall of 2022. To analyze collective risk perception, the case study focused on measures such as households' sociodemographic information, risk factors, and harm reduction strategies. Findings: Findings reveal that individuals are mindful of their household members' vulnerabilities. Additionally, age, preexisting health conditions, and occupations (specifically, public-facing occupations) drive high COVID-19 vulnerability perception within a household. Discussion: These insights highlight that perceptions of risks are not formed individually; rather, it is a social process—one where members are mindful of the health and actions of others in their household when accounting for what makes them most vulnerable to COVID-19. Thus, understanding what MGH points out as risks should be understood as forming out of a relational process. Conclusion: Knowing this is useful in shaping communication strategies for future outbreaks, where risk perceptions affecting the whole household may strongly influence health behaviors and mitigation strategies.

Abstract Name: Quality and Yield Responses of Louisiana Tea to Nitrogen Fertilizer Treatments

AbstractAs the tea industry in Louisiana expands, growers need reliable information to make important fertilization decisions. We have hypothesized that a combination of organic and synthetic fertilizers would

have the highest yield; and that a combination of organic and synthetic Nitrogen in the mid-range of Nitrogen totals will provide the best flavor and desirable chemical content. 'Camellia sinensis', a perennial tea shrub that is cultivated for its young leaves, was at the center of our research and the species that we applied a combination of organic and synthetic fertilizers to. There is currently no research-based information on the correlation between nitrogen fertilization requirements for tea cultivation and how they would pertain to the soil and climatic conditions of Southeast Louisiana. We aim to bridge this gap through this research project; as well as expand our region's knowledge of the tea industry and the physiological aspects of growing 'Camellia Sinensis'. Growers can use the information to avoid over-fertilization, which can lead to excessively acidic soil conditions that burn the plant, and under-fertilization, which can lead to reduced yield and plant health.

Abstract Name: Moving the Canon: A History of Motion Graphic Design

Motion graphic design plays a ubiquitous role in our daily visual experiences, influencing everything from advertisements to entertainment spectacles like Beyoncé's Renaissance World Tour. However, despite its pervasive presence, many design students find motion design intimidating. This reluctance may stem from the historical exclusion of motion design from the design canon. In this exploration, we delve into the rich history of motion graphics, tracing its evolution from early pioneers like Émile Cohl and Winsor McCay to technological milestones such as the multi-plane camera and colored cinematography.

Abstract Name: Analysis of Trauma in Toni Morrison’s "Home"

This analysis explores specific methods that the main character’s in Toni Morrison’s Home used to heal from both racial and circumstantial trauma. Home is set entirely after the events and conflict of the Korean War, but before the National Research Act of 1974 which protected citizens from being subjected to unethical experimentation. Both war (its aftermath) and human experimentation are circumstantial traumatic events faced by the main characters of Morrison’s novel. These events are compounded by the longstanding existence of racism and white supremacy that appear to leak into the everyday experiences of the main characters. However, Morrison indirectly addresses how the characters find themselves healing from the experiences of their past and their present traumas. She offers evidence of a longstanding tradition within the Black community: homegoing, kinship, and networking which are used as a form of renewal and protection. These three strategies are crucial to how the characters in Home begin to heal from traumas which, historically and systematically, Black Americans have faced as a reality of being expendable in the eyes of the American government. This has led to an increased uncertainty of Black Americans’ places as a free

people in the United States. The struggles faced by Morrison's characters reflect a breakdown of communication; their perceived failures or blunders in life are not entirely their fault. Morrison's characters in Home only had the tools to make their situations worse such as: abuse of alcohol and the lack of education. However, through the practice of homegoing, kinship, and networking they begin to validate their experiences with methods unique to their community effectively filling in the spaces that a lack of resources and protective rights had left.

Abstract Name: Power Within a Broken System: Expressing The Black Boys Intersectional Experience within Special Education

Oklahoma's Education rating within the United States falls at 49th out of 50th in the nation. Of the number of potential intersections, focusing on race, gender, and (dis)ability will offer an intersectional analysis deconstructing the structures of power (i.e. interpersonal, disciplinary, cultural, and structural) within the special education system of Oklahoma's Publicly funded schools and programs. Given the increased pitfalls, intersectionality highlights how certain groups, including African American boys diagnosed with disabilities, suffer the greatest criminalization and marginalization. One sample study that demonstrates these concepts comes from Dr. Hani Morgan, "Misunderstood and Mistreated: Students of Color In Special Education". This study explores the intersectional experiences of black students in special education. He focuses on how poverty assists in creating a harsher environment for students within these programs. My study is similar in that I focus on the experiences of black students but specifically young black men. I aim to further explore their socio-economic status to understand how this may affect their experiences within the four structures of power. I utilized surveys as a method to collect qualitative information. Data from the surveys collected create an oral history and represent what it is like to be these affected minds.This project creates a deeper understanding of the challenges involved in young black men's experiences in special education. This project also produces a creative message that can be used to engage a wide audience and promote the importance of integrating research into policy and culture of special education.

Abstract Name: Removal and Bioconversion of Pharmaceutical Waste Created by the Production of Antibiotic Penicillin, and the Spread of Antibiotic Resistance in the Environment

Since its discovery Penicillium sp. has been a highly utilized cure-all for many bacterial caused illnesses, this is in no doubt due to penicillin's antimicrobial property, Penicillium chrysogenum is a mold like growth that prevents reproduction of gram-positive bacteria. In recent years antibiotics like penicillin have seen increased use and production on a national scale. Industry scale production of penicillin is a tenuous process of

purifying and harvesting bio-active penicillin. The synthesis and production of penicillin involves the use of various chemicals, reagents, and solvents. The waste generated from the chemical processes includes unused or spent chemicals, byproducts, and leftover biomass growth from the fermentation process. The release of these products into wastewater creates many ecological concerns and challenges. Primarily the spread of the antimicrobial resistance gene in bacteria. A development in bacteria where a sublethal exposure to antimicrobial properties is subverted and is ineffective to bacterial growth. Potential spread of the antimicrobial resistance gene would not only occur in wastewater but spread to livestock and crops through irrigation and finally towards humans. This project is aimed at studying biological treatment and conversion of these toxic antimicrobial wastes. Some of the methods discussed include Incineration, Chemical oxidation, Biodegradation and Absorption. These processes aim to remove the bioactive function of the byproduct and seek to create an ecologically safe product. Ideally the solution to the pharmaceutical waste issue would be not only environmentally stable but also economically viable. The proposed strategy should encompass proper disposal practices, advanced waste management systems, and innovative treatment methods.

Abstract Name: Enhancing Binding Free Energy Prediction by Integrating Molecular Dynamics and K-Means Clustering into Protein-Ligand Docking

Protein-ligand docking is a computational method widely used in drug discovery to predict binding affinities of small molecules to target receptors. However, despite its widespread use, the method has inherent limitations that can lead to false negative and false positive results affecting its reliability. False positives occur when docking predicts strong binding affinities that experimental evidence does not confirm, while false negatives arise when the method fails to identify potent binders validated in experiments. These inaccuracies stem from multiple factors including limitations in scoring functions and search algorithms. But a more significant issue is the oversight of protein dynamics, specifically receptor flexibility. To address this limitation, flexible docking methods which partially account for receptor flexibility, have been developed, but they come at a considerable computational cost.In this project, we incorporated molecular dynamics simulations and k-means clustering into protein-ligand docking to improve prediction of binding energies in two different protein-ligand systems: one comprised of human dopamine 2 receptor, which is a crucial therapeutic target for neuropsychiatric disorder, and another one containing human serum albumin, which is a known drug transporter.Our findings demonstrate that sampling conformational states through molecular dynamics and clustering followed by docking to representative clusters offers a more accurate assessment of binding energies. Importantly, this enhancement in predictive capability comes with minimal additional computational expense.

Abstract Name: Lighting for Our Home and Galaxy: NASA's LED Technology and its Benefits for Children with ASD

This study examines the efficacy of NASA developed light-emitting diodes for the use with children with Autism Spectrum Disorder to help realign circadian rhythms for sleep regulation. Much like the astronauts at NASA, children with autism often experience difficulty with sleeping due to a lack of melatonin, which can lead to altered circadian rhythms thus causing poor sleep quality, low levels of productivity, and higher levels of anxiety and aggression. This analysis applies the work of George Brainard, NASA project manager, Daniel Shultz and the National Space Biomedical Research Institution in order to uncover how LED modules were developed and installed. Further scholars include lighting experts, Dave Bisbee and Connie Salma and their collaborative circadian lighting study from the Sacramento Municipal Utility District (SMUD), as well as peer-reviewed articles that examine sleeping disorders in autistic children. Building upon this research, this analysis applies NASA's research in LED technology as a foundation in creating innovative technology that can accommodate children with autism while using SMUD's research as a case study of its everyday application. The results suggest that LED technology has the potential to improve the quality of life for children with autism.

Abstract Name: Sustainability: Green Design

Nature, in its broadest sense, encompasses the external world in its entirety, shaping ourdaily lives and influencing everything from culture to technology. As humans increasingly contribute to environmental degradation, from deforestation to pollution, the need for sustainable practices becomes imperative. Sustainability, defined as the avoidance of resource depletion to maintain ecological balance, extends its

influence to various sectors, including graphic design. This paper investigates the role of graphic designers in promoting sustainability through their creative choices, highlighting the potential for design to raise awareness about environmental issues and encourage responsible practice The purpose of this paper is to explore the impact sustainability has on our environment, graphic design and how that is reflected in our world.

Abstract Name: Emotional Dynamics, Escapism, and Storytelling in Haruki Murakami's "Scheherazade" and "Kino"

Translated into English from Japanese and published for western audiences in 2017, Haruki Murakami's short story collection entitled Men Without Women explores complex dynamics between men and women, wherein men become emotionally orphaned by women in their orbit. Many of these men's emotional states center around receiving love, comfort, and sexual intimacy from women, and hardly any of the men in these stories appear autonomous in their relationships. Throughout both "Scheherazade" and "Kino," Murakami forges one inextricable link between femininity and emotional power, and another between masculinity and emotional inferiority. These dynamics stay largely the same throughout both short stories, despite the varied dynamics that each story entertains. Nonetheless, both men and women in these texts express strong desires to escape their circumstances, and rely on various forms of escapism to cope with their dissatisfaction for the present. In portraying these dynamics in both men and women in "Scheherazade" and "Kino," Murakami perhaps suggests existential loneliness to be a universal part of the human condition, even if men and women express their misery in differing ways.

Abstract Name: Effects of anthropogenic activity on stress physiology and its consequences for habitat selection

Human activity represents a novel environmental challenge for wildlife, even for human-tolerant species that reside in human-dominated landscapes. Our long-term study of California ground squirrels (Otospermophilus beecheyi) has previously documented that exposure to human activity (e.g., anthropogenic noise, walking of domestic dogs) increases vigilance, disrupts group foraging and other collective behaviors. Since human activity varies with space and time, we wanted to elucidate potential differences among the stress responses

of individuals exposed to different levels of human activity. To measure this, we collected fecal samples from individual squirrels after their first capture and subsequent release of the week from two populations that differ in their level of human disturbance (e.g., pristine versus disturbed) for over a decade. After each field season, we extracted fecal glucocorticoid metabolites (FGMs) from fecal pellets. In the lab, supernatants were assayed using a fully validated enzyme-linked immunoassay (ELISA) kit to assess the concentration of FGMs. We found that individuals residing at our human-disturbed study site had significantly higher FGMs than those at our more pristine study site. We also found that FGM levels were repeatable over time for individual squirrels residing at the disturbed site. Our findings offer insights into the relationships among anthropogenic disturbance and stress physiology over small temporal and spatial scales.

Caleb Willis

Abstract Name: Connect to the Site

With technology advancing rapidly in recent generations, it appears that the relationship between the architect and the site has only grown thinner. Working from home and technological advancements have created an environment that loosens the grasp that architects have of the site. This had led to a disconnect from the environment that we work in, creating infrastructure that is not sustainable for the future generations to inhabit. With this loss in connectivity, this project aims to reconnect the architect to their site, as they shall be issued land for development, compared to a building. With these points, guidelines are followed to improve the quality and consistency of the project. How can we make our environment, built and living, last? How can we provide our designs with the necessary technology to stick around for the next generation? What do we take and leave behind in a construction environment? How can we become more responsible for our site? This project aims socially as well, as the architect must be interwoven with the local inhabitants and the site's developers, for the sake of efficiency, and sensitivity. With this, the site of the Atlanta Constitution Building is studied and examined for its potential to the southern portion of Atlanta as a spark of development for the area to enhance and enrich the overall abandoned environment that this location exhibits. With this site being on the cornerstone of an active street and a quiet environment, while also providing enough space for new developments, it is a perfect opportunity to rebirth the spirit of downtown Atlanta. This approach will solidify the ways new buildings can be constructed while also showcasing how old ones can be redone, comparing technologies between these techniques as the Atlanta Constitution Building serves as a benchmark for this methodology.

Abstract Name: Music Academy Design to Promote Healing, Growth, and Social Interaction through Music

For many years, the lack of emphasis on music education has left classrooms dated and inefficient. The lack

of attention not only affects classroom technology, but also function, comfort, aesthetics, and social interactions. The purpose of this project is to create and design an academic environment that promotes healing, growth, and learning through music. Music education has shown that people who learn to read and play music have better self-discipline, creative thinking, emotional development, and societal success. Interviews with music education professionals concluded that the most important aspects of music classrooms are acoustic applications, new music technology, and furniture. Many studies also indicated that the importance of creating a calm and homelike environment with few distractions and access to natural lighting can improve mental health. Based on research findings, this project incorporates professional acoustic applications and designs spaces to enhance social interactions, implement new technology, and provide dedicated areas for therapy. Windows bringing in natural lighting are abundantly incorporated into the overall building to improve mental health, increase energy efficiency, and bring biophilic design within the space. The use of green hues and large moss walls provides users with functional and healthy learning environment benefits like decreasing mental stress, reducing blood pressure, and dampening sound by absorbing the reverberations. Other acoustical materials such as carpets, acoustic panels, acoustic ceiling treatments, and upholstery fabrics help to minimize the noise problem in this music academy. Additionally, materials like laminate, tile, and terrazzo are installed throughout the facility which are durable, hygienic, and easy to clean. In conclusion, acoustic considerations and a biophilic design approach foster a functional, safe, and interactive learning environment by adding vibrancy to the community through the power of music.

Abstract Name: The role of cls-2 during chromosome segregation in C. elegans

During mitosis, the mitotic spindle functions to faithfully separate chromosomes which is critical for the survival of the organism. Any error in this process could lead to cancer or developmental abnormalities. Recent publications have established that the microtubules between the segregating chromosomes, the spindle midzone, is critical for chromosome segregation. Prior research has suggested that sliding forces in the midzone may be generated by microtubule polymerization. Although, we lack significant information about how the spindle midzone generates forces supporting chromosome segregation during anaphase. One proposed model for midzone organization and function suggests that microtubule polymerization in the midzone may be regulated by CLASP in order to produce the force needed to segregate chromosomes. Previous research strongly suggest that CLASP is important for formation of microtubules in the midzone. However, it is unclear whether this is due to support of microtubule growth or nucleation by CLASP. We will study the role of CLASP by depleting the C. elegans homolog cls-2 by RNAi during the first cell division in the C. elegans embryo. We quantified overall changes in spindle assembly and chromosome segregation as well as changes in microtubule dynamics, such as growth-rates and turn-over. In addition, we will determine the effect of cls-2 (RNAi) on the localization of other midzone proteins. The results of this study will lead to a better understanding into the mechanisms that are governed by cls-2.

Abstract Name: Killers of the Flower Moon: The Osage Murders and Sexual Conquest

The Osage murders were a series of murders that occurred in Osage County Oklahoma from the 1910s to the 1930s. In 1865, the Osage tribe was forced to move west to prepare for white settlement. The tribe purchased their own land and mineral rights which proved extremely beneficial whenever the largest oil deposits in the United States were discovered in 1906. The murders were committed by the white financial guardians assigned to the Osage people after they struck oil. During the time of the murders, the federal government declared an official number of 24 victims, but more recent investigations place the number of victims in the hundreds. Sexual conquest and colonization created a climate the exploitation of Native women through the ideas constructed by European powers of Native women. From as early as the 16th century, images were produced of either the “evil” Indigenous woman naked holding the head of a white settler, or the complete opposite, beautiful voluptuous women sitting atop food and gold. These images painted a picture of a woman waiting to be colonized through the stripping of her resources or the colonization of her womb. During the same time, there was a common discourse such as that of the English Comedy Eastward Ho! Where men depict a sexual fantasy of creating “English-faced children”. This presentation will cover Oklahoma's history as well as the direct causes and effects of the Osage murders and how the 2023 movie based on the 2017 book Killers of the Flower Moon which covers the murders has changed Oklahoma and the conversations around the Native American Tribes.

Abstract Name: An Ethnographic Sociolinguistic Approach to Vowel Breaking in ‘Smalltown,’ NC

The field of sociolinguistics attempts to examine the social consequences of language by examining language with the eye of an anthropologist (ethnographer). Speech patterns within certain speech communities or Communities of Practice (CoP) contain ethnographic information about that community and the conversations that take place in particular local spaces. This study examines the dialect feature of vowel breaking in a small town (pseudonymed “Smalltown”) in North Carolina (USA). Vowel breaking, or diphthongization, occurs in many Southern American dialects where a single vowel sound (monophthong) becomes a diphthong with two vowel sounds. The speakers interviewed for this study include the small-town business owners and patrons of Trudie’s Classic Cuts and Carpenter’s Jewelry in Smalltown, NC. The specific research questions examined were 1. the frequency of vowel breaking in Smalltown speech and 2. the kind(s) of ethnographic or cultural information transmitted through this dialect feature. Methods of data analysis included constructing a table of Standard English, non-Standard English, and ambiguous examples (Gass & Selinker 2008, 41-43). Hymes’ (1974) sociolinguistic research methodology, the SPEAKING method was used to organize social functions related to vowel breaking. Data showed that vowel breaking does occur within the CoP of Trudie’s Classic Cuts and Carpenter’s Jewelry within particular syntactic environments, including phrase-finally, and in emphatic or instructive discourse contexts. Finally, the study will explore the ethnographic consequences of vowel breaking in these local spaces in terms of community-specific norms for both economic and interpersonal/social transactions.

Abstract Name: Disentangling How Projections from the Ventral Pallidum to the Shell of the Nucleus Accumbens Regulate Non-Homeostatic Feeding

Both humans and non-human animals often consume food even when they are satiated. Thus, our overall goal is to understand how specific brain structures control overeating, or non-homeostatic feeding. Here, we assessed how chemogenetic activation or inactivation of the projections from the ventral pallidum (VP) to the shell of the nucleus accumbens (AcbSh) affected motivation to work for food and consume sucrose in non-food deprived female rats. In the 23 rats, we used a dual vector approach where Cre-dependent adeno-associated viruses (AAV) containing genes for the expression of excitatory or inhibitory designer receptors exclusively activated by designer drugs (DREADD) were injected bilaterally into the VP. Additionally, retrograde AAV Cre were bilaterally injected into the AcbSh. This dual vector approach resulted in specific expression of excitatory or inhibitory DREADD in neurons projecting from the VP to the AcbSh. DREADD were activated via intraperitoneal injections of the DREADD agonist clozapine-N-oxide (CNO). 12 control rats received only CNO injections. In the first experiment, we measured motivation to work for food using a progressive ratio task after CNO injection. In the second experiment, we assessed food consumption by measuring the intake of a 20% sucrose solution after CNO injection. Our results indicate that the selective chemogenetic activation or inhibition of specific projections from VP to the AcbSh did not have significant effects on motivation to work for food. However, chemogenetic activation of projections from the VP to the AcbSh resulted in a decrease in 20% sucrose consumption. Conversely, chemogenetic inhibition of projections from the VP to the AcbSh resulted in an increase in sucrose consumption. Taken together, these results indicate that the studied pallido-striatal pathway is not implicated in modulating motivation to work for food but regulates food consumption in a non-deprived status.

Abstract Name: Beta Waves in Pre-ictal Stages of Rat Seizures

Organophosphates (OPs), such as diisopropyl fluorophosphate (DFP), are toxic chemical substances that are the main component of pesticides. OPs can harm the human nervous system and brain by irreversibly inhibiting acetylcholinesterase (AChE), a key enzyme in helping the nervous system function correctly. AChE catalyzes the hydrolysis of acetylcholine into acetic acid and choline, which lets the neuron return to its resting state after activation. Inhibiting this enzyme leads to over-excitation of neurons that trigger seizures in the brain. As a result of exposure to OPs, antioxidants decrease and free radicals increase in the

body creating an imbalance and leading to oxidative stress that can cause cell and tissue breakdown. In this study, we will be investigating the effect of DFP and the treatment with NADPH oxidase inhibitor, mitoapocynin (MPO), on rat brain activity by examining electroencephalogram (EEG) scans and the different frequency bands that can be seen in the pre-ictal period of a seizure. Alpha, beta, delta, gamma, and theta waves are seen throughout brain activity, but we will focus on beta waves, as it has been seen that in preictal stages in humans, voltages of beta waves increase the most. We hypothesized that beta waves will have a greater increase in voltage in the pre-ictal stage than the other frequency brands. EEG power bands will be compared between DFP+Veh and DFP+MPO to determine if NADPH oxidase inhibition affects preictal seizure activity. Acknowledgment: This project is supported by the National Institute of Health/NINDS through the CounterACT Program (R21 NS120916)

Abstract Name: Trichloroethylene impairs astrogenesis and neurogenesis as a mechanism of Parkinson's neurotoxicity

Pathologically, Parkinson's Disease (PD) is characterized by the loss of dopaminergic neurons in the substantia nigra and non-motor symptoms such as cognitive impairment and anosmia (loss of smell). The organic solvent trichloroethylene (TCE) is an environmental contaminant that is correlated to increased PD risk as well as long-term cognitive deficits. Our lab recently found that TCE caused a reduction of neurogenesis, which is the generation of new neurons in the adult brain and occurs in the subventricular zone of the lateral ventricle and the subgranular zone of the dentate gyrus. In the subventricular zone (SVZ), astrocytes act as neural stem cells, proliferating along the lateral ventricles to form immature precursor cells and neuroblasts that migrate to the olfactory bulb. To this end, we hypothesized that TCE decreases astrogenesis in the SVZ, which reduces the neural stem cell population and impairs neurogenesis as a mechanism of toxicity that contributes to non-motor PD pathology such as anosmia. To investigate this, we exposed 12-month-old male and female wild-type mice to 100 ppm TCE or filtered room air for 12 weeks. TCE-exposed mice showed a significant decrease in astrocytes in the subventricular zone ($p= 0.0096$), indicating that the proliferation of astrocytes was impaired. We tested this further in vitro with primary cultured astrocytes treated with 500uM TCE for 24 hours, which showed a significant decrease in Ki67 ($p=0.0032$), a common proliferation marker. In conjunction, we found that TCE-treated primary astrocytes had significantly increased p21 expression ($p=0.0015$), a senescence marker, suggesting that the reduction of astrogenesis induced by TCE was caused by senescence rather than overt toxicity. Together, these data suggest that reduced astrogenesis caused by TCE exposure impairs neurogenesis in the SVZ, which may explain how inhaled toxicant exposure contributes to certain non-motor PD symptoms such as anosmia.

Abstract Name: Comparison of Greenhouse Gas Emissions from Four Major Soybean Production Areas in Virginia

Understanding how agricultural practices affect greenhouse gas (GHG) emissions from agricultural fields is important to establishing a system for farmers to benefit from carbon credit programs. Soybean cropping systems are an excellent model for examining the interactions of crops, microbes and GHG emissions. The objectives of this project are to: (1) compare GHG emissions from four major soybean production areas in Virginia, and (2) explore the contribution of soil microbes to GHG emissions. We used five representative soil samples taken to a depth of 10 inches from 11 soybean research fields in four major soybean production areas in Virginia. DNA was extracted from all 55 soil samples and the V4/V5 regions of the 16S rRNA gene were sequenced. Microbial taxa were identified at the genus level using R. Each sample was incubated under 40%, 60%, and 80% water filled pore space (WFPS), and GHGs were measured using a Gasmet DX4040 FTIR Gas Analyzer.Our results show that CO2 (99.1762%, 584.403-7434.718 ppm), N2O (.7263%, .081-179.433 ppm) and CH4 (.0975%, 0-161.237 ppm) are the three major GHG emissions from the soybean fields. Significant differences in CO2 and N2O emissions were found between locations with Orange having the highest and Warsaw having the lowest CO2 emissions. In addition, 80% WFPS had the highest level of N2O emissions among locations. Finally, genera were significantly correlated with N2O, CO2, and CH4 across locations. These correlations varied in significance within location and by WFPS treatment, with most of the significantly correlated genera showing positive correlation for each GHG emissions and some showing negative correlation for CO2 and CH4 emissions. This project provides a foundation to further examine how agricultural practices contribute to GHG emissions and how soybean might be utilized to reduce agriculture’s carbon footprint.

Abstract Name: The Effect of Personal Income on National Park Attendance

Spencer WilsonEastern Illinois University, Charleston, IL Abstract There are 63 national parks in the United States and its territories. Previous economic research on national park tourism has focused on parks in other countries, especially those found in Scandinavia. This article uses data from both the United States National Park System (NPS) as well as the Bureau of Economic Analysis (BEA) to test the impact per capita income has upon national park attendance levels. The article also explores the impact that other variables of interest, such as weather and geographic location, have upon these attendance levels to further the understanding of the economics of national park tourism. Using regression analysis, this article attempts to explain if national park visits are a luxury item or not. The NPS promises to protect the country’s natural beauty for “this and the future generations.” The results of this article will show if that promise applies to people of all income levels.

Abstract Name: Analgesia and Performance Anxiety in Division III Football Players

The analgesic response as a result of performance anxiety has been shown in endurance athletes; however, there is a gap in research on football players. The goal is to investigate the physiological responses to performance-related scenarios, which may lead to a better understanding of how analgesia manipulates pain perceptions. The purpose of this study was to analyze the effects of nociception and presence of analgesia between football practice and game settings. Prior to testing, subjects completed a consent form and demographics. Subjects arrived shortly before they went onto the field for warm-up. Upon arrival, subjects passively drooled 50 microliters of saliva into a test tube, and completed the State-Trait Anxiety Inventory (STAI) to assess their mental status. For the cold pressor test (CPT) subjects immersed their hands in ice water, reported pain levels on a scale of 0-100. Pain ratings were recorded after 15s, 30s, and every 30s thereafter for a maximum of 3 minutes. They could withdraw at any time. Subjects ranged from 18 to 23 years of age (M = 20, SD = 1.36). CPT data analysis revealed subjects's mean pre-practice pain ratings were higher than in other conditions (M = 42.4). There was a significant difference between pre-practice and post-practice pain ratings at 90s (p = .0016) as well as mean pre-practice and post-practice ratings (p< .001). The highest pain ratings experienced were higher in pre-practice (M = 60.16) than in pre-game (M = 52.49), post-game (M = 52.31), and post-practice (M = 49.71). Mean STAI scores were higher pre-game (M = 69.9, SD = 15.6) than pre-practice (M = 62.3, SD = 16.2). With higher anxiety scores, the pain responses were lower prior to competition compared to practice. These findings introduce increased understanding of analgesic effects on pain perception under pressures of a game setting and stress.

Abstract Name: Isolation of Plant-promoting bacteria from the rhizoshpere of hybrid buffaloberry Shepherdia x utahensis

Climate-induced environmental stresses and the increased use of fertilizers to meet the increasing demand for food significantly threaten food production and soil health. In natural environments, microbes in the soil are vital for plant growth and development. Their presence in the soil increases nutritional availability for plants, particularly those living in harsh conditions. A plant's microbiome, especially the underground, plays a significant role in its growth and development and mitigates environmental stresses. Idaho and Utah are particularly challenging due to extreme temperatures and arid soil. However, despite these problematic ecological factors, the native plants can thrive. Here, we are exploring the rhizosphere microbiome of

Shepherdia x utahensis ‘Torrey,’ a hybrid of two highly drought-tolerant buffaloberry species, S. argentea and S. rotundifolia native to the Intermountain West region of the US to isolate plant growth promoting bacteria. In this study, we isolated plant growth-promoting bacteria from the rhizosphere of hybrid buffaloberry. Root samples of hybrid buffaloberry were collected from three locations in Utah: the USU campus, Greenville Farm USU, and the USU botanical garden, Kaysville. The rhizosphere was removed from these root samples and pooled together. The bacteria were isolated twice on six different bacterial growth media, including media to isolate bacteria with ACC-deaminase activity. The isolated microbes were then purified using the streak plate method. Fifty-nine unique isolates were selected based on morphological characteristics and tested for five plant growth-promoting traits. 24 bacteria could show the ability to fix nitrogen, 28 produced a siderophore, 25 could solubilize phosphate, 15 show protease activity, and 23 produced catalases. IAA production and ACC deaminase assays are in progress. The isolates will be identified by 16S rRNA Sanger sequencing. The shortlisted bacteria will be tested on Arabidopsis thaliana for growth promotion.

Abstract Name: Laser Induced Graphene Ion-Selective Sensors and Supercapacitors

The effectiveness of a sensor to detect specific ions depends on its surface wettability, whereas the effectiveness of a supercapacitor is characterized by its ability to fulfill a charge-discharge cycle when a charge is applied. The current method of producing ion-selective electrodes is through a time-consuming chemical treatment process or physical methods that lack the fine-tuning capability to determine efficacy and performance and require additional steps before the desired characteristics are met. Supercapacitors are created using various processes, such as chemical or physical routes, that are more expensive and harder to manufacture on a larger scale. Because of this, we demonstrate that the ion-sensing electrodes and supercapacitors can be fabricated using a cheaper and easier method, where the fabrication and adjustment of wettability is done in one step, such that the Graphene is induced onto the substrate by laser and its performance is unaffected. Laser-induced graphene (LIG) is a highly conductive material fabricated through the photothermal conversion of polyimide substrate, using a CO2 laser in our study specifically, into a graphene-like material with high electrical and thermal conductivity. This one-step direct-writing method can fabricate platforms for developing sensors and supercapacitors. This versatile material can be easily tuned and modified to make its characteristics suitable for the intended task, expanding considerably the applications. By tuning the wettability of the LIG during the laser induction process, it has been found that ion-selective sensors present a better potential stability in detecting a target ion within an environment of interfering ions while reducing fabrication time and cost. Furthermore, the LIG supercapacitors were effective in a charge-discharge cycle when an electric charge was applied.

Abstract Name: Rebranding Spain's Difference: A Study of Franco's Spain in the 1960s Through Postcards

Spanish beaches, bullfights, and royal palaces are the subjects of various Spanish postcards dating from the 1960s from the University of Kentucky Libraries Special Collections Research Center. On the surface, these postcards simply portray popular tourist attractions; however, a critical and visual analysis of these postcards revealed how they functioned as tools used to reinvent Spain's global image. From 1936 to 1975, Spain was controlled by General Francisco Franco through a fascist, dictatorial regime. Decades of political and economic isolation led to an inflation crisis by the 1950s, forcing Spain to reopen to the outside world in order to survive. No other factor was as critical in improving Spain's image and economy than tourism. During the Spanish tourism boom in the 1960s, the Ministry of Tourism and Information adopted the slogan "Spain is different" not only to signify that Spain was different from other Western European nations due to Spain's exotic and unique culture and traditions, but also that Spain was different from what it once was during the first decades under Franco. While the slogan "Spain is different" was written on various items for sale to tourists, the slogan was also conveyed visually through postcards. Analyzing this collection of postcards in the context of Franco's dictatorship and the Spanish tourism boom allowed for a deeper understanding of how the slogan "Spain is different" was communicated through these postcards to distract tourists from Franco's oppressive regime and instead shift their focus toward the duality between modernity and tradition that existed simultaneously in Spain. *This presentation will be given in Spanish.

Abstract Name: Finding Sustainable Solutions to Shoreline Erosion using Detailed Slope Measurement with a Laser Tool

Shoreline erosion is a growing issue along ocean and lake coasts, exacerbated by climate change. This problem has intensified due to climate change, causing rising water levels and increasingly intense weather causing more erosion. Creating 3-dimensional maps of unstable slopes using devices like Leica's DISTO E7500I, helps us understand slope dynamics and what factors cause the slope to fail. The focus of my research looks for more environmentally conscious solutions to shoreline erosion without negatively affecting existing ecosystems and providing long-term benefits for the people it affects. My current research is along the shorelines of Lake Superior and Lake Michigan. I use a Leica DISTO E7500I device to create maps of erosive areas to better understand their structure. I have found this device incredibly useful as it can measure the length of particular sections and the angle between two points. This device also enables safe measurements of slopes at the bottom, as opposed to having to climb very uneven and unstable terrain. Using this device is also much cheaper and easier than using drones for aerial measurements.Our approach can provide detailed data for implementing remediation measures other than short-term "hard stabilization" methods such as breakwaters and groins. Those measures often result in worse, long-term issues. Our initial idea is that native plants can be used to help hold soil in place and terracing the slope in to reduce the undercutting on slopes. We plan to test our hypothesis in small and large scale settings to see if these solutions are beneficial for homeowners. Erosion will always be a problem, and we are not attempting to completely solve the problem, but make it more manageable for homeowners to handle.

Abstract Name: Thorn: A Young Adult Fantasy Heist Novel

When the Scarlet Rose—a masked criminal of unmatched skill—first appeared, she struck terror into the hearts of Varenth's ruling class, the crowns. She moved in and out of vaults and treasuries like a ghost. No one could find her; no one could stop her. Her reign of mystery seemed destined to continue forever.But one day, the Rose vanished. Five years later, a young man called Thorn stands poised to become Varenth's next great legend. When Thorn finds his mentor murdered on the eve of his greatest heist yet, however, gold and jewels fall below revenge on his priority list. In his attempt to bring justice to the crowns who, he's certain, killed his dearest friend, he stumbles across a much greater conspiracy. His quest brings him face-to-face with the family he rejected and robbed; his inspiration and hero, the Scarlet Rose; and even the criminal mastermind who's been pulling strings in the background all along.Thorn is a young adult fantasy heist novel of approximately 80,000 words. It follows Thorn in deep third-person point of view, occasionally dipping into others' viewpoints to encompass the full story. In pursuit of justice and truth, Thorn grapples with the meaning of integrity, the complexity of family, and the source of his identity.

Abstract Name: Abandoned routes: Unraveling the Impact of Greyhound Bus Cancellations on Gender-Based Violence Survivors in Rural and Remote Canada

The permanent withdrawal of Greyhound from Canada in 2021 raised concerns about transportation accessibility for Gender-Based Violence (GBV) survivors in rural and remote areas. GBV survivors in these regions face challenges accessing safe spaces, as shelters may be distant and difficult to reach without inter-city bus services, which are often lacking in rural and remote communities. The purpose of this media analysis is to develop a nuanced understanding of how the cancellation of Greyhound Bus Lines impacts GBV in rural and remote communities, and subsequently synthesize the key issues and calls to action as a mechanism for informing policy. This mixed-methods media analysis involved a comprehensive search of 7 news databases and media websites, which yielded 2950 articles. To select articles related to the intersection of the bus cancellations and GBV, we conducted two levels of screening: (1) title-abstract, and (2) full-text. Frequency analysis of key article characteristics revealed that over half of news sources were national-level, and most were online press. Based on time trend analysis, a spike of articles published in 2018 coincided with Greyhound’s withdrawal from Western Canada. Thematic analysis revealed three main themes. Firstly, transportation inequities serve as significant barriers for GBV survivors, limiting access to safe spaces and fostering the need for unsafe travel practices, such as hitchhiking. Secondly, the discontinuation of Greyhound services disproportionately impacts already marginalized Indigenous communities, exacerbating their vulnerability. Limited transportation options contribute to unsafe travel practices, notably hitchhiking,

and to violence against Indigenous women, as emphasized in the Missing and Murdered Indigenous Women report. Lastly, advocates emphasize the need for collaborative efforts between all levels of government to establish an integrated national transportation system as a solution.

Abstract Name: Closing the Gap in Women's Reproductive Health: Leveraging Generative AI for Personalized Contraceptive Solutions

Around 65% of individuals assigned female at birth, aging from 15-49, use some form of contraception during their lifetime. Over 80% of that population suffer from health conditions as a direct result, ranging from PMS to diseases such as Endometriosi. Despite these significantly high statistics affecting half of the global population, it has become evident that there is a noticeable gap in comprehensive research efforts dedicated to understanding and addressing the unique challenges and concerns in women's reproductive health. This imbalance, however, has a brighter future due to Generative AI: by harnessing the power of LLMs, we can expedite research, innovate personalized healthcare solutions, and ensure that women receive the attention and care they rightfully deserve.By utilizing Microsoft Azure’s ChatGPT-4 model, our research explored solving this problem through the creation of a personalized Chatbot centered around contraception. Designed to analyze inputted data, ranging from questions to medical history documents such as hormone tests, the algorithm is able to recommend personalized birth control methods that best fit the users body and desires by extracting relevant information through similarity search algorithms. This information can then be directly sent to a designated healthcare provider if chosen, creating appointments or requesting further analyzation, streamlining assistance.Further, we plan to pair this system with an Ethical Considerations Document focused on emphasizing the critical need for patient privacy and protection within the realm of Generative AI in Healthcare. We recognize the utmost importance of initiating education and spreading knowledge on this pressing topic, especially to young-adults. The scope of this project not meant to tell people what they should do, instead start a dialogue surrounding possible future use cases and options in order to foster awareness and facilitate meaningful progress.

Abstract Name: The Effect of Behavioral Inhibition on Avoidance Behavior During Transdermal Electrical Stimulation

Behavioral inhibition (BI) is a temperament characteristic associated with increased vulnerability to stress compared to their non-behaviorally inhibited (NBI) counterparts. Our previous study demonstrated that BI individuals have lower heart rate variability (HRV) than NBI individuals. This suggests that BI individuals have significantly less parasympathetic nervous system (PNS) output at rest; however, it is unknown how BI affects avoidance acquisition using a mildly stressful stimulus. Previous studies have shown differences in the behavior found in Wistar-Kyoto rats, which exhibit BI behavior, compared to Sprague-Dawley control rats. Our current study will test the hypothesis that BI individuals learn to make escape and avoidance responses using subdermal ulnar nerve transdermal electrical stimulation (TES) more rapidly than NBI individuals and also experience a more significant increase in heart rate (HR) and blood pressure (BP). BI individuals were identified through a series of self-reported questionnaires. Three levels (30 mV, 50 mV, and 70 mV) of subdermal ulnar nerve TES were delivered to participants while receiving warning signals that predicted the delivery of the TES. Participants had access to a button that, when pressed during the light, prevented the delivery of the TES, and the trial was scored as an avoidance response. If the button was pressed during the TES, it terminated the stimulation and was scored as an escape. HR and BP were also measured using a BIOPAC data acquisition system during TES. Our preliminary results indicate that BI individuals show learning acquisition throughout the experiment, while NBI individuals keep the same percent avoidance on trial ten as on trial one.

Abstract Name: Elevating Nursing Advocacy and Patient Knowledge: A Research Proposal on Understanding the Impact of Pitocin on Laboring Mothers and Neonates

Within maternity and labor units, provider discretion has been observed as a factor that may lead to unnecessary management in what is fundamentally a natural process. While synthetic oxytocin is generally considered safe and is routinely used by many hospitals, a more cautious approach emerges from clinical observations. The potential complications associated with Pitocin extend beyond its routine application, encompassing issues such as the need for neonatal resuscitation, Neonatal Intensive Care Unit admissions, shoulder dystocia, abnormal fetal heart rate, cesarean sections, breastfeeding challenges, maternal morbidity or mortality, hyper-stimulation, and various other concerns. To provide an overview of existing research and formulate evidence-based recommendations, a literature search was conducted. The search strategy incorporated University of Central Oklahoma databases, ProQuest, PubMed, and CINAHL. This evidence-based proposal seeks to analyze literature concerning the effects of Pitocin on maternal and neonatal outcomes. Through a methodical review, the aim of this project is to increase nursing knowledge related to the use of Pitocin. This knowledge would assist nurses to advocate in the best interest of the patient and ensure that patients are being provided the education necessary to make informed decisions. The outcomes of this research proposal hope to demonstrate the critical importance of nursing advocacy and patient education. Literature illuminates the necessity of transparent communication regarding the complications associated with Pitocin and lack of of maternal awareness on these matters. This project emphasizes the pivotal role of nursing knowledge, open communication, and comprehensive patient education to empower women in making informed decisions regarding their childbirth interventions.

Abstract Name: The Question of Reunification with China: Taiwanese Opinions and Domestic Audience Cost

Tensions between the People's Republic of China and Taiwan have permeated international affairs since the outset of the Chinese civil war in 1949. In August of 2022 the PRC's military initiated a days-long military campaign to punish Taiwan when U.S. Speaker of the House Nancy Pelosi visited the island. The PLA's military reaction is part of a broader PRC policy shift that appears to mark the beginning of a new phase of the PRC's coercion of Taiwan. While multiple studies have examined the PRC and the United States' positions on Taiwan, the position of the Taiwanese people has rarely been explored. Indeed, even when Taiwanese identity is examined, scholars have not considered the security implications of shifting Taiwanese identities in recent decades. This study begins this exploration, working to examine how changing identity within Taiwan affects how the Taiwanese people view their government and its policies towards the PRC. This research utilized domestic audience cost, the domestic price a leader or government would pay for making a foreign threat and then backing down, in order to evaluate how changing Taiwanese identities could increase pressure (and cost) on the Taiwanese government to remain independent from the PRC. This study used quantitatively based surveys of Taiwanese citizens (N = 348) in an effort to place the very real identities of Taiwanese citizens into the conversation of great power conflict. In so doing, this research will help to understand the implications of changing Taiwanese identity on current and future Taiwanese government policies towards the PRC and Taiwanese citizens' reactions to present and future PRC aggressions.

Abstract Name: The First-Gen Prophecy: Students' Experiences with Career Planning in the Midst of the COVID-19 Pandemic

Students whose parents have not completed a college degree (Associate, Bachelor, or equivalent) are considered First-Generation College Students (FGCS). As the first in their families to explore the higher educational landscape, FGCS shoulder a familial responsibility to excel in an educational system dominated by racialized and socio-economic stratification. In this project, I offer language, the first-gen prophecy, which describes first-generation college students of Color navigating the familial burden of pursuing higher education as collective upward mobility for their families and communities. As a result of the COVID-19 pandemic and its lingering effects, FGCS have experienced increased difficulties pursuing a college degree

and choosing a career path that may enable these hoped-for outcomes. By examining three case studies from the Pandemic Journaling Project (PJP), we consider FGCS career pathways and what factors impacted their decision-making, including the COVID-19 pandemic. Accordingly, this case-study analysis illuminates how FGCS navigated the pandemic while living up to familial expectations of degree attainment and career prosperity, like fulfilling a prophecy.

Abstract Name: Districts of Opportunity: Race and Lehigh Valley School Funding

In February of 2023, the Commonwealth Court of Pennsylvania delivered a landmark verdict in the case William Penn School District v. Pennsylvania Department of Education, declaring the state's education funding system unconstitutional. The ruling underscored the state's failure to uphold its constitutional commitment to provide a "thorough" and "efficient" education for all its students, highlighting the immense educational disparities between primarily Black, Indigenous, and People of Color (BIPOC) school districts and primarily White school districts within Pennsylvania. Despite the 1954 ruling of Brown v. Board of Education, educational segregation and inequities still occur nationwide. This paper investigates the systemic failures of federal and state policies, compounded by Supreme Court decisions, that allow segregation and educational inequities to persist with specific focus on Pennsylvania's predominantly BIPOC school districts. The research was conducted mainly by analyzing federal and state court cases and policy papers and scrutinizing budget allocations for schools within Pennsylvania, in particular, the neighboring Allentown and Parkland school districts in the Lehigh Valley. The results show that the failure to enforce desegregation measures immediately following Brown, the impact of Supreme Court decisions in the 1970s that declared that education was not a constitutional right, as well as Pennsylvania’s reliance on local property taxes for educational funding perpetuates segregation and educational inequities state-wide. By examining educational failures on a federal level, the Pennsylvania state level, and the local level within the Lehigh Valley, the research has identified overlapping patterns, root causes, and specific challenges faced by BIPOC communities, thus paving the way for targeted, comprehensive solutions to address educational disparities in these regions. Upon completion of the research, this thesis will be distributed to members of legislation in the state of Pennsylvania in order to continue the effort to provide equitable education for students statewide.

Abstract Name: Social Media And ADHD Stigma Levels In College Students

The commonality of ADHD or attention deficit hyper disorder is astounding compared to the lack of information available about it. Mass Media induces an information overload, creating an inability to access or decipher accurate information. The purpose of this study is to explore the connection between social media

use and ADHD stigma levels. In this study, media use was measured with the Social Media Trust Scale (Warner-Søderholm et al., 2018). ADHD stigma was measured with the ADHD Stigma Scale (Fuermaier et al., 2012). The sample included 97 full-time college students from a Christian university. A simple regression analysis, a T-test, and ANOVA were conducted to analyze the data. The findings in this research revealed that social media use did not significantly predict ADHD stigma levels (b1 = -.09, p = .322). The amount of social media use and trust perceived had no association with ADHD stigma levels in college students. There also was a test conducted to compare the stigma of ADHD based on a person's gender. Male individuals (M = 3.4, SD = .36) were slightly less stigmatized than the women (M = 3.6, SD = .46). However, this difference was not statistically significant (p = .08). In addition, there was a statistically significant difference in ADHD stigma levels between different school years (t = .21, p <.05). The findings emphasize the need for society and university institutions to identify what increases ADHD stigma levels in college students over their years in school. Furthermore, future implications address the need to understand how ADHD stigma levels can be decreased among college students.

Abstract Name: Finding Literary Freedom

This presentation discusses Jack Kerouac's perception of social issues in On The Road and how more recent contemporary readers critique it. Kerouac's story, featuring a cross-country road trip set in the late 1940s, has received much negative criticism due to its controversial viewpoints on gender, race, and sexual orientation. The author argues that Kerouac's story reflects an unadulterated reality based on how and what he observed during his time, which has caused many incidents and views in the book to conflict with a more contemporary understanding of them. Among these criticisms are Kerouac's surface-level relationships with women, his stereotypical and fetishized views of race, and his contradictory depictions of homosexuality. However, considering the book as a representative product of the Beat Generation who wrote about the controversial topics of their time with an attitude of "bareness" and a belief in free expression, the author maintains that well-rounded readers should keep a critical open-mindedness toward the novel. That is, people should be aware of the fact that historical social environments can influence what and how the writers depict their experiences in their times just as what Jack Kerouac did in On The Road.

Abstract Name: The Trophoblastic Immune Response of Endoplasmic Reticulum Aminopeptidase 2-Arginine In Vivo as a Future Tumor Clearance Therapy

Endoplasmic reticulum aminopeptidase 2 (ERAP2) is a gene that codes for an enzyme that trims

polypeptides, contributing to a robust immune response. With the known missense mutation of ERAP2-Lysine (K) to ERAP2-Arginine (N), the impact of ERAP2N on the immune system's function remains largely unknown. Part of the reason there is limited knowledge of ERAP2N's role is because of the lack of genetic homozygosity in studied populations, which suggest the gene's incompatibility with life in utero. The disruption of healthy pregnancy could be through the immunological contribution of increased Natural Killer (NK) cell activity that targets ERAP2N-expressing cells as we have previously demonstrated in vitro. ERAP2N's proposed cell death during pregnancy has led to the potential application towards tumor clearance. This study examines the applications of ERAP2N introduction to choriocarcinoma cells in vivo. The JEG-3 cell line derived from gestational choriocarcinoma was stably transfected with ERAP2N to be injected into immune-compromised mice, followed by an adaptive transfer of immune cells to evaluate the impact of ERAP2N on tumor clearance. The mice that received transfected JEG-3 with ERAP2N exhibited a significant decrease in the remaining tumor volume compared to JEG-3 tumors that did not have ERAP2N. From a lymphocyte perspective, immunohistochemistry staining provided results indicating that NK cells and T cells colocalize and mediate the clearance of tumorigenic cells with ERAP2N expression. These results have enormous potential to investigate further an immunological therapy involving the ERAP2N gene for tumor clearance. Future studies to be completed would involve investigating ERAP2N's impact on other cancer cell lines and gaining further understanding of the pathway that transpires throughout the tumor clearance process.

Abstract Name: Analysis of Jungian Psychology in the Persona Franchise

The Persona series is a Japanese Role-Playing Game, or JRPG, that was developed by Atlus. It has many implications of the use of Carl Jung's psychoanalysis, or Jungian psychology, and the writer wanted to explore how these concepts fit in the context of the wider story of the games. In this, the writer looked at all the games in the franchise but focused more on Persona 4 and Persona 5, because they had the most implications of the psychology used in the series. The writer focused on three major concepts of Jungian psychology; the Shadow, the Persona, and the Collective Unconscious, but also dealt with the idea of the "Self" and what it means to be a human being in the terms of Jungian psychology, with some myths sprinkled throughout. The data was collected through the watching of silent playthroughs to experience the feeling of playing the games that they did not own. The result of the research was that every single game applied aspect of Jungian psychology in different ways, and even if they changed from the original concepts, the core of them were the same.

Abstract Name: Visual Imagery and the Transformative Power of AfriCOBRA

The paper delves into the profound impact of the AfriCOBRA (African Commune of Bad Relevant Artists) Movement, a pivotal force in African-American art during the tumultuous 1960s and 1970s. Rooted in the aftermath of Martin Luther King Jr.'s and Malcolm X's deaths, AfriCOBRA sought to forge a collective identity and destiny for African Americans through a dynamic fusion of African aesthetics, vibrant colors, and powerful messages of cultural pride and social justice. The movement's commitment to dismantling structural racism and promoting Black emancipation positioned it as a living monument to art's ability to shape identity and drive social change.Central to AfriCOBRA's ethos was the embrace of Black nationalism, a belief system that sought to establish and maintain a distinct black racial and national identity. The movement's aesthetic, characterized by what the artists referred to as "Kool-Aid colors" or bold hues, mirrored the vibrancy of the 1960s and '70s. Examples like Wadsworth Jarrell's Revolutionary (Angela Davis) and Gerald Williams's Say It Loud showcased the use of bold patterns and bright colors, serving as both artistic expressions and tools of resistance.Beyond aesthetics, the paper underscores AfriCOBRA's unique role in activism and feminism during the Black Arts Movement. The deliberate inclusion of rhythmic patterns mirroring musical waves in their artwork became a symbolic representation of the African-American experience. The movement's commitment to portraying the multifaceted experiences of African Americans extended to feminism, with the Studio Museum in Harlem providing a platform to amplify the voices of African-American women artists associated with AfriCOBRA.

Abstract Name: Photography: The Importance of Its Use in Graphic Design Then and Now

This paper explores the profound impact of photography on graphic design, delving into its historical evolution and contemporary applications. The proverb "A picture is worth a thousand words" serves as a guiding theme, attributed to Frederick R. Barnard but rooted in the ancient wisdom of Confucius. Tracing the development of photography from its inception, the paper highlights pivotal moments and innovations that transformed it into a powerful tool for graphic designers.The narrative begins with Joseph Nicephore Niepce's groundbreaking but laborious eight-hour exposure to produce the first photograph. Despite its blurriness, Niepce's work inspired further innovations, including wood-engraved illustrations. The transition from wood engraving to photoengraving, as exemplified by John Calvin Moss's efficient method, marked a significant step forward in cost-effective printing blocks while maintaining photo details.The paper emphasizes Frederick Ives's introduction of halftone processes as a game-changer, allowing the reproduction of photographs in newspapers and significantly reducing production time. This innovation laid the foundation for the integration of photography into graphic design. The narrative further explores photography's role in documenting historical events, citing Matthew Brady's photographic coverage of the American Civil War as a transformative moment that brought the war's emotion and reality to the public.The paper extends beyond historical contexts to explore photography's contemporary applications in graphic design, emphasizing its ability to evoke emotion and connection in the audience. Examples from organizations like Habitat for Humanity showcase how photography, combined with graphic design, can effectively convey messages and inspire action. Magazines such as National Geographic and Reader's Digest utilize photography to draw readers into their articles, while other publications like Time and People use a blend of photography and typography to communicate effectively.

Abstract Name: Drexel Dragon Heart: Next Generation Blood Pump Design for Pediatric Patients with Heart Failure

The treatment of children with heart failure is a formidable challenge. Heart transplantation, when available, becomes the only lifesaving option. Children could benefit from a blood pump: a medical device designed to assist the ailing heart with pumping blood. Blood pumps for children, however, lag behind those for adults. While adult devices have been employed in children, the operation of these adult pumps off-design increases the risk of blood cell damage and clotting. Pediatric patients have limited options due to the anatomy of childhood heart disease and increased cardiovascular demands of physical growth. To address this unmet clinical need, we have innovated The Dragon Heart, which uniquely integrates multiple pediatric blood pumps. This compact device (60mm x 50mm) suspends the pumps in a magnetic field, thus facilitating a long operational lifespan and lower blood cell trauma. We performed high-quality modeling of two new pump designs, which produced target performance; 40-180 mmHg for 0.5-4 L/min at 2000-3000 RPM. Internal fluid forces were below 2.5 N, and fluid stresses were at acceptable levels. This work serves as the foundation for the next phase of prototype benchtop testing, moving toward animal studies.

Kayleigh Woodward

Abstract Name: THE SPIRIT OF THE AMERICAN WEST: AN EXPLORATION THROUGH PAINTING

This series of paintings and drawings was created to illustrate the wildness of America’s past and the spirit of the Old West. This group of work was started as an exploration into the portraiture of animals, paying homage to their strength and resilience, as well as the land they live on. Throughout history, people have become symbols and immortalized for what they achieved in their lifetimes and the question to be asked is, why are animals not usually given the same status and respect? I have a deep respect for the working animals who carried this nation forward for centuries, as well as the native North American species who have always survived off the land and became a rich resource for both the indigenous peoples and the masses who later made this country their home. Also, as a contemporary artist and student, I’ve built my series on the inspiration of Georgia O’Keeffe’s work as well as her life. It is said that she is the “Mother of American Modernism”, and that she painted her masterful compositions with a “signature blend of realism and abstraction”. This is something I have found to be formative in my evolution as an artist and crucial in my creative expression. Throughout my painting process, I use acrylic paint on canvas and depict various animals in a realistic way, but also allowing for a subjective use of color. As a result, I believe I’ve created a series of paintings that are successful in drawing attention to aspects of the Old West and its spirit through visual interest and an accurate rendering of my subjects.

Abstract Name: COVID-19 Vaccination Status Associated with Discrimination and Victimization Among Non-Binary/Genderqueer and Transgender Participants

Introduction: Transgender/non-binary/genderqueer individuals experience discrimination, stigma, and violence which contribute to overall higher levels of anxiety, depression, and lower general psychological well-being compared to cisgender counterparts. Further, people in this community often face discrimination/victimization from healthcare providers. This study examines whether higher rates of victimization and discrimination against transgender/non-binary/genderqueer participants people is associated with their rates of COVID-19 vaccination. Methods: A cross-sectional survey assessed community health behaviors and perspectives, inclusive of an 11-item Gender and Minority Stress Resilience (GMSR) measure. Higher GMSR scores correlate to more stressors. Participants self-identified gender identity with two questions: the first asked about assigned sex at birth (male or female) and the second asked about current gender identity. Surveys were collected at seven PRIDE festivals throughout Missouri (June - August 2023). Logistics regression models compared vaccinated and unvaccinated participants.Results: A total of 381 participants met inclusion criteria. Black participants were 82% less likely to be vaccinated [95%CI: 0.04-0.88; p-value = 0.010] compared to white participants. Furthermore, participants that trusted nobody for COVID-19 information were 78% less likely to be vaccinated [95%CI: 0.06-0.81; p-value = 0.020]. For every increasing point on the victimization score, the odds of getting vaccinated decreased [OR: 0.74; 95%CI: 0.73-0.99; p-value = 0.030]. Finally, participants who were worried about developing long-covid were ~3.7x more likely to be vaccinated [95%CI: 1.591-8.487; p-value = 0.002].Conclusion: Among transgender/non-binary/genderqueer participants, the reported victimization based on gender identity was associated with lower rates of COVID-19 vaccination, particularly among Black participants. In contrast, the GMSR discrimination score was not associated with vaccination status. Further evaluation of factors influencing transgender/non-binary/genderqueer individuals' decisions to obtain COVID-19 vaccination and the influence of victimization on choices about health care is warranted.

Abstract Name: "Passing" as Identity Loss for Chinese Immigrants

Passing has been discussed centrally in literature and literary studies as a primarily African-American experience. Using the example of Phillip Brian Harper's definition, it's classified as "anyone while who, while legally designated as black, lives successfully as white for a significant time". This definition overlooks a different kind of passing, in which Chinese immigrants did not pass as white to enter America but instead passed as another Chinese immigrant via a method called paper sons, by entering America through a different Chinese name and life in order to bypass laws preventing them from immigrating into America. This undefined kind of passing raises some questions that both depart from and intersect with passing as an African-American experience; How exactly did these "passing" experiences affect Chinese immigrants and their lives? Has literature represented these experiences, and are they positive or negative? This paper investigates the effects of "passing" as presented in literature, specifically analyzing the stories of the author's father, Think Virtue, from Maxine Hong Kingston's China Men. Pairing close readings of the novel with material in historical archives, I show that exploring the experiences of Chinese immigrants can show how "passing" affected the way Chinese immigrants struggled to reconcile their new identities in America with their inherited identities in China. Discussing this form of "passing" can also show us how literature, in the case of Think Virtue, demonstrates this loss and its effects, celebrating Chinese-American heritage but also showing the truths of the loss of identity due to "passing". This paper thus shows how literature may open and broaden the critical conversation about passing as it refers to Chinese Americans. Thank you for your time and consideration.

Abstract Name: Effects of Glyphosate on Mosquito Development, Survival, and Immune Regulation

Herbicides are an integral part of agriculture. Glyphosate is the most widely used herbicide by volume, with over 650,000 tons used in 2011 alone. The effects on off-target organisms are widely unknown. Mosquitoes are of interest due to their ability to vector diseases and because they develop in agricultural plots where Glyphosate is deposited. Previous work suggests that Glyphosate interferes with melanin-based immunity and makes mosquitoes better vectors. However, the previous work mentioned suffered from unrealistic Glyphosate dosages and delivery. This study aims to readdress this issue using biologically relevant dosages and applications. Experiments were conducted to examine the effects of Glyphosate on mosquito larvae throughout the rearing process and how it would alter fitness and immune activity including PO, a key enzyme in melanin production of mosquitoes. Survival and development time were recorded with 3 Glyphosate treatments and a control with no herbicide. The treatments added Glyphosate to larval rearing dishes, adult mosquito's nectar feed, and to adult mosquitoes directly via spray to emulate a field spray. The recommended field application dose of 68μm of Glyphosate reduced the survival rate to 0.80 and significantly increased development time. As Glyphosate dose increased, adult PO activity decreased for the feeding and spray treatments. Glyphosate induced upregulation in dicer (feed and spray), and a

downregulation in defensin, MyD88 (feed only), and PPO (feed only). These results suggest that Glyphosate causes stress for the mosquitoes and can negatively affect their immunity in agricultural settings. Decreased immunity may lead to increased vector competence which can lead to a higher probability of spreading disease.

Abstract Name: Eating Disorder Development in College Students

Background Young adults beginning college often face an environment conducive to the development of eating disorders (EDs), which have an elevated and rising prevalence among college students. EDs are mental health conditions characterizing a person’s unhealthy relationship with food and the dangerous compensatory behaviors they often engage in as a result. The college ecosystem presents the unfortunately perfect setting for ED development, as it suddenly exposes students to hundreds of development risk factors, all while they’re trying to navigate life independently for the very first time. Objective This research aims to break down and rebuild not only the system of eating disorder development, which is made up of all of the risk factors for the initiation and exacerbation of EDs, but also the University of Kentucky’s student support system (which was taken as a case study) to form insights about opportunity spaces or significant problem areas within each system that would best benefit from design intervention. Methods Employing a multi-method approach, the research combines surveys on current students across multiple universities, interviews with subject matter experts (including dietitians, researchers, and student wellbeing professionals), and an extensive literature review to gather previously published findings. Findings Key findings include the identification of the "developmental loop," a term coined to describe the phenomenon where complications that arise from EDs also exacerbate development themselves. Additionally, this research reveals the inadequate outreach efforts at UK, contributing to students' lack of awareness about available resources and how to access them. Anticipated Outcomes By identifying key risk factors that make up the “developmental loop” and locating the root of the disconnect between UK’s students and university support resources, design intervention can be guided to attack those two areas as a means of mitigating the abilities for eating disorders to develop in college students.

Abstract Name: Long-term Effects of Cancer Treatment in Childhood

Childhood cancer treatments, while contributing to improved survival rates, have raised concerns about the enduring impact on survivors' health and well-being. This research aims to conduct an in-depth examination of the long-term effects of childhood cancer treatments, focusing on identifying causes, and exploring management strategies. It will be conducted thorough literature review which will look at statistical analysis

of relevant databases, treatment modalities conducted through clinical studies and a review of real-life case studies. Through an extensive literature review, this research will systematically categorize and document the myriad long-term effects associated with childhood cancer treatments. This encompasses physical, psychological, and socio-economic dimensions, providing a holistic view of the impact on survivors. The anticipated outcome of this research project is to develop a deeper understanding of the long-term effects of childhood cancer treatments to enhance nursing care of these children.

Abstract Name: Modelling in Computational Neuroscience

With the recent advancements in technology and the rise in the general public's awareness of artificial intelligence and neural network models, it is imperative to reflect on the field of neuroscience for its foundational contributions. Data analysis is typically paired with biologically plausible models that can encapsulate the multitudes of behaviors for a single neuron to connections between multiple neural populations. Despite these developments, there remains a lack of understanding of how single-neuron behaviors integrate into neural network models. This study presents a comprehensive review of the current models in practice, examining their descriptive and computational constraints, including accuracy, complexity, mathematical limitations, and solution stability. Our findings aim to pinpoint specific areas that require further research to enhance our quantitative understanding of the connection between individual neuron functions and neural networks.

Abstract Name: Mutational analysis of the promoter and 5’UTR of the fljB flagellin in Salmonella Typhimurium identified base mutations defective in transcription and translation of fljB.

Salmonella enterica subspecies contribute significant public health concern in the United States, causing roughly 1.4 million infections and nearly 600 deaths annually. Many Salmonella enterica, including S. Typhimurium and S. Typhi, are motile pathogens and their virulence and survival are dependent on the presence of surface motility organelles termed flagella. The bacterial flagellum is comprised of three main structural components: the basal body, the hook, and the filament. A Salmonella bacterium expresses, on average, four peritrichous flagella per cell. Each flagellum constitutes one percent of the total cellular protein production. The biosynthesis of these structures is tightly regulated. A single bacterial flagellar filament is composed of approximately 20,000 flagellin protein subunits encoded by either the fliC or fljB genes. Most

of the flagellum is located extracellularly, and structural components need to be secreted from the cytosol through the growing organelle where they self-assemble at the structure's tip. The translocation of these proteins is mediated by a Type III secretion system embedded at the base of the flagellum. Previous work has suggested that the 5'-untranslated region (5'UTR) of the flagellar genes contains crucial regulatory signals responsible for efficient protein production during flagellum assembly. In the present study, we aim to dissect the regulatory signals within the 5'UTR of filament gene fljB with targeted doped mutagenesis via lambda red recombineering. Our results identified several distinct stem-loop structures in the 5'UTR region of fljB mRNA. Analysis of motile revertants from the fljB mutant pool revealed alternative RNA stem-loop structures in the 5'UTR that affect ribosome binding needed for fljB mRNA translation. The outcome of the study intends to understand the unexplored aspects of Salmonella flagellar regulation. Understanding these regulatory signals at the molecular level holds potential implications for developing targeted strategies, including novel therapeutic interventions or vaccines, to mitigate Salmonella infections.

Abstract Name: Understanding the Role of Microglia in Neurodegenerative Diseases

Neurodegenerative diseases, characterized by protein aggregation and synaptic dysfunction, pose significant challenges to the global health sector. My study explores two interlinked facets of these disorders: protein aggregation and synaptic content. With recent studies highlighting microglia activation in neurodegenerative diseases, the first objective of my study is to investigate the potential impact of microglia removal on protein aggregation. Therefore, I eliminated microglia in culture to assess the histological and biochemical aggregation properties of proteins (Aβ, α-Synuclein, TMEM106B), which aggregate in neurodegenerative diseases. Our preliminary findings from these explorations suggest that removing microglial cells in primary culture does not significantly alter protein aggregates or protein expression. Beyond protein aggregation, synaptic alterations is another common feature in neurodegeneration. Therefore, we pioneer a new method for visualizing and tracking synapses in real-time by adding fluorescently labeled nanobodies to an ALFA tag inserted to the presynaptic marker Neurexin3β in primary culture. This novel technique offers valuable capabilities for studying synaptic dynamics in neurodegenerative diseases. Overall, our integrated approach seeks to unravel the intricate interplay among protein aggregation, microglial function, and synaptic activity, potentially revealing novel therapeutic avenues for these debilitating diseases.

Abstract Name: Fibroblast & Smooth Muscle Cell Co-Cultures in a Microfluidic Prostate-on-a-Chip

Prostate cancer is the second most common cancer in American men, responsible for about 34,700 deaths in 2023. About 90% of human cancer deaths are due to metastasis, the process by which tumor cells from the primary site form colonies in secondary sites. Although the mechanism of prostate cancer metastasis remains poorly understood, it is well established that the interaction between the epithelium and the surrounding stroma plays a key role in prostate cancer progression. Thus, we developed an in vitro model of the human prostate gland to evaluate the effects of intercellular crosstalk. The prostate-on-a-chip model features two stacked channels designed for culturing epithelial and stromal cells, separated by a polyester porous membrane for cellular anchoring while allowing cell signaling. Produced via soft-lithography techniques, each 520 μm-high channel is made of polydimethylsiloxane (PDMS) for microscopic imaging and biocompatibility. The mature prostate stroma contains two major cell types, fibroblast and smooth muscle cells. To mimic the in vivo stroma, Smooth Muscle cells (SMCs) and Benign Human Prostate Stromal cells (BHPrSs) were mixed, and we report the effects of channel coating, cell media, and media supplements on stromal cell differentiation and proliferation. Despite initial mixture seeding containing 80-90% SMCs, the fraction of BHPrSs increased over 5 days of co-culture. Desmin staining of the SMCs suggests that switching from regular to differentiation media, following confluency, indeed promoted SMC differentiation. While the presence of fetal bovine serum (FBS) supplement in the differentiation media appears to be necessary for BHPrSs and SMCs viability, no significant effect of the FBS level was noticed. Furthermore, the alpha-smooth muscle actin (α-SMA) biomarker was substantially over-expressed in comparison with desmin. Establishing a biologically relevant SMC-BHPrS cell mixture, to faithfully represent the in vivo stroma, is critical for enabling in vitro analysis of prostate cancer development and progression.

Abstract Name: Impact of Racial Disparities in Home Mortgage Lending Outcomes on Intergenerational Mobility

This paper evaluates the level of racial disparities within the home mortgage lending market and their relationship with intergenerational upward mobility. Using data from the Home Mortgage Disclosure Act (HMDA) 2010 dataset and Opportunity Insights datasets, this study scrutinizes lending disparities and intergenerational upward mobility at the Commuting Zone (CZ) level. By only evaluating lending outcomes for first-lien home purchase loans, I can capture the cohort of prospective home buyers moving to better neighborhoods and self-sorting themselves into geographical regions. Through the implementation of logistic regression and ordinary least squares (OLS) regressions, I evaluate the correlation between variables, including but not limited to, applicant race and sex, applicant income, loan amount, minority population, and median household income with the probability of loan application denial. These correlates are then compared with intergenerational childhood outcomes at the CZ level to determine the relationship between home mortgage lending outcomes and childhood outcomes.

Abstract Name: Cultivation of Novel High-lipid and High-protein Producing Strains of Chlamydomonas reinhardtii for Use in Aquaculture Applications

The continued use of fish meal and fish oil (FMFO) in commercial fish feed disrupts marine ecosystems and contributes to unsustainable practices within the aquaculture industry. As aquaculture production has increased by 527% over the past twenty years, the need for alternatives to FMFO has become paramount (FAO, 2019). Chlamydomonas reinhardtii is a single-celled green alga that could serve as an ideal model organism for the development of an environmentally sustainable, economical, and nutritious alternative to FMFO due to its adaptability, ease of cultivation, and genetic manipulation, as well as its variability in protein and lipid content among wild-type (WT) strains. A combination of Classical Strain Improvement (CSI) techniques consisting of UV mutagenesis and mating of ten WT strains resulted in two generations of offspring. A total of 340 progeny were assessed for protein through crude protein extractions and Bradford assays, while lipids were assessed using BODIPY 493/503 staining, fluorescence assays, and confocal microscopy with ImageJ analysis. Eight high-protein and 18 high-lipid strains were identified, with the top producing strains having a 57.6% increase in protein content and 150.2% increase in lipid content relative to the WT parental strains. Currently, we are conducting experiments to monitor cell growth of parental and high-protein and high-lipid strains in culture to determine if an increase in protein or lipids affects their growth. As this research aims to develop high-protein and high-lipid producing strains of C. reinhardtii that can be efficiently cultivated in large volumes, it is important to investigate patterns in growth rates.

Abstract Name: Where Does Your Help Come From? An analysis of Chicago minority business owners and their support networks

Minority business owners have less capital access, capital accumulation, and business expansion opportunities leading to disparate outcomes and a widening racial wealth gap. Minority “out-groups” have responded by banding together in both support networks and physical spaces giving rise to theories on race as social capital and ethnic enclaves as business incubators. However, the role of racial homogeneity on business and financial advancement has limitations such as lower community wealth, overly taxing norms of reciprocity and personal obligation, and fierce competition for customers. Further, purely co-ethnic business support networks can limit entrance into mainstream markets and financial stability. This thesis aims to study the support networks that have been most impactful for minority business owners in Chicago and how social capital plays a role in their efficacy. Understanding how a minority business owner’s value-creating

relationships exist not only on the basis of their ethnic identity is imperative in developing business support models. Increasing trust, knowledge sharing, and outreach for minority business owners can be informed by ways in which social capital at the local municipality level has been historically underleveraged. Chicago's diverse metropolitan population provides opportunity to study interactions within and across ethnic lines. Qualitative interviews guided this effort by digging into ways each business owner funded, ideated, developed, and sourced support through times of crisis across a range of industries. Indicators of social capital were coded in interview transcripts and compared across the experiences of 30 entrepreneurs at various stages in their journey. Implications from this study will guide public and private institutions as they look towards better supporting minority businesses either through community organizations or co- and cross-ethnic networks and relationships.

Abstract Name: Control of Circuit Computations for Cue-Guided Movement Initiation by Dopamine

This study challenges the standard model of basal ganglia function, which proposes that the direct and indirect pathways play opposing roles during movement. Recent recording studies have demonstrated that direct and indirect pathway medium spiny neurons behave similarly during simple motor behaviors, suggesting the coordinated activation of both pathways is critical during action selection. To clarify this, my project aims to investigate the contribution of the dorsal striatum and its downstream targets, the external globus pallidus and the substantia nigra pars reticulata, in motor control. We will use a toxin- and genetic-based mouse model of Parkinson's disease (PD) at different severities of dopamine depletion to study the onset and progression of basal ganglia dysfunction: the 6-hydroxydopamine and MitoPark mouse model. Our experiments will involve acute, head-fixed recordings in awake mice navigating a virtual linear track to obtain sugar rewards. Since previous studies have shown memory deficits precede motor impairment in a PD mouse model, we hypothesize the neuronal firing activity of striatal circuits involved in cognitive control to be disrupted at an earlier timepoint than the neuronal firing activity of striatal circuits engaged in sensorimotor integration. We will also reveal how dopamine supports the firing patterns of striatal neurons during movement initiation and cessation, expecting adaptive mechanisms to stabilize population firing properties when dopamine depletion is more gradual in MitoPark mice compared to mice with sudden dopamine depletion after 6-OHDA administration. Our study will provide insight into how large-scale activity and oscillation patterns contribute to motor and cognitive function.

Abstract Name: De-Orientalizing Memories of the Cultural Revolution in Chinese America: Towards a Diasporic Framework of Mourning and Remembrance

In 1966, Mao Zedong initiated the Cultural Revolution, a decade-long violent movement that sought to revitalize China's socialist revolution through the purging of Communist Party bureaucracy and Western influence. This complicated and devastating political event has defined 20th century Chinese history and is embedded in China's collective memory. My research looks at the ways in which Chinese American museums and archives contribute to an Orientalized remembering of the Cultural Revolution. Many scholars have written about this Orientalization from the perspective of Chinese American memoirs, yet they have overlooked the archive, which represents another strand of knowledge production for Chinese Americans. Using frameworks from postcolonial scholars on the archive, I ask how Chinese Americans may have contributed to a colonial view of their ancestral homeland in return for Western exoticization and exploitation of their histories. Moreover, because the archive lacks nuanced perspectives on Chinese history, I explore how second generation Chinese Americans generate their own discourses with this violent, complicated history through fiction. Using the frameworks of postmemory studies, I ask if the second generation will continue this Orientalized remembering, or uncover a more productive framework of mourning--understanding all the complicated pieces of history that have been covered, over-exposed, and remembered. Through this interdisciplinary approach to memory from both the archive and literary fiction, I argue that Chinese Americans, as subjects living under the identities of two global superpowers in the wake of neo-Cold War politics, must move towards a framework of mourning as a political act that is highly critical of the role US empire plays in memory-making.

Abstract Name: Embracing the Posthuman: Subverting Techno-Orientalism and Reclaiming Asian Futurity in Salt Fish Girl and Light From Uncommon Stars

My research analyzes Ryka Aoki's Light from Uncommon Stars (2021) and Larissa Lai's Salt Fish Girl (2002), both works of Asian American speculative fiction that suggest queer temporality as an intervention to techno-orientalism, the persistent depiction of futuristic Asian bodies by the West as highly intelligent yet unfeeling and robotic. Techno-orientalism, in its operation to assert Western superiority over the Asian body, is inextricably linked to a colonial view in which Asia is imagined, threatening and dehumanized. While many scholars have written about how Asian American cultural production asserts its own resistance towards techno-orientalist stereotypes, few have focused on the queer intersection that complicate representations of futurity. Aoki validates the queer Asian body as a site of resistance towards colonial understandings of technological progress. Elsewhere, Lai's work queers folklore of the ancestral homeland and intertwines its narrative with a dystopian future to complicate notions of linear, heteronormative progress. Through a historical contextualization and queer of color critique of these two works, this article argues that queer Asian American speculative fiction, as a representation of queer temporality, has anticolonial potential and demands new ways of conceptualizing a future that is resistant to exploitation and extraction.

Abstract Name: Characterizing Expression of Meristem Genes in a Lig5 Maize Mutant

Plant meristems are developmental tissues that shape the structure of all plant organs. Aberrations in expression of meristematic genes as well as mutations in the proteins active in meristematic tissues could affect plant development. Understanding the relationships between meristem-specific genes and unveiling the regulatory mechanisms for their expression is essential to controlling plant development and breeding crops with desired characteristics. Liguleless genes are a group of meristem-specific genes affecting plant leaf development. A Liguleless5 (Lig5) mutation causes aberrations in the leaf ligule, a thin outgrowth at the junction of leaf and stem, changing the shape and the angle of seedling leaves. In addition, this mutation causes knot formation on leaves. In this project, we investigated the expression patterns of meristem-specific genes from several families (knotted, knotted-like, and liguleless) in meristematic and leaf tissues in lig5 mutant in comparison to the wildtype, to understand the possible causes of this phenotype. RNA was extracted from the meristematic (stem) and leaf tissues in young seedlings, converted into cDNA and analyzed using qPCR to determine gene expression. We determined that several meristem-specific genes were overexpressed in the mutant leaf tissues and underexpressed in the mutant meristematic tissues compared to the wild type plants. A few of those genes that expressed a change in expression patterns were kn1, knox1, knox2, and knox3. Our findings suggest that lig5 mutation causes changes in expression patterns of meristem-specific genes. Further studies are needed to understand the details of this effect.

Abstract Name: Creating Culturally Relevant Genetic Education Modules for the Asian American, Native Hawaiian and Pacific Islander (AANHPI) Community

Purpose: The purpose of this study was the completion of an extensive review of the literature, aimed to facilitate a comprehensive ethnic-based, genetic program tailored to the needs of AANHPI community that would be used by the ALLofUS program, fostering a culturally sensitive lens for genetic education.Background: Ethnicity has effects on many biological and behavioral traits, and so is an important consideration when personalizing culturally relevant educational modules. Ethnicity encompasses an individual’s genetic ancestry, geographic background, and cultural tradition. As an international undergraduate nursing student, I was asked to be part of collaborative efforts with the Asian Health Coalition (AHC) and the International Society of Nurses in Genetics (ISONG). A comprehensive literature review was conducted.Results: The results of this study provided significant exemplars to be used in the learning modules. Two examples include: 1) in Europeans, the usual genetic recessive trait example is blue eyes and brown eyes; yet in Asia, when there is very little variability in eye color, a more appropriate example is eyelids; and 2) in the mountains of Tibet, genetic variants that have been passed down for centuries allow Tibetans to adapt to the high altitude. Pharmacogenomics are also an important component of the modules, including variants in the CYP2D6 and CYP2C19 genes that are more frequent in the Asian American population.Conclusion: This thorough literature review contributed to a well-developed program that will be translated into five Asian languages, with the intention of advancing genomic health literacy across the AANHPI community; with the broader goal of bridging the gap in genetic knowledge and fostering a deeper understanding of genetic and genomic information within diverse communities.

Abstract Name: Can children learn concrete and abstract science nouns through a storybook?

Word learning is important for children's development. Vocabulary scores predict outcomes such as overall school performance, reading comprehension, and literacy skills. Previous research has studied different mechanisms and cues that children use to learn words. In many word-learning studies, children are taught novel concrete nouns through fast-mapping and other types of ostensive learning. In classroom settings, however, children are not typically taught words this way. Rather, they encounter concrete and abstract nouns in different contexts, one of which is through storybooks. We were interested in whether children could learn concrete and abstract nouns using a naturalistic setting: storybooks. In a pilot study, we taught 3 to 5-year-old children four concrete and four abstract nouns through a lab-created science storybook. Children completed a pre- and post-test which assessed their learning of the words. Caregivers filled out questionnaires about their children's reading habits and exposure to science words. The results revealed that the appropriate age range for concrete and abstract noun learning in this storybook is 4 to 5 years. These children successfully learned some concrete and abstract nouns. In our next round of piloting, we will focus on updating the tests to better reflect children's understanding of the target nouns. We will also update the caregivers' questionnaire to better reflect children's comprehension and production of science nouns. With the new pilot data, we expect that children who read more often will learn more science words. We also predict that children who have more exposure to science vocabulary will learn more science-related abstract nouns. This result would suggest that reading science books could help children expand their understanding of abstract science nouns. We will conduct exploratory analyses to determine whether prior exposure to science-related concepts relates to how well children learn nouns from the storybook.

Abstract Name: Rehabilitation as Social Control- a Review of Existing Research and Data

Rehabilitation programs in the post-Second Chance Pell Grant time comes in greater variation in the United States Prison system than ever before, but they all generally share the same goals: to prepare inmates for re-entry into their communities and society at-large, and as deterrence for recidivation. Despite the fact that many studies on rehabilitation programs suggest positive effects, existing studies on recidivism and participation in rehabilitation must be approached with the understanding that critical amounts of data are missing or inaccessible for public policy and/or privacy concerns. This does not mean that no conclusions of any kind can be drawn from the data, nor does it mean that existing data is not in favor of rehabilitation. In

fact, most research done on rehabilitation programs and their effects strongly suggest that there are significant positive effects for both the individual participating and their communities on release. In order to further study rehabilitation and its general effects on prison populations, we first review existing literature surrounding rehabilitation programs. Next, we move into a statistical review of open source data from the Bureau of Prisons to look more closely at the relationship between the availability of rehabilitation programs and in-prison conduct as a measure of the efficacy of these programs. We conclude with our findings from our statistical review, and the implications of our findings, as well as their limitations. In our findings from both the qualitative and quantitative reviews, we find evidence that suggests access to college education, and possibly other types of rehabilitation in the prison system, may currently be used against incarcerated people as a form of social control. Further research and testing is needed, both to prove the positive benefits of rehabilitation programming, as well as our hypothesis of access to rehabilitation programming as social control.

Abstract Name: Fitness and Social Attention: Insights from a Study on Socioemotional Sensitivity in Free-ranging Rhesus Macaques

The ability to discern socioemotional cues from conspecifics is crucial for social competence in primates and overall individual performance, including humans. However, the connection between social information processing and key fitness components remains unclear. Here, we investigated whether preferences for social signals predict fitness components in a primate population by testing associations between survival, reproduction, and social interest of free-ranging rhesus macaques (Macaca mulatta) in Cayo Santiago, Puerto Rico. We experimentally assessed socio-emotional sensitivity in 393 individual adult monkeys. For this, we measured looking time to conspecific female photographs displaying diverse emotional expressions (i.e., neutral face, threat face), and tested whether such response was associated to survival and reproductive performance. After controlling for age, the annual survival of males and females was positively associated with social attention to a female photo ($b = 0.60$, $z = 2.01$ $p = 0.04$). In contrast, we found a negative association between the annual probability of reproduction in females and social attention to a female photo ($b = -0.27$, $z = -3.08$, $p = 0.002$), indicating a potential trade-off between social interest and reproductive performance. As social attention to a threat stimulus increased relative to the neutral stimulus (i.e., negative socioemotional bias), the probability of reproduction decreased ($b = -0.15$, $z = -2.24$, $p = 0.03$). Our results highlight the potential role of social interest in various aspects of fitness and suggest achieving reproductive success may come at the cost of social engagement in this group of primates.

Abstract Name: “No time for work”: Investigating the Financial Concerns of STEM Undergraduate Students at the University of Kentucky

Research has shown that financial stress affects many undergraduate college students and that first-generation college students and members of historically minoritized groups are more likely to experience financial difficulties. No prior studies have investigated the impact of academic major on one's financial concerns. Specifically, the goals of this study were to better understand how the schedules and course requirements of undergraduate STEM students at the University of Kentucky affect their ability to earn money from a job and to determine if STEM-major related financial concerns differ among demographic groups. We utilized a mixed methods approach consisting of analysis of both close- and open-ended survey responses. Our preliminary analysis (n = 27) indicates that the majority of participants surveyed worry about paying their monthly expenses. Over 75% of participants agree that if they did not receive grants, loans or scholarship money, they would not be able to attend college. Over 85% of students surveyed indicated that the class and lab schedule required of STEM majors makes it difficult to earn money from a job. Qualitative analysis of open-ended survey responses indicated that being a STEM student is heavily time consuming, affecting students’ work hours. Specifically, long hours in scheduled labs, research activities, timing of course offerings, and heavy exam weeks contribute to students’ inability to work as many hours as they would like. During future phases of this project, we will interview students to explore in greater depth the identified financial concerns and stress that undergraduate STEM majors face. The results of this study can help improve the accessibility of undergraduate STEM majors and help faculty and university administrators understand the stress and barriers that these students face.

Abstract Name: Quantification of Ribosomes and Zinc in Mycobacterium smegmatis Grown Under Zinc Limitation

Zinc (Zn2+) is an essential micronutrient to living cells, required by various proteins involved in physiological processes. However, bacteria often encounter zinc-limited environments. Of particular interest is the zinc-limited environment inside necrotic granulomas experienced by Mycobacterium tuberculosis (Mtb) in tuberculosis patients. Mycobacteria respond to zinc limitation by expressing zinc-independent, alternative ribosomal proteins (AltRPs) for the replacement of zinc-dependent, primary ribosomal proteins (PrimRPs). Four AltRPs are contained within the altRP operon, which is conserved in mycobacterial species, including Mtb. AltRPs studied in a model mycobacterium Mycobacterium smegmatis (Msm) have been demonstrated to cause morphological changes and allow for continued growth and survival when Zn2+ is limited. This suggests that AltRPs can functionally replace PrimRPs as an adaptation to limited zinc. However, the expression and behavior of alternative ribosomes are not yet completely understood. This project aims to increase understanding of alternative ribosome biogenesis and its role in zinc homeostasis by analyzing how alternative ribosomes bind zinc compared to primary ribosomes. This will be done by comparing the number of ribosomes synthesized by a wild type and deletion mutant (ΔaltRP) of the altRP operon in Msm, which should synthesize alternative ribosomes and primary ribosomes, respectively, when grown in zinc-limited conditions. Additionally, Zn2+ abundance in ribosomes and ribosome-free cell lysates will be quantified and compared between strains. Because of the high zinc requirement of primary ribosomes

synthesized by the altRP deletion mutant, it is expected to have fewer ribosomes and bind more zinc per ribosome compared to the wild type whose alternative ribosomes have a lower requirement for zinc. This project will help to determine how AltRPs contribute to ribosome biogenesis and zinc homeostasis in mycobacteria. Since Msm is a model organism for Mtb, new knowledge from this project can also be applied to identify better drug targets to treat tuberculosis.

Abstract Name: Glutamine Metabolism Is Altered in Myeloproliferative Neoplasms and Represents a Potential Novel Therapeutic Target

Cancer cells exhibit metabolic reprogramming to facilitate growth and proliferation. Previous studies in various cancers show cancer cells rely significantly on elevated glutamine metabolism for macromolecule biosynthesis and redox homeostasis. However, very few studies have investigated the role of glutamine metabolism in myeloproliferative neoplasms (MPNs). Glutamine catabolism begins via glutaminase (GLS1) catalyzing the rate-limiting conversion of glutamine into glutamate. Many studies in different cancers have found GLS1 to be a dependency and can be therapeutically targeted, but these studies have been extremely limited in MPNs. The potential mechanisms with respect to MPN driver mutations (CALR, JAK2, MPL) and their differential utilization of glutamine have yet to be fully explored. One previous study demonstrated that in JAK2V617F mutant-Ba/F3 cells, GLS1 expression was significantly increased and that GLS1 inhibition suppressed colony formation in patient samples but not healthy donors. To more comprehensively decipher the role of glutamine metabolism in MPNs, we performed RNA-sequencing on MPN patient peripheral blood mononuclear cells (PMBCs) and found that genes involved in glutamine metabolism are significantly altered. In contrast to the previous study mentioned above, our RNA-seq, qPCR, western blots, and enzyme activity data demonstrate that GLS1 mRNA, protein, and enzyme activity levels are not significantly up-regulated, and MPN PBMCs are not sensitive to GLS1 inhibition using CB-839, a selective GLS1 inhibitor. Rather, we characterized another key enzyme in glutamine metabolism, glutamine synthetase (GS), as a molecular and metabolic dependency in MPNs. GS converts glutamate into glutamine and serves to satisfy the metabolic demand for increased glutamine. We found that GS mRNA is significantly up-regulated, and inhibition of GS decreases MPN cell proliferation. In summary, we have demonstrated that GLS1 may not be an effective therapeutic target for MPNs and instead characterize GS as a novel dependency and potential point of therapeutic intervention.

Abstract Name: Pilot Study of A Pain Assessment Information Visualization Intervention to Improve Limited English Proficiency Hmong Patients and Healthcare Providers Communication in Primary Care

Pain assessment and treatment heavily rely on patients' descriptions of the location, severity, and quality of their pain. However, limited English proficiency (LEP) Hmong patients often struggle to provide accurate pain descriptors due to their different communication style (e.g., use of metaphors), resulting in providers' inability to understand and treat their pain. Therefore, this study's purpose was to assess the impact of a pain assessment information visualization (InfoViz) communication intervention to improve patient-provider communication about pain location, quality, and severity in primary care settings. Using a static design, we collected data from 20 triads of patients, interpreters, and providers in the usual care group (i.e., no communication tool) followed by 20 triads in the intervention group (i.e., using the Pain InfoViz Tool). Patient-interpreter-provider communication was audio recorded during clinical visits. We analyzed 36 visits using a pre-determined coding scheme on pain location, severity, and quality as well as on clinician conversation (e.g., probing for clarification, elaboration, reflection, and paraphrasing for pain information). We found that the intervention group experienced a decrease of 13.89 minutes in visit duration compared to the usual care group (Mean=18.25 minutes, SD=10.44 vs Mean=32.14, SD=27.81, respectively). There was also a reduction in provider's probing, such as clarification, elaboration, reflection, and paraphrasing in the intervention group. These results suggest that the Pain InfoViz intervention may have positively impacted the LEP Hmong patients' ability to describe their pain more clearly, resulting in fewer assessment probes by providers.

Abstract Name: Usability in Design: Trends in Assistive Technologies for Cognitive Impairments (1980-2022)

Assistive technology for cognition (ATC) has been proven to successfully support individuals with cognitive impairments, but how much of the research discusses the usability of these technologies for patients and caregivers? With the growing population of elderly people and the natural cognitive impairments that typically accompany aging, there is an increasingly dire need for more efficient assistive technology for cognitive deficits. The purpose of this study is to identify trends in ATC research from 1980 to 2022 to inform future research to design the safest and most effective systems for people with cognitive impairments. Along with the timeframe of 1980-2022, the parameters specify five major publications of the Human Factors and Ergonomics Society, including Human Factors: The Journal of the Human Factors and Ergonomics Society, Ergonomics in Design: The Quarterly of Human Factors Applications, Journal of Cognitive Engineering and Decision Making, Proceedings of the HFES Annual Meeting, and Proceedings of the HFES Health-Care Symposium. An original exhaustive search term list was used to analyze the publications by

creating keyword combinations. Results indicate a scarcity of research on the usability of assistive technology related to cognition and patients or caregivers, and it reveals an overall gap in research for the target population. Furthermore, recurring design recommendations suggest products be more “user-friendly” and minimize memory load. The lack of research on ATC and usability targeted towards patients and caregivers results in those in need of these technologies having a harder time finding and using them. The identification of trends and gaps within this research will encourage further studies on improving these technologies for cognitively impaired individuals.

Abstract Name: Depression in Relation to Vitamin B Intake After Traumatic Brain Injury

In the modern day with medical advances, Traumatic Brain Injury (TBI) continues to present a formidable challenge. Not only does it entail cognitive impairments and emotional repercussions, but depression is also emerging as a noteworthy consequence, particularly in severe cases. However, the conventional reliance on antidepressants only exacerbates the symptoms with a substantial number of patients contending with the adverse side effects. Recent research has illuminated a promising alternative in the form of Vitamin B complex, specifically B3, B6, and B7, which play pivotal roles in aiding neurotransmitter synthesis and axonal transport, fostering enhanced brain function and activity. With its demonstrated efficacy in reducing anxiety and depression significantly, Vitamin B complex emerges as a potential preventive measure for individuals in TBI recovery. Its ability to mitigate symptoms without the typical side effects shows promising results for promoting the overall well-being of TBI patients, which could address both physical trauma and mental health challenges. As a result, the prescription of Vitamin B complex as a preventive medicine should be advocated for the alleviation of TBI-induced depression. However, a formidable obstacle arises as many patients lack awareness of Vitamin B complex’s significance and share concerns about potential side effects. This study further underscores the potential of introducing nutritional interventions to enhance the mental well-being of TBI patients, better patient education, personalized vitamin B guidance, adherence monitoring, and interprofessional collaboration. Overall, this proposal aims to optimize TBI-induced depression management with improved patient outcomes. Through collaboration among healthcare providers, it is anticipated that the standard of care for TBI-induced depression patients will be greatly enhanced.

Abstract Name: Magnetic resonance imaging of macrophage response to radiation therapy

Cellular response to cancer treatment is difficult to track in real time. Standard practice of macrophage

quantification currently involves immunostaining of a biopsied tumor. However, this technique is fraught with numerous limitations, including the invasive nature of the test, heterogeneous tumor associated macrophage distribution, and lack of a clear cut-off point for positive staining. Non-invasive imaging methods such as MRI could obviate the need for biopsies and serve as a biomarker of radiation therapy efficacy. Radiation therapy is widely utilized to clinically treat common cancers. By injecting a fluorine based nano-emulsion, macrophages that passively ingest the emulsion can be tracked via MRI. The results demonstrate the potential of 19F MRI to non-invasively track macrophages during radiation therapy and its prognostic value with regards to tumor growth. This study is the first to correlate macrophage signal change to tumor volume and a first step towards accurate non-invasive assessment of RT efficacy. A significant change in 19F signal was found between radiotherapy treated and untreated groups for both the breast and colon cancer mouse models two weeks after irradiation. Treated groups in both cohorts also displayed significant tumor regression. Fluorine signal change correlated to tumor volumes, indicating that MR imaging of macrophage recruitment in tumors may be a valid biomarker of RT efficacy. Additionally, tumors possess apparent mechanistic differences depending on their origin and have therefore varied responses to RT. This technique will be extremely beneficial in future analysis of inflammation's role in tumor recurrence. The findings support the potential, pre-clinical therapeutic benefit of incorporating MRI of macrophage dynamics in RT workflow. Non-invasive imaging tools are becoming increasingly necessary to provide safe and accurate tumor prognosis. Finding ways to increase probe specificity to distinguish macrophage phenotypes will be the next challenge but ultimately can dramatically better patient outcomes.

Abstract Name: Assessing the Role of WRKY57 in Bolting Associated Leaf Senescence in Arabidopsis thaliana

Leaf senescence is the successive process in which older leaves mature and then die, indicated by leaf yellowing. This is a critical developmental stage in all plants, including the model species Arabidopsis thaliana, and is imperative to the plant's fitness, as nutrients are recycled back into the growing and storage tissues of the plant. The WRKY gene family encodes transcription factors that play critical roles in response to abiotic stressors. WRKY57 gene expression is induced by drought and overexpression of WRKY57 results in drought tolerance. Our lab is interested in WRKY57 as it may also be important for the regulation of leaf senescence in response to flowering, termed bolting in Arabidopsis thaliana. Our project is to monitor WRKY57 gene expression after bolting and to isolate wrky57 T-DNA mutants and determine if they display early senescence. Two T-DNA insertions, SALK_006206 and SALK_076716, localize to the WRKY57 gene. To identify individuals that were homozygous for mutant alleles, we used PCR primers that spanned the insertion site. Two homozygous individuals were isolated for each T-DNA insertion. These PCR products were then sent for sequencing, after which we designed real-time qPCR primers to quantify WRKY57 transcripts. The WRKY57-1 primer pair amplified cDNA linearly and was used to quantify transcripts in response to bolting. We found that WRKY57 gene expression was up-regulated after bolting. We purified, sequenced, and mapped the SALK_006206 allele, which is an intron. We then repeated the process with SALK_076716, which mapped to the promoter region. Next, we will determine if T-DNA insertion lines block WRKY57 gene expression, or in the case of the promoter insertion, activate WRKY57 gene expression, and will quantify bolting-associated leaf senescence through loss of chlorophyll and activation of NIT2 gene expression.

Abstract Name: "Just Teasing" or "unJust" Insulting?

The aim of this research project is to shed light on how bantering messages may be received and why. Limited work has been conducted on the communicative act of banter. Various definitions for banter exist, making such incidents open to interpretation. To determine how outsiders perceive banter, 200 participants of the general adult workforce(ages 18-25) anonymously completed a Qualtrics survey through MTurk. All participants were randomly assigned a 20-30 second bantering scenario video. Participants then evaluated the interaction quality observed. MANCOVA, conducted on the effects assessment of interaction, measured multiple factors to determine variables affecting results. The new measure of bullying experiences responses compared personal accounts to banter perceptions to identify relations. Major findings show participant viewpoint is significantly influenced by the sex of the teaser and observer, nonverbal cues, and personal experience. This implies that our experiences shape how we later influence and perceive those around us.

Abstract Name: Developing an Empathetic Socially Assistive Robot for Mental Health Support: Performing Personality Matching with Deep Learning

The research goal is to design a socially assistive robot (SAR) that will help in the day-to-day activities of a person coping with mental health challenges. The social robot will react to the behavior changes in mental health deterioration and deliver interventions, such as: 1) performing grounding techniques to mitigate such behavior changes and, in the case of needing a more severe intervention, 2) contacting family members and medical staff, all while maintaining empathy toward the user. In this research, our primary hypothesis is that the empathetic feature of the SAR can be achieved by matching the user’s personality. To achieve this personality matching, the user's personality will be measured using the Big Five Personality Test, focusing on the extroversion/introversion dimension. The Deep Learning Architecture chosen to develop this model is Long Short Term Memory (LSTM). Our preliminary result for this model indicates an accuracy score of 0.47. The personality database used in this research was obtained by Soheil Novinfard during his 2018 master’s dissertation at the Queen Mary University of London. Socially Assistive Robotics (SARs) in Mental Health is a field that has the potential to help people with mental health disorders feel more independent in their day-to-day lives. Our secondary hypothesis is that making an empathetic SAR could help the patient develop a bond with the robot and, in this way, make the SAR have a more positive impact on the patient. To conclude, we plan to develop a SAR that will mirror the patient's personality to test if the robot-user interaction reaches a high empathetic level.

Abstract Name: Economic Outlook and Political Polarization in Trade Impacted American Labor

Since the start of China's WTO membership in 2001, there has been a decline in over one million U.S. manufacturing jobs. This process has been linked to an increase in U.S. political polarization. This paper explores the relationship between local labor market trade exposure and Senate candidate ideological realignment. To this end, I exploit exogenous variation from economic outcome perceptions. The analysis combines import penetration data, the Database on Ideology, Money in Politics, and Elections' (DIME) candidate ideology scores, and household debt to income ratios since the early 2000s. The empirical strategy implements an IV method, in which Chinese import penetration in the U.S. is instrumented with Chinese import penetration in other advanced economies. I find a significant impact on Senate polarization from increases in import penetration and household debt to income. The estimated effect in polarization per unit increase in import penetration is comparable to 4/5ths of the baseline ideological difference between candidates without the 2001 trade shock. This increase in polarization is comparable to 75% of the ideological difference between Joe Biden in 2002 and Rand Paul in 2016. The increase in polarization from a unit increase in debt to income is slightly smaller, comparable to half of the ideological difference between Joe Biden in 2002 and Rand Paul in 2016. Further work will investigate alternate measures of polarization and introduce controls. These results support pre-existing literature and offer insight into the importance of economic optimism in widening political cleavages from trade.

Abstract Name: Life's Essential 8 Score in Pregnant Females: Insights from National Health and Nutrition Examination Survey

Introduction: Cardiovascular diseases(CVD) is the primary cause of increased mortality in pregnant women in the US. Maternal cardiovascular health(CVH) influences both maternal CVD risk and offspring's CVH. However, the CVH of pregnant females has not been characterized and compared with non-pregnant females using the newly introduced Life's Essential 8(LE8) score.Methods: This study included females aged 20-44 years without a history of cardiovascular disease from the National Health and Nutrition Examination Survey(NHANES) cycles from 2011-2020. The cohort was stratified into pregnant and non-pregnant females. Adjusted weighted linear regression models were used for analyses. Results: This study included 3,580 females representing 36.1 million females of US population. There were 171 pregnant and 3,409 non-

pregnant females. The weighted mean LE8 score was lower in pregnant females [69.3 (1.2)] than in non-pregnant females[72.3 (0.4)]. Compared with non-pregnant females, the lower LE8 score in pregnant females could be attributed to lower mean physical activity[42.7 (3.9) vs. 56.2 (1.3)], blood lipids[61.8 (3.4) vs. 79.4 (0.6)], and body mass index[54.4 (3.2) vs. 60.5 (1.0)] scores. The LE8 score remained stable in pregnant(Ptrend:0.27) and non-pregnant(Ptrend:0.67) females between 2011-2020. Compared with non-pregnant females, pregnant females had lower odds of having an ideal LE8 score[ORadj: 0.50 (0.32–0.77)], ideal physical activity score[ORadj: 0.46 (0.31-0.69)], ideal blood lipids score[ORadj: 0.39 (0.26-0.59)], and ideal body mass index score[ORadj: 0.42 (0.25-0.70)]. The odds of having ideal blood pressure scores were two-fold higher in pregnant females compared with non-pregnant females[ORadj: 2.07 (1.02-4.21)].Conclusion: Compared with non-pregnant females, pregnant females have a lower CVH without improvement in the past decade. Pregnancy was associated with 50% lower odds of ideal CVH in females. This study highlights the need to improve CVH screening and promote rigorous risk factor control during pregnancy.

Abstract Name: The Awakening Hongkongers: A History of Identity Cultivation via Education in Hong Kong, 1984-2024

My honors thesis explores the cultural and political influence of the Hong Kong education system on the development of local identity (Hongkonger) since the signing of the 1984 Sino-British Joint Declaration.Benedict Anderson has explained why and how "nation" is constructed, arguing that language is the stem of an imagined community. Focusing on the Chinese region, Peter Zarrow and Robert Culp have demonstrated education as an effective medium to cultivate Chinese national identity during the Republican Era. However, since the emergence of the Hongkonger identity is a phenomenon that arose in the 2010s, research on the relevant topic is scarce.Liz Jackson is currently the only scholar who has explored the interrelation between Hong Kong's civic education and identity cultivation. However, her reliance on secondary scholarship limits her contributions to understanding the evolution of Hong Kong's education and identity. The essence of primary sources lies in their ability to challenge old historical testimonies and create new insights. Thus, while the endpoint of my study is understanding the construction of contemporary Hongkonger identity, my analysis is grounded in primary sources. The study is organized into three major periods: 1984-1997, 1998-2011, and 2012-present, each divided into four subsections: top-down policy, educational materials, the "hidden curriculum," and the bottom-up experience from oral interviews. This approach aims to create a solid and holistic historical foundation for the underexplored interrelation between civic education and identity formation in Hong Kong.My working hypothesis is that a nascent Hongkonger identity originated from the "depoliticized" civic education policy implemented by the British administration. The British colonial policy helped forge an identity that differed from nationalist narratives, which constantly emphasized pride in Chinese culture and the nation-state. Hongkonger identity did not become actualized, however, until students interacted with the nation-centric curriculum implemented under PRC sovereignty.

Abstract Name: Flow Characterization of Low-Pressure Cold Spray Systems

Cold spray is an additive manufacturing process that utilizes a compressed gas through a supersonic nozzle to accelerate powder materials which impact and bond to a substrate. The common technique for studying cold spray systems is to change machine settings and measure the particle velocities near the exit for those settings. However, this results in a lack of understanding of what happens through the system. By analyzing the characteristics of air and particle flow in a low-pressure cold spray (LPCS) system, operating conditions, and nozzle design can be optimized. Our goal is to validate Computational Fluid Dynamic (CFD) models that can be used to further understand cold spray nozzles and systems. We will be measuring total pressure and total temperature throughout the gas plume. A test bench has been developed to align the cold spray nozzle with the instrumentation. Measurements will be taken at supplied pressures from .5 to .9 MPa at temperatures from 22 to 600 degrees Celsius. The total temperature probe is under development, but preliminary results have been recorded using a total pressure probe. Results indicate the presence of Mach disks along the plume. An optical schlieren system is being used to locate these Mach disks and additional shocks. Large Eddy Simulation (LES) 3D CFD models of the system are being created using ANSYS Fluent and an unsteady compressible Direct Numerical Simulation (DNS) solver is under development, both of which will be validated using the data obtained. The findings can potentially improve nozzle geometry design and assist in producing repeatable exit velocities for cold spray technology.

Abstract Name: TiO2-coated Plasmonic Gold Nanoparticles as Photonic Nanoreactors

This research explores the synthesis of TiO2-coated plasmonic gold nanoparticles as a novel platform for photonic nanoreactors focused on advancing catalytic applications. The hybrid nanostructure, comprising AuNPs as plasmonic cores and TiO2 as a coating material, harnesses the unique optical and catalytic properties of both constituents. The plasmonic resonance of gold nanoparticles and the UV light absorption of TiO2 enables charge separation and electron transfer, which produces active electrons and/or charges, by both UV light spectrum and visible light spectrum. The enhanced harvesting and localization should enhance the overall photonic efficiency. This work demonstrates a comprehensive analysis of catalytic activity and optical properties using photometric spectroscopy and optical electron microscopy. We investigate the interactions between plasmonic and photocatalytic components to elucidate the mechanisms that control improved reactivity within photothermal and photocatalytic processes. Furthermore, we explore potential applications

of photothermal and photocatalytic processes of these hybrid nanostructures, highlighting their promising roles in environmental improvement and energy application. This work will lead to progress in the design and optimization of plasmonic AuNP-TiO2 nanocomposites, which have wide-ranging implications in various scientific and technical areas such as the development of environmentally friendly energy technologies, safe new healthcare methods, and the development of high efficiency and multipurpose photonic nanocomposites.

Abstract Name: The Double Reeds of the World

Most people who have experience with the global phenomenon of western classical music are aware of the double reed instruments mainly used within that style. The most common in this genre are the oboe and the bassoon. Some may also be familiar with other members of these two instrumental families such as the English horn, oboe d'amore, and contrabassoon. However, few people are familiar with double reed instruments from other traditions. As an oboe player, I am particularly interested in how different double reed instruments, and particularly the timbre of the double reed, are used within the context of the culture from which they developed. In addition, the path in which similar instruments were exported or copied throughout history will be explored. Cultural aspects include traditional rituals, their role in folk music, the other instruments they are combined with, as well as historical and contemporary performance practices. I will find various papers and experts on a variety of different double reed instruments in order to gain a better understanding of the history of these instruments and to compare and contrast them. A partial list of instruments my project will cover include crumhorn, duduk, piffero, sourna, guan, hichiriki, piri, and shehnai. I will create a website that can serve as a database of different double reed instruments in the world with a general overview and history. In addition, I will have a poster and/or a paper in order to make this information presentable in various forms. Dissemination will include our campus undergraduate research celebration and student-led journal.

Abstract Name: Role of Bmal1 in Restenosis & cPLA2 Expression in Smooth Muscle Cells

Coronary Artery Disease (CAD) is a leading cause of death globally. Drug-eluting stents (DES), coated with medication that slowly releases into the arterial wall over time, are used to manage CAD and prevent

restenosis, the re-narrowing of the treated vessel. A potential target of drug development for DES is the transcription factor Bmal1. Smooth muscle cell (SMC) specific Bmal1 deletion protects against neointimal hyperplasia in femoral artery vascular injury mouse models for restenosis. Enrichment pathway analysis of RNA-seq in SMC-Bmal1 knockout and wild-type mouse aortas indicated a relationship between Bmal1 and the arachidonic acid metabolism pathway. Further RNA-seq of specific enzymes in this pathway revealed that the phospholipase cPLA2α, involved in inflammation, is selectively downregulated in aortas of SMC-Bmal1 knockout mice relative to wild-types. Western blot analysis was performed to verify that siRNA downregulation of Bmal1 reduces cPLA2 protein expression in cultured Rat aorta SMCs. The result of the administration of increasing concentrations of Bmal1 siRNA was an apparent dose-dependent downregulation of Bmal1 and cPLA2. This study aims to identify the mechanism by which Bmal1 regulates cPLA2. Since Bmal1 is a transcription factor and preliminary data has shown that cPLA2 mRNA is downregulated by SMC-Bmal1 knockout, we hypothesize that Bmal1 influences cPLA2 in SMCs via binding to the promoter to control transcription. We plan to clone the cPLA2 promoter, insert it into a vector containing the luciferase reporter gene, and transfect this construct into wild-type and Bmal1 KO mouse SMCs prior to running a promoter luciferase assay. This will us to directly compare cPLA2 transcription in the presence and absence of Bmal1 to identify whether Bmal1 regulates cPLA2 transcriptionally. In the future, we plan to identify potential binding sites (E-boxes) for Bmal1 within the cPLA2 promoter. We hope this project may reveal a new pharmacological avenue to treat restenosis.

Abstract Name: The 2023 University of West Florida Campus Ecosystem Study: Effects of forest vegetation on light availability and soil processes

College and university campuses with a notable arboreal component provide unique opportunities for carrying out ecological research. The University of West Florida Campus Ecosystem Study (UWF CES) was established in 2019 as interconnected research to take advantage of the extensive arborescent nature of the UWF campus, particularly concerning longleaf pine (Pinus palustris). This year's study established permanent plots in forested sites of two contrasting types, one dominated by longleaf pine (‘pine site’) and the other dominated by hardwoods (‘hardwood site’). This study used these plots to examine the influence of forest vegetation on light availability and soil processes. Light was measured as photosynthetically active radiation (and expressed as photon flux density—PFD) with a handheld meter in each plot. Soil was sampled to 5 cm in each plot with texture was measured with the hydrometer method. Identical sampling was carried out in a persistent canopy opening to assess light and soil conditions under maximum solar radiation. Mean PFD was ~4x higher in pine stands than in hardwood stands; PFD was 12.8 and 3.5% of full light in the pine and hardwood stands, respectively. All soils were dominated by coarse-textured sands, but silt was significantly higher in pine stand soil and higher still in the canopy opening. Among forest stand plots, sand was negatively related to PFD, whereas clay was positively related to PFD. Across the three sites, silt was positively related to PFD. These relationships are consistent with the importance of solar radiation as one of many drivers of soil weathering.

Abstract Name: Enhanced Data Integrity in Digital Health: Advanced Error Detection and Robust Batch Processing for Optimizing Wearable Sensor Outputs in Lower Extremity Fracture Rehabilitation

Lower extremity fractures (LEFs) are common injuries with complex healing periods. The incorporation of wearable sensors for patient monitoring has enabled healthcare practitioners and researchers to obtain high-level insights into fracture characteristics and the healing process. My research group developed a wearable sensor to continuously monitor patient behavior during LEF rehabilitation. The substantial volume of data generated over up to 92 days of sensor recordings, at approximately 4.15 million data points per day, can pose challenges in error detection, as errors may be concealed within this extensive dataset.This project addresses the challenge of detecting errors in large physiological datasets by implementing a robust batch-processing method that systematically analyzes an entire physiological dataset. First, a batch method to convert the sensor signal from binary data to a readable data structure was validated against the conventional one-by-one data analysis method with a Pearson correlation coefficient. The average Pearson correlation coefficient for all 7 datasets was 0.99797. Next, we incorporated checks in the batch processing to detect erroneous rates of change in the slope of the sensor signal. Our error detection algorithms uncovered 9 times more errors than previously identified through the legacy approach. This discovery has significant implications for preventing erroneous data analysis and informing future sensor design modifications.This advanced error detection and data processing pipeline contributes to the field of large physiological data management. Utilizing this pipeline, our group is better equipped to use objective data gathered from wearable sensors to optimize patient care and treatment outcomes. This project underscores the importance of continual refinement in data processing methods to navigate the challenges posed by big data, ensuring the consistent reliability and validity of research findings in the era of advanced digital health technology.

Abstract Name: How Demographics Influence Self-Image

When creating psychological research surveys, demographics are typically recorded at the end of the primary survey. Psychologists suggest placing demographic questions at the end to omit any biases from the participants (Hughes et al., 2016). Does the placement of these types of questions influence people without them knowing? How does this apply across different ethnic groups? Can demographic question placement prime individuals in their self-rating of attractiveness and the overall impact of demographic placement on survey results? After an initial round, we wanted to see if ethnic groups would be primed differently when viewing people of the same race. We also investigated whether parents' views on beauty standards impacted them more than the American beauty standards participants grew up with. To test this question, this project

will conduct five surveys, each gearing towards a specific racial group: White, Black, East/Southeast Asian, South Asian, and Hispanic. Each survey will have two versions of the study to compare self-ratings of overall attractiveness. In version one, individuals will first answer demographic questions, rate the celebrities' attractiveness of their stated racial group, and then rate their own attractiveness. In version two, participants will first rate the celebrities' attractiveness, rate their attractiveness, and then answer demographic questions. Participants primed with their demographics at the beginning rated their attractiveness lower than participants who answered them at the end. In the second round of data, we will test if ethnic groups are more impacted by seeing celebrities of their same racial group. Overall, this research will further our understanding of demographic question placement and which marginalized groups are impacted the most. This is important since many testing formats currently place demographic questions at the beginning. Thus, this research will influence not only how psychologists conduct research, but also how proctors execute standardized testing in classroom settings.

Abstract Name: A Critical Assessment of the Digital Markets Act. Can the EU Win the Competition Law Battle Against Big Tech?

Digital technology is a crucial part of our lives. While it transformed the way we live, large digital platforms could stifle competition by acting as gatekeepers. Because of their distinctive features in the digital markets, global regulators have questioned the effectiveness of competition law in addressing anticompetitive behaviour perpetrated by certain digital platforms. On 14 September 2022, the Digital Markets Act (DMA) was signed into law. It is a piece of legislation that has the potential to revolutionise the regulation of digital platforms and the enforcement of EU competition law. However, questions remain about its legal framework including designation, ex-ante rules, and enforcement.In this paper, I will answer the questions surrounding the DMA using existing competition law as a stepping stone. In part one, I will explain the characteristics of the digital economy and the issues created by dominant digital platforms. In part two, I will review the process of designation and the nature of the obligations of "gatekeepers". I will use entities that have been designated as "gatekeepers" as examples to analyse the obligations they are assigned. The prescriptive ex-ante rules for "gatekeepers" represent a drastic departure from traditional competition law philosophy. It is unknown whether it will lead to a loss in innovation. In part three. I will focus on the legal framework of enforcement. In particular, I will examine the necessity of structural remedies as the antidote for systematic non-compliance. Breakups have rarely been featured as a remedy in abuse of dominance cases under Article 102 TFEU. With the growing political and academic consensus that "gatekeepers" represent a distortion in digital markets, the possibility of divestiture could arise for repeat offenders. I will use entities that have been or have the potential to be designated as "gatekeepers" as examples to demonstrate the obligations they are assigned.

Abstract Name: An Examination of Negative Markers in Minnan

This study aims to analyze the use of negative markers in Minnan. Chappell (2016) describes Minnan as having nine primary negative markers: six used in negative sentences (two of which can also be used in question sentences) and three used in imperative sentences. Two additional compound negatives were reported. However, Chappell's paper does not provide an in-depth analysis of the usages of these markers, as it combines data from multiple dialects and sources. To explore the current usage of negative markers in Minnan spoken in Central Taiwan, we conducted eleven elicitation sessions with a native speaker. The study found evidence for only a subset of these negative markers (m, bo, mai, boai, be, (m)bian, m tang), suggesting a shift in distribution, meaning, and assimilation among the markers. Notably, the perfective negative marker bo has replaced m as the general negative marker in negative and question sentences in this dialect. Furthermore, in question sentences, bo is not always paired with its corresponding auxiliary affirmative modal, u, and can be paired with other modals such as e. Additionally, the imminent negative be has undergone a phonetic shift and is now realized as bue. Regarding imperative sentences, we confirmed three negative markers and observed a possible assimilation between m eng and (m)bian. These findings indicate a simplification of negative markers in Minnan, particularly among markers that belong to similar semantic categories. Therefore, further research is necessary to accurately represent the grammatical functions of Minnan negative markers in multiple structures.

Abstract Name: Analyzing Unknown DNA Alleles in a Murder Exoneration Case: The Role of Paternity Testing in Forensic Analysis

There are many creative applications of the paternity test apart from determining parentage. One such implementation is in forensic genetics. In this case study, a man convicted of murder has been found to be "exempt" based on DNA analysis conducted on biological materials (DNA) found under the fingernail clippings of the dead body almost two decades later. This DNA profile did not match that of the convicted instead shows that of a possible unknown other. However, the convicted remains incarcerated due to the possibility that the unknown DNA profile could be that of the victim and not of a perpetrator. If the DNA from the deceased would not match the unknown profile, the exemption can be confirmed further. However, no more biological materials are available from the deceased. A biological son of the deceased volunteered his blood for DNA testing. The results of this study were considered inconclusive since the unknown DNA profile has dropouts at several alleles, although the son’s profile was intact. We therefore conducted a per allele study at each marker, comparing allele by allele. The results show that at least one allele does not match, making it possible for the unknown profile to be placed on the CODIS database to see if it matches with a possible perpetrator. While one allele may not exonerate the convicted, a CODIS match probably will provide evidence necessary for exoneration. We have further researched several possibilities that could support this finding and have provided the results here.

Abstract Name: Foster Parent Experiences of Stress During the COVID-10 Pandemic

Foster parents face many unique parenting challenges due to their role. Many foster parents feel isolated and may lack close friends who understand their experiences. They face constant change and uncertainty as they navigate the caring of vulnerable children, often with complex needs and in complex situations. The COVID-19 pandemic only exacerbated these feelings of isolation and uncertainty, as well as adding increased stress to the lives of foster parents. The present study explored the experience of stress among foster parents during COVID-19. Semi-structured interviews were conducted with 16 licensed foster parents in one Midwestern state during the summer of 2021. Fifteen participants were female and one participant was male. Fostering experience ranged broadly from less than one year as a foster parent to over 10 years as a foster parent, with some parents only fostering one child and others having fostered six children or more. The interviews were transcribed and coded and the authors conducted thematic analysis to develop themes surrounding the experience of stress for foster parents during the pandemic, specifically what was experienced and how it was experienced. Findings indicated that foster parents were "asked to do more" and faced an increase in role-related tasks. Some of these tasks included helping with school and therapy, supervising visits and parenting time, providing childcare, creating routines, and facilitating any other virtual communication for their children. Foster parents reported that these additional responsibilities caused them to experience increased stress. These findings suggest implications for both research and policy, specifically research on developing evidence-based practices for the virtual delivery of services, as well as developing clear policies around virtual parenting time.

Abstract Name: Efficacy of Electrospun Chitosan Membranes with C2DA in Preventing Infectivity in an in-vivo Composite Tissue Infection Model

Background: Electrospun chitosan membranes (ECSM) with C2DA (ECX) have previously been shown to exhibit a prolonged release of non-antibiotic biofilm inhibitors (up to 72 hours) and modifying inflammatory responses through the release of local anesthetics such as bupivicaine. Chitosan was chosen due to its natural antibacterial properties and has been proven to foster cell growth and optimize drug delivery. In response to the need for advanced wound dressings for extremity trauma, we use ECX to develop a wound dressing for prolonged infection prevention and inhibiting bacterial colonization. Methods: A mid-diaphyseal bicortical femoral defect was induced in 13-week-old female Sprague Dawley rats by inserting an orthopedic screw containing ~5x10^4 CFU of GFP-expressing S. aureus to simulate a biofilm-associated composite tissue infection. Treatment materials applied around the femoral defect included the untreated control group, Celox gauze (standard-of-care), ECSM treated with decanoic chloride , ECX, and ECX loaded with bupivacaine. (n=12) Two animals from each group were longitudinally monitored at days 1, 2, and 3 post-infection before

animals were euthanized using CO2 inhalation. Bacterial loads in the collected tissues were quantified through colony-forming unit (CFU) counts (n=10), and the data was subjected to statistical analysis. Results and Conclusion: Despite initial hypotheses, our results revealed that bacterial burden was not decreasedin the treatment groups. The untreated group exhibited the least bacterial formation on both bone and surrounding soft tissue compared to other groups, which may be due to the presence of material promoting biofilm and packing within the defect limiting flow. To optimize drug release in future evaluations, we plan to wet the membranes using PBS, thereby initiating release within the wound. Furthermore, we will explore variations in therapeutic loading and application methods.

Abstract Name: Testing SHY: The Synaptic Homeostasis Hypothesis of Sleep

The Synaptic Homeostasis Hypothesis (SHY), introduced by Drs. Cirelli and Tononi, proposes that the price we pay for synaptic plasticity is sleep. During wake, neurons are excited and interact with other neurons through trillions of synapses, causing these interactions to strengthen. During sleep, neuronal firing decreases and we propose that unimportant synapses become weakened compared to those that are significant. The weakening of many synapses during sleep also has other key advantages, including saving energy and avoiding synaptic saturation, thus allowing new learning the next day. Previous studies on SHY have demonstrated that synapses become stronger during wake and weaker after sleep in areas such as the cerebellum, cerebral cortex, and hippocampus. The goal of this investigation is to test SHY in the striatum, hypothesizing similar results. Therefore, 12 mice are used, and divided into three groups for comparison (4 mice/group): mice allowed to sleep (3 pm), mice spontaneously awake (3 am), and mice that are sleep deprived, all for ~6-8 hours. Three groups allow us to attribute any differences to behavioral state, rather than stress (sleep deprivation) or time of day (3 am and 3 pm). For each mouse, approximately 500 synapses are measured to view the changes that occurred in synapse plasticity between sleep and wake. In my project, I am using FIJI, an image-J extension that allows one to reconstruct dendrites and measure synapses from 2D images using serial-block face scanning electron microscopy. Furthermore, my project is also focused on analyzing the interactions between astrocytes and synapses. Previous studies in the mouse cerebral cortex have shown that during wake, astrocytes are closer in proximity to synapses, and glycogen turnover is increased within astrocytes during wake to provide energy to neurons in the form of lactate. Therefore, we hypothesize similar results in the mouse striatum.

Phoebe Zagrobelny

Abstract Name: The Human Impression

Humans have permanently altered the natural world. I learned this from a young age growing as a person who loved the rural landscape of Waddington, New York. The town that I grew up in was not known for being a wealthy area; however, it was rich in nature and agriculture. I spent my time gardening and exploring the river. While I appreciated the relationship I formed with nature, it taught me a sad lesson. There was always garbage around. This realization altered my path. I became focused on how I could help the environment. This passion would later influence my college decision and my pursued major. This idea that nature and humans are interconnected is also the inspiration behind many of Ana Mendieta's works from the 1970's. Mendieta's Silueta Series uses the Earth to carve and sculpt human figures. With these pieces, Mendieta argues that humans and nature are one. With my work I would argue that humans have permanently changed nature. My photography will explore how humans have damaged even the purest environments. An example of these pure environments is the Adirondack Mountain Range in upstate New York. Some of the trash has become a part of its environment. Nature has begun to overtake the garbage and grow around it and with it. However, our Earth is resilient, it perseveres to the challenges that humans create for it. Through this research human pollution of nature will be captured. Along with this research I also expect to give back to nature by picking up litter that I see along the way, as long as it does not harm the environment to do so. This series of photographs will prove that humans have altered the Earth. I will try to capture the environment in its natural state garbage and all.

Abstract Name: The Implications of Social Isolation Amongst College Students on their Levels of Political/Civic Engagement

As young individuals enter college, many also simultaneously pass into adulthood, presenting them with the challenge of forming a social identity and political attitudes which, as prior studies have shown, will likely remain implanted over the course of their lives. Therefore, there is immense importance in ensuring that students receive the right tools, support, and safe opportunities to both develop their views/stances regarding social causes, and also to express them in an effort to contribute to the betterment of society. My project aims to examine this idea conjointly with the prevalence of social isolation amongst college students, both as a result of COVID-19 as well as effects that range beyond the pandemic. What are the reasons many young individuals may conform to existing societal norms/systems, rather than actively transforming those they see unfit? Do their college years leave them with dangerous habits that could lead to their opting for silence in the face of human rights violations and other injustices? Previous research has examined the civic engagement of Gen X and the Millennials, revealing that the older generation attributed less relevance to politics and found little meaning in participating in related activities. Through surveys and interviews conducted on campus, my research will gauge a better understanding of how students of the current generation perceive civic engagement, the sources of student isolation, and how these two concepts intersect. Expected results include Gen Z ascribing an overall greater importance to political engagement, but demonstrating more difficulty and hesitance in active participation. Further study into this relationship will help discover how additional strategies can enable students to increase their political engagement levels, and ultimately stress the importance of recognizing the moral obligation every individual has to be involved in civic matters.

Abstract Name: Investigating the Genetic Network of Histone 2B (H2B) Genes in Glycine max

Soybeans (Glycine max) are a globally vital crop that has versatile uses — from human consumption mainly via soybean oil, animal feed, or biofuel. . However, despite this crop's widespread usage, we have yet to fully understand developmental and molecular processes responsible for agricultural yield of soybean. Doing so can aid in the development of more resilient plants to abiotic stress via climate change. Recent reports in a model plant Arabidopsis thaliana suggest that plant responses to elevated temperatures are in part regulated by epigenetic mechanisms. We aim to investigate epigenetic regulations driving developmental processes in soybean. We aim to investigate epigenetic regulations driving developmental processes in soybean. Due to their importance in regulatory gene networks and chromatin modeling, we aim to study soybean Histone 2B (H2B) genes to address the surprisingly large knowledge gap of this gene family in plant systems. Gene expression studies on selected soybean H2B genes will be done to ascertain functionality and to identify novel gene interaction, further bridging the gap on gene networks involved in developmental and molecular processes. First, we will grow the soybean plants in growth chambers with controlled environments and harvest protoplasts from unifoliate leaves ~10 days after germination following established protocols. Following this, we will transfect protoplasts with the CRISPR Cas-9 system and allow for ~48 hr incubation to induce CRISPR mutagenesis in H2B genes. RNA will be isolated and libraries will be prepared for RNA sequencing experiments. Analysis on differential genome-wide gene expression will be conducted to identify genes regulated by H2B-containing chromatin in hopes of elucidating functionality of H2B genes.

Abstract Name: Implementation of Residual Tandem Neural Networks in Inverse Photonic Design

Residual Network (ResNet) represents an effective approach to traversing deep neural networks and addresses critical challenges in computing, particularly the vanishing gradient problem that arises in extremely deep models. ResNet resolves this issue by introducing "skip connections", enabling the retention of information from previous layers. In this project we implement a ResNet tandem architecture to inverse design multi-layered photonic structures for desired reflection and transmission spectra (i.e., spectral filters). The tandem network [Liu et. al. ACS Photonics, 5, 2018.] introduces a unique architectural paradigm consisting of two interconnected models. These models collaborate, with one generating a spectrum from 11 input variables (thickness of layers in the photonic structure) to emulate a Maxwell's equations calculator

(forward model), while the other looks at the spectrum as an input given from the user (generator network) and adjust its outputs to match the spectrum from the forward network. The tandem network proves valuable in addressing non-uniqueness problems in optical design typically hindering efficient training of networks for inverse design of optical structures. This problem is rooted in the fact that different optical structures can create similar spectrums, thus slowing down the training process. In the tandem architecture the output designed by the network is not required to be identical to the original training sample, if the correct spectrum is achieved. This allows the network to rapidly converge even while using non-unique training data. We report successful inverse design of layered structures using such networks.

Abstract Name: Mentoring strategies to inspire, educate, and empower undergraduate researchers

This presentation focuses on the value and impact of academic mentorship through the eyes of a recipient of the Council on Undergraduate Research (CUR) Early-Career Undergraduate Research Mentoring Award and highlights the lessons learned from her professional mentors that contributed to her ability to successfully mentor undergraduate students. By using the Triangular Model of Mentor Competence proposed by W. Brad Johnson, a theoretical framework for the development of effective mentorship will be introduced. Subsequently, several strategies for inclusive mentoring of undergraduates to foster research productivity and simultaneously provide valuable high-impact educational experiences for the student will be discussed, and the extent to which various research skills are enhanced by students' participation in an undergraduate STEM research experience will be evaluated. Particularly, seven tips obtained from the literature and the author's personal experience will be provided to help improve mentoring skills of faculty working with undergraduate STEM students using an authentic, holistic approach, as well as to ensure student engagement and high-quality scholarly experiences. The role of the academic mentor in encouraging work-like balance and self-care will also be emphasized. Furthermore, four undergraduate researchers from a diverse range of backgrounds and identities will detail their experiences and discuss a mentor's role in helping them overcome challenges and succeed in their academic research careers. Examples include supporting mentees in their efforts to disseminate their research and encouraging them to pursue broader research opportunities. Finally, the obstacles and opportunities of working with students beyond the traditional classroom framework will be explored to help overcoming barriers and thereby provide greater opportunity for undergraduate students to gain research experience.

Abstract Name: Mentoring strategies to inspire, educate, and empower undergraduate researchers

This presentation focuses on the value and impact of academic mentorship through the eyes of a recipient of the Council on Undergraduate Research (CUR) Early-Career Undergraduate Research Mentoring Award and highlights the lessons learned from her professional mentors that contributed to her ability to successfully mentor undergraduate students. By using the Triangular Model of Mentor Competence proposed by W. Brad Johnson, a theoretical framework for the development of effective mentorship will be introduced. Subsequently, several strategies for inclusive mentoring of undergraduates to foster research productivity and simultaneously provide valuable high-impact educational experiences for the student will be discussed, and the extent to which various research skills are enhanced by students' participation in an undergraduate STEM research experience will be evaluated. Particularly, seven tips obtained from the literature and the author's personal experience will be provided to help improve mentoring skills of faculty working with undergraduate STEM students using an authentic, holistic approach, as well as to ensure student engagement and high-quality scholarly experiences. The role of the academic mentor in encouraging work-like balance and self-care will also be emphasized. Furthermore, four undergraduate researchers from a diverse range of backgrounds and identities will detail their experiences and discuss a mentor's role in helping them overcome challenges and succeed in their academic research careers. Examples include supporting mentees in their efforts to disseminate their research and encouraging them to pursue broader research opportunities. Finally, the obstacles and opportunities of working with students beyond the traditional classroom framework will be explored to help overcoming barriers and thereby provide greater opportunity for undergraduate students to gain research experience.

Abstract Name: Community Center for Low-Income Families: Design of a Safe and Healthy Environment

The positive impact of the interior design on the lives of low-income families has been considered as one of the important design goals when planning a community center. The design of the community center for low-income families is a relevant project nowadays because there are still many low-income families across the United States that lack access to resources and learning opportunities. Many studies indicate that structured after-school activities are associated with higher educational outcomes, therefore, the absences of these centers can cause children to look for other activities to pass time that can lead them to make poor decisions that may affect their future. Through this type of facility, the children of low-income families can have the opportunity to pursue a higher education and develop a better life. These studies show that physical activity daily is also important for children's development and health. The research findings were collected by using quantitative and qualitative research approaches. A survey was conducted with low-income families to ask what spaces and resources they would like to see in a community center. As for the qualitative research, case studies were collected on Community Centers that were built in areas where there are low-income families. Case studies of existing community centers showed that having these facilities accessible to families improves their physical activity and higher education outcomes.This project aims to design a community center for providing low-income families, especially their children, with safe and healthy environments by planning spaces like a gymnasium/indoor running track, art room, music room, esports lounge, library, and dining area/kitchen. The resources and services of this facility will expand children's learning opportunities and help them be physically active and healthy.

Abstract Name: Beyond Boundaries: From Undergraduate Research to Leadership in Energy and Environmental Equity

How can the emerging field of engineering contribute to devising innovative and holistic strategies that lead to a substantial improvement in the quality of life and overall well-being of underserved immigrant communities? Hispanic communities make up the second-largest ethnic group yet, live in more polluted environments than their white counterparts and battle higher rates of poverty. With low-income neighborhoods come unsafe and often hazardous environmental factors that harm the health of their inhabitants. Environmental engineering, a newer branch of the discipline that combines civil and chemical engineering ideas, could offer various solutions to such socio-cultural and environmental issues, in particular relating to air and water pollution. Previous reports have found strong connections between race and pollution in a neighborhood but fail to propose long-term solutions to these issues. This research focuses on the effects of environmental racism and how it harms the health of Latino communities through specific scenarios. The study would also investigate possible solutions that environmental engineering practices can offer. How can the engineering solutions effectively address the challenges and opportunities presented by specific socio-cultural demographics, with the ultimate goal of fostering resilience and thriving communities, especially among Latino immigrants? The study will identify common issues in different environmental settings, gather socio-cultural data from previous relevant studies about environmental health, and then analyze and compare it to data from a more affluent and predominantly white area. The expected findings of this research would include establishing a more robust connection between the environment and sociocultural factors affecting Latino immigrants. Additionally, the research aims to highlight how an exciting new field of engineering could contribute to providing innovative solutions to improve the lives and well-being of these individuals - taking into account factors such as sustainable resource management, cultural sensitivity, and community engagement.

Abstract Name: Cultivating Changemakers: Undergraduate Research, Community Partnerships and Student Empowerment in Higher Education

The Research Center for Sustainable Communities (RCSC) at Kennesaw State University (KSU) has been mentoring undergraduate students in conducting analytical studies on enhancing sustainability and reducing the carbon footprints of school infrastructures statewide in GA. The RCSC seeks ways in which the state could advance healthier and more sustainable, equitable, and cost-effective learning environments. Rooted in this initiative and funded by the KSU Office of Undergraduate Research, this research aims to examine the employment of Leadership in Energy and Environmental Design (LEED) certification as an outline for promoting the existing operation of school buildings. LEED is a globally recognized rating system with a set of rigorous standards developed by the U.S. Green Building Council (USGBC). There are 808 high schools in Georgia, 18 of which are LEED-certified. Centered on Fulton County, the team will inquire about what measures were taken by these certificated high schools that were not implemented in the rest of the County.

The research will encompass a multi-faceted methodology, including a literature review, interviews (i.e., with county officials), and analysis of building certificate data. The findings will provide insights into deepening the undergraduate architecture students' understanding of the economic and environmental aspects of such certificates and the role of county decision-makers and stakeholders. Ultimately, the research will underline sustainability through environmental stewardship, economic prosperity, and social responsibility.

Abstract Name: Differences in Cannabis Usage and Clinical Outcomes Based on Fibromyalgia Severity

Fibromyalgia (FM) affects 2% to 8% of the general population, more commonly found in women than men. The current diagnosis of FM depends on physician experience, patient characteristics, and different diagnostic criteria. Core symptoms of FM include widespread pain, sleep disturbances, musculoskeletal pain, chronic fatigue, cognitive impairment, and mood disorders. Patients with FM face complicated prognoses, limited treatment options, and experience diminished quality of life. The current treatment standards (cognitive behavior therapy, pharmaceutical therapies, and aerobic exercises) have shown limited efficacy. Cannabis is an alternative therapy for various chronic pain disorders, such as multiple sclerosis, irritable bowel syndrome, and neuropathy. Recent literature suggests cannabinoids (tetrahydrocannabinol– THC and cannabidiol– CBD) have a potential role in managing FM; however, the efficacy of these trials remains unclear, and the evidence is limited. The objective of this analysis was to identify cannabis usage patterns and clinical outcome differences in patients with FM based on symptom severity. An electronic, cross-sectional survey was sent to FM patients previously seen at Mayo Clinic’s Fibromyalgia and Chronic Fatigue Clinic (Rochester, MN). Patients were diagnosed with FM (based on 1990 and/or 2016 American College of Rheumatology criteria) between January 1, 2018, and August 31, 2022. All data management and statistical analyses were performed using Statistical Analysis Software (SAS) Version 9.4. Our results show that cannabis use is associated with improvement in various FM symptoms, including pain, mood, insomnia, sensory hypersensitivities, and cognitive changes to different degrees across all four symptom severity clusters in this retrospective survey analysis.

Abstract Name: Mental Illness as Maladaptive Expertise

This project delves into the deep and intricate connection between “top-down processing” and “maladaptive expertise.” Top-down processing describes the role of prior knowledge, expectations, goals, and context in an individual's process of making sense of the world. The research conceptualizes maladaptive expertise as specialized knowledge inherent in maladaptive thinking, providing a unique lens through which certain mental illnesses can be reinterpreted. I hypothesized that therapeutic interventions could be used as tools to combat maladaptive thinking by fostering cognitive restructuring in one's top-down processing system. Cognitive behavioral therapy is structured talk psychotherapy that aims to identify and reduce the amount of negative behavior an individual exhibits. In the context of this project, cognitive behavioral treatment reaches this goal by fostering cognitive restructuring, effortful problem-solving, and behavioral change. Particular attention was placed on cognitive behavioral therapy due to its efficacy in "unlearning" defective strategies and fostering optimism. Additionally, various forms of self-talk are explored as interventions to reshape cognitive patterns, such as language through self-affirmation and negative thoughts through cognitive restructuring and reframing. Underneath these mental patterns exists the realm of metacognitive thinking. Metacognitive thinking is a process that refers to the awareness and understanding of one's thoughts. Integrating the realm of metacognition into this project reveals an even deeper layer of how cognitive behavioral therapy can become more effective in unlearning dysfunctional behaviors. An analysis of existing literature surrounding the material was conducted to comprehend the topic. Through this empirical research, it can be concluded that the majority of the current research suggests that a cognitive restructuring of one’s top-down processing is possible through cognitive behavioral therapy, optimistic self-talk, and the use of metacognition in treatment. By shedding light on therapeutic interventions' role in reshaping mental patterns, this research aims to contribute to understanding and treating maladaptive thinking.

Abstract Name: Comparative Sequence Analysis of COVID-19 Variants

This study investigated the genetic relationships between 20 different COVID-19 variants by analyzing their whole genomes and main protease sequences. Multiple Sequence Alignment and Phylogenetic trees were constructed using MEGA software to visualize the evolutionary divergence among the variants. The whole phylogenetic tree showed greater clustering of variants compared to the main protease phylogenetic tree, indicating a higher degree of similarity in the genome sequences. COVID-19 variants share a close genetic relationship based on their nucleotide sequences, the divergence in their main protease sequences may contribute to the observed differences in symptoms. This highlights the importance of studying both aspects of the virus to fully understand its evolution and impact.

Abstract Name: The effect of known biomineralization inhibitors on calcification in marine coccolithophores.

Coccolithophores, a group of calcifying marine phytoplankton, are known contributors of carbon fixation and geochemical cycling in oceans. They synthesize unique calcium carbonate cell coverings called coccoliths, although there are certain genes and proteins expected to be involved in the making of coccoliths, the precise molecular mechanisms underlying the biomineralization processes including coccolithogenesis, remain unknown. While the long-term objective of this work is to identify the genes and proteins governing biomineralization in coccolithophores using RNAseq, the specific objective of this work is to identify compounds that impact calcification without causing pleitrophic affects. Here, three inhibitors (etidronic acid monohydrate (HEBP), inositol hexaphosphoric acid (IP6), and sodium polyphosphate) known to affect biomineralization of bone were tested using three coccolithophore species, Calcidiscus leptoporus, Ochrosphara Sp., and Umbilicosphaera foliosa. Cultures of each species were grown in filtered seawater supplement with inhibitors at various concentrations. Growth rate and calcification was monitored over time in experiments conducted for 10-days, 3-days, and 24 hours. Calcification was quantified using the reflectance of coccoliths under plane polarized light and analyzing the resulting images using ImageJ, while cell growth was monitored by direct cell counts. HEPB (0.25mM, 0.5mM, 0.75mM, and 1.0mM) and IP6 (0.1mM, 1mM, 10mM, 100mM) showed marked effects on biomineralization and to a lesser extent on cell growth across the four coccolithophore species, while sodium polyphosphate did not appear to impact calcification at the concentrations tested. HEPB and IP6 affected the morphology of the coccoliths and the degree of calcification.

Abstract Name: Understanding Death in Yucatec Maya Communities

Recent studies have been conducted to look at how children learn about death and dying across communities. Researchers have found that children learn about death through observation, participation in Dia de los Muertos, and through media (Gutiérrez et al., 2014, Miller et al., 2014, & Brigewater et al., 2021). The present study is guided by Bronfenbrenner's Ecological System (1979) theory, specifically the microsystem that includes children's immediate environment. In this descriptive study, we examined how children acquired knowledge related to death and the dying process. Data were collected via semi-structured interviews with 40 Yucatec Maya children in two schools to look at their experiences related to the death of a relative during the pandemic. The interviews were transcribed and coded by native Spanish speakers using the qualitative software Nvivo. Children's responses were coded using thematic analysis (Saldaña, 2013) broadly guided by the 4 categories of death conception used by Speece (1994) to assess children's level of understanding about death. Those 4 categories of death include finality, universality, causality, and non-functionality. The preliminary findings are based on a sub-sample of seven children. Their ages ranged from 8 to 12 years old (M= 9.8). Funding from this fellowship will support our engagement in this research project

and allow us to spend the time to complete the data analysis and present findings at two conferences to support our career goals of entering academia.

Abstract Name: Evaluating and Comparing Total Flavonoid Content and DPPH● Free Radical Sequestration Across Various Coffee Species

The utilization of plant products as a source of bioactive compounds has long been explored, in order to extract pharmacological reagents and develop drug strategies. One such avenue in this exploration is the extraction of flavonoids, a key secondary plant metabolite, from coffee beans. These flavonoids are useful in sequestering reactive-oxygen-species, as well as in therapies for cancer, Alzheimer's, and other diseases. One key area that has been underexplored is how different types of coffee species, as well as relevant growing conditions and genomic differences, may lead to differing levels of flavonoid content. In this study, the current authors explored flavonoid content levels and antioxidant capacity across three different coffee bean species – namely, the Coffea arabica, Coffea liberica, and Coffea canephora (Robusta) species. Filtered extracts for each species were collected using hydroethanolic solvents and water-bath extraction, to maximize bioactive compound yield from each species. Thereafter, the Total Flavonoid Content and DPPH• (2,2-diphenyl-1-picrylhydrazyl) colorimetric assays were utilized to characterize flavonoid content and antioxidant capacity, respectively, for each species. Differences between each species' flavonoid content and antioxidant capacity were analyzed using UV-Visible spectroscopy. Absorbance values for the Total Flavonoid Content Assay were compared against a calibration curve made from (+)-Catechin, while DPPH values were compared against a control to find inhibition percentages. Analysis revealed that Robusta coffee beans contained significantly higher levels of total flavonoid content in mg of Catechin/mL, compared to Arabica/Liberica beans. Moreover, the DPPH assay revealed that Robusta coffee maintained higher inhibition of the DPPH radical, indicating higher antioxidant capacity. In turn, exploring the yield of flavonoids from Robusta coffee bean extracts could further inform the use of such extracts in drug design for oxidative-stress-related diseases, as well as physio-agronomic research about the role of genomic/growing conditions in altering flavonoid content across different plant products.

Abstract Name: Fast-Growing Trees For Municipal Wastewater Management

Due to soil and water pollution risks, wastewater management is an environmental issue in NC. Irrigated

wastewater application to grow fast-growing forest species (FGSs) is a nature-based approach to dispose of the wastewater properly and reduce contaminant discharges to local water systems while producing biomass for various industrial applications. FGSs are selected based on their productivity and ability to thrive under various environmental conditions and marginal lands, and there is a need for a long-term performance assessment of the various species. To develop FGS recommendations for future effective wastewater management and biomass production, I collected and analyzed (ANOVA) stem growth (DBH) and survival of FGSs (Pinus taeda, Chamaecyparis thyoides, Liquidambar styraciflua, Quercus alba, Fraxinus pennsylvanica, Quercus pagoda, Quercus phellos, Taxodium distichum, Populus deltoides) planted in 2011 and 2012 and irrigated with treated wastewater (Gibson, NC). There were significant growth differences among the FGSs in 2011 (p<.0001) and 2012 (p<.0001). P.taeda exhibited superior DBH (2011: 8.9±1.8 in., 2012: 9.0±2.1in.) compared to other tree species (2011: F.pennsylvanica 4.2±2.1in. to P.deltoides 7.5±2.2 in.; 2012: F.pennsylvanica3.7±1in. to L.styraciflua 6.1±1.1 in.). Survival was the highest for C.thyoides (2011: 79% vs. P.deltoides 38% - T.distichum 69%) and L.styraciflua (2012: 90% vs. P.taeda 58% - F.pennsylvanica 82%). Consequently, P.taeda and L.styraciflua, would be recommended as FGS with the highest potential for wastewater management application; meanwhile, C.thyoide and Q.alba have modest potential.

Abstract Name: “Shaping Futures: The Evolution of Elementary School Architecture.”

Evolution of Elementary School Architecture:Elementary school architecture has evolved significantly, reflecting shifts in educational philosophies, technological advancements, and societal priorities. From humble one-room schoolhouses to technologically advanced, sustainable, and inclusive learning spaces, the architectural form mirrors broader changes in education and society. What architectural form best reflects the ideal elementary school learning environment? Studying the evolution of elementary school architecture offers society several advantages:· Informed Design: By understanding the historical context and design trends, architects and educators can create more effective, engaging, and sustainable learning spaces.· Educational Enhancement: Insights from past designs can lead to environments that support modern teaching methods and foster improved student outcomes.· Equity in Education: Recognizing disparities in school facilities informs efforts to ensure all students have access to high-quality educational spaces. Research Methods:This research employs a comprehensive approach, combining historical analysis, architectural documentation, case studies, and conducting surveys with community members. Comparative studies of architectural styles, education methods, and pedagogical influences will shed light on ideal architectural forms for learning environments. Expected Results:Anticipated outcomes include a nuanced historical narrative of elementary school architecture, identification of pivotal design trends, insights into the societal forces that shaped these changes, and a repository of best practices. Ultimately, this research aims to empower architects, educators, policymakers, and communities to collaboratively shape the future of elementary school architecture, fostering equitable, innovative, and sustainable educational environments. An elementary school is the first public building that a child is called to regularly experience, be educated, find a playground, and socialize. In that sense, it is about to become a second home. By understanding the past, we can better prepare for the future of elementary school design.

Abstract Name: The Mexican American Eldest Daughter Experience

In a Latinx traditional household, the prevalence of larger families often results in a higher likelihood of children assuming parentified roles, with the eldest daughter bearing the role. The background research will discuss what parentification is, which is when a child takes on the parenting role over their parent(s) and/or siblings, how it affects the child, and what the eldest daughters are saying on TikTok. The Mexican American Eldest Daughter Experience (MAEDE) adds knowledge to the lack of academic research for these daughters, but something to note is that on social media, the eldest daughters are being vocal about their experiences. The MAEDE's method is photovoice, in which the participants, who study at Cal State Fullerton, take five photographs of their day-to-day experiences as their role and write a narrative paragraph about what they have captured. They presented the photovoice to the investigator so that the recordings could be posted on YouTube for public access. When analyzing, the themes that were found were parentified roles for both parents and siblings, responsibilities, familial pressure, and a tendency toward self-silencing. The themes indicate that the eldest daughter's role is integral to the family, reveal their challenges, and express the effects of being parentified.

Abstract Name: Unlocking the potential of community-based services to promote holistic life outcomes for children with autism and developmental disabilities

Rising prevalence rates of autism and developmental disabilities over the past decade have increased demand for intervention services. However, families continue to face significant barriers, such as waitlists and high costs, in accessing evidence-based interventions. Alternative community-based options, including day habilitation, are well suited for addressing these service gaps and improving accessibility for families of varying socioeconomic backgrounds. Yet, there is limited research on caregiver perspectives of community-based services, despite their significant contributions toward overall intervention plans. In this study, I will examine three core aspects of community-based services: accessibility, skill areas addressed, and family-centered practice. Approximately 60 caregivers of individuals with developmental disabilities, ranging from school-age children to young adults, accessing day habilitation services at Grant's House in Lafayette, IN will complete a survey in two parts. Part I focuses on caregiver and child characteristics, including socioeconomic status, demographic variables, and diagnostic information. Part II obtains caregiver perspectives on intervention services, including current service use, interest in additional services, and service access barriers; importance and status of skill areas being addressed in services; and degree of family-centered practice in services, as assessed by the Measure of Processes of Care (MPOC) questionnaire. As an indicator of accessibility at Grant's House, I expect service access barriers to be minimally influenced by caregiver attributes, such as demographic and socioeconomic factors. Additionally, I expect caregivers to report Grant's House services as addressing a variety of skill areas, reflecting a comprehensive service approach. Finally, I expect Grant's House services to closely follow a family-centered model as evidenced by high MPOC scores. By independently analyzing core aspects of community-based services, my study provides unique insights on

the value of such services, laying the foundation for future research aimed at comparing community-based approaches to traditional clinical services used in supporting individuals with autism and developmental disabilities.

Abstract Name: Striatal dopamine acetylcholine interactions during reinforcement learning

Reward values dictate the way we make decisions. However, the neural circuitry that guides decision-making is not fully understood. Dopamine and the basal ganglia are hypothesized to play a critical role in behavioral flexibility during reward learning and motivation. To assess how mice learn probabilistic reward outcomes and understand the role of the dopaminergic reward circuit in facilitating learning, we designed a head-fixed probabilistic reversal task. Mice showed a correlation between latency to press and reward rate, indicating their actions are goal-directed. Moreover, choice performance scaled with reward probabilities. During task performance, we used spectrally separated, simultaneous fiber photometry recording of dopamine and acetylcholine across different striatal subregions. Preliminary data indicates an antagonistic behavior between dopamine and acetylcholine at rewarding events. Specifically in the NAc, we observed dopamine firing increased at reward whereas acetylcholine firing decreased. Moving forward we will analyze the relationship between dopamine and acetylcholine in the NAc, DMS, and DLS.

Abstract Name: Understanding and fighting the emergence of antibiotic resistant bacteria in wastewater

The development and spread of antibiotic resistance in wastewater poses a significant threat to both the environment and human health. Biofilm is a key factor that promotes antibiotic resistance in bacteria by increasing their tolerance to antibiotics and facilitating the transfer of antibiotic resistance genes. This project aims to isolate and identify antibiotic-resistant bacteria from a wastewater treatment plant WWTP and discover natural molecules that can inhibit biofilm formation. The hypotheses are (1) wastewater bacteria can develop multiple antibiotic resistances through biofilm formation, and (2) specific natural compounds can hinder bacterial biofilm formation, thus reducing the spread of antibiotic resistance among wastewater microbes. To test both hypotheses, LB agar plates containing different antibiotics were used to isolate antibiotic-resistant bacteria from the Logan Regional WWTP effluent. Two streptomycin-resistant S2-1 and S2-2, four carbenicillin-resistant Cb2-1 to Cb2-4 and four kanamycin-resistant K2-1 to K2-4 bacteria were isolated. Notably, five strains S2-1, Cb2-2, Cb2-4, K2-2 and K2-4 are double-antibiotic-resistant and one Cb2-3 is resistant to three antibiotics. These strains were identified using 16S rRNA sequencing. Next, eleven

natural compounds were screened for the ability to inhibit biofilm formation. It was found that curcumin, quercetin, and resveratrol effectively inhibited biofilm formation in Pseudomonas aeruginosa PAO1 and two biofilm-forming double or triple-antibiotic-resistant strains Cb2-2 and Cb2-3 at a concentration of 26.67 micrograms per milliliter. These findings show that natural products could be an effective tool in reducing the spread of antibiotic resistance and preventing the development of superbugs in wastewater.

Abstract Name: “Proud to be Autistic”: Greta Thunberg’s Queering Rhetorical Genre in Climate Change Advocacy

Greta Thunberg, a young, autistic climate change activist from Sweden, has generated mixed opinions about her rhetoric since her #FridaysForFuture climate movement started in 2018. Many people have found her inspiring, leading global youth to protest political inaction about climate change. Many neurodivergent people have also found power in Thunberg’s fearless identification as autistic. However, some strongly oppose her rhetoric and autistic identity. Former U.S. president Donald Trump, for example, famously tweeted that Thunberg should improve her “Anger Management.” Previous literature, such as Frey (2021), Shcroeder (2021), and Bach (2022), has analyzed Thunberg’s rhetoric, partially explaining the controversy and power of her rhetoric. This literature, however, doesn’t pay sustained attention to the role of Thunberg’s autistic identity in her rhetoric. To address this gap, my research focuses on the role of Thunberg’s autistic identity in making her rhetoric controversial yet powerful. I base my research on the framework of genre as social action pioneered by Carolyn Miller (1984) and queering rhetoric by Remi Yergeau (2018). I argue that by queering (altering conventions with the rhetor’s unique identity) the genre of political speeches, Thunberg adds variations to traditional political speeches and thus uses the genre as a social action to redefine the exigence of immediate climate change action. In her political speeches, for example, Thunberg distances herself from her immediate audience of powerful yet inactive people instead of creating identifications with them and uses this distance to create the exigence of immediate climate change action. My findings expand opportunities for climate change advocacy, especially for neurodivergent rhetors, and also raise questions about how to accommodate neurodivergent students in classroom settings and how to better teach the concept of rhetorical genre.

Abstract Name: Impact of Folding Climate-Responsive Façade System: Assessment of Energy Performance for the Future Adaptation and Evolution of Houses in Louisiana Climate Zone (Under Extreme Heat

Conditions)

Excess CO2 in our atmosphere is causing the Earth to heat up exponentially, creating stressed living conditions on its surface. This means rising cooling demand to maintain a building's thermal comfort which uses fossil fuels as an energy source. Consequently, it becomes a cycle that exacerbates extreme heat conditions. In addition, there is a strong positive correlation between the increase in the frequency of extreme heat days to health risks among residents with lower socioeconomic status.The shotgun house typology is an efficient and economical option for Louisiana residents. Its existence in the Louisiana landscape persists and has gained renewed interest following the trend of increasing sustainable living. Contemporary adaptations of the typology employ various techniques to help mediate heat. In this research, we chose the KIWI house, which is an interpretation of the traditional shotgun house located in Baton Rouge, as a case study. Kinetic facades are dynamic envelopes defined by their ability to change forms in response to user-specific needs. We categorized the systems based on their movement mechanisms, such as folding, sliding, contracting, expanding, etc. By adopting the kinetic facade system, buildings will be able to improve their energy efficiency, targeting specific climate problems. For the purpose of this research, we are going to focus on assessing the effectiveness of a manually-operated folding kinetic facade as a solar-shading strategy for buildings in the Louisiana climate. The design is manual which removes the need for an energy source. Therefore, it is economically accessible and encourages a sustainable way of living. Through this research, we aim to adapt the facade on the south and east sides of the KIWI House. We used Rhinoceros and Climate Studio softwares to collect quantitative data on the energy performance of the two orientations under extreme heat conditions.

Abstract Name: Optimizing Learning: Effective Approaches to Enhance Students' Long Term Memory

Undergraduate biochemistry is known to be a challenging subject as it contains many difficult concepts that require students to understand and make connections with other concepts that have been previously learned. Concept mapping and problem based learning are pedagogical tools that have been practiced in many curriculums. Both tools have been proven to increase students' long term memory and retention by their unique learning processes. Concept mapping allows students to create their own mind map, visualize different concepts, enhance their understanding and in result increases their long term memory. Problem based learning allows students to use prior knowledge and provide opportunities for elaboration in small groups. During this project we want to answer the following question: How does the use of concept maps affect student's long-term storage (retention) of information compared with problem-based learning? In the preliminary phase of this project, we will be designing the instructional activities and pop quizzes to be used in a future course. We will also enroll participants in a beta-testing version of the activities for preliminary results. The preliminary results will allow us to determine if the materials that we designed allowed us to answer our research question. In future experiments, we will be able to incorporate the concept mapping and pop quiz into the course. Once the experiment has been conducted we will then use the results of the pop quiz to analyze how well students perform on each pop quiz will help us determine which pedagogical tool: concept mapping or problem based learning works the best for students taking biochemistry. With the results of this experiment, we can further structure class formats in more challenging classes like biochemistry, to allow students to retain the most information in their long term memory.

Abstract Name: Home Prices and Proximity to a College Campus: The Case of Boulder, Colorado

This paper investigates the impact of houses' distances from universities on neighborhood prices and the volatility of returns. Prior research establishes that residential real estate in college towns is resilient to economic downturns compared to non college-townhouses, showing that economic stability leads to higher home prices with lower volatility of returns for houses in college towns. Using transaction data from Boulder County, Colorado, I employ GIS data to examine whether homes near the University of Colorado have higher prices than outlying homes in the county and whether returns to nearby campus homes have lower volatility than houses far away from the university in the county. The sample covers the period between 2000 and 2022 and contains more than 90,000 single-family home transactions. To test the hypothesis, I utilize the hedonic pricing model to estimate the value of single-family properties in Boulder County. This model includes neighborhood fixed effects, as well as property information, such as the number of bedrooms, bathrooms, square feet of houses, and lot size. In addition to testing for spatial differences, the analysis examines price patterns in boom and bust times in the sample period. This paper contributes to a deeper understanding of the housing markets in U.S. college towns, offering insights that may benefit homebuyers, investors, and policymakers in their decision-making processes. The findings may also have broader implications for property rents in close proximity to universities.

Abstract Name: Computational inference of thermal tolerance across insect taxa

It is imperative to understand how climate change effects arthropods, the most diverse and abundant animals on earth. Climate change is impacting the distribution of arthropods and facilitating the establishment of invasive species. Accurate quantification of thermal limits can improve predictions of species distributions and invasion risk, but current methods can be labor intensive and error-prone. We recently developed an open-source Python command line application, DIME (Detector of Insect Motion Endpoint) to automatically assess thermal limits in Drosophila melanogaster from videos of flies exposed to heat or cold, and here we assessed whether this method works across diverse insect species. To achieve this objective, we 1) selected a group of arthropods inhabiting various ecological niches, 2) carried out the thermal limit assay, 3) analyzed the data with both manual and computational approaches (i.e., DIME). We collected upper thermal limit (CTmax) data for 6 insects species and compared them to previously published thermal limits, and our data were consistent across 5 of the 6 taxa, supporting our hypothesis that the assay developed for the Drosophila is applicable to other species. For remaining species, however, there has yet to be an apt standard to which the results would be comparable. Nevertheless, our results demonstrate that DIME can produce high-throughput,

accurate measurements of thermal limits, which can contribute to ongoing efforts to predict ectotherm responses to climate change.

Abstract Name: The Unique Buyer-Supplier Relationship for Small and Medium-Sized Underrepresented Firms: An Empirical Examination

Firms have come to recognize the importance of diversity, however an angle that warrants further study is firms that are owned by those who are underrepresented. According to the census, around 40% of firms were owned by minorities or women in 2021. Research from Lashley and Pollock (2020) shows that companies led by someone in an underrepresented group have fewer resources. Therefore, understanding what it takes to help them thrive, unique to non-minority or women-run firms is vital for the economy and success of these business relationships. Further, small and medium-sized firms represent an extremely important segment of our economy, as they are the majority of the firms in existence, according to the Small Business Administration. Utilizing a company's CRM database, we are able to capture the unique resources and strategies that help minority or women-owned, small and medium sized firms thrive. CRM used to be sought after and powerful. We know this using data from companies such as Brother International Corporation, whose call times dropped by 43 seconds on average, resulting in substantial savings (Ledingham 2004). However, fast forward to the present, CRM has room for improvement, in ways such as developing strategies to reduce their burden, creating innovative solutions, focusing on retention rather than scalability, fostering mentoring, creating a goal of a long-term relationship, utilizing nontargeting marketing initiatives, guiding investment decisions to foster growth, and helping to create training initiatives (Marks 2021). Zeroing in on incomplete data and buyer supplier relationships is where we focused our research. Our findings demonstrate that minority and women-run firms are not only younger and smaller, they have distinctive relationships with their suppliers. Suppliers can use this research to help identify the ideal strategies to enhance their buyer-supplier relationships, using CRM to the maximum capability.

Abstract Name: Long-read Nanopore Sequencing Reveals the Impact of Starvation Induced Ribosome Collisions in HeLa Cells

Translation and protein synthesis are the most energy intensive processes in the cell, and as such are highly regulated during periods of stress and non-optimal growth conditions. Recent evidence has shown that amino

acid starvation can affect translation by causing ribosome stalling and collisions that ultimately trigger the Ribotoxic Stress Response (RSR). The RSR results in rescue of ribosomal subunits, degradation of the nascent peptide, and mRNA decay through endonucleolytic cleavage at the stall site. However, while the RSR and resulting mRNA decay have been well-characterized mechanistically, there is currently no method to comprehensively analyze transient mRNA decay intermediates resulting from ribosome stalling. To address this limitation, we adapted a long-read sequencing approach called True End-to-end RNA Sequencing (TERA-seq) to identify putative mRNA decay intermediates of the starvation-induced RSR. Using this approach, we identified an increase in potential intermediates of endonucleolytic decay and saw a starvation-dependent change in nucleotide composition around the 5' end of identified mRNA molecules. In summary, we found that starvation caused detectable changes in mRNA features that could be uniquely identified using TERA-seq.

Abstract Name: Fungus Among Us: People, Place, and Species in Fungal Cholera Theories of 19th Century Britain and India

Friend, foe, food, fashion statement, and funerary accoutrement: fungi are enjoying increased cultural visibility in recent years. With climbing global temperatures, widespread use of antibiotics and immunosuppressants, and a growing immunocompromised population in the wake of COVID-19, human susceptibility to serious fungal infection is also on the rise. Until recently, popular understanding of fungal disease has largely been relegated to the realm of the inconvenient: athlete's foot, ringworm, yeast infections. But before Koch and Pasteur facilitated mainstream adoption of germ theory in the last decades of the nineteenth century, fungi were among the first "germs" to be conceived of as major threats to human health. In order to historicize the human-fungi relationship, highlight the contributions of plant scientists to the history of medicine, and complicate triumphalist narratives about scientific progress, this project examines three instances of misidentification wherein cholera was thought to be caused by a fungal pathogen. The fungal cholera theory was first popularized in Bristol in 1849, was the subject of debate in British India in 1867, and made its final appearance at Cambridge in 1886. Though never achieving widespread acceptance, fungal theories of cholera were remarkably resilient in nineteenth-century Britain and its empire. What made fungi a compelling explanation for perhaps the most devastating epidemic disease of the global nineteenth century? How did fungal theories of cholera imagine the relationship between humans, nonhumans, and the environment? Why did fungal cholera theorists ultimately fail to convince the medical establishment to take their theories seriously? Drawing on both professional and popular publications, and approaching scientific inquiry as a cultural, political, and epistemological problem, I aim to write a history which resituates fungi in the history of human disease and which embraces controversy, uncertainty, and failure on their own terms as part of the perpetual effort to preserve human life.

Abstract Name: The Impact of Climate Change on Paper Birch Habitats

Climate change is impacting the distribution of many species across the globe. Keystone species are vital to their respective ecosystem however biodiversity is also an important factor. As biodiversity decreases, cascading effects impact the ecosystem. Paper Birch trees are important species within hardwood-conifer forests in North America, adding to the biodiversity. Due to the changing climate, we seek to answer how has and will the suitable habitat of Paper Birch species change throughout the United States. To determine the result, spatial analysis and Geographic Information Science (GIS) are used to map out the climate conditions most suitable for Birch Tree health in the past, present, and future. Once the baseline climate regimes for birch trees are identified, climate data from early 20th century, mid 20th century, current data, and end of 21st century is analyzed to see how the suitable habitat is growing or shrinking in the United States. To determine future suitable habitats RCP2.6, RCP4.5, and RCP8.5 are used to illustrate the different future pathways of climate change on birch tree habitat regions. It is hypothesized that over time the suitable habitat ranges of Paper Birch trees will shrink and have larger changes depending on the human handling of climate change. This analysis method can be used to map other species in ecosystems and show how ecosystems may change and possibly be lost all together.

Abstract Name: Community Gardens, Free Vegetables, and Food Sovereignty

Food sovereignty is a concept arising from Indigenous movements, and refers to the universal access to nutritious, local, affordable, and culturally-appropriate food. Food security is an important aspect of food sovereignty and refers to the accessibility of healthy foods. Some scholars argue that food security on a broad scale is not possible without also addressing food sovereignty issues and transforming the food system. Community gardens have the potential to return the production of food, and the control of land, water, and seeds back to local communities, though they are often faced with structural barriers to achieving food sovereignty goals. Community gardens can help community members access fresh produce and provide opportunities to give back to the community through garden work. This project looks at the University of Wisconsin-Platteville Edible Garden and local food pantries and food assistance programs to understand the impacts of these programs on perceptions of health, wellbeing, and food security for program recipients/beneficiaries and community members. This research was conducted through participant observation in working in the Edible Garden, including note-taking and other ethnographic methods, key informant interviews of people working in the community garden and food assistance programs, and a survey issued to program recipients and beneficiaries on the impacts of the programs. My hypothesis was that both perceptions of health and wellbeing and food security would be improved through participation in food assistance programs and the community garden space. Results from this study are preliminary but indicate that while initial interest in the community garden was high, the interest was not sustained by community members. I will be analyzing this outcome as well as presenting results from the interview and survey data to understand the impacts of these programs on community wellbeing and food security.

Abstract Name: Understanding the CRAFT Algorithm for Predicting Conversational Derailment on GitHub

The Conversational Recurrent Architecture for ForecasTing (CRAFT) algorithm is a machine learning model developed by researchers at Cornell University for the sake of forecasting conversational derailment before it occurs (Chang et al. 2019). Conversational derailment in online discussions is when conversations shift from civil, productive discussions into insults, trolling, and demanding comments that hinder the productivity of the conversation. However, CRAFT was trained solely on WikiTalks and Reddit conversations meaning it can predict toxicity in everyday conversations, but not technical discussions that occur on open-source software (OSS) hosting platforms such as GitHub, StackOverflow, and SourceForge which are filled with code, hyperlinks, and technology terms that are not common outside of the community. When toxicity occurs in open-source software, it is often demanding, condescending, or discriminating towards minorities. To combat this, we modified the CRAFT algorithm to understand OSS discussions without letting technical terminology trigger an extreme amount of false positives. We collected a dataset of GitHub conversations (N=362) that were half toxic (N=181) and half civil (N=181). They were human-annotated with a derailment point and a toxicity point. Data was preprocessed to remove hyperlinks, camel case variable names, and resource names to determine which of these was creating false positives. An analysis demonstrated that CRAFT was unable to understand most technical jargon because it had never been exposed to those words or patterns before. The model was then fine-tuned by receiving annotated conversations so it could process technical comments, such as stack traces and code, that were not necessarily uncivil. By using the annotated dataset and fine-tuning the model, we improved the toxic comment prediction accuracy from 0.66 to 0.82. This contributes to the growing field of conversational derailment research and provides future researchers with a starting point on where the CRAFT algorithm needs improvement.

Abstract Name: The Missing Baseball Game: Ernest Hemingway and Baseball in "The Old Man and the Sea"

Recently, the United Nations passed a resolution that asked the United States to end its embargo on Cuba. Though the United States and Cuba have had a tumultuous relationship since 1961, two things that the two countries have in common are baseball and the American author, Ernest Hemingway. In 1952 Ernest Hemingway published The Old Man and the Sea, which is about an elderly fisherman who goes far into the sea in order to catch a great marlin. Before he leaves for his fishing trip, he discusses with Manolin – a boy he is friendly with – several baseball games that occurred that week. Though the discussion of the baseball game is often glossed over, Hemingway is actually showing the exact date the book took place. He does this by leaving hints throughout the discussion. These Include the mention of Dick Sisler being on the Phillies and the record of two baseball teams. By understanding the date Hemingway chose, the reader can perform a more detailed analysis of the book and the date the book took place. Additionally, the emphasis on baseball highlights the importance of baseball in Cuban cultural identity by demonstrating how all parts of the population talked about the game. Knowing the exact date Hemingway referenced allows scholars to bring in social and historical facts in a more precise fashion. My analysis will walk the reader through figuring out the exact date of the book. Although previous scholars addressed what they thought the date of the baseball game

was, I will show in my analysis the faults in their reasoning. In January I will be traveling to Cuba on a grant from my Undergraduate Research institution and I will perform first-hand research to understand the significance of baseball in Cuba.

Abstract Name: Leveraging Motivational Videos to Mitigate Student Withdrawal and Academic Failure

This study investigates the impact of motivational videos on student retention and academic performance in online classes at a college level. With increasing concerns about student withdrawal rates and academic failure during and after the pandemic, educators are exploring inventive approaches to engage and support students. Motivational videos, characterized by inspiring content and visually appealing presentations, have emerged as a potential tool to enhance student motivation and persistence.The research employs a mixed-methods approach, combining quantitative analysis of student performance data with qualitative insights gathered through motivational videos. We will be comparing students' performance in Dr. Lynch's classes with weekly motivational videos as opposed to classes that did not offer motivational videos. In the classes with the videos, motivational videos are strategically integrated into the learning environment, supplementing traditional teaching methods.Preliminary results indicate a positive correlation between exposure to motivational videos and academic performance. The analysis of academic performance data reveals a significant reduction in withdrawal rates and an improvement in overall grades among students in the classes with motivational videos compared to the classes without the videos.Qualitative data provides deeper insights into the mechanisms through which motivational videos influence student behavior. The most popular themes that attracted students were videos on managing stress, studying when you do not feel like it, and stopping wasting time which seemed to appear as key factors contributing to the observed positive outcomes.This research illustrates how instructors can empower their students through innovative pedagogical strategies by shedding light on the potential of motivational videos as a preventive measure against student withdrawal and academic failure. As educational institutions continue to adapt to the changing needs of students, the findings from this study offer valuable insights into the practical application of motivational videos to foster a more resilient and motivated student body.

Abstract Name: Perceptions of students and teachers on the success and shortcomings of open classrooms

This study will focus on the perceptions of students and teachers to define what contributes to the success or shortcomings of open classrooms. Open plan classrooms are student-centered design layouts for classrooms

with various areas of activity that are flexible to use, using a minimal amount of walls if any. Open classrooms arose in the late 1960s but declined in popularity by the 1980s due to distractions. Recently, open classrooms have been returning to schools with the commitment to provide “21st-century education.” One of the benefits of learning in open classrooms is that students score higher on “creativity, cooperative behavior, and class activities” compared to those in traditional classrooms. However, Solomon and Kendall (1976) note that students in open classrooms score lower on tasks that require concentration, which Ito and Yokoyamato (2019) suggest may be due to a large number of distractions in open classrooms. If problems from previous studies persist, they can outweigh the benefits of open classrooms. Students’ creativity at the cost of academic performance will be the primary issue arising from these up-and-coming classrooms. A minimum of 30 teachers and 30 students from the 4th through 8th grades will be requested to participate in an online survey that asks questions regarding how the space is being utilized, the perceived level of concentration, and the differences between their open classrooms and traditional classrooms. If an insufficient number of schools are willing to participate, the methodology will adapt to a qualitative interview study featuring designers and architects with a focus on education. Interviews will be conducted until saturation point to evaluate the strategies they use to minimize distractions and increase open classroom benefits. These results can yield guidelines on solutions to improve open classrooms and open the door for more research on this subject.

Abstract Name: Understanding the role of Connexin44.2 with CRISPR/Cas9-induced deletions in zebrafish

Connexin44.2, or gjc4a, is predicted to be involved in gap junction channel activity as well as cell-cell signaling. Based on its expression and similar structure, Connexin44.2 is believed to be involved in similar processes as Connexin43.4 or have overlapping function during of left-right development in zebrafish. cx44.2 is a tandem duplicated locus in zebrafish, so we created a large deletion of both genes using CRISPR/Cas9. For this, we targeted the tandemly repeated genes, gjc4a.1 and 2, with gRNAs/Cas9 protein that target the 5’ UTR of gjc4a.1 and the 3’ UTR of gjc4a.2 with and without an oligonucleotide containing 48 bp of homologies to each flanking cut. We have identified a F0 injected fish that transmits a deletion to the next F1 generation. We will cross these fish with each other and cx43.4 to understand their unique and overlapping roles during zebrafish embryogenesis.

Abstract Name: Intergenerational Transmission of Violence in Latino Families: The Role of Mothers in Navigating the Cycle of Abuse

This paper asks the question: How do Latina mothers who survive intimate partner violence navigate breaking intergenerational cycles of abuse and the intergenerational transmission of violence? More specifically, this paper explores the tensions between personal experiences with witnessing violence and the actions Latina mothers, living in the United States, took in order to stop cycles of abuse and its outcomes for their own children. As previous research documents, Latino children and youth are the fastest-growing ethnic minority in the United States. They also are unique in the sense that they experience mixed-status families in which one, or more, of their family members lack the proper authorization to live and work in the United States. Due to this, they face a distinctive form of family violence in which fear of deportation silences victims. The data analyzed in this paper are a subset of a larger study that included Black women, Latina women, white women who were partnered with Black men, and a small sub-sample of Black and white men. The subsample analyzed here comes from in-depth, face-to-face interviews with 11 Latina women impacted by intimate partner violence. Based on interviews with 11 Latina women, I find evidence of cases in which the roles of mothers either interrupt or contribute to the continuation of the intergenerational transmission of the violence cycle. The paper concludes with suggestions for future research that centers on the experiences of Latino communities in order to reduce intergenerational trauma and transmission of violence in Latino communities.

Abstract Name: Addressing Online Recruitment Challenges for Research Studies: A practical example utilizing Research Electronic Data Capture (REDCap) platform features

Background: Online study recruitment is a promising method to reach a large, diverse sample in a shorter period than in-person recruitment. When recruiting online, it is important to identify potential threats and develop strategies to ensure data quality and legitimacy. During the recruitment of our cross-sectional survey study examining the impact of cancer on the work and well-being of nurses in the United States, we employed the web-based, encrypted Research Electronic Data Capture (REDCap) platform to address challenges associated with online recruitment. Purpose: This presentation aims to identify online recruitment challenges, using our study as an example, and strategies to mitigate these challenges utilizing REDCap features. Methods: Recruitment. Our study recruited through multiple online channels, including social media platforms (LinkedIn, Facebook, Instagram), patient registries (Pitt+Me and Research Match), and professional nursing organizations. Interested individuals completed a 3-minute screening form, which the team used to verify their eligibility. Challenges. The screening form yielded 1690 responses over six months, with significant increases following social media advertisements. The process of verifying this large dataset was labor-intensive and time-consuming. Strategies. Our team adapted indicators of fraudulent responses from existing literature with various REDCap features (i.e., branch logic, data piping) to develop a form to validate eligibility. We prioritized two main criteria as most indicative of a fraudulent response: US Time Zones and identical open-ended responses. Additionally, sent personalized emails to individuals whose eligibility was uncertain and cross-checked survey with screening data. Results: Prioritizing these indicators decreased eligibility validation time from 3-5 minutes to ~30 seconds per record. Of the responses, 92.2% were screened as fraudulent. Conclusion: Research studies are suggested to develop proactive strategies for recruitment through online channels to address threats to data quality and legitimacy. REDCap is an effective tool to implement a multi-layer validating process to verify large and time-consuming datasets.
